The following are some important features of the compiler:

**Getting Started with the Compiler**
*Getting Started* explains how to invoke the compiler on the command line or from within an IDE.

**OpenMP* Support**
The compiler supports many OpenMP* features, including most features in the OpenMP* Version 4.0 API specification.

**Intel® Many Integrated Core Architecture**
The Intel compiler supports elements that enable programming for and building binaries to run on the Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

**Compiler Options**
*Compiler Options* provides information about options you can use to affect optimization, code generation, and more.

**Language Reference**
The *Language Reference* provides information on language syntax and semantics, on adherence to various Fortran standards, and on extensions to those standards.

**Fortran Language Extensions**
*Fortran Language Extensions* provides information about how to use additional implementation features, such as creating a Component Object Model server and generating listing and map files, among others.

**Mixed Language Programming**
*Mixed Language Programming* provides information about Fortran and C interoperable procedures and data types, as well as various specifics of mixed-language programming.

**List of Run-Time Error Messages**
*List of Run-Time Error Messages* describes the errors processed by the Intel® Fortran run-time library (RTL).

Chapter 12: Floating-point Operations
Understanding Floating-point Operations........................................ 527
  Programming Tradeoffs in Floating-point Applications............... 527
  Floating-point Optimizations.................................................. 529
  Using the -fp-model (/fp) Option............................................. 530
  Denormal Numbers.................................................................. 532
  Floating-Point Environment.................................................... 532
  Setting the FTZ and DAZ Flags............................................... 533
  Checking the Floating-point Stack State................................. 534
Tuning Performance........................................................................ 534
  Overview: Tuning Performance............................................... 534
  Handling Floating-point Array Operations in a Loop Body............. 535
  Reducing the Impact of Denormal Exceptions............................ 535
  Avoiding Mixed Data Type Arithmetic Expressions.................... 536
  Using Efficient Data Types..................................................... 537

Chapter 13: Libraries
Creating Static Libraries............................................................. 539
Creating Shared Libraries............................................................ 540
Using Shared Libraries on OS X*................................................. 541
Calling Library Routines............................................................ 542
Comparison of Intel® Visual Fortran and Windows* API Routines...... 543
Specifying Consistent Library Types..................................................544
Redistributing Libraries When Deploying Applications.......................545
Storing Object Code in Static Libraries.............................................545
Storing Routines in Shareable Libraries.............................................546
Using the Windows* API Routines...................................................546
   Including the Intel® Visual Fortran Interface Definitions for
       Windows* API Routines......................................................546
       Calling Windows API Routines...........................................546
       Supplied Windows* API Modules........................................549
Math Libraries...............................................................................549

Chapter 14: Data and I/O

Data Representation..........................................................................551
   Data Representation Overview..................................................551
   Integer Data Representations..................................................553
   Logical Data Representations..................................................554
   Character Representation.......................................................555
   Hollerith Representation.........................................................556
Fortran I/O...................................................................................556
   Devices and Files Overview.....................................................557
   Logical Devices.......................................................................557
   Physical Devices (Windows*)...................................................559
   Types of I/O Statements.........................................................560
   Forms of I/O Statements........................................................562
   Assigning Files to Logical Units...............................................563
   File Organization.....................................................................565
   Internal Files and Scratch Files..............................................565
   File Access and File Structure................................................566
   File Records...........................................................................568
   Record Types..........................................................................568
   Record Length.........................................................................574
   Record Access.........................................................................574
   Record Transfer.......................................................................575
   Specifying Default Pathnames and File Names...............................576
Opening Files: OPEN Statement.......................................................577
Obtaining File Information: INQUIRE Statement.................................579
Closing Files: CLOSE Statement......................................................581
Record I/O Statement Specifiers......................................................581
File Sharing (Linux* and OS X*)....................................................582
Specifying the Initial Record Position...............................................583
Advancing and Nonadvancing Record I/O.........................................583
User-Supplied OPEN Procedures: USEROPEN Specifier.....................584
Microsoft Fortran PowerStation Compatible Files (Windows* OS)....590
Using Asynchronous I/O................................................................594

Chapter 15: Mixed Language Programming

Programming with Mixed Languages Overview..................................597
Standard Fortran and C Interoperability..........................................597
Using Standard Fortran Interoperability Syntax for Existing Fortran
   Extensions.............................................................................599
# Chapter 19: Program Elements and Source Forms

Program Units ........................................................................... 693
Statements .................................................................................. 693
Keywords ...................................................................................... 695
Names .......................................................................................... 696
Character Sets ............................................................................... 696
Source Forms ................................................................................ 697
  Free Source Form.................................................................. 699
  Fixed and Tab Source Forms................................................... 701
  Source Code Useable for All Source Forms.............................. 704

# Chapter 20: Data Types, Constants, and Variables

Data Types, Constants, and Variables Overview................................. 705
Intrinsic Data Types....................................................................... 705
  Integer Data Types................................................................ 706
  Real Data Types.................................................................... 709
  Complex Data Types............................................................ 713
  Logical Data Types.............................................................. 715
  Character Data Type.............................................................. 716
Derived Data Types......................................................................... 720
  Derived-Type Definition Overview............................................ 720
  Default Initialization............................................................... 720
  Procedure Pointers as Derived-Type Components....................... 721
  Type-Bound Procedures.......................................................... 722
  Type Extension...................................................................... 724
  Parameterized Derived-Type Declarations................................ 725
  Structure Components............................................................ 730
  Structure Constructors........................................................... 732
Binary, Octal, Hexadecimal, and Hollerith Constants........................... 734
  Binary Constants................................................................... 734
  Octal Constants..................................................................... 734
  Hexadecimal Constants.......................................................... 735
  Hollerith Constants................................................................ 735
  Determining the Data Type of Nondecimal Constants............... 736
Enumerations and Enumerators....................................................... 738
Variables...................................................................................... 739
  Data Types of Scalar Variables................................................ 739
  Arrays.................................................................................. 741
  Coarrays.............................................................................. 750

# Chapter 21: Expressions and Assignment Statements

Expressions................................................................................... 755
  Numeric Expressions.............................................................. 756
  Character Expressions............................................................ 759
  Relational Expressions............................................................ 759
  Logical Expressions................................................................ 760
  Defined Operations................................................................ 761
  Summary of Operator Precedence............................................ 762
  Initialization and Specification Expressions............................. 762
Assignments.................................................................................. 765
## Chapter 28: I/O Formatting

- I/O Formatting Overview ................................................................. 913
- Format Specifications .................................................................. 913
- Data Edit Descriptors .................................................................. 918
  - Forms for Data Edit Descriptors ............................................. 918
  - General Rules for Numeric Editing ......................................... 919
  - Integer Editing ...................................................................... 920
  - Real and Complex Editing .................................................... 924
  - Logical Editing (L) ................................................................ 932
  - Character Editing (A) .......................................................... 933
  - Defined I/O Editing (DT) ....................................................... 934
- Default Widths for Data Edit Descriptors ................................... 934
- Terminating Short Fields of Input Data ..................................... 935
- Control Edit Descriptors ............................................................. 936
  - Forms for Control Edit Descriptors ........................................ 936
  - Positional Editing .................................................................. 937
  - Sign Editing .......................................................................... 938
  - Blank Editing ....................................................................... 939
  - Round Editing ...................................................................... 940
  - Decimal Editing ..................................................................... 941
  - Scale-Factor Editing (P) ...................................................... 942
  - Slash Editing ( / ) .................................................................. 944
  - Colon Editing (: ) .................................................................... 944
  - Dollar-Sign ($) and Backslash ( \ ) Editing ............................. 945
  - Character Count Editing (Q) ................................................ 945
- Character String Edit Descriptors ................................................ 947
  - Character Constant Editing .................................................. 947
  - H Editing .............................................................................. 948
  - Nested and Group Repeat Specifications .................................. 948
  - Variable Format Expressions .................................................. 949
  - Printing of Formatted Records ................................................ 950
- Interaction Between Format Specifications and I/O Lists ............. 951

## Chapter 29: File Operation I/O Statements

- File Operation I/O Statements Overview ..................................... 955
- INQUIRE Statement Specifiers ..................................................... 960
  - INQUIRE: ACCESS Specifier ............................................... 961
  - INQUIRE: ACTION Specifier ............................................... 961
  - INQUIRE: ASYNCHRONOUS Specifier ................................... 961
  - INQUIRE: BINARY Specifier (W*S) ....................................... 962
  - INQUIRE: BLANK Specifier .................................................. 962
  - INQUIRE: BLOCKSIZE Specifier .......................................... 962
  - INQUIRE: BUFFERED Specifier ............................................ 962
  - INQUIRE: CARRIAGECONTROL Specifier ......................... 963
INQUIRE: CONVERT Specifier .................................................. 963
INQUIRE: DECIMAL Specifier ................................................... 964
INQUIRE: DELIM Specifier ....................................................... 964
INQUIRE: DIRECT Specifier ..................................................... 965
INQUIRE: ENCODING Specifier ................................................ 965
INQUIRE: EXIST Specifier ........................................................ 965
INQUIRE: FORM Specifier ........................................................ 966
INQUIRE: FORMATTED Specifier ............................................. 966
INQUIRE: IOFOCUS Specifier (W*S) .......................................... 966
INQUIRE: MODE Specifier ........................................................ 967
INQUIRE: NAME Specifier ....................................................... 967
INQUIRE: NAMED Specifier ..................................................... 967
INQUIRE: NEXTREC Specifier .................................................. 967
INQUIRE: NUMBER Specifier .................................................... 968
INQUIRE: OPENED Specifier .................................................... 968
INQUIRE: ORGANIZATION Specifier ......................................... 968
INQUIRE: PAD Specifier .......................................................... 968
INQUIRE: PENDING Specifier ................................................... 969
INQUIRE: POS Specifier .......................................................... 969
INQUIRE: POSITION Specifier ................................................. 969
INQUIRE: READ Specifier ........................................................ 970
INQUIRE: READWRITE Specifier ............................................. 970
INQUIRE: RECL Specifier ........................................................ 970
INQUIRE: RECORDTYPE Specifier .......................................... 971
INQUIRE: ROUND Specifier ..................................................... 971
INQUIRE: SEQUENTIAL Specifier .............................................. 972
INQUIRE: SHARE Specifier ...................................................... 972
INQUIRE: SIGN Specifier ........................................................ 973
INQUIRE: SIZE Specifier ......................................................... 973
INQUIRE: UNFORMATTED Specifier ........................................ 974
INQUIRE: WRITE Specifier ...................................................... 974

OPEN Statement Specifiers ................................................... 974
OPEN: ACCESS Specifier ......................................................... 978
OPEN: ACTION Specifier ......................................................... 978
OPEN: ASSOCIATEVARIABLE Specifier .................................... 979
OPEN: ASYNCHRONOUS Specifier .......................................... 979
OPEN: BLANK Specifier ........................................................... 979
OPEN: BLOCKSIZE Specifier ................................................... 979
OPEN: BUFFERCOUNT Specifier ............................................. 980
OPEN: BUFFERED Specifier ..................................................... 980
OPEN: CARRIAGECONTROL Specifier .................................... 981
OPEN: CONVERT Specifier ....................................................... 982
OPEN: DECIMAL Specifier ....................................................... 983
OPEN: DEFAULTFILE Specifier .............................................. 984
OPEN: DELIM Specifier .......................................................... 984
OPEN: DISPOSE Specifier ....................................................... 984
OPEN: ENCODING Specifier .................................................... 985
OPEN: FILE Specifier ............................................................ 985
OPEN: FORM Specifier .......................................................... 986
OPEN: IOFOCUS Specifier (W*S) ............................................ 987
Chapter 30: Compilation Control Lines and Statements

Chapter 31: Directive Enhanced Compilation

Directive Enhanced Compilation Overview
Syntax Rules for Compiler Directives
General Compiler Directives
Rules for Placement of Directives
Rules for General Directives that Affect DO Loops
Rules for Loop Directives that Affect Array Assignment
OpenMP* Fortran Compiler Directives
Clauses Used in Multiple OpenMP* Fortran Directives
Conditional Compilation Rules
Nesting and Binding Rules
OFFLOAD Compiler Directives
Equivalent Compiler Options

Chapter 32: Scope and Association

Scope and Association Overview
Scope
Unambiguous Generic Procedure References
Resolving Procedure References
References to Generic Names
References to Specific Names
References to Nonestablished Names
Association
Name Association
Pointer Association
Storage Association
Inheritance Association
Chapter 33: Deleted and Obsolescent Language Features
Deleted and Obsolescent Language Features.................................1033
Deleted Language Features in Fortran 2003 and Fortran 95..............1033
Obsolescent Language Features in the Fortran Standard...............1035

Chapter 34: Additional Language Features
Additional Language Features Overview.......................................1037
FORTRAN-66 Interpretation of the EXTERNAL Statement...............1037
Alternative Syntax for the PARAMETER Statement......................1038
Alternative Syntax for Binary, Octal, and Hexadecimal Constants.....1039
Alternative Syntax for a Record Specifier..................................1040
Alternative Syntax for the DELETE Statement.............................1040
Alternative Form for Namelist External Records..........................1040
Record Structures.......................................................................1041
  Structure Declarations.........................................................1042
  References to Record Fields..................................................1043
  Aggregate Assignment..........................................................1045

Chapter 35: Additional Character Sets
Additional Character Sets Overview............................................1047
Character and Key Code Charts for Windows*..............................1047
  ASCII Character Codes for Windows*.....................................1047
  ANSI Character Codes for Windows*.......................................1049
  Key Codes for Windows*........................................................1050
ASCII Character Set for Linux* and OS X*.................................1052

Chapter 36: Data Representation Models
Data Representation Models......................................................1055
Model for Integer Data.............................................................1056
Model for Real Data.................................................................1056
Model for Bit Data......................................................................1057
  Bit Sequence Comparisons....................................................1058

Chapter 37: Run-Time Library Routines
Module Routines Overview.......................................................1059
  Overview of NLS and MCBS Routines (Windows* OS)...............1059
  Standard Fortran Routines That Handle MBCS Characters
    (Windows* OS).....................................................................1062
  Overview of Portability Routines..........................................1063
  Overview of Serial Port I/O Routines (Windows* OS).............1065
OpenMP* Fortran Routines Overview........................................1067

Chapter 38: Summary of Language Extensions
Summary of Language Extensions...............................................1071
  Language Extensions: Source Forms.......................................1071
  Language Extensions: Names..................................................1071
  Language Extensions: Character Sets......................................1071
  Language Extensions: Intrinsic Data Types..............................1072
  Language Extensions: Constants............................................1072
  Language Extensions: Expressions and Assignment..................1072
Chapter 39: A to Z Reference

A to Z Reference Overview .......................................................... 1079
Language Summary Tables ..........................................................1079
  Statements for Program Unit Calls and Definitions ............... 1079
  Statements Affecting Variables ........................................ 1080
  Statements for Input and Output ....................................... 1081
  Compiler Directives .......................................................... 1082
  Program Control Statements ........................................... 1088
  Inquiry Intrinsic Functions ........................................... 1089
  Random Number Intrinsic Procedures ................................ 1090
  Date and Time Intrinsic Subroutines ................................ 1091
  Keyboard and Speaker Library Routines ........................... 1091
  Statements and Intrinsic Procedures for Memory Allocation and
    Deallocations .................................................................. 1092
  Intrinsic Functions for Arrays ........................................ 1092
  Intrinsic Functions for Numeric and Type Conversion ......... 1093
  Trigonometric, Exponential, Root, and Logarithmic Intrinsic
    Procedures ........................................................................ 1095
  Intrinsic Functions for Floating-Point Inquiry and Control .... 1098
  Character Intrinsic Functions ......................................... 1099
  Intrinsic Procedures for Bit Operation and Representation .... 1099
  QuickWin Library Routines (W*S) ....................................... 1101
  Graphics Library Routines (W*S) ....................................... 1103
  Portability Library Routines ............................................ 1107
  National Language Support Library Routines (W*S) ............. 1115
  POSIX* Library Procedures ............................................ 1117
  Dialog Library Routines (W*S) .......................................... 1122
  COM and Automation Library Routines (W*S) ..................... 1123
  Miscellaneous Run-Time Library Routines ......................... 1125

Intel disclaims all express and implied warranties, including without limitation, the implied warranties of merchantability, fitness for a particular purpose, and non-infringement, as well as any warranty arising from course of performance, course of dealing, or usage in trade.

This document contains information on products, services and/or processes in development. All information provided here is subject to change without notice. Contact your Intel representative to obtain the latest forecast, schedule, specifications and roadmaps.

The products and services described may contain defects or errors which may cause deviations from published specifications.

Intel processor numbers are not a measure of performance. Processor numbers differentiate features within each processor family, not across different processor families. Go to: Learn About Intel® Processor Numbers

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice. Notice revision #20110804

The following are some important features of the compiler:

**Getting Started with the Compiler**
Getting Started explains how to invoke the compiler on the command line or from within an IDE.

**OpenMP* Support**
The compiler supports many OpenMP* features, including most features in the OpenMP* Version 4.0 API specification.

**Intel® Many Integrated Core Architecture**
The Intel compiler supports elements that enable programming for and building binaries to run on the Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

**Compiler Options**
Compiler Options provides information about options you can use to affect optimization, code generation, and more.

**Language Reference**
The Language Reference provides information on language syntax and semantics, on adherence to various Fortran standards, and on extensions to those standards.

**Fortran Language Extensions**
Fortran Language Extensions provides information about how to use additional implementation features, such as creating a Component Object Model server and generating listing and map files, among others.

**Mixed Language Programming**
Mixed Language Programming provides information about Fortran and C interoperable procedures and data types, as well as various specifics of mixed-language programming.

**List of Run-Time Error Messages**
List of Run-Time Error Messages describes the errors processed by the Intel® Fortran run-time library (RTL).
Part

Using the Intel® Fortran Compiler, you can compile and generate applications that can run on the Intel® 64 and IA-32 architectures.

Intel® 64 architecture applications can run on the following:

- Windows* operating systems for Intel® 64 architecture-based systems.
- Linux* operating systems for Intel® 64 architecture-based systems.
- OS X* operating systems for Intel® 64 architecture-based systems. (Executables built with the Intel compiler can be combined into universal binaries using the Apple LIPO utility.)

IA-32 architecture applications can run on the following:

- Supported Windows* operating systems
- Supported Linux* operating systems
- Supported OS X* systems

Intel® Many Integrated Core Architecture (Intel® MIC Architecture) focused applications can build on supported Windows* and Linux* operating systems. However, these applications can run only on Intel® 64 architecture-based systems, targeting Intel® MIC Architecture.

Some information that applies to Intel® 64 architecture may also apply to Intel® Many Integrated Core Architecture (Intel® MIC Architecture).

Unless specified otherwise, assume the information in this document applies to all supported architectures and all operating systems.

You can use the compiler on the command line or in a supported Integrated Development Environment (IDE):

- Microsoft Visual Studio* (Windows* only)
- Eclipse/CDT (Linux* only)
- Xcode (OS X* only)

See the Release Notes for complete information on supported architectures, operating systems, and Integrated Development Environments for this release.

Feature Requirements

Some features may require that other products also be installed.

To use these tools and features, you need licensed versions of the tools and you must have an appropriate supported version of the relevant product edition. For more information, check your product release notes.

The following table shows components (tools) and some of the products with which they are included.

<table>
<thead>
<tr>
<th>Component</th>
<th>Included with these Products</th>
</tr>
</thead>
<tbody>
<tr>
<td>Intel® Trace Analyzer and Collector</td>
<td>Intel® Parallel Studio Cluster Edition</td>
</tr>
</tbody>
</table>

The following table lists dependent features and their corresponding required products.

For certain compiler options, compilation may fail if the option is specified but the required product is not installed. In this case, remove the option from the command line and recompile.

For more information about requirements for a particular product, see http://www.intel.com/software/products/.

**Feature Requirements**

<table>
<thead>
<tr>
<th>Feature</th>

</tr>
</tbody>
</table>

You should also refer to the Release Notes for this product for detailed information about system requirements, late changes to the products, supported architectures, operating systems, and Integrated Development Environments.
Getting Help and Support

Windows*
Documentation is available from within the version of Microsoft Visual Studio* installed on your system. From the Help menu, choose Intel Compilers and Libraries to view the installed user and reference documentation.

Context-Sensitive Help
You can get information on certain features by using context-sensitive help.

• Press F1 to get an overview of the active pane or window.
• Press F1, or click the ? button in the upper-right corner of the dialog box to get help on the active dialog box.
• Select the keyword and press F1 to get help on a language keyword within your program.

Linux* and OS X*
On both Linux* and OS X*, the documentation has limited integration in the Eclipse/CDT and Xcode. In both cases, the integrated documentation only provides details about where to find the product documentation on your local system.

Intel Software Documentation

Product Website and Support
To find technical support information, to register your product, or to contact Intel, please visit: https://software.intel.com/en-us/support/

At this site, you will find comprehensive product information, including:

• Links to each product, where you will find technical information such as white papers, support, articles, and user forums
• Links to news and events

Release Notes
For detailed information on system requirements, late changes to the products, supported architectures, operating systems, and Integrated Development Environments (IDE) see the Release Notes for this product.

Forums
You can find helpful information in the Intel Software user forums. You can also submit questions to the forums. To see the list of the available forums, go to https://software.intel.com/en-us/forum/.
Related Information

Reference and Tutorial Information
The following commercially published documents provide reference or tutorial information about Fortran:

Intel does not endorse these books or recommend them over other books on the same subjects.

Additional Product Information
For additional technical product information including white papers, forums, and documentation, visit https://software.intel.com/en-us/intel-sdp-home/

Additional Language Information
- For information about the OpenMP* standards, see the OpenMP website at http://www.openmp.org/
- For information about the Fortran standards, visit the Fortran standards technical committee website at http://j3-fortran.org/.
## Notational Conventions

Information in this documentation applies to all supported operating systems and architectures unless otherwise specified.

This documentation uses the following conventions:

- **Notational Conventions**
- **Platform Labels**

### Notational Conventions

<table>
<thead>
<tr>
<th>THIS TYPE</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>THIS TYPE</td>
<td>Indicates statements, data types, directives, and other language keywords. Examples of statement keywords are WRITE, INTEGER, DO, and OPEN.</td>
</tr>
<tr>
<td>this type</td>
<td>Indicates command-line or option arguments, new terms, or emphasized text. Most new terms are defined in the Glossary.</td>
</tr>
<tr>
<td>This type</td>
<td>Indicates a example code.</td>
</tr>
<tr>
<td>This type</td>
<td>Indicates what you type as input.</td>
</tr>
<tr>
<td>This type</td>
<td>Indicates menu names, menu items, button names, dialog window names, and other user-interface items.</td>
</tr>
</tbody>
</table>

### File > Open

Menu names and menu items joined by a greater than (>) sign indicate a sequence of actions. For example, "Click **File > Open**" indicates that in the **File** menu, click **Open** to perform this action.

### {value | value}

Indicates a choice of items or values. You can usually only choose one of the values in the braces.

### [item]

Indicates items that are optional. Brackets are also used in code examples to show arrays.

### item [, item ]...

Indicates that the item preceding the ellipsis (three dots) can be repeated. In some code examples, a horizontal ellipsis means that not all of the statements are shown.

### Intel Fortran

This term refers to the name of the common compiler language supported by the Intel® Fortran Compiler.

### Windows* (or Windows* OS)

These terms refer to all supported Microsoft* Windows* operating systems.
These terms refer to all supported Linux* operating systems.

These terms refer all supported OS X* operating systems.

An asterisk at the end of a word or name indicates it is a third-party product trademark.

This term refers to Windows* options, Linux* options, or OS X* options that can be used by the compiler to compile applications.

The following conventions are used as shortcuts when referencing compiler option names in text:

- Many options have names that are the same on Linux*, OS X*, and Windows*, except that the Windows form starts with an initial / and the Linux and OS X form starts with an initial -. Within text, such option names are shown without the initial character; for example, check.

- Many options have names that are the same on Linux*, OS X*, and Windows*, except that the Windows form starts with an initial Q. Within text, such option names are shown as [Q]option-name.

  For example, if you see a reference to [Q]ip, the Linux* and OS X* form of the option is -ip and the Windows form of the option is /Qip.

- Several compiler options have similar names except that the Linux* and OS X* forms start with an initial q and the Windows form starts with an initial Q. Within text, such option names are shown as [q or Q]option-name.

  For example, if you see a reference to [q or Q]opt-report, the Linux* and OS X* form of the option is -qopt-report and the Windows form of the option is /Qopt-report.

Compiler option names that are more dissimilar are shown in full.

Conventions Used in Compiler Options

A slash before an option name indicates the option is available on Windows*. A dash before an option name indicates the option is available on Linux* and OS X* systems. For example:

Windows* option: /fast
Linux* and OS X* option: -fast
Note: If an option is available on Windows*, Linux*, and OS X* systems, no slash or dash appears in the general description of the option. The slash and dash will only appear where the option syntax is described.

/option:argument or
-option=argument

Indicates that an option requires an argument (parameter). For example, you must specify an argument for the following options:
Windows* option: /Qdiag-error-limit:n
Linux* and OS X* option: -diag-error-limit=n

/option:keyword or
-option=keyword

Indicates that an option requires one of the keyword values.

/option[:keyword] or
-option [=keyword]

Indicates that the option can be used alone or with an optional keyword.

option[n] or option[:n] or option [=n]

Indicates that the option can be used alone or with an optional value; for example, in /Qfnalign[:n] and -falign-functions [=n], the n can be omitted or a valid value can be specified for n.

option[-]

Indicates that a trailing hyphen disables the option; for example, /Qglobal_hoist-disables the Windows* option /Qglobal_hoist.

[no]option or
[no-]option

Indicates that "no" or "no-" preceding an option disables the option. For example:
In the Windows* option /[no]traceback, /traceback enables the option, while /notraceback disables it.
In the Linux* and OS X* option - [no-]global_hoist, -global_hoist enables the option, while -no-global_hoist disables it.
In some options, the "no" appears later in the option name; for example, -fno-alias disables the -falias option.

Conventions Used in Language Reference

This color

Indicates Intel extensions (non-standard features) that may or may not be implemented by other compilers. Features defined by the Fortran 2008 Standard or the OpenMP 4.1 API are shown in black.

Fortran

This term refers to language information that is common to previously supported Fortran standards, Fortran 2008, and the Intel® Fortran Compiler.

Standard Fortran

This term refers to language information that is common to ANSI/ISO Fortran 95, ANSI/ISO Fortran 90, and Intel Fortran.

Fortran 95

This term refers to language features specific to ANSI/ISO Fortran 95.
Fortran 2003
This term refers to language features specific to ANSI/ISO Fortran 2003.

Fortran 2008
This term refers to language features specific to ISO/IEC 1539-1:2010 (Fortran 2008).

integer
This term refers to the INTEGER(KIND=1), INTEGER(KIND=2), INTEGER (INTEGER(KIND=4)), and INTEGER(KIND=8) data types as a group.

real
This term refers to the REAL (REAL(KIND=4)), DOUBLE PRECISION (REAL(KIND=8)), and REAL(KIND=16) data types as a group.

REAL
This term refers to the default data type of objects declared to be REAL. REAL is equivalent to REAL(KIND=4), unless a compiler option specifies otherwise.

complex
This term refers to the COMPLEX (COMPLEX(KIND=4)), DOUBLE COMPLEX (COMPLEX(KIND=8)), and COMPLEX(KIND=16) data types as a group.

logical
This term refers to the LOGICAL(KIND=1), LOGICAL(KIND=2), LOGICAL (LOGICAL(KIND=4)), and LOGICAL(KIND=8) data types as a group.

<Tab>
This symbol indicates a nonprinting tab character.

^  
This symbol indicates a nonprinting blank character.

Platform Labels
A platform is a combination of operating system and central processing unit that provides a distinct environment in which to use a product (in this case, a computer language). An example of a platform is Microsoft* Windows* on processors using IA-32 architecture.

In this documentation, information applies to all supported platforms unless it is otherwise labeled for a specific platform (or platforms).

These labels may be used to identify specific platforms:

L*X  
Applies to Linux* on processors using IA-32 architecture and Intel® 64 architecture.

M*X  
Applies to OS X* on processors using IA-32 architecture and Intel® 64 architecture.

W*S  
Applies to Microsoft Windows* on processors using IA-32 architecture and Intel® 64 architecture.

i32  
Applies to 32-bit operating systems on IA-32 architecture.

i64em  
Applies to 32-bit operating systems on Intel® 64 architecture and Intel® Many Integrated Core Architecture (Intel® MIC Architecture).
| i64em_mic | Applies to 32-bit operating systems on Intel® 64 architecture targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture). |
Part II

Getting Started

Topics:

- Overview: Getting Started
- Using the Command Line
- Using Microsoft* Visual Studio* (Windows* OS)
- Using Xcode* (OS X*)
You can start using the Intel Fortran Compiler from:

- The Command line
- Microsoft* Visual Studio*
- Xcode*

Each of the above is described in further detail in this section.
Specifying Location of Compiler Components with compilervars File

Before you invoke the compiler, you may need to set certain environment variables that define the location of compiler-related components.

The Intel® Fortran Compiler includes compilervars scripts that you can run to set environment variables.

- On Linux® and OS X®, the file is a shell script called compilervars.sh or compilervars.csh.
- On Windows®, the file is a batch file called compilervars.bat.

The following information is operating system dependent.

Linux® and OS X®:
Set the environment variables before using the compiler. You can use the source command to execute the shell script compilervars.sh or compilervars.csh. You can also type the location of the shell script, beginning with ./.

```bash
//# syntax: source /<install-dir>/bin/compilervars.sh <arg>
./<install-dir>/bin/compilervars.sh <arg>  //# examples: (assuming <install-dir> is /installed/ compiler/) prompt> source /installed/compiler/bin/compilervars.sh ia32
prompt> ./installed/compiler/bin/compilervars.sh ia32

// OR  //# syntax: source /<install-dir>/bin/compilervars.csh <arg>
./<install-dir>/bin/compilervars.csh <arg>  //# examples: (assuming <install-dir> is /installed/ compiler/) prompt> source /installed/compiler/bin/compilervars.csh ia32
prompt> ./installed/compiler/bin/compilervars.csh ia32
```

The environment script file requires an architecture argument <arg>:

- ia32: Compiler and libraries for IA-32 architecture only.
- intel64: Compiler and libraries for Intel® 64 architecture only.

The default install path is /opt/intel/bin/<version>/ if the installation was conducted by the root user, where <version> is the version of the compiler you wish to set the environment for.

If you want the script to run automatically, add the same command to the end of your startup file.

Sample .bash_profile entry for compilervars.sh for IA-32 architecture only:

```bash
# set environment vars for Intel(R) Fortran Compiler
source <install-dir>/bin/compilervars.sh ia32
```

NOTE

Symbolic links are created in the /opt/intel directory at install. The environment variables use symbolic links; however, if two versions of the Intel® Fortran Compiler are installed, the most recently installed version will be symbolically linked.

If the proper environment variables are not set, an error similar to the following will appear when attempting to execute a compiled program:

```
./a.out: error while loading shared libraries:
libimf.so: cannot open shared object file: No such file or directory
```
Windows*:
Under normal circumstances, you do not need to run the compilervars.bat batch file. The Intel® Fortran command-line window sets these variables for you automatically.

For information on using the command-line window see Using the Intel® Command-Line Window.

NOTE
You need to run the batch file if a command-line window is opened without using one of the provided menu items in the Start menu, or if you want to use the compiler from a script of your own.

The batch file inserts the directories used by the Intel® Fortran Compiler at the beginning of the existing paths. Because these directories appear first, they are searched before any directories in the path lists provided by Windows*. This is especially important if the existing path includes directories with files having the same names as those needed by the Intel® Fortran Compiler.

If needed, you can run compilervars.bat each time you begin a session on Windows* systems by specifying it as the initialization file with the PIF Editor.

The batch file takes two arguments:

<install-dir>\bin\compilervars.bat <arg1> [<arg2>]

where <arg1> is one of the following:
- intel64: Compiler and libraries for Intel® 64 architecture only (host and target)
- ia32: Compiler and libraries for IA-32 architecture only (host and target)
- ia32_intel64: Compiler running on IA-32 architecture (host) that generates code for Intel® 64 architecture (target) using Intel® 64 architecture libraries

<arg2>, is optional. If specified, is one of the following:
- vs2015: Microsoft Visual Studio* 2015
- vs2013: Microsoft Visual Studio* 2013
- vs2012: Microsoft Visual Studio* 2012
- vs2010: Microsoft Visual Studio* 2010
- vs2013shell: Microsoft Visual Studio* Shell 2013

NOTE
If <arg2> is not specified, the script uses the version of Visual Studio* that was detected during the installation procedure.

Invoking the Intel® Compiler

Requirements Before Using the Command Line
You may need to set certain environment variables before using the command line. For more information, see Specifying Location of Compiler Components with compilervars File.

Using the Intel® Fortran Compiler from the Command Line
You can invoke the Intel® Fortran Compiler on the command line using the ifort command.
NOTE
For Windows* and OS X* systems, you can also use the compiler from within the integrated development environment (IDE).

For more information on using the Visual Studio* IDE, see Using Microsoft Visual Studio*. For information on using the Xcode* IDE, see Using Xcode*.

The syntax of the ifort command is:

`ifort [options]input_file(s)`

The ifort command can compile and link projects in one step or compile them then link them as a separate step.

In most cases, a single ifort command will invoke both the compiler and linker. You can also use ld (Linux* and OS X*) or link (Windows*) to build libraries of object modules. These commands provide syntax instructions at the command line if you request it with the help (Linux* and OS X*) or /? (Windows*) option.

The ifort command automatically references the appropriate Intel® Fortran Run-Time Libraries when it invokes the linker. To link one or more object files created by the Intel® Fortran compiler, you should use the ifort command instead of the link command.

The ifort command invokes a driver program that is the user interface to the compiler and linker. It accepts a list of command options and file names and directs processing for each file. The driver program does the following:

- Calls the Intel® Fortran Compiler to process Fortran files.
- Passes the linker options to the linker.
- Passes object files created by the compiler to the linker.
- Passes libraries to the linker.
- Calls the linker or librarian to create the executable or library file.

Because the driver calls other software components, error messages may be returned by other components. For instance, the linker may return a message if it cannot resolve a global reference. The watch option can help clarify which component is generating an error.

For a complete listing of compiler options, see the Compiler Options reference.

NOTE
The compiler recognizes Language Extensions for Offloading in the source program by default and builds a heterogeneous binary that runs on both the target and host when any are present. If your program includes these language extensions and you do not want to build a heterogeneous binary, specify the -no-offload compiler option. For more information, see the Programming for Intel® MIC Architecture: Heterogeneous Programming section and the -no-offload compiler option.

NOTE
Windows* systems support characters in Unicode* (multibyte) format; the compiler will process file names containing Unicode* characters.

Syntax Rules
The following rules apply when specifying ifort on the command line:
**Argument** | **Description**
---|---
options | An option is specified by one or more letters preceded by a hyphen (-) for Linux* and OS X* or a slash (/) for Windows*. (You can use a hyphen (-) instead of a slash (/) for Windows*, but this is not the preferred method.)

Options cannot be combined with a single slash or hyphen, you must specify the slash or hyphen for each option specified. For example: /1 /c is correct, but /1c is not.

Options can take arguments in the form of filenames, strings, letters, and numbers. If a string includes spaces, they must be enclosed in quotation marks.

Some options take arguments in the form of filenames, strings, letters, or numbers. Except where otherwise noted, a space between the option and its argument(s) can be entered or combined. For a complete listing of compiler options, see the Compiler Options reference.

Some compiler options are case-sensitive. For example, c and C are two different options.

Option names can be abbreviated, enter as many characters as are needed to uniquely identify the option.

Compiler options remain in effect for the whole compilation unless overridden by a compiler directive.

Certain options accept one or more keyword arguments following the option name on Windows*. To specify multiple keywords, you typically specify the option multiple times. However, some options allow comma-separated keywords. For example:

- Options that use a colon can use an equal sign (=) instead.
- Standard output and standard error can be redirected to a file, avoiding displaying excess text, which will slow down execution; scrolling text in a terminal window on a workstation can cause an I/O bottleneck (increased elapsed time) and use more CPU time. See the examples in the next section.

**NOTE**
Options on the command line apply to all files. In the following example, the -c and -nowarn options apply to both files x.f and y.f:

```
ifort -c x.f -nowarn y.f
```

input file(s) | Multiple files can be specified, using a space as a delimiter. When a file is not in PATH or working directory, specify the directory path before the file name. The filename extension specifies the type of file. See Understanding File Extensions.

Xlinker (Linux* and OS X*) or /link (Windows*) | Unless specified with certain options, the command line will both compile and link the files you specify. To compile without linking, specify the c option.

All compiler options must precede the Xlinker (Linux* and OS X*) or /link (Windows*) options. Options that appear following Xlinker or /link are passed directly to the linker.

**Examples of the ifort Command**

The following command compiles x.for, links, and creates an executable file. This command generates a temporary object file, which is deleted after linking:

```
ifort x.for
```
The following command compiles $x$.for and generates the object file $x.o$ (Linux* and OS X*) or $x.obj$ (Windows*). The $c$ option prevents linking (it does not link the object file into an executable file):

```bash
// (Linux* and OS X*)
ifort -c $x$.for  // (Windows*)
ifort $x$.for /c
```

The following command links $x.o$ or $x.obj$ into an executable file. This command automatically links with the default Intel® Fortran libraries:

```bash
// (Linux* and OS X*)
ifort $x$.o  // (Windows*)
ifort $x$.obj
```

The following command compiles $a$.for, $b$.for, and $c$.for, creating three temporary object files, then linking the object files into an executable file named $a$.out (Linux* and OS X*) or $a.exe$ (Windows*).

```bash
ifort a.for b.for c.for
```

Compile the source files that define modules before the files that reference the modules (in USE statements) when using modules and compile multiple files.

When you use a single `ifort` command, the order in which files are placed on the command line is significant. For example, if the free-form source file `moddef.f90` defines the modules referenced by the file `projmain.f90`, use the following syntax:

```bash
ifort moddef.f90 projmain.f90
```

To specify a particular name for the executable file, specify the option `–o` (Linux* and OS X*) or `/exe` (Windows*):

```bash
// (Linux* and OS X*)
ifort $x$.for –o myprog.out  // (Windows*)
ifort $x$.for /exe:myprog.exe
```

To redirect output to a file and then display the program output (Linux* and OS X*):

```bash
// (Linux* and OS X*)
myprog > results.lis
more results.lis
```

To place standard output into file `one.out` and standard error into file `two.out`:

```bash
// (Windows*)
ifort filenames /options 1>one.out 2>two.out
// OR
ifort filenames /options >one.out 2>two.out
```

To place standard output and standard error into a single file `both.out` (Windows*):

```bash
// (Windows*)
ifort filenames /options 1>both.out 2>&1
// OR
ifort filenames /options >both.out 2>&1
```

**Other Methods for using the Command Line Window to Invoke the Compiler**

- **Using makefiles from the Command Line**: Use makefiles to specify a number of files with various paths and to save this information for multiple compilations. For more information on using makefiles, see **Using Makefiles to Compile Your Application**.

- **Using the devenv command from the Command Line (Windows* only)**: Use `devenv` to set various options for the integrated development environment (IDE) as well as build, clean, and debug projects from the command line. For more information on the `devenv` command, see the `devenv` description in the Microsoft Visual Studio* documentation.

- **Using a batch file from the Command Line**: Use a `.bat` file to consistently execute the compiler with a desired set of options instead of retyping the command each time you need to recompile.
Using the Intel® Command-Line Window

The Intel compiler provides a command-line window with the appropriate environment variables already set. To invoke the compiler from the command line:

- **Windows 8**
  1. From the Start screen, swipe up from the bottom edge, or right-click the screen and click All apps at the bottom-left corner of the screen.
  2. In the Apps screen, scroll to the right until you see the program group for your Intel product.
  3. Click Intel 64 Visual Studio mode or IA-32 Visual Studio mode to open a command window.

- **Windows**
  Click the appropriate mode from the Start menu item for your Intel product under Compiler and Performance Libraries > Command Prompt with Intel Compiler.

The command-line window opens.

You can use any command recognized by the Windows command prompt, plus some additional commands. Because the command-line window runs within the context of Windows®, you can easily switch between the command-line window and other applications for Windows or have multiple instances of the command-line window open simultaneously.

When you are finished working in a command-line window, use the EXIT command to close the window and end the session.

Running Fortran Applications from the Command Line

For programs run from the command line, the operating system searches directories listed in the PATH environment variable to find the requested executable file.

The program can also be run by specifying the complete path of the executable file. On Windows® operating systems, any DLLs you are using must be in the same directory as the executable or in one specified in the path.

Multithreaded Programs

If the program is multithreaded, each thread starts on whichever processor is available at the time. On a computer with one processor, the threads all run in parallel, but not simultaneously; the single processor switches among them. On a computer with multiple processors, the threads can run simultaneously.

Using the -fpscomp filesfromcmd Option

If you specify the fpscomp option with keyword filesfromcmd, the command line that executes the program can include additional filenames to satisfy OPEN statements in the program for which the filename field (FILE specifier) has been left blank. The first filename on the command line is used for the first OPEN statement executed, the second filename for the second OPEN statement, and so on.
NOTE
In the Visual Studio* IDE, you can provide these filenames using Project > Properties. Choose the Debugging category and enter the filenames in the Command Arguments text box.

Each filename on the command line (or in an IDE dialog box) must be separated from the names around it by one or more spaces or tab characters. You can enclose each name in quotation marks ("<filename>"), but this is not required unless the argument contains spaces or tabs. A null argument consists of an empty set of quotation marks with no filename enclosed ('"').

The following example runs the program MYPROG.EXE from the command line:

```
MYPROG "" OUTPUT.DAT
```

Because the first filename argument is null, the first OPEN statement with a blank filename field produces the following message:

```
File name missing or blank - please enter file name
UNIT number ?
```

The number is the unit number specified in the OPEN statement. The filename OUTPUT.DAT is used for the second OPEN statement executed. If additional OPEN statements with blank filename fields are executed, you will be prompted for more filenames.

Instead of using the fpscomp option with keyword filesfromcmd, you can:

- Call the GETARG library routine to return the specified command-line argument. To execute the program in the Visual Studio* IDE, provide the command-line arguments to be passed to the program using Project > Properties. Choose the Debugging category and enter the arguments in the Command Arguments text box.
- On Windows* OS, call the GetOpenFileName Windows* API routine to request the file name using a dialog box.

fpscomp option

Understanding File Extensions

Input File Extensions
The Intel® Fortran Compiler interprets the type of each input file by the file name extension.

The file extension determines whether a file gets passed to the compiler or to the linker. The following types of files are used with the compiler:

- Files passed to the compiler: .f90, .for, .f, .fpp, .i, .i90, .ftn
  Typical Fortran source files have a file extension of .f90, .for, and .f. When editing your source files, you need to choose the source form, either free-source form or fixed-source form (or a variant of fixed form called tab form). You can use a compiler option to specify the source form used by the source files (see the description for the free or fixed compiler option) or you can use specific file extensions when creating or renaming your files. For example, the compiler assumes that files with an extension of:
  - .f90 or .i90 are free-form source files.
  - .f, .for, .ftn, or .i are fixed-form (or tab-form) files.
- Files passed to the linker: .a, .lib, .obj, .o, .exe, .res, .rbb, .def, .dll
  The most common file extensions and their interpretations are:
### Filename Table

<table>
<thead>
<tr>
<th>Filename</th>
<th>Interpretation</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>file.a (Linux* OS and OS X*)</td>
<td>Object library</td>
<td>Passed to the linker.</td>
</tr>
<tr>
<td>file.lib (Windows* OS)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>file.f</td>
<td>Fortran fixed-form source</td>
<td>Compiled by the Intel® Fortran compiler.</td>
</tr>
<tr>
<td>file.for</td>
<td></td>
<td></td>
</tr>
<tr>
<td>file.frn</td>
<td></td>
<td></td>
</tr>
<tr>
<td>file.i</td>
<td></td>
<td></td>
</tr>
<tr>
<td>file.fpp</td>
<td>Fortran fixed-form source</td>
<td>Automatically preprocessed by the Intel® Fortran preprocessor fpp; then compiled by the Intel® Fortran compiler.</td>
</tr>
<tr>
<td>On Linux* OS, filenames with the following uppercase extensions:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>file.FPP</td>
<td></td>
<td></td>
</tr>
<tr>
<td>file.F</td>
<td></td>
<td></td>
</tr>
<tr>
<td>file.FOR</td>
<td></td>
<td></td>
</tr>
<tr>
<td>file.FTN</td>
<td></td>
<td></td>
</tr>
<tr>
<td>file.f90</td>
<td>Fortran free-form source</td>
<td>Compiled by the Intel® Fortran compiler.</td>
</tr>
<tr>
<td>file.i90</td>
<td></td>
<td></td>
</tr>
<tr>
<td>file.F90 (Linux* OS and OS X*)</td>
<td>Fortran free-form source</td>
<td>Automatically preprocessed by the Intel® Fortran preprocessor fpp; then compiled by the Intel® Fortran compiler.</td>
</tr>
<tr>
<td>file.s (Linux* OS and OS X*)</td>
<td>Assembly file</td>
<td>Passed to the assembler.</td>
</tr>
<tr>
<td>file.asm (Windows* OS)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>file.o (Linux* OS and OS X*)</td>
<td>Compiled object file</td>
<td>Passed to the linker.</td>
</tr>
<tr>
<td>file.obj (Windows* OS)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

When you compile from the command line, you can use the compiler configuration file to specify default directories for input libraries. To specify additional directories for input files, temporary files, libraries, and for the files used by the assembler and the linker, use compiler options that specify output file and directory names.

### Output File Extensions (Windows* OS)

On Windows* operating systems, many compiler options allow you to specify the name of the output file being created. These compiler options are summarized in the table below.

If you specify only a filename without an extension, a default extension is added for the file being created.

<table>
<thead>
<tr>
<th>Compiler option</th>
<th>Default file extension</th>
</tr>
</thead>
<tbody>
<tr>
<td>/F file</td>
<td>.ASM</td>
</tr>
<tr>
<td>/dll:file</td>
<td>.DLL</td>

<tr>
<td>/exe:file</td>
<td>.EXE</td>
</tr>
<tr>
<td>/map:file</td>
<td>.MAP</td>
</tr>
</tbody>
</table>
Using Makefiles to Compile Your Application

This topic describes use of makefiles to compile your application. You can use makefiles to specify a number of files with various paths and to save this information for multiple compilations.

Using Makefiles to Store Information for Compilation on Linux* OS or OS X*

To run make from the command line using the Intel® Fortran Compiler, make sure that /usr/bin and /usr/local/bin are in your PATH environment variable.

If you use the C shell, you can edit your .cshrc file and add the following:

```
setenv PATH /usr/bin:/usr/local/bin:$PATH
```

Then you can compile using the following syntax:

```
make -f yourmakefile
```

where -f is the make command option to specify a particular makefile name.

Using Makefiles to Store Information for Compilation on Windows* OS

To use a makefile to compile your source files, use the nmake command. For example, if your project is your_project.mak, you can use the following syntax:

```
nmake /f [makefile_name.mak] FPP=[compiler_name.exe] LINK32=[linker_name.exe]
```

For example:

```
prompt> nmake /f your_project.mak FPP=ifort.exe LINK32=xilink.exe
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/f</td>
<td>The nmake option to specify a makefile.</td>
</tr>
<tr>
<td>your_project.mak</td>
<td>The makefile to use to generate object and executable files.</td>
</tr>
<tr>
<td>FPP</td>
<td>The preprocessor/compiler that will generate object and executable files.</td>
</tr>
<tr>
<td>(The name of this macro may be different for your makefile.)</td>
<td></td>
</tr>
<tr>
<td>LINK32</td>
<td>The linker that will be used.</td>
</tr>
</tbody>
</table>

The nmake command creates object files (.obj) and executable files (.exe) from the information specified in the your_project.mak makefile.

Generating Build Dependencies for Use in a Makefile

Use the gen-dep compiler option to generate build dependencies for a compilation.

Build dependencies include a list of all files included with INCLUDE statements and .mod files accessed with USE statements. The resulting output can be used to create a makefile to with the appropriate dependencies resolved.

Consider a source file that contains the following:

```fortran
module b
  include 'gendep001b.inc'
end module b

program gendep001
```

See Also
Invoking the Intel® Compiler
When you compile the source using the gen-dep option, the following output is produced:

```
b.mod : \  
gendep001.f90 
gendep001.obj : \  
gendep001.f90 gendep001b.inc
```

This output indicates that the generated file `b.mod` depends on the source file `gendep001.f90`. Similarly, the generated file `gendep001.obj` depends on the files `gendep001.f90` and `gendep001b.inc`.
Using Microsoft Visual Studio*

(Windows* OS)

Using Microsoft Visual Studio*

You can use the Intel® Fortran Compiler within the Visual Studio* integrated development environment (IDE) to develop Fortran applications, including static library (.LIB), dynamic link library (.DLL), and main executable (.EXE) applications. This environment makes it easy to create, debug, and execute programs. You can build your source code into several types of programs and libraries, using the IDE or from the command line.

The IDE offers these major advantages:

- Makes application development quicker and easier by providing a visual development environment.
- Provides integration with the native Microsoft Visual Studio* debugger.
- Makes other IDE tools available.

Using Visual Studio* Windows

After you start Visual Studio*, a screen similar to the following appears:
This screen shows an open Solution named Console1, a Project named Console1, and the source file Console1.f90 have been opened. The right pane shows the file Console1.f90, opened in the default language-sensitive integrated development environment text editor, which uses different colors to identify the following:

- Source comments (green).
- Fortran standard language elements (blue).
- Other language text (black).

**Solution Explorer View**

The left pane shows the Solution Explorer view, which lets you view different aspects of your solution, such as the source files in your solution. The tabs displayed in Solution Explorer vary depending upon the products installed and the files associated with the current solution. The sample screen shown above shows a Solution tab and a Property Manager tab (not used by Intel® Fortran). To display the Solution Explorer view, select View > Solution Explorer.

To edit a file listed in Solution Explorer, either double-click its file name or select File > Open and specify the file.

The Output window displays compilation and linker messages. To display the Output window, select View > Output. The Output window also links to the build log, if the Generate Build logs option is enabled in Tools > Options > Intel Compilers and Tools > Visual Fortran.

**Creating a New Project**

**Creating a New Project**

When you create a project, Visual Studio* automatically creates a corresponding solution to contain it. To create a new Intel® Fortran project using Visual Studio*:

The hello32 project assumes focus in the Solution Explorer view. The default Visual Studio* solution is also named hello32.

1. Select File > New > Project.
2. In the left pane, click Intel® Visual Fortran to display the Fortran project types. For each project type, available templates are listed in the right pane.
3. Click the appropriate project type (see Understanding Project Types).
4. Accept or specify a project name.
5. Accept or specify the Location for the project directory. Project files will be stored here. If the directory specified does not exist, it will be created.
6. Click OK to complete the new project.

The project and its files appear in the Solution Explorer view. For a COM Server project, you will see a second page with additional user options.

**Adding Source Files**

**To add an existing file to the project:**

1. If not already open, open the project (use the File menu).
2. Select Project > Add Existing Item.
3. In the Add Existing Item dialog box that appears, select the Fortran files to be added to the project.
To add a new file to the project:

1. If not already open, open the project (use the File menu).
2. Select Project > Add New Item.
3. In the Add New Item dialog box that appears, choose the type of file.
4. Specify the file name. Click Open. The file name appears in the Solution Explorer view.
5. Use the Visual Studio* editor to type in source code. Be sure to save your work when you are finished.

Organizing Existing Source Code

If you have existing source code, you should organize it into directories before creating a project, although it is easy to move files and edit your project definitions if you should later decide to reorganize your files.

Working with Fortran Modules

If your program uses Fortran modules, you do not need to explicitly add them to your project; they appear as dependencies (.MOD files).

A module file is a precompiled, binary version of a module definition, stored as a .mod file. When you change the source definition of a module, you can update the .mod file before you rebuild your project. To do this, compile the corresponding source file separately by selecting the file in the Solution Explorer window and selecting Build > Compile. If the module source file is part of your project, you do not need to compile the file separately. When you build your project, the Intel® Fortran Compiler determines what files need to be compiled.

To control the placement of module files in directories, use Project > Properties > Fortran > Output Files > Module Path in the IDE or the compiler option [no]module on the command line. The location you specify is automatically searched for .mod files.

To control the search for module files in directories, select one of the following:

- **In the IDE**
  - Project > Properties > Fortran > Preprocessor > Default Include and Use Path
  - Project > Properties > Fortran > Preprocessor > Ignore Standard Include Path
- **On the Command Line**
  - X or I and assume:source_include compiler options.

For a newly created project (or any other project), the IDE scans the file list for sources that define modules and compiles them before compiling the program units that use them. The IDE automatically scans the added project files for modules specified in USE statements, as well as any INCLUDE statements. It scans the source files for all tools used in building the project.

Performing Common Tasks with Visual Studio*

This topic outlines the basic steps for using the Intel® Fortran Compiler with Microsoft Visual Studio*.

Building and Running a Fortran Project

- To build the application, select Build > Build Solution. Any errors will be displayed in the Output Window. Double-click on a message to go to the line in error.
- To run without debugging, select Debug > Start Without Debugging. The console window will remain open after the program exits until you press Enter.
• To run under the debugger, first set a breakpoint at the first executable line of the program by clicking in the gray column to the left of the source line. Then select **Debug > Start**. If the program exits normally, the console window will be closed automatically.

**Converting Compaq* Visual Fortran Projects**

For information on converting projects from Compaq* Visual Fortran to Intel® Fortran, see **Converting Projects**.

**Further Reading**

Documentation is available in Visual Studio* from the **Help** menu.

You can request documentation on Fortran language features, including library routines, using context-sensitive help in the Visual Studio* IDE. In a source window, position the cursor on a language keyword (for example, **INTEGER** or **CONTAINS**) or a library routine (for example, **DATE_AND_TIME** or **SIGNALQQ**) and press the F1 key. This displays the appropriate topic in the documentation.

Similarly, dialog boxes and property pages that are specific to the Intel® Fortran compiler offer context-sensitive help that is accessed by pressing the F1 key.

**See Also**

Creating a New Project
Converting Projects

**Selecting a Version of the Intel® Compiler**

If you have more than one version of the Intel® Fortran Compiler installed, you can choose which version to be used when building applications. You can also select different versions for different target platforms and the version of the compiler you are using. The target platform you select determines the compiler versions that appear in the **Selected** drop-down box.

To select the compiler version:

1. Select **Tools > Options > Intel Compilers and Tools > Visual Fortran > Compilers**.
2. Select a compiler from **Selected compiler**. Click **OK**.

**See Also**

Specifying a Target Platform

**Specifying Fortran File Extensions**

You can specify additional Fortran free format and fixed format file extensions to be recognized as valid file extensions within the IDE. The IDE treats these additional extensions as compilable Fortran source files. You can also remove or modify existing extensions.

When you add a new extension, the IDE checks the registry to determine whether the extension is already associated with a language, tool, or file format. If there is such an association, a message informs you of this and you will not be allowed to add the extension.

**To specify Fortran file extensions:**

1. Open **Tools > Options**.
2. In the left pane, go to **Intel Compilers and Tools > Visual Fortran > General**.
3. Specify one or more Fortran File Extensions, each beginning with a period and separated by semicolons. You can specify extensions for both **Free Format** and **Fixed Format**. Click **OK**.

These new settings take effect the next time you start Visual Studio*.

Use the **Reset** button to restore Fortran file extensions to their default settings.
Using the Intel® Fortran Samples

The Intel® Fortran Compiler installs a number of sample programs. These programming samples illustrate a variety of concepts such as:

- Creating console applications
- Creating QuickWin applications
- Creating Win32 applications
- Using mixed-language support
- Using OpenGL® in Fortran applications

The programming samples are located in the `<install-dir>\Samples\` directory. These samples have associated build files that use the Intel® Fortran Compiler, in command-line mode, to compile and build the Fortran sources.

For further information on the samples and how to use them, use a web browser to open and read the `samples.htm` document in the `\Samples\` folder.

Understanding Solutions, Projects, and Configurations

The Visual Studio® integrated development environment (IDE) consists of one or more projects contained within a solution. A solution can contain multiple projects. For example, if you have several Fortran applications that do different calculations, but are related to the same research application you are working on, you can store all the individual projects in a single solution. Along with a solution file (.sln), the IDE creates a solution user options (.suo) file for storing IDE customization.

The following table summarizes the files created by Visual Studio® when you create a new project:

<table>
<thead>
<tr>
<th>File</th>
<th>Extension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Project Solution file</td>
<td>.sln</td>
<td>Stores solution information, including the projects and items in the solution and their locations on disk.</td>
</tr>
<tr>
<td>Project file</td>
<td>.vfproj</td>
<td>Contains information used to build a single project or subproject.</td>
</tr>
<tr>
<td></td>
<td>.vcproj</td>
<td></td>
</tr>
<tr>
<td></td>
<td>.icproj</td>
<td></td>
</tr>
<tr>
<td>Solution options file</td>
<td>.suo</td>
<td>Contains IDE customization for your solution, based on options you select.</td>
</tr>
</tbody>
</table>

**CAUTION**

Directly modifying these files with a text editor is not supported.

**CAUTION**

Before you open Compaq® Visual Fortran 6.0 projects or Intel® Visual Fortran 7.x projects in Visual Studio®, review the guidelines listed in Converting Projects.

Each project can specify one or more configurations to build from its source files. A configuration specifies such information as the type of application to build, the platform on which it is to run, and the tool settings to use when building. Having multiple configurations lets you extend the scope of a project but still maintain a consistent source code base from which to work.

When you create a new project, Visual Studio® automatically creates Debug and Release (also known as Retail) configurations for you. The default configuration is the Debug configuration. To specify the current configuration, select Configuration Manager from the Build menu.

You can specify build options in the Project > Properties dialog box, for one of the following:
For all configurations (project-wide).
For certain configurations (per configuration).
For certain files (per file).

For example, you can specify certain kinds of compiler optimizations for all configurations in general, but turn them off for certain configurations or certain files.

Once you have specified the files in your project, the configurations that your project is to build, and the tool settings for those configurations, you can build the project with the commands on the Build menu.

NOTE
For a multiple-project solution, make sure that the executable project is designated as the startup project (shown in bold in the Solution Explorer view). If not, right click on the project and select Set as StartUp Project.

Converting Projects

Navigating Programmatic Components in a Fortran File

You can quickly navigate the code of the file currently open in the source editor using the Tree Navigation Window. The Tree Navigation Window displays the following components of the file as nested, selectable nodes in a tree:

- programs
- modules
- subroutines with signature
- functions with signature
- types
- interfaces

Nodes at each nested level are sorted alphabetically.

Any changes you make to a file, such as adding or deleting a component or changing a signature, are immediately reflected in the tree.

To navigate a file:

1. Select View > Other Windows > Tree Navigation Window.
   The Tree Navigation Window tab appears near the Solution Explorer tab. When no Fortran project is opened, the Tree Navigation Window is empty. When you open a Fortran file in the source editor, all components of the file appear in the window.
2. Select a node in the tree to view the corresponding component in the source editor.
   The cursor appears at the correct location in the file.

Selecting a Configuration

A configuration contains settings that define the final binary output file that you create within a project. It specifies the type of application to build, the platform on which it is to run, and the tool settings to use when building.

Debug and Release Configurations

When you create a new project, Visual Studio* automatically creates the following configurations:
<table>
<thead>
<tr>
<th>Configuration</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Debug</strong> configuration</td>
<td>By default, the debug configuration sets project options to include the debugging information in the debug configuration. It also turns off optimizations. Before you can debug an application, you must build a debug configuration for the project.</td>
</tr>
<tr>
<td><strong>Release</strong> (Retail) config</td>
<td>The release configuration does not include the debugging information, and it uses any optimizations that you have chosen.</td>
</tr>
</tbody>
</table>

Use the Visual Studio* **Configuration Manager** to select:

- **Release** or **Debug** configuration for the active solution.
- **Release** or **Debug** configuration for any project within the active solution.
- Target platform for each project.

Multiple configurations allow extending the scope of a project while maintaining a consistent source code base from which to work. The default configuration is the **Debug** configuration. To add, change, or delete a configuration, select **Build > Configuration Manager** from the main menu or use the drop-down box on the main menu bar. Only one configuration can be active at one time. Configurations can be used for the whole solution or for specific projects in the solution.

When you build your project, the currently selected configuration is built, as follows:

- If you selected the debug configuration, a directory called **Debug** contains the output files created by the build for the debug version of your project.
- If you selected the release configuration, a directory called **Release** contains the output files created by the build for the release version of your project.

(You can change the output directory using the **General** category in **Project > Properties**.)

A configuration has the following characteristics:

- **Configuration type**: specifies the type of Fortran application to build.
- **Build options**: specifies the build options, which include the compiler and linker options.

By default, the **Debug** configuration sets project options to include debug symbol information and turns off optimizations. Before you can debug an application, you must build a debug configuration for the project. Although debug and release configurations usually use the same set of source files, the project setting information usually differs. For example, the default debug configuration supplies full debug information and no optimizations, whereas the default release configuration supplies minimal debug information and full optimizations.

To make configuration changes for your project:

1. Choose an active solution in the **Solution Explorer**.
2. Go to **Build > Configuration Manager**.
3. Select a configuration.

**Platform Types**

The platform type sets options required specifically for the selected platform, such as options that the compiler uses for the source files, the libraries that the linker uses for the platform, defined constants, and so on.

**New Configurations**

In addition to the default **Debug** and **Release** configurations, you can also define new configurations within your project. These configurations may use the existing source files in your project, the existing project settings, or other characteristics of existing configurations.
Specifying a Target Platform

You can specify a target platform for a Visual Studio® solution or an individual project within a solution.

1. Select a solution or project in Solution Explorer.
2. Select Build > Configuration Manager.
   
   • Use the Active solution platform drop-down list to specify the target platform for the whole solution.
   
   • Use the Platform column to specify the target platform for an individual project within a solution.
3. To add a platform to the current list of active solution platforms, on the Active solution platform drop-down menu, select <New...>.
4. In the New Solution Platform dialog box that opens, type or select a new platform, such as x64, from the new platform drop-down menu.
5. In Copy settings from: , choose a platform whose settings will be used as a template or choose <Empty>.
6. If you want the platform to be set for the projects within the solution, select Create new project platforms. Click OK.
7. Close the Configuration Manager.

**NOTE**

You can also change target platforms from the Visual Studio® toolbar by selecting a platform from the Solution Platforms drop-down selection.

Removing Target Platforms

You can remove a target platform from the Configuration Manager:

1. Select <Edit...> from the Active solution platform list of options.
2. In the Edit Solutions Platforms dialog that opens, select a platform and click Remove.
3. Click Yes in the confirmation box that appears.

Specifying Path, Library, and Include Directories

You can specify directories that the Visual Studio® project system should search for certain types of files.

To set path, library, and include directories for your Intel® Fortran project environment on a particular machine:

1. Select Tools > Options .
2. In the left pane, select Intel Compilers and Tools > Visual Fortran > Compilers
3. In the right pane, specify directories where the Visual Studio® project system should look for files:
   
   • **Executables**: the directories to be searched for executable files. (Works like the PATH environment variable.)
   
   • **Libraries**: the directories to be searched for libraries. (Works like the LIB environment variable.)
   
   • **Includes**: the directories to be searched for include files. (Works like the INCLUDE environment variable.) You can use macros like $(VSIInstallDir) in directory names. For list of supported macros, see Supported Build Macros.

   Click OK.
Use the **Reset** and **Reset All** buttons to restore original installation settings for Executables, Libraries, and Includes fields. **Reset** restores initial settings for the currently selected compiler; **Reset All** restores initial settings for all compilers listed in the **Selected** drop-down box.

**NOTE**
If you specify `devenv` or `useenv` on the command line to start the IDE, the IDE uses the PATH, INCLUDE, and LIB environment variables as defined for that command line when performing a build. It uses these values instead of the values defined in **Tools** > **Options**.

For more information on the `devenv` command, see the `devenv` description in the Visual Studio* documentation.

For more information on environment variables, see Supported Environment Variables.

See Also
Supported Environment Variables
Supported Build Macros

**Setting Compiler Options in the Visual Studio* IDE Property Pages**

To set compilation and related options for the current project:

1. Select the project name in the **Solution Explorer** view (the project name `Console1` in the sample screen below).
2. In the **Project** menu, select **Properties**.

The Intel® Fortran Compiler also lets you specify compiler options for individual source files. To do this, select the file name and select **View** > **Property Pages**.
NOTE
For convenience, context-sensitive pop-up menus containing commonly used menu options are available by right-clicking on an item (for example, a file name or solution) in the IDE.

Displaying the Options
To display the Fortran compiler option categories, click the Fortran folder in the left pane to display the compiler option categories. The following sample screen shows the compiler options in the General category in the right pane. The selected option within the General category is Suppress Startup Banner, with a default value of Yes. The corresponding command line compiler option is \texttt{nologo}, as shown in the Help text at the bottom of the right pane.

NOTE
As shown in the screenshot below, option values that are different than the compiler defaults are displayed in bold.

![Console1 Property Pages](image)

Changing Option Settings
To change the setting for a compiler option:

1. Select a category and then click the desired option. Click the button at the right of an option line to display the available settings or display a dialog box. Available settings may include \textit{<inherit from project defaults>}, which resets the option value to the compiler default.
2. Select the desired setting and click \texttt{OK}.

To change the configuration (such as from Debug to Release), do one of the following:

- Select a different configuration in the Configuration: drop-down box in the upper-left of the window, or
- Click the Configuration Manager button in the upper-right of the window and reset the configuration in the dialog box that appears.
Fortran Option Categories

The Intel® Fortran compiler options available from the IDE are grouped in categories. Some options appear in multiple categories. Available options in each category may vary, depending the platform you have selected in the Platform box at the top of the dialog box. Options not listed in one of the categories can be typed into the Command Line category window.

Command Line Category

The Command Line category contains the Additional Options field where you can type in an option as you would from the command line. The IDE will process them as part of the Property Pages options for the particular project. For instance, you can use the Command Line category to type in miscellaneous Intel® Fortran compiler options that are not represented in any of the listed categories. If you type in a compiler option that is represented in one of the listed categories, the option you specify in the Command Line category will take precedence and override the equivalent setting in another category.

Supported Build Macros

The Intel® Fortran compiler supports certain build macros for use in the Property Pages dialog boxes associated with a project. Use these macros where character strings are accepted. The macro names are not case-sensitive.

The following table lists macros supported by Visual Studio* that are also supported by the Intel® Fortran Compiler.

<table>
<thead>
<tr>
<th>Macro Name</th>
<th>Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>Configuration name</td>
<td>$(ConfigurationName)</td>
</tr>
<tr>
<td>Platform name</td>
<td>$(PlatformName)</td>
</tr>
<tr>
<td>Intermediate directory</td>
<td>$(IntDir)</td>
</tr>
<tr>
<td>Output directory</td>
<td>$(OutDir)</td>
</tr>
<tr>
<td>Input directory</td>
<td>$(InputDir)</td>
</tr>
<tr>
<td>Input path</td>
<td>$(InputPath)</td>
</tr>
<tr>
<td>Input name</td>
<td>$(InputName)</td>
</tr>
<tr>
<td>Input filename</td>
<td>$(InputFileName)</td>
</tr>
<tr>
<td>Input file extension</td>
<td>$(InputExt)</td>
</tr>
<tr>
<td>Inherit properties</td>
<td>$(Inherit)</td>
</tr>
<tr>
<td>Do not inherit properties</td>
<td>$(NoInherit)</td>
</tr>
<tr>
<td>Project directory</td>
<td>$(ProjectDir)</td>
</tr>
<tr>
<td>Project path</td>
<td>$(ProjectPath)</td>
</tr>
<tr>
<td>Project name</td>
<td>$(ProjectName)</td>
</tr>
<tr>
<td>Project filename</td>
<td>$(ProjectFileName)</td>
</tr>
<tr>
<td>Project file extension</td>
<td>$(ProjectExt)</td>
</tr>
<tr>
<td>Solution directory</td>
<td>$(SolutionDir)</td>
</tr>
<tr>
<td>Solution path</td>
<td>$(SolutionPath)</td>
</tr>
</tbody>
</table>
Macro Name | Format
---|---
Solution name | $(SolutionName)
Solution filename | $(SolutionFileName)
Solution file extension | $(SolutionExt)
Target directory | $(TargetDir)
Target path | $(TargetPath)
Target name | $(TargetName)
Target filename | $(TargetFileName)
Target file extension | $(TargetExt)
Visual Studio* installation directory | $(VSInstallDir)
Visual C++* installation directory | $(VCInstallDir)
.NET Framework directory | $(FrameworkDir)
.NET Framework version | $(FrameworkVersion)
.NET Framework SDK Directory | $(FrameworkSDKDir)

The Intel® Fortran compiler also supports the following macros (not supported by Visual Studio*).  

Macro Name | Format
---|---
Intel® Fortran IDE installation directory | $(IFIDEInstallDir)

For additional information on using build macros, see the Microsoft MSDN* online documentation.

**Using Manifests**

The Intel® Fortran Compiler supports manifests, a Visual Studio* feature. Manifests describe run-time dependencies of a built application. A manifest file can be embedded in the assembly, which is the default behavior, or can be a separate standalone file. You can use the Manifest Tool property pages, which are accessed through Project > Properties, to change project settings that affect the manifest.

**NOTE**
In earlier releases, manifest files were embedded in the assembly, and were not able to be accessed or changed.

**Using Intel® Performance Libraries**

The Intel® Fortran Compiler comes bundled with the Intel® Math Kernel Library (Intel® MKL), one of the Intel® Performance Libraries.

To access the library: using the Libraries > Use Intel Math Kernel Library property.

1. Select the project and open Project > Properties.
2. In the left pane, go to Configuration Properties > Fortran > Libraries.
3. Set the Use Intel Math Kernel Library option to one of the following from the drop-down menu:
• **Parallel:** Use parallel Intel® MKL libraries.
• **Sequential:** Use sequential Intel® MKL libraries.
• **Cluster:** Use cluster Intel® MKL libraries.

For more information, see the Intel® Math Kernel Library documentation.

### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

---

**Using Guided Auto Parallelism in Visual Studio***

The Guided Auto Parallelism (GAP) feature helps you locate portions of your serial code that can be parallelized. When you enable analysis using GAP, the compiler guides you to places in your code where you can increase efficiency through automatic parallelization and vectorization.

### Running Analysis on a Project

You can start analysis from the Microsoft Visual Studio* IDE in several ways:

- **From the Tools menu:** Select **Intel Compiler > Guided Auto Parallelism > Run Analysis**....

  Starting analysis in this way results in a one time run for the current project. The default values are taken from **Tools > Options** unless you have chosen to override them in the dialog box.

- **From the Diagnostics property page:** use the **Guided Auto Parallelism Analysis** property.

  Specifically, choose **Project > Properties > Fortran > Diagnostics** and enable analysis using the **Guided Auto Parallelism Analysis** property. Enabling analysis in the property page allows you to run an analysis as part of a normal project **Build** request in Visual Studio*. In this mode, GAP-related settings in **Tools > Options** are ignored, in favor of other GAP-related settings available in the property page.

- **From the context menu:** Right-click and select **Intel Compiler > Guided Auto Parallelism > Run Analysis**....

  This is equivalent to using the **Guided Auto Parallelism > Run Analysis** option on the **Tools** menu.

To receive advice for auto parallelization, be sure that certain property page settings are correct. Select **Project > Properties > Fortran > Optimization** and set **Parallelization** to **Yes** to enable auto-parallelization optimization. You may also need to set the **Optimization** level at option 02 or higher.

### GAP Scenarios

To illustrate how the various Guided Auto Parallelism settings work together, consider the following scenarios:

<table>
<thead>
<tr>
<th>Scenario</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>The GAP analysis setting in the property pages is set to Enabled</td>
<td>Analysis always occurs for the project, whenever a regular project build occurs. Other analysis settings specified in the property pages are used. Analysis setting in <strong>Tools &gt; Options</strong> are ignored.</td>
</tr>
</tbody>
</table>
Running Analysis on a File or within a File

Use the right-click Guided Auto Parallelism context menu item to run analysis on the following:

- **Single file**: Select a file and right-click.
- **Function (routine)**: Right-click within the function scope.
- **Range of lines**: Select one or more lines for analysis and right-click.

See Also
- Options: Guided Auto Parallelism dialog box
- Guided Auto Parallelism Overview
- Using Guided Auto Parallelism

Using Code Coverage in Visual Studio*

The code coverage tool provides the ability to determine how much application code is executed when a specific workload is applied to the application. The tool analyzes static profile information generated by the compiler, as well as dynamic profile information generated by running an instrumented form of the application binaries on the workload. The tool can generate a report in HTML-format and export data in both text- and XML-formatted files. The reports can be further customized to show color-coded, annotated source-code listings that distinguish between used and unused code.

To start code coverage:

1. Select **Tools > Intel Compiler > Code Coverage**....
2. Specify settings for the various phases.
3. Click **Run**.

The **Output** window shows the results of the coverage and a general summary of information from the code coverage.

See Also
- Code Coverage dialog box
- Code Coverage Settings dialog box
- Code Coverage Tool

Using Profile Guided Optimization in Visual Studio*

Profile Guided Optimization (PGO) improves application performance by reorganizing code layouts to reduce instruction-cache problems, shrinking code size, and reducing branch misprediction. Profile guided optimization provides information to the compiler about areas of an application that are most frequently executed. By knowing these areas, the compiler is able to be more selective and specific in optimizing the application.

To start profile guided optimization:

1. Choose **Tools > Intel Compiler > Profile Guided Optimization**... .
2. Specify settings for the various phases.
3. Click Run.

The Output windows will show the results of the optimization with a link to the composite log.

See Also
Profile Guided Optimization dialog box
Options: Profile Guided Optimization (PGO) dialog box
Profile-Guided Optimizations Overview

Using Source Editor Enhancements in Visual Studio*
A number of Fortran source editor enhancements are available in Microsoft Visual Studio*.

Modules and Procedures Navigation Bar
A two-part navigation bar, located above the source editor pane, lets you navigate to a specific module (left part) and procedure (right part). To enable the navigation bar, choose Navigation Bar in Tools > Options > Text Editor > Fortran > General.

Source Editor Pane
Smart indenting
Smart indenting automatically indents block constructs (such as IF and DO) and left justifies the corresponding end statement. To enable smart indenting, select it in Tools > Options > Text Editor > Fortran > Tabs.

Code snippet insertion
Code snippet insertion lets you insert a prototype construct (such as DO, WHILE, or MODULE) from a list. Use the right-click context menu Insert Snippet... option to display the list and insert a snippet.

Delimiter matching
Delimiter (brace) matching lets you jump to a matching statement in a block construct (IF...THEN...END IF, DO...END DO). Use Ctrl] to jump. To enable delimiter matching, use Automatic delimiter highlighting in Tools > Options > Text Editor > General.

Call/Callers graph
Call/Caller information can be collected and shown visually in a graph that indicates the call stacks that lead to a unit of code. To enable Call/Callers graph information, change Collect Call/Callers graph information to True in Tools > Options > Text Editor > Fortran > Advanced > Browsing/Navigation.

Fortran Editor Options Page
Use Tools > Options > Text Editor > Fortran > Advanced to view the Fortran Advanced Options page.

Browsing/Navigation section
Collect Object Browser information: Choose this option to enable the display of procedures in your project in a hierarchical tree. Once enabled, you can use View > Object Browser to display your procedures.

NOTE
If the procedures in your project do not show when browsing in My Solution, you can right-click the message (No information. Try browsing a different component set.) and select View Containers as a possible solution.
Disable Database: Choose this option to disable creation of the code browsing database. This may help increase performance on slow machines. If you disable the database, all features that rely on code browsing information will not work.

Enable Find all References: Choose this option to enable display of the location(s) in your code where a symbol is referenced. When this option is enabled, you can use the right-click context menu Find All References option to display a list of references to the selected symbol. Double-click on a reference to find that reference.

Enable Go To Definition: Choose this option to enable quick navigation to an object definition. When this option is enabled, you can use the right-click context menu Go to Definition option to locate where the selected object was declared, opening the associated source file if required. (If you have also enabled Scan system includes, any objects declared in system modules such as IFWINTY cause the associated source for that module to be opened.)

Scan system includes: Choose this option to scan system include files. This option is used with one or more of the following options: Collect Object Browser Information, Enable Find All References, Enable Go To Definition.

Intrinsics section
Enable Intrinsic Parameter Info: Choose this option to enable the display of intrinsic function and subroutine parameter information. When this option is enabled, you can type a name of an intrinsic procedure, followed by an open parenthesis, and information about the procedure and its arguments appears.

Enable Intrinsic Quick Info: Choose this option to enable the display of additional information when the mouse pointer is moved over an intrinsic function or subroutine name.

Miscellaneous section
Enumerate Comment Tasks: Choose this option to enable the display of a list of tasks consisting of source files containing comments. Comments take the form of the ! character, followed by a token such as TO DO. Valid tokens are those listed in Tools > Options > Environment > Task List. When this option is enabled, you can select Comments from the task list using View > Other Windows Task List. Double-click on a comment in the list to jump to its location.

Highlight Matching Tokens: Choose this option to allow identifier highlighting and block delimiter matching. When enabled, this option highlights all references to the identifier under the cursor.

Outlining section
Enable Outlining: Choose this option to allow the collapsing of whole program units. When this option is enabled, you can click the minus (-) or plus (+) symbols for PROGRAM, SUBROUTINE, FUNCTION, MODULE, and BLOCK DATA statements.

Outline Statement Blocks: Choose this option to allow collapsing of block constructs such as IF and DO. You must also choose Enable Outlining.

Creating the Executable Program
When you are ready to create an executable image of your application, use the options on the Build menu. You can:

- Compile a file without linking.
- Build a project or solution.
- Rebuild a project or solution.
- Batch build several configurations of a project.
- Clean a project or solution (which deletes all files created during the Build).
- Select the active solution and configuration.
Edit the project configuration.

When you have completed your project definition, you can build the executable program.

When you select **Build <projectname>** from the **Build** menu (or **Build** toolbar), the integrated development environment (IDE) automatically updates dependencies, compiles and links all files in your project. When you build a project, the IDE processes only the files in the project that have changed since the last build and those files dependent on the changed files. The following example illustrates this.

**NOTE**
To define the build order of projects, right-click on the solution and choose **Properties > Project Dependencies**.

**Example:**

Assume you have multiple projects (A, B, and C) in a solution with the following defined dependencies:

- A depends on B
- B depends on C

If you build A, the build process verifies that B is up-to-date. During verification of B, C is also verified that it is likewise up-to-date. When either, or both, are determined to be out of date, the appropriate build operations will occur to update them. When C and B produce .lib or .dll output, the output of C is linked into B and the output of B is linked into A.

The **Rebuild <project name>** option forces a new compilation of all source files listed for the project.

You either can choose to build a single project, the current project, or multiple project configurations (using the **Batch Build...** option) in one operation. You can also choose to build the entire solution.

You can execute your program from the IDE using **Debug > Start Without Debugging** (Ctrl and F5) or **Debug > Start** (F5). You can also execute your program from the command line prompt.

**Compiling Files In a Project**

You can select and compile individual files in any project in your solution. To do this, select the file in the **Solution Explorer** view. Then, do one of the following:

- Select **Compile** from the **Build** menu (or **Build** toolbar).
- Right-click to display the pop-up menu and select **Compile**.

You can also use **Compile** from the **Build** menu (or **Build** toolbar) options when the source window is active and has input focus.

**Encountering Errors During Compilation**

When the compiler encounters an error in a file, compilation stops and the error is reported. You can change this default behavior and allow compilation to continue despite an error in the current file. When you do this, an error in the current file will cause the compiler to begin compiling the next file.

To enable **Continue on errors** behavior:

1. In **Tools > Options > Intel Compilers and Tools > Visual Fortran**, select the **General** category.
2. Check **Continue on errors** and click **OK**.

To set the maximum number of errors to encounter before compilation stops, choose **Configuration Properties > Fortran > Diagnostics > Error Limit**.

**Performing Parallel Project Builds**

Visual Studio* provides a parallel project build feature, allowing you to build multiple projects within a solution simultaneously, using separate threads. The Visual Studio* IDE initially sets the number of parallel project builds to equal the number of CPUs. To change this setting, do the following:
1. Choose **Tools > Options > Projects and Solutions.**

2. In the **Build and Run** property page, change the number in maximum number of parallel project builds and click **OK.**

For more information on using this feature, see the Microsoft MSDN* documentation.

**Converting and Copying Projects**

**Converting Projects**

Intel® Visual Fortran 10.x projects require conversion to the format used by Intel® Fortran 14.0 and later to be used with Visual Studio* integration. When you open a 10.x project in later versions of Intel® Fortran, a dialog box displays, asking you to confirm the conversion. If you select **No**, the project will not be loaded. If you select **Yes**, the project is converted and opens in the Visual Studio* IDE.

A 10.x project opened in Intel® Visual Fortran 11.0 or later cannot be subsequently opened again in Intel® Visual Fortran 10.x.

11.x projects or later open in Intel® Fortran 14.0 without any conversion.

The following applies to projects that were created with earlier versions of Intel® Visual Fortran or with Compaq* Visual Fortran and require conversion.

Intel® Fortran supports the following types of project conversions:

- Intel® Visual Fortran 7.x projects to Intel® Visual Fortran 8.x (and later) projects.
- Compaq* Visual Fortran 6.x projects to Intel® Visual Fortran 8.x (and later) projects.

Within these major project conversion categories, a number of different conversion scenarios are possible, depending on your version of Microsoft Visual Studio*. For example, a Compaq* Visual Fortran 6.0 project built in the Microsoft Developer Studio* 98 environment can be converted to an Intel® Fortran 14.0 project in the Visual Studio* environment.

Some general conversion principles apply:

- It is good practice to make a copy of the project before doing conversions.
- Intel® Fortran projects are created and built in a particular version of Visual Studio*. If you open the project in a later version of Visual Studio*, you are prompted to convert the solution. Once converted, a solution cannot be used in its previous environment.
- Compaq* Visual Fortran 6.x projects can be converted to Intel® Fortran projects in Visual Studio* 2010, 2012, 2013 or 2015 environments. Fortran-only projects are simpler to convert.
- Project conversion support is provided for Compaq* Visual Fortran Version 6.x only. Compaq* Visual Fortran projects created with earlier versions may not convert correctly.
- Conversion of Compaq* Visual Fortran projects is not supported if you are using the Microsoft Visual Studio* 2013 Shell. Instead, create a new Intel® Fortran project and add your source files to it.
- Fortran source files, resource files, and **MIDL** files lose any custom build step information when converted from Compaq* Visual Fortran to Intel® Fortran. For other file types, custom build steps will be propagated during the project's conversion.
- Conversion of Fortran and C/C++ mixed language projects results in the creation of two separate projects (a Fortran project and a C/C++ project) in a single solution.
- Intel® Fortran projects that are created with a point release (for instance, 14.x) are typically backward compatible to the first release of that number (in this case, 14.0). Projects are not backward-compatible between major release numbers.

**See Also**

**Copying Projects**

**Copying Projects**

You need to follow certain procedures to move a project’s location, whether you copy a project to:

- another disk or directory location on the same system
• another system where the Intel® Fortran Compiler is installed

If you upgrade your operating system version on your current system, you should delete the *.SUO and *.NCB files in each main project directory before you open solutions with the new operating system. It is good practice to clean a solution before moving and copying project files. To do this, select Clean in the Build menu.

To copy an existing Intel® Fortran project to another disk or system:

1. Copy all project files to the new location. You do not need to copy the subdirectories created for each configuration.
   
   Keep the directory hierarchy intact by copying the entire project tree to the new computer. For example, if a project resides in the folder \MyProjects\Projapp on one computer, you can copy the contents of that directory, and all subdirectories, to the \MyProjects\Projapp directory on another computer.

2. Delete the following files from the main directory at the new location. These files are disk- and computer-specific and should not be retained:
   - *.SUO files
   - *.NCB files (if present)

3. If you copied the subdirectories associated with each configuration (for example, Debug and Release), delete the contents of subdirectories at the new location. The files contained in these subdirectories are disk- and computer-specific files and should not be retained. For example, Intel® Fortran module (.MOD) files contained in these subdirectories should be recreated by the compiler, especially if a newer version of Intel® Fortran has been installed.

   **NOTE**
   The internal structure of module files can change between Intel® Fortran releases.

If you copied the project files to the same system or a system running the same platform and major Intel® Fortran version, do the following steps to remove most or all of the files in the configuration subdirectory:

- Open the appropriate solution. In the File menu, either select Open Solution or select Recent Solutions. If you use Open Solution, select the appropriate .SLN file.
- Select Set Active Configuration in the Build menu and select a configuration.
- Select Clean in the Build menu.
- Repeat the previous two steps for other configurations whose subdirectories have been copied.

4. If possible, after copying a project, verify that you can open the project at its new location using the same Fortran version that it was created in. This ensures that the project has been moved successfully and minimizes the chance of conversion problems. If you open the project with a later version of Fortran, the project will be converted and you will not be able to convert the project back. For this reason, making an archive copy of the project files before you start is recommended.

5. View the existing configurations. To view the existing configurations associated with the project, open the solution and view available configurations using the drop-down box at the top of the screen.

6. Check and reset project options.

   Because not all settings are transportable across different disks and systems, you should verify your project settings on the new platform. To verify your project settings:

   a. From the Project menu, choose Properties. The Project Property Pages dialog box appears.
   b. Configure settings as desired. Pay special attention to the following items:
• **General:** Review the directories for intermediate and output files. If you moved the project to a different system, be aware that any absolute directory paths (such as `C:\TEMP` or `\Myproj\TEMP`) will most likely need to be changed. Instead, use relative path directory names (without a leading back slash), such as `Debug`

• **Custom Build Step:** Review for any custom commands that might change between platforms.

• **Pre-build, Pre-link, and Post-build Steps in Build Events:** Review for any custom commands that may have changed.

7. Check your source code for directory paths referenced in `INCLUDE` or similar statements. Visual Studio* provides a multi-file search capability called Find in Files, available from the Edit menu.

### About Fortran Project Types

**Understanding Project Types**

When you create a project in Visual Studio*, you must choose a project type. You need to create a project for each binary executable file to be created. For example, the main Fortran program and a Fortran dynamic-link library (DLL) would each reside in the same solution as separate projects.

The project type specifies what to generate and determines some of the options that the visual development environment sets by default for the project. It determines, for instance, the options that the compiler uses to compile the source files, the static libraries that the linker uses to build the project, and the default locations for output files.

When you select a project type, an Application wizard (AppWizard) is launched, which guides you through project set-up. The AppWizard supplies default settings for both the **Release** and **Debug** Configurations of the project. For more information about configurations, see Understanding Solutions Projects and Configurations and Selecting a Configuration.

The following table lists the available Intel® Fortran Compiler project types. The first four projects listed are main project types, requiring main programs. The last two are library projects, without main programs.

<table>
<thead>
<tr>
<th>Project Type</th>
<th>Key Features</th>
</tr>
</thead>
<tbody>
<tr>
<td>Using Fortran Console Application Projects (.EXE)</td>
<td>Single window main projects without graphics (resembles character-cell applications). Requires no special programming expertise.</td>
</tr>
<tr>
<td>Using Fortran Standard Graphics Application Projects (.EXE)</td>
<td>Single window main projects with graphics. The programming complexity is simple to moderate, depending on the graphics and user interaction used.</td>
</tr>
<tr>
<td>Using Fortran QuickWin Application Projects (.EXE)</td>
<td>Multiple window main projects with graphics. The programming complexity is simple to moderate, depending on the graphics and user interaction used.</td>
</tr>
<tr>
<td>Using Fortran Windowing Application Projects (.EXE)</td>
<td>Multiple window main projects with full graphical interface and access to all Windows* API routines. Requires advanced programming expertise and knowledge of the Calling Windows API Routines.</td>
</tr>
<tr>
<td>Using Fortran Static Library Projects (.LIB)</td>
<td>Library routines to link into .EXE files.</td>
</tr>
<tr>
<td>Project Type</td>
<td>Key Features</td>
</tr>
<tr>
<td>--------------------------------------------------</td>
<td>-------------------------------------------------</td>
</tr>
<tr>
<td>Using Fortran Dynamic-Link Library Projects (.DLL)</td>
<td>Library routines to associate during execution.</td>
</tr>
<tr>
<td>Fortran COM Server Overview (.DLL)</td>
<td>Fortran in-process COM server</td>
</tr>
</tbody>
</table>

If you need to use the command line to build your project, you can:

- Use the command line compiler options to specify the project type (see Specifying Project Types with ifort Command Options).
- Create the application from the command line (see Invoking the Intel® Fortran Compiler).

**See Also**
Understanding Solutions, Projects, and Configurations
Selecting a Configuration
Additional Documentation: Creating Fortran Applications that Use Windows® OS Features

**Specifying Project Types with ifort Command Options**
This section provides the ifort command-line options that correspond to Visual Studio® project types.

**Creating Main Project Types**
The first four projects described below are main project types, requiring main programs. You can create any of the following project types with the ifort command:

- To create Console Application Projects, you do not need to specify any options. (If you link separately, specify the link option /subsystem:console.) This is the default project type created.
- To create Standard Graphics Application Projects, specify the libs option with keyword qwins (also sets certain linker options).
- To create QuickWin Application Projects, specify the libs option with keyword qwin (also sets certain linker options).
- To create Windowing Application Projects, specify the winapp option (also sets certain linker options).

**Creating Library Project Types**
The following project types are library projects, without main programs. You can create them with the ifort command:

- To create Dynamic-Link Library Projects, specify the dll option (which sets the libs option with keyword dll).
- To create Static Library Projects:
  - If your application will not call any QuickWin or Standard Graphics routines, specify the libs option with keyword static and c options to create the object files.
  - If your application will call QuickWin routines, specify the libs option with keyword qwin and c options to create the object files.
  - If your application will call Standard Graphics routines, specify the libs option with keyword qwins and c options to create the object files.
  - Use the LIB command to create the library.

Using Fortran Console Application Projects

A Fortran Console application (.EXE) is a character-based Intel® Fortran program that does not require screen graphics output.

Fortran Console projects operate in a single window and let you interact with your program through normal read and write commands. Console applications are better suited to problems that require pure numerical processing rather than graphical output or a graphical user interface. This type of application is also more transportable to other platforms than the other types of application.

Fortran Console applications can be faster than Fortran Standard Graphics or Fortran QuickWin graphics applications, because of the resources required to display graphical output (see Using the Console).

Any graphics routine that your program calls will produce no output, but will return error codes. A program will not automatically exit if such an error occurs, so your code should be written to handle this condition.

With a Fortran Console project, you cannot use the QuickWin functions. However, you can use single- or multi-threaded static libraries, DLLs, and dialog boxes.

As with all Windows* command consoles, you can toggle between console viewing modes by pressing ALT and ENTER.

To create a console application from the IDE:

1. Select the Console Application project type.
2. Select from two templates: Empty project or Main program code, which includes sample code.

See Also
Using the Console

Using Fortran Standard Graphics Application Projects

A Fortran standard graphics application (.EXE) is an Intel® Fortran QuickWin program with graphics that runs in a single QuickWin window. A standard graphics (QuickWin single window, sometimes called single document) application looks similar to an MS-DOS* program when manipulating the graphics hardware directly, without Windows* OS.

A Fortran standard graphics application allows graphics output (such as drawing lines and basic shapes) and other screen functions, such as clearing the screen. Standard Graphics is a subset of QuickWin. You can use all of the QuickWin graphics functions in these projects. You can use dialog boxes with these and all other project types.

You can select displayed text either as a bitmap or as text. Windows* OS provides APIs for loading and unloading bitmap files. Standard graphics applications should be written as multithreaded applications.

Fortran standard graphics (QuickWin single window) applications are normally presented in full-screen mode. The single window can be either full-screen or have window borders and controls available. You can change between these two modes by using ALT and ENTER.

If the resolution selected matches the screen size, the application covers the entire screen; otherwise, scroll bars are present to resize the window. You cannot open additional windows in a standard graphics application. Standard graphics applications have neither a menu bar at the top of the window, nor a status bar at the bottom.

Fortran standard graphics applications are appropriate for problems that:

• Require numerical processing and some graphics.
• Do not require a sophisticated user interface.

To create a standard graphics application using the Visual Studio* IDE:
1. Select the **QuickWin Application** project type.
2. Select the **Standard Graphics Application** template.

When you select the Fortran standard graphics project type, the integrated development environment includes the QuickWin library automatically, which lets you use the graphics functions. When building from the command line, you must specify the `libs` option with keyword `qwins`. You cannot use the run-time functions meant for multiple-window projects if you are building a standard graphics project. You cannot make a Standard Graphics application a DLL.

**See Also**

Additional Documentation: Creating Fortran Applications that Use Windows* OS Features

### Using Fortran QuickWin Application Projects

Fortran QuickWin graphics applications (.EXE) are multi-threaded and are more versatile than standard graphics (QuickWin single window) applications because you can open multiple windows while your project is executing. This multiple window capability is also referred to as multiple-document interface or MDI. Multiple windows can be used in a variety of ways. For example, you might want to generate several graphic plots and be able to switch between them while also having a window for controlling the execution of your program. These windows can be full screen or reduced in size and can be placed in various parts of the screen.

QuickWin library routines let you build applications with a simplified version of the Windows* interface using Intel® Fortran. The QuickWin library provides a rich set of Windows* features, but it does not include the complete Windows* Applications Programming Interface (API). If you need additional capabilities, you must set up a Windows* application to call the Windows* API directly rather than using QuickWin to build your program.

Applications that use a multiple-document interface (MDI) have a menu bar at the top of the window and a status bar at the bottom. The QuickWin library provides a default set of menus and menu items that you can customize with the QuickWin APIs. An application that uses MDI creates many "child" windows within an outer application window. The user area in an MDI application is a child window that appears in the space between the menu bar and status bar of the application window. Your application can have more than one child window open at a time.

Fortran QuickWin applications can use the `IFLOGM` module to access functions to control dialog boxes. These functions allow you to display, initialize, and communicate with special dialog boxes in your application. They are a subset of Windows* API functions, which Windows* OS applications can call directly.

**To create a QuickWin application in Visual Studio***:

1. Select the **QuickWin Application** project type.
2. Select the **QuickWin Application** template in the right pane.

When you select the Fortran QuickWin project type, the IDE includes the QuickWin library automatically, which lets you use the graphics functions.

When building from the command line, you must specify the `libs` compiler option with keyword `qwins` to indicate a QuickWin application.

A QuickWin application covers the entire screen if the resolution selected matches the screen size; otherwise, the window will contain scroll bars.

You cannot make a Fortran QuickWin application a DLL.

**See Also**

Additional Documentation: Creating Fortran Applications that Use Windows* OS Features

### Using Fortran Windowing Application Projects

Fortran Windowing applications (.EXE) are main programs that you create when you choose the Fortran Windowing Application project type. This type of project lets you call the Windows* APIs directly from Intel® Fortran. This provides full access to the Windows* APIs, giving you a larger (and different) set of functions to work with than QuickWin.
Although you can call some of the Windows* APIs from the other project types, Fortran Windowing applications allow you to use the full set of API routines and use certain system features not available for the other project types.

The IFWIN module contains interfaces to the most common Windows APIs. If you include the USE IFWIN statement in your program, the most common Windows* API Routines are available to you. The IFWIN module gives you access to a full range of routines including window management, graphic device interface, system services, multimedia, and remote procedure calls.

Window management routines give your application the means to create and manage a user interface. You can create windows to display output or prompt for input. Graphics Device Interface (GDI) functions provide ways for you to generate graphical output for displays, printers, and other devices. Windows* system functions allow you to manage and monitor resources such as memory, access to files, directories, and I/O devices. System service functions provide features that your application can use to handle special conditions such as errors, event logging, and exception handling.

Using multimedia functions, your application can create documents and presentations that incorporate music, sound effects, and video clips as well as text and graphics. Multimedia functions provide services for audio, video, file I/O, media control, joystick, and timers.

Remote Procedure Calls (RPC) gives you the means to carry out distributed computing, letting applications tap the resources of computers on a network. A distributed application runs as a process in one address space and makes procedure calls that execute in an address space on another computer. You can create distributed applications using RPC, each consisting of a client that presents information to the user and a server that stores, retrieves, and manipulates data as well as handling computing tasks. Shared databases and remote file servers are examples of distributed applications.

Using Fortran Static Library Projects

Fortran static libraries (.LIB) are blocks of code compiled and kept separate from the main part of your program. The Fortran static library is one of the Fortran project types.

To create a static library from the integrated development environment (IDE), select the Static Library project type. To create a static library from the command line, use the c option to suppress linking and use the LIB command.

NOTE
When compiling a static library from the command line, include the c option to suppress linking. Without this option, the compiler generates an error because the library does not contain a main program.

When you create a static library, you are asked to specify whether you want to prevent the insertion of link directives for default libraries. By default, this checkbox is selected, which means insertion of link directives is prevented. Select this option if you plan to use this static library with other Fortran projects. The option prevents the static library from specifying a version of the Fortran run-time library. When the static library is linked with another Fortran project, the Fortran run-time library choice in the other Fortran project is used for the static library as well.

You may decide against selecting this option if you plan to use this static library with C/C++ projects. If you do select it, you need to explicitly name the Fortran run-time library to use in the Linker Additional Dependencies property. You can change your selection after creating the project using the Fortran Disable Default Library Search Rules property.

A static library is a collection of source and object code defined in the Solution Explorer window. The source code is compiled when you build the project. The object code is assembled into a .LIB file without going through a linking process. The name of the project is used as the name of the library file by default. Static libraries offer important advantages in organizing large programs and in sharing routines between several programs. These libraries contain only subprograms, not main programs. A static library file has a .LIB extension and contains object code.
When you associate a static library with a program, any necessary routines are linked from the library into your executable program when it is built. Static libraries are usually kept in their own directories. If you use a static library, only those routines actually needed by the program are incorporated into the executable image (.EXE). This means that your executable image will be smaller than if you included all the routines in the library in your executable image. The Linker determines which routines to include.

Because applications built with a static library all contain the same version of the routines in the library, you can use static libraries to help keep applications current. When you revise the routines in a static library, you can easily update all the applications that use it by relinking the applications.

If you have a library of substantial size, you should maintain it in a dedicated directory. Projects using the library access it during linking.

When you link a project that uses the library, selected object code from the library is linked into that project's executable code to satisfy calls to external procedures. Unnecessary object files are not included.

To debug a static library, you must use a main program that calls the library routines. Both the main program and the static library should have been compiled using the debug option. After compiling and linking is completed, open the Debug menu and choose Go to reach breakpoints, or use the step controls on the Debug toolbar.

**Using Static Libraries**

To add static libraries to a main project in the IDE, use the Add Existing Item... option in the Project menu. You can enter the path and library name with a .LIB extension in the dialog box that appears. If you are using a makefile, you must add the library by editing the makefile for the main project. If you are building your project from the command line, add the library name with a .LIB extension and include the path specification if necessary.

**Using Fortran Dynamic-Link Library Projects**

A dynamic-link library (.DLL) is a source-code library that is compiled and linked to a unit independently of the applications that use it. A DLL shares its code and data address space with a calling application. A DLL contains only subprograms, not main programs.

A DLL offers the organizational advantages of a static library, but with the advantage of a smaller executable file at the expense of a slightly more complex interface. Object code from a DLL is not included in your program's executable file, but is associated as needed in a dynamic manner while the program is executing. More than one program can access a DLL at a time.

When routines in a DLL are called, the routines are loaded into memory at run-time, as they are needed. This is most useful when several applications use a common group of routines. By storing these common routines in a DLL, you reduce the size of each application that calls the DLL. In addition, you can update the routines in the DLL without having to rebuild any of the applications that call the DLL.

With Intel® Fortran, you can use DLLs in two ways:

1. You can build a DLL with your own routines. In Visual Studio*, select Dynamic-link Library as your project type. From the command line, use the DLL option with the ifort command.

2. You can build applications with the run-time library stored in a separate DLL instead of in the main application file. In the integrated development environment, open a solution and do the following:
   - From the Project menu, select Properties to display the project properties dialog box.
   - Click the Fortran folder.
   - Select the Libraries category.
   - In the Runtime Library option, select an option ending with "DLL."

   From the command line, use the libs compiler option with keyword dll to build applications with the run-time library stored in a separate DLL.

**See Also**

Additional Documentation: Creating Fortran Applications that Use Windows* OS Features
Using the Console

On Windows* OS, a console window allows input and output of characters (not graphics).

For example, data written (explicitly or implicitly) by Fortran WRITE (or other) statements to Fortran logical unit 6 display characters on a console window. Similarly, data read by Fortran READ (or other) statements to unit 5 accept keyboard character input.

The console consists of two components:

- The actual console window that shows the characters on the screen.
- The console buffer that contains the characters to be displayed.

If the console screen buffer is larger than the console window, scroll bars are automatically provided. The size of the console screen buffer must be larger (or equal to) the size of the console window. If the buffer is smaller than the size of the console window, an error occurs. For applications that need to display more than a few hundred lines of text, the ability to scroll quickly through the text is important.

Fortran Console applications automatically provide a console. Fortran QuickWin (and Fortran Standard Graphics) applications do not provide a console, but display output and accept input from Fortran statements by using the program window.

The following Fortran Project Types provide an application console window:

<table>
<thead>
<tr>
<th>Project Type</th>
<th>Description of Console Provided</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fortran Console</td>
<td>Provides a console window intended to be used for character-cell applications that use text only.</td>
</tr>
<tr>
<td></td>
<td>When running a Fortran Console application from the command prompt, the existing console environment is used. When you run the application from Windows* or Developer Studio* (by selecting Start Without Debugging in the Debug menu), a new console environment is created.</td>
</tr>
<tr>
<td></td>
<td>Basic console use is described in Code Samples of Console Use.</td>
</tr>
<tr>
<td>Fortran QuickWin or Fortran Standard Graphics</td>
<td>Does not provide a console, but output to unit 6 and input to unit 5 are directed to the application program window, which can handle both text and graphics. Because the program window must handle both text and graphics, it is not as efficient as the console for just text-only use. A Fortran QuickWin or Fortran Standard Graphics program window (or child window) provides a console-like window.</td>
</tr>
<tr>
<td>Fortran Windows</td>
<td>Does not provide a console window, but the user can create a console by using Windows* API routines. See Console Use for Fortran Windows* Applications and Fortran DLL Applications.</td>
</tr>
<tr>
<td>Fortran DLL</td>
<td>Does not provide a console window, but the user can create a console by using Win32 routines. See Console Use for Fortran Windows* Applications and Fortran DLL Applications.</td>
</tr>
<tr>
<td>Fortran Static Library</td>
<td>Depends upon the project type of the main application that references the object code in the library (see above project types).</td>
</tr>
</tbody>
</table>

In addition to the Windows* API routines mentioned below, there are other routines related to console use described in the Microsoft Platform SDK* documentation.

**Console Use for Fortran QuickWin and Fortran Standard Graphics Applications**

For a Fortran QuickWin or Fortran Standard Graphics application, because the default program window handles both graphics and text, the use of a QuickWin window may not be very efficient:

- QuickWin windows use lots of memory and therefore have size limitations.
- They can be slow to scroll.
Although you can access the console window using `WRITE` and `READ` (or other) statements, applications that require display of substantial lines of text, consider creating a DLL that creates a separate console window for efficiency. The DLL application needs to call Windows* API routines to allocate the console, display text, accept keyed input, and free the console resources.

Basic use of a console is described in Code Samples of Console Use.

**Console Use for Fortran Windows Applications and Fortran DLL Applications**

With a Fortran Windows* or Fortran DLL application, attempting to write to the console using `WRITE` and `READ` (or other) statements before a console is created results in a run-time error (such as error performing `WRITE`).

A console created by a Fortran DLL is distinct from any application console window associated with the main application. A Fortran DLL application has neither a console nor an application window created for it, so it must create (allocate) its own console using Windows* API routines. When used with a Fortran QuickWin or Fortran Standard Graphics application main program, the Fortran DLL can provide its main application with a very efficient console window for text-only use.

Like a Fortran DLL application, a Fortran Windows application has neither a console nor an application window created for it, so it must create its own console using Windows* API routines. After allocating a console in a Fortran DLL, the handle identifier returned by the `GetStdHandle` Windows* API routine refers to the actual console the DLL creates.

When the Fortran Windows application does create a console window, it is very efficient for text-only use. The handle identifier returned by the `GetStdHandle` Calling Windows* API Routines refers to the actual console the Fortran Windows application creates.

For information about creating a console, see Allocating and Deallocating a Console below.

**Code Samples for Console Use**

The following sections shows sample code for using a console:

- Allocating and Deallocating a Console for Fortran Windows* and DLL Applications.
- Extending Size of the Console Window and Console Buffer for console use in any project type.
- Writing and Reading Characters at a Cursor Position for console use in any project type.

**Allocating and Deallocating a Console**

To create a console, you use the `AllocConsole` routine. When you are done with the console, free its resources with a `FreeConsole` routine. For example, the following code allocates the console, enlarges the buffer size, writes to the screen, waits for any key to be pressed, and deallocates the console:

```fortran
! The following USE statement provides Fortran interfaces to Windows routines
USE IFWIN
! Begin data declarations
   integer lines,length
   logical status
   integer fhandle
   Type(T_COORD) wpos
! Set buffer size variables
   length = 80
   lines = 90
! Begin executable code
! Allocate a console
   status = AllocConsole() ! get a console window of the currently set size
   handle = GetStdHandle(STD_OUTPUT_HANDLE)
   wpos.x = length      ! must be >= currently set console window line length
   wpos.y = lines       ! must be >= currently set console window number of lines
   ! Set a console buffer bigger than the console window. This provides
   ! scroll bars on the console window to scroll through the console buffer
```
status = SetConsoleScreenBufferSize(fhandle, wpos)
! Write to the screen as needed. Add a READ to pause before deallocation
write (*,*) "This is the console output! It might display instructions or data"
write (*,*) ""
write (*,*) "Press any key when done viewing"
read (*,*)
! Deallocate the console to free its resources.
status = FreeConsole()

Calling Windows* API routines is described in Calling Windows* API Routines.
If you are using a DLL, your DLL code will need to create subprograms and export their symbols to the main program.

Basic use of a console is described in Extending Size of the Console Window and Console Buffer and Writing and Reading Characters at a Cursor Position.

Extending the Size of the Console Window and Console Buffer

When you execute a Fortran Console application, the console is already allocated. You can specify the size of the console window, size of the console buffer, and the location of the cursor. If needed, you can extend the size of the console buffer and console window by using the following Windows* API routines:

1. You first need to obtain the handle of the console window using the GetStdHandle routine. For example:

   ! USE statements to include routine interfaces
   use ifqwin
   use ifport
   use ifcore
   use ifwin
   ! Data declarations
   integer fhandle
   logical lstat
   ! Executable code
   fhandle = GetStdHandle(STD_OUTPUT_HANDLE)
   ! ...

2. If needed, you can obtain the size of the:
   - Console window by using the GetConsoleWindowInfo routine.
   - Console buffer by using the GetConsoleScreenBufferInfo routine.

   For example:

   ! USE statements to include routine interfaces
   use ifqwin
   use ifport
   use ifcore
   use ifwin
   ! Data declarations
   integer fhandle
   logical lstat
   Type(T_CONSOLE_SCREEN_BUFFER_INFO) conbuf
   type (T_COORD) _dwSize
   type (T_SMALL_RECT) srWindow
   fhandle = GetStdHandle(STD_OUTPUT_HANDLE)
   ! Executable code to get console buffer size
   lstat = GetConsoleScreenBufferInfo(fhandle, conbuf)
   write (*,*) ""
   write (*,*) "Window coordinates= ", conbuf srWindow
   write (*,*) "Buffer size= ", conbuf.dwSize
   ! ...
3. To set the size of the console window and buffer, use the `SetConsoleWindowInfo` and `SetConsoleScreenBufferSize` routines with the `fhundle` value returned previously:

```fortran
! USE statements to include routine interfaces
use ifqwin
use ifport
use ifcore
use ifwin

! Data declarations
integer nlines, ncols
logical lstat
Type(TCOORD) wpos
Type(T_SMALL_RECT) sr
Type(T_CONSOLE_SCREEN_BUFFER_INFO) cinfo

! Executable code to set console window size
sr.top    =   0
sr.left   =   0
sr.bottom =   40 ! <= console buffer height -1
sr.right  =   60 ! <= console buffer width -1
lstat = SetConsoleWindowInfo(fhandle, .TRUE., sr)

! Executable code to set console buffer size
nlines = 100
ncols  =  80
wpos.x = ncols ! columns >= console window width
wpos.y = nlines ! lines   >= console window height
lstat = SetConsoleScreenBufferSize(fhandle, wpos)
! ...
```

### Writing and Reading Characters at a Cursor Position

You can position the cursor as needed using the `SetConsoleCursorPosition` routine before you write characters to the screen:

```fortran
! Use previous data declarations
! Position and write two lines
  wpos.x = 5 ! 6 characters from left
  wpos.y = 5 ! 6 lines down
  lstat = SetConsoleCursorPosition(fhandle, wpos)
  write(*,*) 'Six across Six down'
! ...
```

You read from the screen at an appropriate place, but usually you should set the cursor relative to the starting screen location:

```fortran
! Use previous and the following data declaration
CHARACTER(Len=50) charin
! Go back to beginning position of screen
  wpos.x = 0 ! 0 characters from left
  wpos.y = 0 ! 0 lines down
  lstat = SetConsoleCursorPosition(fhandle, wpos)
! Position character input at start of line 11
  wpos.x = 0 ! first character from left
  wpos.y = 10 ! 11 lines down
  lstat = SetConsoleCursorPosition(fhandle, wpos)
  read(*,*) charin
! ...
```

For console I/O, you can use Windows* OS routines `WriteConsoleLine` and `ReadConsoleLine` instead of Fortran `WRITE` and `READ` statements.

Additional Documentation: Creating Fortran Applications that Use Windows* OS Features
A separate document is available that details creating Intel® Fortran applications that use Windows* OS features.
You can find Using Intel® Visual Fortran to Create and Build Windows*-Based Applications on the Intel® Software Documentation Library website at http://software.intel.com/en-us/intel-software-technical-documentation. To get to this document, filter the page for the product suite or the single product.
The document covers the following:
• Creating Fortran Windowing Applications: Windows-based applications use the familiar Windows* interface, complete with tool bars, pull-down menus, dialog boxes, and other features. You can include data entry and mouse control in your application and allow for interaction with programs written in other languages or commercial programs such as Microsoft Excel*.
• Creating and Using Fortran DLLs: A dynamic-link library (DLL) contains one or more subprogram procedures (functions or subroutines) that are compiled, linked, and stored separately from the applications using them. Because the functions or subroutines are separate from the applications using them, they can be shared or replaced easily.
• Using QuickWin: The Intel® Fortran QuickWin run-time library helps you turn graphics programs into simple Windows* applications. Though the full capability of Windows* is not available through QuickWin, QuickWin applications support pixel-based graphics, real-coordinate graphics, text windows, character fonts, user-defined menus, mouse events, and editing (select/copy/paste) of text, graphics, or both.
• Using Dialog Boxes for Application Controls: Dialog boxes are a user-friendly way to solicit application control. As your application executes, you can make a dialog box appear on the screen and the user can click on a dialog box control to enter data or choose what happens next. Using the dialog routines provided with Intel® Fortran, you can add dialog boxes to your application. These routines define dialog boxes and their controls (scroll bars, buttons, and so on), and call your subroutines to respond to user selections.

Optimization Reports: Enabling in Visual Studio*
Optimization reports can help you to address vectorization and optimization issues that you may encounter.
When you build a solution or project and the compiler generates optimization diagnostics, you can view optimization reports in the following windows:
• Compiler Optimization Report window, either grouped by loops or in a flat format
• Compiler Inline Report window
• Optimization annotations integrated within the source editor
To enable viewing optimization reports:
1. In your project's property pages, select Configuration Properties > Fortran > Diagnostics.
2. Set a non-default value for any of the following options:
Interprocedural Optimization (IPO) is turned off by default. To view IPO diagnostics, set the property
Fortran > Optimization > Interprocedural Optimization to Single-file or Multi-file.

3. Build your project to generate an optimization report.

When the compiler generates optimization diagnostics, the Compiler Optimization Report and the
Compiler Inline Report windows open, and optimization report annotations appear in the source editor.

NOTE
You can specify how you want optimization reporting to appear with the Optimization Reports dialog box. Access this dialog box by selecting Tools > Options > Intel Compilers and Tools > Optimization Reports.

See Also
Options: Optimization Reports dialog box

Optimization Reports: Viewing
When the compiler generates optimization diagnostics, the Compiler Optimization Report and the
Compiler Inline Report windows open, and optimization report annotations appear in the editor.

Compiler Optimization Report window
The Compiler Optimization Report window displays diagnostics for the following phases of the
optimization report:
- PGO
- LOOP
- PAR
- VEC
- Offload
- OpenMP
- CG

Information appears in this window grouped by loops, or in a flat format. To switch the presentation format,
click the gear button on the toolbar of the window, and uncheck Group by loops.

In addition to sorting information by clicking column headers and resizing columns, you can use the windows
described in the following table:

<table>
<thead>
<tr>
<th>Do This</th>
<th>To Do This</th>
</tr>
</thead>
<tbody>
<tr>
<td>Double-click a diagnostic.</td>
<td>Jump to the corresponding position in the editor.</td>
</tr>
<tr>
<td>Click a link in the Inlined into column.</td>
<td>Jump to the call site of the function where the loop is inlined.</td>
</tr>
<tr>
<td>Expand or collapse a diagnostic in Group by loops view.</td>
<td>View detailed information for the diagnostic.</td>
</tr>
<tr>
<td>Click on a column header.</td>
<td>Sort the information according to that column.</td>
</tr>
<tr>
<td>Do This</td>
<td>To Do This</td>
</tr>
<tr>
<td>---------</td>
<td>-----------</td>
</tr>
<tr>
<td>Click the filter button.</td>
<td>Select a scope by which to filter the diagnostics that appear in the window.</td>
</tr>
<tr>
<td></td>
<td>The title bar of the Compiler Optimization Report window shows the applied filter. Labels on optimization phase filter buttons show how many diagnostics of each phase are in the current scope.</td>
</tr>
<tr>
<td>Click a Compiler Optimization Report window toolbar button corresponding to an optimization report phase.</td>
<td>Turn filtering diagnostics on or off for an optimization phase.</td>
</tr>
<tr>
<td></td>
<td>Labels on optimization phase filter buttons show the total number of diagnostics for each phase.</td>
</tr>
<tr>
<td>Enter text in the search box in the Compiler Optimization Report window toolbar.</td>
<td>Filter diagnostics using the text pattern.</td>
</tr>
<tr>
<td></td>
<td>Diagnostics are filtered when you stop typing. Pressing Enter saves this pattern in the search history.</td>
</tr>
<tr>
<td></td>
<td>To disable filtering, clear the search box.</td>
</tr>
<tr>
<td></td>
<td>To use a pattern from the search history, click on the down arrow next to the search box.</td>
</tr>
</tbody>
</table>

**Compiler Inline Report window**

The Compiler Inline Report window displays diagnostics for the IPO phase of the optimization report.

Information appears in this window in a tree. Each entry in the tree has corresponding information in the right-hand pane under the Properties tab and the Inlining options tab.

You can use the window as described in the following table:

<table>
<thead>
<tr>
<th>Do This</th>
<th>To Do This</th>
</tr>
</thead>
<tbody>
<tr>
<td>Double-click a diagnostic in the tree, or click on the source position link under the Properties tab.</td>
<td>Jump to the corresponding position in the editor.</td>
</tr>
<tr>
<td>Click Just My Code.</td>
<td>Only display functions from your code, filter all records from files that don't belong to the current solution file tree.</td>
</tr>
<tr>
<td>Right-click on a function body in the editor and select Intel Compiler &gt; Show Inline report for function name.</td>
<td>View detailed information for the specified function.</td>
</tr>
<tr>
<td>Right-click on a function body in the editor and select Intel Compiler &gt; Show where function name in inlined.</td>
<td>Show where the specified function is inlined.</td>
</tr>
<tr>
<td>Enter text in the search box in the Compiler Inline Report window toolbar.</td>
<td>Filter diagnostics using the text pattern.</td>
</tr>
<tr>
<td></td>
<td>Diagnostics are filtered when you stop typing. Pressing Enter saves this pattern in the search history.</td>
</tr>
<tr>
<td></td>
<td>To disable filtering, clear the search box.</td>
</tr>
</tbody>
</table>
To use a pattern from the search history, click on the down arrow next to the search box.

**Viewing Optimization Notes in the Editor**

Viewing optimization notes in the editor provides context for the diagnostics that the compiler generates.

1. In Caller Site
2. In Callee Site
3. In Caller and Callee Site

You can use optimization notes as described in the following table:

<table>
<thead>
<tr>
<th>Do This</th>
<th>To Do This</th>
</tr>
</thead>
<tbody>
<tr>
<td>Right-click an optimization note</td>
<td>• Expand or collapse the current optimization note, or all of them.</td>
</tr>
<tr>
<td>Double-click an optimization note heading</td>
<td>• Open the <strong>Optimization Reports</strong> dialog box to adjust settings for optimization report viewing. You can view optimization notes in one of the following locations:</td>
</tr>
<tr>
<td>Double-click a diagnostic detail</td>
<td>• <strong>Caller Site</strong></td>
</tr>
<tr>
<td>Click a hyperlink in the optimization note.</td>
<td>• <strong>Callee Site</strong></td>
</tr>
<tr>
<td>Click the help (?) icon.</td>
<td>• <strong>Caller Site and Callee Site</strong></td>
</tr>
<tr>
<td>Hover the mouse over a collapsed optimization note.</td>
<td>View a detailed tooltip about that optimization note.</td>
</tr>
</tbody>
</table>

**Dialog Box Help**

**Options: General dialog box**

To access the **General** page, click **Tools > Options** and then select **Intel Compilers and Tools > Visual Fortran > General**. Use this page to specify Fortran File Extensions and Build Options.

**Build Options**

**Continue on Errors**: Check this box to allow compilation to continue regardless of an error in the current file. The compiler will begin compiling the next file. (To set the maximum number of errors to encounter before compilation stops, choose **Configuration Properties > Fortran > Diagnostics > Error Limit**).
**Generate Build Logs:** Check this box to generate build logs.

**Show Environment in Log:** Check this box to show environment variable settings in the log file.

**Fortran File Extensions**
You can specify additional Fortran free format and fixed format file extensions to be recognized as valid file extensions within the IDE. The IDE treats these additional extensions as compilable Fortran source files. You can also remove or modify existing extensions that appear in the list.

When you add a new extension, the IDE checks the registry to determine whether the extension is already associated with a language, tool, or file format. If there is such an association, a message informs you of this and you will not be allowed to add the extension.

**Headers:** Specify one or more file extensions for header files, each beginning with a period and separated by semi-colons.

**Sources:** Specify one or more file extensions for source files, each beginning with a period and separated by semi-colons.

Click **OK** to save your changes.

**Options: Compilers dialog box**
To access the **Compilers** page:

**See Also**
- Selecting a Version of the Intel® Compiler
- Specifying Path, Library, and Include Directories

**Options: Advanced dialog box**
To access the **Advanced** page, expand the **Tools > Options > Text Editor > Intel® Fortran** nodes and select **Advanced**. Here you can specify advanced options for text editing.

**Browsing/Navigation section**
**Collect Object Browser information:** Choose this option to enable the display of procedures in your project in a hierarchical tree. Once enabled, you can use **View > Object Browser** to display your procedures.

**Disable Database:** Choose this option to disable creation of the code browsing database. This may help increase performance on slow machines. When you disable the database, all features that rely on code browsing information do not work.

**Enable Database Saving/Loading:** Choose this option to save collected data to a file on disk so that all source browsing features are available immediately when you open the project. When this option is disabled, the code browsing database is generated via background source parsing, so many features that rely on code browsing information do not work until this process completes. Saving and loading the database requires some additional time when saving and loading the project.

**Enable Find all References:** Choose this option to enable display of the location(s) in your code where a symbol is referenced. When this option is enabled, you can use the right-click context menu **Find All References** option to display a list of references to the selected symbol. Double-click on a reference to find that reference.

**Enable Go To Definition:** Choose this option to enable quick navigation to an object definition. When this option is enabled, you can use the right-click context menu **Go to Definition** option to locate where the selected object was declared, opening the associated source file if required. (If you have also enabled **Scan system includes**, any objects declared in system modules such as IFWINTY cause the associated source for that module to be opened.)
**Scan system includes**: Choose this option to scan system include files. This option is used with one or more of the following options: **Collect Object Browser Information, Enable Find All References, Enable Go To Definition**.

**Intrinsics section**

**Enable Intrinsic Parameter Info**: Choose this option to enable the display of intrinsic function and subroutine parameter information. When this option is enabled, you can type a name of an intrinsic procedure, followed by an open parenthesis, and information about the procedure and its arguments appears.

**Enable Intrinsic Quick Info**: Choose this option to enable the display of additional information when the mouse pointer is moved over an intrinsic function or subroutine name.

**Miscellaneous section**

**Enumerate Comment Tasks**: Choose this option to enable the display of a list of tasks consisting of source files containing comments. Comments take the form of the ! character, followed by a token such as TO DO. Valid tokens are those listed in Tools > Options > Environment > Task List. When this option is enabled, you can select Comments from the task list using View > Other Windows Task List. Double-click on a comment in the list to jump to its location.

**Highlight Matching Tokens**: Choose this option to allow identifier highlighting and block delimiter matching. When enabled, this option highlights all references to the identifier under the cursor.

**Outlining Section**

**Enable Outlining**: Choose this option to allow the collapsing of whole program units. When this option is enabled, you can click the minus (⁻) or plus (⁺) symbols for PROGRAM, SUBROUTINE, FUNCTION, MODULE, and BLOCK DATA statements.

**Outline Statement Blocks**: Choose this option to allow collapsing of block constructs such as IF and DO. You must also choose Enable Outlining.

**Configure Analysis dialog box**

Use the Configure Analysis dialog box to specify settings for Guided Auto Parallelism (GAP) analysis and run the analysis.

To access this dialog box, click Tools > Intel Compiler > Guided Auto Parallelism > Run Analysis...

**Configure Analysis Options**

Scope: Specify the desired scope.

**Level of Analysis**: Specify the desired level of analysis. Choose Simple, Moderate, Maximum, or Extreme.

**Suppress Compiler Warnings**: Check this box to suppress compiler warnings. This adds the option W0 to the compiler command line.

**Suppress remark IDs**: Specify one or more remark IDs to suppress. Use a comma to separate IDs.

**Send remarks to a file**: Check this box to send GAP remarks to a specified text file.

**Remarks file**: Specify the filename where GAP remarks will be sent.

**Save these settings as the default (in Tools -> Options for Guided Auto Parallelism)**: Check this box to save the specified settings as the default settings.

**Show all GAP configuration and informational dialogs**: Check this box to display this dialog box next time.

When you are done specifying settings, click Run Analysis.

Profile Guided Optimization dialog box
This topic has information on the following dialog boxes:
• Profile Guided Optimization dialog box
• Application Invocations dialog box
• Edit Command dialog box
• Command dialog box

Profile Guided Optimization dialog box
To access the Profile Guided Optimization dialog box, choose Tools > Intel Compiler > Profile Guided Optimization.
Use the Profile Guided Optimization dialog box to set the options for profile guided optimization.
Phase 1 - Instrument: This phase produces an instrumented object file for the profile guided optimization
The command line compiler option for each optimization instrument you choose appears in Compiler Options.
• Enable Function Ordering in the optimized application: Select this checkbox to enable ordering of static and extern routines using profile information. This optimization specifies the order in which the linker should link the functions of your application. This optimization can improve your application performance by improving code locality and by reducing paging.
• **Enable Static Data Layout in the optimized application:** Select this checkbox to enable ordering of static global data items based on profiling information. This optimization specifies the order in which the linker should link global data of your program. This optimization can improve application performance by improving the locality of static global data, reduce paging of large data sets, and improve data cache use.

• **Instrument with guards for threaded application:** Select this checkbox to produce an instrumented object file that includes the collection of PGO data on applications that use a high level of parallelism.

Selecting an option produces a static profile information file (.spi), but also increases the time needed to do a parallel build.

Deselect the checkbox to skip this phase to save time running profile guided optimization. When you skip this phase, you use the existing profile information when running profile guided optimization. For example, you may want to skip this phase when you change the code to fix a bug and the fix doesn't affect the architecture of the project.

**Phase 2 - Run Instrumented Application(s):** This phase runs the instrumented application produced in the previous phase as well as other applications in the Applications Invocations dialog box. To add a new application or edit an existing application in the list, click Applications Invocations.

Deselect the checkbox to skip this phase to save time running profile guided optimization. When you skip this phase, you do not run the applications in the list when running profile guided optimization. For example, you might want to skip this phase when you change the code to fix a bug and the fix doesn't affect the architecture of the project.

**Phase 3 - Optimize with Profile Data:** This phase performs the profile guided optimization.

Deselect the checkbox to skip this phase.

**Profile Directory:** The directory that contains the profile. Click Edit to edit the profile directory or the Browse button to browse for the profile directory.

**Show this dialog next time:** Deselect this checkbox to run profile guided optimization without displaying this dialog box. The profile guided optimization will use these settings.

**Save Settings:** Click to save your settings.

**Run:** Click to start the profile guided optimization.

**Cancel:** Click to close this dialog box without starting the profile guided optimization.

**Application Invocations dialog box**

To access the Application Invocations dialog box, click Application Invocations... in the Profile Guided Optimization dialog box. Use the Profile Guided Optimization dialog box to configure the application options for your application as well add additional applications when you run profile guided optimization.

The list of applications comes from the debug settings of the Startup Project.

**Merge Environment:** Select this checkbox to merge the application environment with the environment defined by the operating system.

To add, edit, or remove an application, click one of the buttons.

**Add:** Click to add a new application in the Edit Command dialog box.

**Duplicate:** Click after selecting an application to copy its settings so that you can use a different setting.

**Edit:** Click after selecting an application to change its settings in the Edit Command dialog box.

**Delete:** Click to remove the selected application from the list.

**OK:** Click to save the settings and close this dialog box.

**Cancel:** Click to discard the settings and close this dialog box.
Edit Command dialog box
To access the edit command dialog box, click Add or Edit in the Application Invocations dialog box. Use the Edit Command dialog box to add a new or edit an existing application in the Application Invocations dialog box.

Command: Add a new or edit an existing application. Click Edit to open the Command dialog box with a list of macros. Click Browse to navigate to another directory that contains the application.

Command Arguments: Enter the arguments required by the application.

Working Directory: Enter a new or edit the working directory for the application. Click Edit to open the Command dialog box with a list of macros. Click Browse to navigate to working directory of the application.

Environment: Enter the environment variable required by this application.

Merge Environment: Select this checkbox to merge the application environment with the environment defined by the operating system.

Load from Debugging Settings: Click to load the debug settings for this application.

OK: Click to save the settings and close this dialog box.

Cancel: Click to discard the settings and close this dialog box.

Command dialog box
To access the Command dialog box, click Edit in the Edit Command dialog box. Use the Command dialog box to specify or change the macro used in the application to run as part of the profile guided optimization.

Select a macro from the list and then click one of the buttons.

Macro: Click to show or close the list of available macros.

Insert: Click to use the selected macro.

OK: Click to save the settings and close this dialog box.

Cancel: Click to discard the settings and close this dialog box.

Options: Optimization Reports dialog box
To access the Optimization Reports page, click Tools > Options and then select Intel Compilers and Tools > Optimization Reports. Use this page to specify how you want optimization reporting to appear.

This page, in conjunction with the Diagnostics property page for your project or solution, defines settings for optimization report viewing in Visual Studio*.

General
Always Show Compiler Inline Report: Specify if the Compiler Inline Report appears after building or rebuilding your solution or project when inline diagnostics are present.
Always Show Compiler Optimization Report: Specify if Compiler Optimization Report appears after building or rebuilding your solution or project when optimization diagnostics are present. This option has higher priority than Always Show Compiler Inline Report. If both options are set to True, then this window has focus by default.
Show Optimization Notes in Text Editor Margin: Specify if optimization notes appear in the editor as source code annotations.

Optimization Notes in Text Editor
Collapse by Default: Specify if optimization notes appear expanded or collapsed by default.
Show Optimization Notes: Specify if source code annotations appear in the editor.
Site: Specify where optimization notes appear in the editor. Select from one of the following options:
• Caller Site
• Callee Site
• Caller Site and Callee Site

Optimization Reports: Enabling in Visual Studio*
Creating an Xcode* Project

The following topic applies to Xcode*.
To create a new Xcode* project:

1. Launch the Xcode* application.
2. Select **File > New > Project...**
   The **Choose a template for your new project** window opens.

3. In the left pane, select **OS X > Application**.
4. Select a template, for example, **Command Line Tool**, and click **Next**.
5. Name your project, for example, **Hello World**, enter a string for **Organization Name** and **Organization Identifier**, and select the C or C++ language. You will be able to change it to Fortran later. Click **Next**.
6. Specify a directory for your project, and optionally select **Create local git repository for this project** to place your project under version control.
7. Click **Create**.
Xcode* creates the named project directory, with an .xcodeproj extension. Your new project directory contains a main.cpp source file, as well as other project files. You can delete main.cpp.

Each Xcode* project has its own Project Editor window that displays project source files, targets, and executables.

Adding a New File

**Selecting the Intel® Compiler**

The following topic applies to Xcode*.

To select the Intel® Fortran Compiler:

1. Select the target you want to change and click **Build Rules**.
2. Add a new rule by clicking **Editor > Add Build Rule** or pressing a + button.
3. Under **Process**, choose **Fortran source files**.
NOTE
If the Intel® compiler does not show up in the drop-down list, it may mean that the Intel® compiler does not support the version of Xcode* that you are using.

To enable the Intel® compiler in Xcode*:

1. Reinstall the compiler. When the installer prompts you to specify a path to Xcode*, specify a path to a supported version of Xcode*.
2. After the install has finished, open a terminal window and change directory to the installation directory for the Intel® compiler IDE integration:
   cd /Library/Application\ Support/Developer/
3. Create a symbolic link for a new, unsupported version of Xcode*:
   sudo ln -s supported_xcode_version unsupported_xcode_version
   For example:
   sudo ln -s 7.1 7.2
4. Restart Xcode*.

4. Under Using, select Intel® Fortran Compiler XE.

   • If you select a tool that does not support the source file type, that source file type will be processed by a later rule that specifies that type.
   • Once you have set a new build rule for the Xcode* to use the Intel® Fortran Compiler for Fortran source files, you can view and adjust the Intel® Fortran Compiler option settings.

See Also
Setting Compiler Options

Adding a New File
The following topic applies to Fortran for Xcode*.

To add a new Fortran file:
1. In the Xcode* Project Editor, select **File > New > File...**.

2. Select **Fortran** in the left pane, and then select **Fortran Fixed Format File** or **Fortran Free Format File** in the upper right pane. Click **Next**.

3. Enter a name for the file, including a Fortran source file extension, such as `.f90`, and select a location for the new file. Click **Create**.

### Building the Target

The following topic applies to Xcode*.

A single project can contain multiple targets; the currently active target determines how your project is built. This topic describes how to build the target using the Xcode* IDE and also documents the build steps using the `xcodebuild` command line utility.

#### Building using the Xcode* IDE

1. Select the target to be built in the project editor under **Targets**.

2. Select **Product > Build**.

   To view the results of your build, click the **Log Navigator** button.

You can change the compilation order of the files in an Xcode* target. This may be necessary to compile Fortran source files that define modules (producing `.MOD` files). These can, in turn, be used by Fortran sources that use the modules. To re-order the files listed under a target’s **Compile Sources**, click a source file and drag it before or after other compilations.

**NOTE**

Xcode* 4.6 is the last major Xcode* release that includes the llvm-gcc compiler and the GDB debugger. Please plan to use the LLVM CLANG Compiler and LLDB debugger in future releases.

#### Building from the Command Line Using the xcodebuild Utility

You can also use the `xcodebuild` utility to build a target. This utility uses the Xcode* project settings to build target projects from the command line. If you have previously configured your Xcode* project to build with the Intel Fortran Compiler ifort, `xcodebuild` invokes that compiler from the command line.

**NOTE**

Starting with Xcode* version 4.3, you must manually download and install the Xcode* command-line tools.

See the Xcode* documentation for details.

To build from the command line:

1. Check that the Xcode* project is configured to use the Intel® Fortran Compiler.

2. Launch a terminal window from the Finder by selecting **Applications > Utilities > Terminal**.

3. Change directories to the directory containing the Xcode* project file (`.xcodeproj`).

4. If you have multiple versions of Xcode*, use the `xcode-select` utility to verify the current Xcode* version.

5. Issue an `xcodebuild` command. For example:

   ```bash
   xcodebuild -project HelloWorld.xcodeproj -target HelloWorld -configuration Debug
   ```

6. Run the program built in the example from the previous step by entering the following:

   ```bash
   ./build/Debug/HelloWorld
   ```

For more information, refer to the `xcodebuild` man page.
**Setting the Executable's Architecture**

Before building a 64-bit executable from within Xcode®, you may need to edit the executable’s target architecture. To change the **Architectures** setting:

- Click the target you want to change in the project editor under **Targets** and select the **Build Settings** tab.
- Under **Architectures**, select the desired architecture.

**NOTE**

The Intel® Fortran Compiler generates code solely for Intel® architectures.

**Building Universal Binaries**

You can build universal binaries, which operate on both IA-32 and Intel® 64 architectures. If you select more than one architecture in your build configuration, a universal binary containing the executables for all the selected architectures is created.

For example, for the **Release** configuration, if you set the architecture property to the value **Standard (32/64-bit Intel)**, then binaries for both the IA-32 and Intel® 64 architectures are created and put into the executable.

**See Also**

Building a Universal Binary from the Command line

**Setting Compiler Options**

The following topic applies to Xcode®.

To use the Xcode® environment to set compiler options, including options specific to Intel® Architecture:

1. Select a target.
2. Under the **Build Settings** tab, click **All**.
3. Scroll down until the list of Intel® Fortran Compiler XE categories.
4. To set an Intel® Fortran Compiler option in the Floating Point category, for example, scroll down to display **Floating Point**.
5. Select a **Setting**, such as **Extend Precision of Single-Precision Constants**, and set the option's state. If the **Quick Help** inspector is visible, information about the selected option appears under **Quick Help**.

The next time you build your project, the selected options are used in the compilation.

**NOTE**
To view the setting that have changed from the established defaults, select the **Levels** button under **Build Settings**.

---

**Running the Executable**

The following topic applies to Xcode*.

Once you have built your Xcode* project, click the **Run** button. This button runs the configuration currently associated with the button. Use the **Scheme Editor** to change the configuration associated with the button.

**TIP**
To open the **Scheme Editor**, select **Product > Scheme... > Edit Scheme**.

The output from the executable is displayed.

**Using Dynamic Libraries**

You can build your Xcode* project with the `-shared-intel` compiler option to link with the Intel dynamic libraries or with the `-openmp` or `-parallel` options, both of which link in `libiomp5.dylib`. If you do this, you need to set the `DYLD_LIBRARY_PATH` environment variable in the Xcode* environment.

To add the environment variable:

1. Open the Scheme Editor and select the **Run** action.
2. On the **Arguments** tab, under **Environment Variables**, click the `+` button.
3. Add `DYLD_LIBRARY_PATH`. Set the value to the full path to the Intel compiler's `/lib` directory.

**NOTE**
If you build your project with the `-shared-intel`, `-openmp`, or `-parallel` compiler option without setting the `DYLD_LIBRARY_PATH` environment variable, a "library not found" error message results at runtime. Depending on your application, the error message may refer to a library other than the one noted in this example:

```
dyld: Library not loaded: libiomp5.dylib
Referenced from: /Users/test/hello_world
Reason: image not found
```

---

**See Also**

- `shared-intel` option
- `qopenmp`, `Qopenmp` option
- `parallel`, `Qparallel` option
Building a Universal Binary from the Command line

The following topic applies to Xcode*.

Consider the following source file, `HelloWorld.f90`.

```fortran
PROGRAM HelloWorld
  IMPLICIT NONE
#if defined( _i386_)
define _PLATFORM_ "IA32"
#elif defined(_x86_64_)
define _PLATFORM_ "Intel(R) 64"
#else
#define _PLATFORM_ "????"
#endif
  WRITE( *, * ) "Hello, ", _PLATFORM_, " World"
END PROGRAM HelloWorld
```

To build a universal binary executable from `HelloWorld.f90`:

1. Initialize the compiler environment by setting the environment variables. You can do this by executing `compilervars.sh` (or `compilervars.csh`) with the `source` command:
   ```bash
   source install-dir/bin/compilervars.sh <arg>
   ```
   where `<arg>` is `ia32` or `intel64`.

2. Invoke the compiler with the `m32` option and generate the object file, `HelloWorld_32`:
   ```bash
   ifort -m32 -o HelloWorld_32 HelloWorld.f90
   ```

3. Invoke the compiler with the `m64` option and generate the object file, `HelloWorld_64`:
   ```bash
   ifort -m64 -o HelloWorld_64 HelloWorld.f90
   ```

4. Use the `lipo` utility to create the universal executable, `HelloWorld`, from the object files, `HelloWorld_32` and `HelloWorld_64`:
   ```bash
   lipo -create -arch i386 HelloWorld_32 -arch x86_64 HelloWorld_64 -output HelloWorld
   ```

To confirm that your process generates the correct result for both architectures, run the `file` utility on your universal binary:

```bash
file HelloWorld
HelloWorld: Mach-O universal binary with 2 architectures
HelloWorld (for architecture i386):Mach-O executable i386
HelloWorld (for architecture x86_64): Mach-O 64-bit executable x86_64
```

**NOTE**
The compiler defines the `_x86_64_` macro on Intel® 64 architecture only. So, if you execute the universal binary, `HelloWorld`, on a system based on Intel® 64 architecture, the output is:

```
Hello, Intel(R) 64 World
```

On a system based on IA-32 architecture, the output is:

```
Hello, IA32 World
```

Building the Target

Using Intel® Performance Libraries

The following topic applies to Fortran for Xcode*.

The Intel® Fortran Compiler now comes bundled with the Intel® Math Kernel Library. You can access this library in Xcode*, using the **Use Intel® Math Kernel Library** property, located in the **Build Settings > Performance Library Build Components**.
The **Use Intel® Math Kernel Library** property provides the following options in a drop-down menu:

- **None**: Disable use of Intel® Math Kernel Library
- **Use threaded Intel® Math Kernel Library**: Link using the threaded version of the library.
- **Use non-threaded Intel® Math Kernel Library**: Link using the non-threaded version of the library.

For more information, see the Intel® Math Kernel Library documentation.

- Compiler Options
- Floating-point Operations
- Libraries
- Data and I/O
- Mixed Language Programming
- Error Handling
### Compiler Limits

The amount of data storage, the size of arrays, and the total size of executable programs are limited only by the amount of process virtual address space available, as determined by system parameters.

The table below shows the limits to the size and complexity of a single Intel® Fortran program unit and to individual statements contained within it:

<table>
<thead>
<tr>
<th>Language Element</th>
<th>Limit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Actual number of arguments per CALL or function reference</td>
<td>Limited only by memory constraints</td>
</tr>
<tr>
<td>Arguments in a function reference in a specification expression</td>

</table>

See the product Release Notes for more information on memory limits for large data objects.
Using Visual Studio* IDE
Automation Objects (Windows* OS)

This topic briefly describes the Automation interfaces provided by Intel® Visual Fortran. Automation interfaces are programmable objects used to access underlying IDE components and projects to provide experienced developers with a means of automating common tasks and allow a finer degree of control over the IDE and the Fortran projects being used within it.

You can use the Visual Studio* Object Browser (View > Object Browser) to view an object and its associated properties. Open the following in the browser: Browse > Edit Custom Component Set > .NET > Microsoft.VisualStudio.VFProject.

**NOTE**
The objects listed here are provided as an advanced feature for developers who are already familiar with using Automation objects and the Visual Studio* object model.

<table>
<thead>
<tr>
<th>Object</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IVFCollection</td>
<td>Contains the functionality that can be exercised on a collections object.</td>
</tr>
<tr>
<td>VFConfiguration</td>
<td>Programmatically accesses the properties in the General property page of a project's Property Pages dialog box. This object also allows access to the tools used to build this configuration.</td>
</tr>
<tr>
<td>VFCustomBuildTool</td>
<td>Programmatically accesses the properties in the Custom Build Step property page in a project's Property Pages dialog box.</td>
</tr>
<tr>
<td>VFDebugSettings</td>
<td>Contains properties that allow the user to programmatically manipulate the settings in the Debug property page.</td>
</tr>
<tr>
<td>VFFile</td>
<td>Describes the operations that can take place on a file in the active project.</td>
</tr>
<tr>
<td>VFFileConfiguration</td>
<td>Contains build information about a file (VFFile object), including such things as what tool is attached to the file for that configuration.</td>
</tr>
<tr>
<td>VFFilter</td>
<td>Exposes the functionality on a folder in Solution Explorer for an Intel® Visual Fortran project.</td>
</tr>
<tr>
<td>VFFortranCompiler Tool</td>
<td>Exposes the functionality of the IFORT tool.</td>
</tr>
<tr>
<td>VFFortranCompiler Version</td>
<td>Provides access to properties relating to the Intel® Visual Fortran compiler version.</td>
</tr>
<tr>
<td>VFLibrarianTool</td>
<td>Exposes the functionality of the LIB tool.</td>
</tr>
<tr>
<td>VFLinkerTool</td>
<td>Exposes the functionality of the LINK tool.</td>
</tr>
<tr>
<td>VFManifestTool</td>
<td>Programmatically accesses the properties in the Manifest Tool folder of a project's Property Pages dialog box.</td>
</tr>
<tr>
<td>VFMidITool</td>
<td>Programmatically accesses the properties in the MIDL folder of a project's Property Pages dialog box.</td>
</tr>
<tr>
<td>VFPlatform</td>
<td>Provides access to properties relating to supported platforms.</td>
</tr>
</tbody>
</table>
VFPreBuildEventTool
Programmatically accesses the properties on the **Pre-Build Event** property page, in the Build Events folder in a project's Property Pages dialog box.

VFPreLinkEventTool
Programmatically accesses the properties on the **PreLink Event** property page, in the Build Events folder in a project's Property Pages dialog box.

VFPostBuildEventTool
Programmatically accesses the properties on the **Post-Build Event** property page, in the Build Events folder in a project's Property Pages dialog box.

VFProject
Exposes the properties on an Intel® Visual Fortran project

VFResourceCompilerTool
Programmatically accesses the properties in the Resources folder in a project's Property Pages dialog box.

The following example, written in Visual Basic®, demonstrates how to use automation objects to modify the list of available platforms and versions in the Visual Studio® IDE Configuration Manager:

```vbnet
Imports System
Imports EnvDTE
Imports EnvDTE80
Imports System.Diagnostics
Imports Microsoft.VisualStudio.VFProject
Imports System.Collections

Public Module MultiPV
  ' Create a Console application before executing this module
  ' Module demonstrates Multi Platform & Multi Version Automation Support
  ' Variable definition

Compiler Options

Introduction to Compiler Options
The Intel® Fortran compiler supports many compiler options you can use in your applications.
In this section, we provide the following:
- General information about our compiler options (including lists of new options and lists of deprecated or removed options).
- Information about what we show in each compiler option description, the conventions we use when referring to options, and general rules for compiler option usage in programs.
- A description of each compiler option. The descriptions appear under the option's functional category; within each category, the options are listed in alphabetical order.

New Options
This topic lists the options that provide new functionality in this release.
If no label appears, the option is available on all supported systems.
If "only" appears in the label, the option is only available on the identified system.
For more details on the options, refer to the individual option descriptions.
For information on conventions used in this table, see Notational Conventions.
New compiler options are listed in tables below:

<table>
<thead>
<tr>
<th>Windows* OS Options</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>/fpp-name:name</td>
<td>Lets you specify an alternate preprocessor to use with Fortran.</td>
<td>OFF</td>
</tr>
<tr>
<td>/gen-depshow:</td>
<td>Determines whether certain features are excluded from dependency analysis. Currently, it only applies to intrinsic modules.</td>
<td>/gen-depshow:intr_mod</td>
</tr>
<tr>
<td>[no]intr_mod</td>
<td></td>
<td></td>
</tr>
<tr>
<td>/Qopt-prefetch-issue-excl-hint</td>
<td>Supports the prefetchW instruction in Intel® microarchitecture code name Broadwell and later.</td>
<td>OFF</td>
</tr>
<tr>
<td>/Qprotect-parens</td>
<td>Determines whether the optimizer honors parentheses when expressions are evaluated.</td>
<td>/Qprotect-parens-</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Linux* OS and OS X* Options</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>-fpp-name=name</td>
<td>Lets you specify an alternate preprocessor to use with Fortran.</td>
<td>OFF</td>
</tr>
</tbody>
</table>
### Linux* OS and OS X* Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>-fprotect-parens</td>
<td>Determines whether the optimizer honors parentheses when expressions are evaluated.</td>
<td>-fno-protect-parens</td>
</tr>
<tr>
<td>-fstack-protector-strong</td>
<td>Enables stack overflow security checks for routines with any buffer.</td>
<td>-fno-stack-protector-strong</td>
</tr>
<tr>
<td>-gen-depshow=[no]int_r_mod</td>
<td>Determines whether certain features are excluded from dependency analysis. Currently, it only applies to intrinsic modules.</td>
<td>-gen-depshow=intr_mod</td>
</tr>
<tr>
<td>-gsplit-dwarf (Linux* OS only)</td>
<td>Creates a separate object file containing DWARF debug information.</td>
<td>OFF</td>
</tr>
<tr>
<td>-print-sysroot (Linux* OS only)</td>
<td>Prints the target sysroot directory that is used during compilation.</td>
<td>OFF</td>
</tr>
<tr>
<td>-qopt-prefetch-issue-excl-hint (Linux* OS only)</td>
<td>Supports the prefetchW instruction in Intel® microarchitecture code name Broadwell and later.</td>
<td>OFF</td>
</tr>
</tbody>
</table>

### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

### Deprecated and Removed Compiler Options

This topic lists deprecated and removed compiler options and suggests replacement options, if any are available.

For more information on compiler options, see the detailed descriptions of the individual options in Compiler Option Categories and Descriptions.

### Deprecated Options

Occasionally, compiler options are marked as "deprecated." Deprecated options are still supported in the current release, but are planned to be unsupported in future releases.

The following two tables list options that are currently deprecated.

Note that deprecated options are not limited to these lists.

<table>

### Removed Options

Some compiler options are no longer supported and have been removed. If you use one of these options, the compiler issues a warning, ignores the option, and then proceeds with compilation.

The following two tables list options that are no longer supported.

Note that removed options are not limited to these lists.

### Linux* OS and OS X* Options

### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

### Ways to Display Certain Option Lists

#### Displaying Options Passed to Offload Compilation

This topic only applies to Intel® MIC Architecture.

Certain compiler options are passed to offload compilation automatically.

To display compiler options that are passed to offload compilation after they are specified on the host compilation command line, specify the following option, which is only available on Intel® MIC Architecture:

- `watch=mic-cmd` ! Linux systems
- `/watch:mic-cmd` ! Windows systems

Only options that are automatically passed are displayed. Note that the above option is ignored when you specify option `-mmic` on Linux* systems or option `/Qmic` on Windows* systems.

For more information about the `watch` option, which can also be used to display other information, see `watch`.

Other compiler options are not passed to offload compilation automatically.

If you want to pass additional options to offload compilation, or you would like to override the command line options automatically passed to offload compilation, you must use option `[q or Q]offload-option` to specify the additional or overriding options.

For more information about this option, see `qoffload-option`, `Qoffload-option`.

#### Displaying Online Lists and Functional Groupings

To display a list of all available compiler options, specify option `help` on the command line.
To display functional groupings of compiler options, specify a functional category for option help. For example, to display a list of options that affect diagnostic messages, enter one of the following commands:

```
-hel help diagnostics     ! Linux and OS X systems
/help diagnostics     ! Windows systems
```

For details on other categories you can specify, see help.

Displaying Alphabetical Lists of Compiler Options

In some online help formats, you can see an alphabetical list of all available compiler options by going to the Index in your documentation and doing the following:

- Enter a single dash (-) to see a list of all Linux* OS and OS X* compiler options
- Enter a slash (/) to see a list of all Windows* OS compiler options

Note that some online help formats do not offer an index.

Compiler Option Categories and Descriptions

Compiler Option Descriptions and General Rules

This section includes descriptions of all the current Linux*, OS X*, and Windows* compiler options. The option names are arranged by functional category, and within each category, the options are listed in alphabetical order.

Option Descriptions

Each option description contains the following information:

- The primary name for the option and a short description of the option.
- Architecture Restrictions
  This section only appears if there is a known architecture restriction for the option.
  Restrictions may appear for any of the following architectures:
  - IA-32 architecture
  - Intel® 64 architecture
  - Intel® 64 architecture targeting Intel® Many Integrated Core Architecture (Intel® MIC Architecture)
    Note that within the relevant compiler option descriptions, this architecture will be referred to as:
    Intel® 64 architecture targeting Intel® MIC Architecture

  Certain operating systems are not available on all the above architectures. For the latest information, please check your Release Notes.
- Syntax
  This shows the syntax on Linux* and OS X* systems and the syntax on Windows* systems. If the option has no syntax on one of these systems, that is, the option is not valid on a particular operating system, it will specify "None".
- Arguments
  This shows any arguments (parameters) that are related to the option. If the option has no arguments, it will specify "None".
- Default
  This shows the default setting for the option.
- Description
  This shows the full description of the option. It may also include further information on any applicable arguments.
- IDE Equivalent
This shows information related to the integrated development environment (IDE) Property Pages on Windows*, Linux*, and OS X* systems. It shows on which Property Page the option appears, and under what category it's listed. The Windows* IDE is Microsoft* Visual Studio* .NET; the Linux* IDE is Eclipse*; the OS X* IDE is Xcode*. If the option has no IDE equivalent, it will specify "None". Note that in this release, there is no IDE support for Fortran on Linux*.

- **Alternate Options**
  This lists any options that are synonyms for the described option. If there are no alternate option names, it will show "None".
  Some of the alternate option names are deprecated and may be removed in future releases.
  Many options have an older spelling where underscores ("_") instead of hyphens ("-") connect the main option names. The older spelling is a valid alternate option name.

Some option descriptions may also have the following:

- **Example**
  This shows a short example that includes the option

- **See Also**
  This shows where you can get further information on the option or related options.

### Compiler Option Names in Descriptions

The following conventions are used as shortcuts when referencing compiler option names in descriptions:

- Many options have names that are the same on Linux*, OS X*, and Windows*, except that the Windows form starts with an initial / and the Linux and OS X form starts with an initial -. Within text, such option names are shown without the initial character; for example, check.

- Many options have names that are the same on Linux*, OS X*, and Windows*, except that the Windows form starts with an initial Q. Within text, such option names are shown as [Q]option-name.
  
  For example, if you see a reference to [Q]ip, the Linux* and OS X* form of the option is -ip and the Windows form of the option is /Qip.

- Several compiler options have similar names except that the Linux* and OS X* forms start with an initial q and the Windows form starts with an initial Q. Within text, such option names are shown as [q or Q]option-name.
  
  For example, if you see a reference to [q or Q]opt-report, the Linux* and OS X* form of the option is -qopt-report and the Windows form of the option is /Qopt-report.

Compiler option names that are more dissimilar are shown in full.

### General Rules for Compiler Options

You cannot combine options with a single dash (Linux* and OS X*) or slash (Windows*). For example:

- On Linux* and OS X* systems: This is incorrect: -wc; this is correct: -w -c
- On Windows* systems: This is incorrect: /wc; this is correct: /w /c

All Linux* and OS X* compiler options are case sensitive. Many Windows* options are case sensitive. Some options have different meanings depending on their case; for example, option "c" prevents linking, but option "C" checks for certain conditions at run time.

Options specified on the command line apply to all files named on the command line.

Options can take arguments in the form of file names, strings, letters, or numbers. If a string includes spaces, the string must be enclosed in quotation marks. For example:

- On Linux* and OS X* systems, -dynamic-linker mylink (file name) or -Umacro3 (string)
- On Windows* systems, /Famyfile.s (file name) or /V"version 5.0" (string)

Compiler options can appear in any order.

On Windows* systems, all compiler options must precede /link options, if any, on the command line.
Unless you specify certain options, the command line will both compile and link the files you specify.

You can abbreviate some option names, entering as many characters as are needed to uniquely identify the option.

Certain options accept one or more keyword arguments following the option name. For example, the `arch` option accepts several keywords.

To specify multiple keywords, you typically specify the option multiple times. However, there are exceptions; for example, the following are valid: `-axNB` (Linux*) or `/QaxNB` (Windows*).

**NOTE**

On Windows* systems, you can sometimes use a comma to separate keywords. For example, the following is valid:

```bash
ifort /warn:usage,declarations test.f90
```

On these systems, you can use an equals sign (=) instead of the colon:

```bash
ifort /warn=usage,declarations test.f90
```

Compiler options remain in effect for the whole compilation unless overridden by a compiler directive.

To disable an option, specify the negative form of the option.

On Windows* systems, you can also disable one or more optimization options by specifying option `/Od` last on the command line.

**NOTE**

On Windows* systems, the `/Od` option is part of a mutually-exclusive group of options that includes `/Od`, `/O1`, `/O2`, `/O3`, and `/Ox`. The last of any of these options specified on the command line will override the previous options from this group.

If there are enabling and disabling versions of an option on the command line, the last one on the command line takes precedence.

**Offload Options**

`mmic`, `Qmic`

Builds an application that runs natively on Intel® MIC Architecture. This option only applies to Intel® MIC Architecture.

**Architecture Restrictions**

Only available on Intel® 64 architecture targeting the Intel® Xeon Phi™ coprocessor x100 product family (formerly code name Knights Corner)

**Syntax**

**Linux OS:**

- `mmic`

**OS X:**

None

**Windows OS:**

`/Qmic`
Arguments
None

Default
OFF

The compiler builds a heterogeneous application. You must specify this option to build an application that runs natively on Intel® MIC Architecture.

Description
This option enables the cross compiler to build an application that runs natively on Intel® MIC Architecture. It is only available on the command line. When you use this option, the compiler defines the macro __MIC__.

NOTE
When you specify Windows* option /Qmic, you must specify any other options on the command line in the Linux* form. This is because all other options are passed directly to the native Intel® MIC Architecture compiler, which is a Windows*-hosted Linux* compiler.

IDE Equivalent
None

Alternate Options
None

Example
The following option generates the object file a.out, which only runs on Intel® MIC Architecture:

ifort -mmic hello.f90

The following shows that when you use option /Qmic, you must specify any other options in Linux form:

ifort /Qmic -qopt-report=3 -c example.F90

When debugging applications for Intel® MIC Architecture on Windows* OS, you should use:

ifort /Qmic -g

See Also
Supported Environment Variables
qoffload, Qoffload

Lets you specify the mode for offloading or tell the compiler to ignore language constructs for offloading. This option only applies to Intel® MIC Architecture. Option -q[no-]offload is the replacement option for -[no-]offload, which is deprecated.

Architecture Restrictions
Only available on Intel® 64 architecture targeting Intel® MIC Architecture

Syntax

Linux OS:
-qoffload[=keyword]
-qno-offload
OS X:
None

Windows OS:
/Qoffload[:keyword]
/Qoffload-

Arguments

**Keyword**

Specifies the mode for offloading or it disables offloading. Possible values are:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>Tells the compiler to ignore language constructs for offloading. Warnings are issued by the compiler. This is equivalent to the negative form of the option.</td>
</tr>
</tbody>
</table>
| mandatory| Specifies that offloading is mandatory (required). If the target is not available, one of the following occurs:  
  - If no STATUS clause is specified for the OFFLOAD directive, the program fails with an error message.  
  - If the STATUS clause is specified, the program continues execution on the CPU. |
| optional | Specifies that offloading is optional (requested). If the target is not available, the program is executed on the CPU, not the target. |

**Default**

**mandatory**

The compiler recognizes language constructs for offloading if they are specified. If option `-qoffload` (Linux*) or `/Qoffload` (Windows*) is specified with no `keyword`, the default is **mandatory**.

**Description**

This option lets you specify the mode for offloading or tell the compiler to ignore language constructs for offloading.

Option `-q[no-]offload` is the replacement option for `-[no-]offload`, which is deprecated.

If no `-qoffload` (Linux*) or `/Qoffload` (Windows*) option appears on the command line, then OFFLOAD directives are processed and:

- The MANDATORY or OPTIONAL clauses are obeyed if present
- If no MANDATORY or OPTIONAL clause is present, the offload is mandatory

If any of the following appears on the command line, then OFFLOAD directives are ignored:

- Linux* OS: `-qoffload=none` or `-qoffload`  
- Windows* OS: `/offload:none` or `/Qoffload`

However, OpenMP* directives for coprocessor control (for example, `$OMP TARGET`) are recognized if the `[q or Q]openmp` option is specified, regardless of whether or not OFFLOAD directives are recognized or ignored.

If `keyword` **mandatory** or **optional** appears for `[Q]offload`, then OFFLOAD directives are processed and:
• The MANDATORY or OPTIONAL clauses are obeyed, regardless of the -qoffload (Linux*) or /Qoffload (Windows*) keyword
• If no MANDATORY or OPTIONAL clause is present, then the -qoffload (Linux*) or /Qoffload (Windows*) keyword is obeyed

If the STATUS clause is specified for an OFFLOAD directive, it affects run-time behavior.

**IDE Equivalent**

Visual Studio:  **Code Generation > Offload Constructs**

Eclipse: None

Xcode: None

**Alternate Options**

None

**See Also**

qoffload-option, Qoffload-option compiler option

OFFLOAD directive

**Supported Environment Variables**

qoffload-attribute-target, Qoffload-attribute-target

Causes the compiler to flag procedures and data objects in the source file with the offload attribute target(mic). This option only applies to Intel® MIC Architecture. Option -qoffload-attribute-target is the replacement option for -offload-attribute-target, which is deprecated.

**Architecture Restrictions**

Only available on Intel® 64 architecture targeting Intel® MIC Architecture

**Syntax**

**Linux OS:**

-qoffload-attribute-target=target-name

**OS X:**

None

**Windows OS:**

/Qoffload-attribute-target:target-name

**Arguments**

**target-name**

Is a specific target. The only supported value for this argument is mic.

**Default**

OFF

The compiler does not flag procedures and data objects in the source file with the offload attribute target(mic).

**Description**

This option causes the compiler to flag procedures and data objects in the source file with the offload attribute target(mic).
This option is similar to using the required individual directive ATTRIBUTES OFFLOAD:MIC to set the attribute target(mic) for all procedures and data objects in the source file.

Individual directive ATTRIBUTES OFFLOAD:MIC embedded in the source takes precedence over this option.

**IDE Equivalent**

None

**Alternate Options**

None

**Example**

The following example shows the \[q\ or Q\]offload-attribute-target option. The module variable t_glob is updated only on the host; the module variable t_priv is updated only on the target. The \[q\ or Q\]offload-attribute-target option is used to flag all of the global procedures and global variables with the target(mic) attribute so individual ATTRIBUTES directives do not need to be inserted in the sources for the global procedures and global variables that are available on both the host and the target.

```
t.F90
=======
program sample
    use m, only : t_glob, glob_func
    integer :: i
    !dir$ offload target(mic) out(i, t_glob)
    i = glob_func()
    write(*, '( "main: t_glob = ",i0," i = ",i0" )') t_glob, i
end program sample

m.F90
=======
module m
    integer :: t_glob = 65
    public :: glob_func
    integer :: t_priv = 43
    private :: priv_func, t_priv
contains
    integer function priv_func ()
      ! Increment on target only
      # ifdef __MIC__
      t_priv = t_priv + 1
      # endif
      priv_func = t_priv / 2
    end function priv_func

    integer function glob_func ()
      integer :: j
      j = priv_func()
      write(*, '( "glob_func: t_priv = ",i0," j = ",i0" )') t_priv, j
      ! Increment on target only#
      # ifdef __MIC__
      t_glob = t_glob + 1
      # endif
      glob_func = t_glob / 2
    end function glob_func
end module m
```

The command-lines for compiling the source files are:
**Linux* OS:**

```bash
$ ifort -c m.F90 -qoffload-attribute-target=mic
$ ifort m.o t.F90 -o t.exe
```

**Windows* OS:**

```bash
$ ifort /c m.F90 /Qoffload-attribute-target:mic
$ ifort m.obj t.F90 /exe:t.exe
```

The output of `t.exe` will look similar to the following:

```plaintext
glob_func: t_priv = 44 j = 22
main: t_glob = 66 i = 33
```

**See Also**

ATTRIBUTES OFFLOAD
Placing Variables and Functions on the Coprocessor

**qoffload-option, Qoffload-option**

Lets you explicitly specify options to be used for the specified target and tool. This option only applies to Intel® MIC Architecture. Option -qoffload-option is the replacement option for -offload-option, which is deprecated.

**Architecture Restrictions**

Only available on Intel® 64 architecture targeting Intel® MIC Architecture

**Syntax**

**Linux OS:**

```
-qoffload-option, target, tool,"option-list"
```

**OS X:**

None

**Windows OS:**

```
/Qoffload-option, target, tool,"option-list"
```

**Arguments**

**target**

Is the target architecture. The only supported value for this argument is mic.

**tool**

Is the tool that the `option-list` is associated with. It can be one of the following values: ld, link, as, or compiler.

ld is the linker tool on Linux* OS; link is the linker tool on Windows* OS.

**option-list**

Is one or more options that are specific to the tool. The quotation mark delimiters are required. Each option in the `option-list` must be separated by a space.

For tool compiler, use compiler-specific options; for tool ld, use linker-specific options; for tool as, use assembler-specific options. The options for the tools always use the Linux form even when compiling on Windows.
The compiler does not pass additional options to the separate tools on the target architecture.

Description

This option lets you explicitly specify options to be used for the specified target and tool. It can be specified multiple times on the command line.

When building a heterogeneous application, the driver passes all compiler options specified on the command-line to the host compilation and only certain options to the offload compilation. To see a list of options passed to the offload compilation, specify option watch=mic-cmd.

If you want to pass additional options to the offload compilation, or you would like to override the command line options passed to offload compilation, you must use option [q or Q]offload-option to specify the additional or overriding options.

NOTE

If you specify the options I, L, D, or U with the option [q or Q]offload-option, they override any other I, L, D, and U options that are automatically passed from host to offload compilation.

To achieve the overriding effect, the I, L, D, and U options specified using [q or Q]offload-option are placed ahead of the I, L, D, and U options automatically copied over from the host compilation. All other options specified using [q or Q]offload-option are placed after the options copied over from host to offload compilation.

IDE Equivalent

Visual Studio: Code Generation > Additional Options for MIC Offload Compiler
Eclipse: None
Xcode: None

Alternate Options

None

Example

The following shows a valid example for the compiler tool:
-qoffload-option,mic,compiler, "-O3 -diag-disable 1234 -vec-report2" ! Linux* OS
/Qoffload-option,mic,compiler, "-O3 -diag-disable 1234 -vec-report2" ! Windows* OS

The following shows another example for the compiler tool:
-qoffload-option,mic,compiler, "-O3 -vec-report3" ! Linux* OS
/Qoffload-option,mic,compiler, "-O3 -vec-report3" ! Windows* OS

The following shows a valid example for the Linux* ld tool:
-qoffload-option,mic,ld,"-lmylib -L/my/path"

The following shows a valid example for the Windows* link tool:
/Qoffload-option,mic,link,"--no-undefined "C:\Program Files (x86)\Intel\Composer XE 2015\mk1\lib\mic\libmkl_intel_lp64.a""

Note that when you specify a path containing spaces in the option-list, you must enclose the path in quotes with escape characters (\") so it is interpreted correctly by the compiler.
The following shows a valid example for the Linux* as tool:

```bash
/qoffload-option,mic,as,"<assembler options>"     ! Linux* OS
/Qoffload-option,mic,as,"<assembler options>"     ! Windows* OS
```

The following Linux* example causes the offload compilation to search `-I/my_dir/mic/include` first, and to use `DMY_DEFINE=20` because they override the previously mentioned `-I/my_dir/include and -DMY_DEFINE=10`. The compiler also passes `-L/my_dir/mic/lib -L/my_dir/lib` to the offload ld step:

```bash
ifort -qoffload-option,mic,compiler, "-I/my_dir/include -L/my_dir/lib -DMY_DEFINE=10 -I/my_dir/mic/
include -DMY_DEFINE=20" -offload-option,mic,ld, "-L/my_dir/mic/lib" hello.f
```

The following Linux* example demonstrates how options specified in `-qoffload-option` override options automatically passed from host compilation to offload compilation:

```bash
-qoffload-option,mic,compiler,"-O3 -DMY_DEFINE=MIC" -DMY_DEFINE=HOST -O2
```

`-DMY_DEFINE=HOST -O2` will be used for the host compilation. However, `-DMY_DEFINE=MIC -O3` will override `-O2` and `-DMY_DEFINE=HOST` for the offload compilation.

qoffload, Qoffload compiler option

Optimization Options

**falias**

*Determine whether aliasing should be assumed in the program.*

**Syntax**

Linux OS and OS X:

`-falias`

`-fno-alias`

Windows OS:

None

**Arguments**

None

**Default**

`-fno-alias` No aliasing is assumed in the program.

**Description**

This option determines whether aliasing should be assumed in the program.

If you want aliasing to be assumed in the program, specify `-falias`. However, this may affect performance.

**IDE Equivalent**

None

**Alternate Options**

Linux and OS X: None

Windows: `/Oa[-]`
**See Also**

ffnalias compiler option

**fast**

Maximizes speed across the entire program.

**Syntax**

Linux OS and OS X:

- `-fast`

Windows OS:

/`fast`

**Arguments**

None

**Default**

OFF  
The optimizations that maximize speed are not enabled.

**Description**

This option maximizes speed across the entire program.

It sets the following options:

On OS X* systems: `-ipo, -mdynamic-no-pic, -O3, -no-prec-div, -fp-model fast=2, and -xHost`

On Windows* systems: `/O3, /Qipo, /Qprec-div-, /fp:fast=2, and /QxHost`

On Linux* systems: `-ipo, -O3, -no-prec-div, -static, -fp-model fast=2, and -xHost`

On Intel® 64 architecture-based systems that target Intel® MIC Architecture: `[Q]ipo, O3, -no-prec-div`  
(Linux* OS) or `/Qprec-div-` (Windows* OS), `-fp-model fast=2` (Linux* OS) or `/fp:fast=2` (Windows* OS)

When option `fast` is specified, you can override the `[Q]xHost` option setting by specifying a different processor-specific `[Q]x` option on the command line. However, the last option specified on the command line takes precedence.

For example:

- On Linux* OS, if you specify option `-fast -xSSE3`, option `-xSSE3` takes effect. However, if you specify `-xSSE3 -fast`, option `-xHost` takes effect.
- On Windows* OS, if you specify option `/fast /QxSSE3`, option/QxSSE3 takes effect. However, if you specify `/QxSSE3 /fast`, option /QxHost takes effect.

For implications on non-Intel processors, refer to the `[Q]xHost` documentation.

---

**NOTE**

Option `fast` sets some aggressive optimizations that may not be appropriate for all applications. The resulting executable may not run on processor types different from the one on which you compile. You should make sure that you understand the individual optimization options that are enabled by option `fast`. 
IDE Equivalent

None

Alternate Options

None

See Also

fp-model, fp compiler option
xHost, QxHost compiler option
x, Qx compiler option
ffnalias

Specifies that aliasing should be assumed within functions.

Syntax

Linux OS and OS X:

-ffnalias
-fno-fnalias

Windows OS:

None

Arguments

None

Default

-ffnalias

Aliasing is assumed within functions.

Description

This option specifies that aliasing should be assumed within functions.
The -fno-fnalias option specifies that aliasing should not be assumed within functions, but should be assumed across calls.

IDE Equivalent

None

Alternate Options

Linux and OS X: None
See Also
fa1ias compiler option
foptimize-sibling-calls
Determines whether the compiler optimizes tail recursive calls.

Syntax
Linux OS and OS X:
-foptimize-sibling-calls
-fno-optimize-sibling-calls
Windows OS:
None

Arguments
None

Default
-foptimize-sibling-calls
The compiler optimizes tail recursive calls.

Description
This option determines whether the compiler optimizes tail recursive calls. It enables conversion of tail recursion into loops.

If you do not want to optimize tail recursive calls, specify -fno-optimize-sibling-calls.

Tail recursion is a special form of recursion that doesn't use stack space. In tail recursion, a recursive call is converted to a GOTO statement that returns to the beginning of the function. In this case, the return value of the recursive call is only used to be returned. It is not used in another expression. The recursive function is converted into a loop, which prevents modification of the stack space used.

IDE Equivalent
None

Alternate Options
None

fprotect-parens, Qprotect-parens
Determines whether the optimizer honors parentheses when expressions are evaluated.

Syntax
Linux OS and OS X:
-fprotect-parens
-fno-protect-parens
Windows OS:
/Qprotect-parens
/Qprotect-parens-
Arguments
None

Default
-fno-protect-parens  Parentheses are ignored when determining the order of expression evaluation.

or /Qno-protect-parens

Description
This option determines whether the optimizer honors parentheses when determining the order of expression evaluation.

When option -fprotect-parens (Linux* OS and OS X*) or /Qno-protect-parens (Windows* OS) is specified, the optimizer will maintain the order of evaluation imposed by parentheses in the code.

When the option -fno-protect-parens (Linux* OS and OS X*) or /Qno-protect-parens (Windows* OS) is specified, the optimizer may reorder expressions without regard for parentheses if it produces faster executing code.

IDE Equivalent
None

Alternate Options
None

Example
Consider the following expression:
A+(B+C)

By default, the parentheses are ignored and the compiler is free to re-order the operations based on the optimization level, the setting of option -fp-model (Linux* OS and OS X*) or /fp (Windows* OS), etc. to produce faster code. Code that is sensitive to the order of operations may produce different results (such as with some floating-point computations).

However, if -fprotect-parens (Linux* OS and OS X*) or /Qno-protect-parens (Windows* OS) is specified, parentheses around floating-point expressions (including complex floating-point and decimal floating-point) are honored and the expression will be interpreted following the normal precedence rules, that is, B+C will be computed first and then added to A.

This may produce slower code than when parentheses are ignored. If floating-point sensitivity is a specific concern, you should use option -fp-model precise (Linux* OS and OS X*) or /fp:precise (Windows* OS) to ensure precision because it controls all optimizations that may affect precision.

fp-model, fp compiler option

GF
Enables read-only string-pooling optimization.

Syntax
Linux OS and OS X:
None

Windows OS:
/GF
Arguments

None

Default

OFF

Description

This option enables read only string-pooling optimization.

IDE Equivalent

None

Alternate Options

None

\textit{nolib-inline}

\textit{Disables inline expansion of standard library or intrinsic functions.}

Syntax

\textbf{Linux OS and OS X:}

\texttt{-nolib-inline}

\textbf{Windows OS:}

None

Arguments

None

Default

OFF

The compiler inlines many standard library and intrinsic functions.

Description

This option disables inline expansion of standard library or intrinsic functions. It prevents the unexpected results that can arise from inline expansion of these functions.

IDE Equivalent

None

Alternate Options

None

\textbf{O}

\textit{Specifies the code optimization for applications.}

Syntax

\textbf{Linux OS and OS X:}

\texttt{-O [n]}
Windows OS:
/0 [n]

Arguments
n Is the optimization level. Possible values are 1, 2, or 3. On Linux* and OS X* systems, you can also specify 0.

Default
02 Optimizes for code speed. This default may change depending on which other compiler options are specified. For details, see below.

Description
This option specifies the code optimization for applications.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 (Linux* OS and OS X*)</td>
<td>This is the same as specifying 02.</td>
</tr>
<tr>
<td>00 (Linux OS and OS X)</td>
<td>Disables all optimizations. This option may set other options. This is determined by the compiler, depending on which operating system and architecture you are using. The options that are set may change from release to release. This option causes certain warn options to be ignored. This is the default if you specify option -debug (with no keyword).</td>
</tr>
</tbody>
</table>
| 01 | Enables optimizations for speed and disables some optimizations that increase code size and affect speed. To limit code size, this option:  
  * Enables global optimization; this includes data-flow analysis, code motion, strength reduction and test replacement, split-lifetime analysis, and instruction scheduling.  
  This option may set other options. This is determined by the compiler, depending on which operating system and architecture you are using. The options that are set may change from release to release. The 01 option may improve performance for applications with very large code size, many branches, and execution time not dominated by code within loops. |
| 02 | Enables optimizations for speed. This is the generally recommended optimization level. Vectorization is enabled at 02 and higher levels. On systems using IA-32 architecture: Some basic loop optimizations such as Distribution, Predicate Opt, Interchange, multi-versioning, and scalar replacements are performed. This option also enables:  
  * Inlining of intrinsics  
  * Intra-file interprocedural optimization, which includes:  
    * inlining  
    * constant propagation |

</table>

This option may set other options, especially options that optimize for code speed. This is determined by the compiler, depending on which operating system and architecture you are using. The options that are set may change from release to release.

On Windows* systems, this option is the same as the O0 option.

On Linux* and OS X* systems, if -g is specified, O2 is turned off and O0 is the default unless O2 (or O1 or O3) is explicitly specified in the command line together with -g.

On Linux systems, the -debug inline-debug-info option will be enabled by default if you compile with optimizations (option -O2 or higher) and debugging is enabled (option -g).

Many routines in the shared libraries are more highly optimized for Intel® microprocessors than for non-Intel microprocessors.

Perform O2 optimizations and enables more aggressive loop transformations such as Fusion, Block-Unroll-and-Jam, and collapsing IF statements.

This option may set other options. This is determined by the compiler, depending on which operating system and architecture you are using. The options that are set may change from release to release.

When O3 is used with options -ax or -x (Linux OS) or with options /Qax or /Qx (Windows OS), the compiler performs more aggressive data dependency analysis than for O2, which may result in longer compilation times.
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>The O3 optimizations may not cause higher performance unless loop and memory access transformations take place. The optimizations may slow down code in some cases compared to O2 optimizations. The O3 option is recommended for applications that have loops that heavily use floating-point calculations and process large data sets. Many routines in the shared libraries are more highly optimized for Intel® microprocessors than for non-Intel microprocessors.</td>

**Od**  
*Disables all optimizations.*

**Syntax**

Linux OS and OS X:  
None  

Windows OS:  
/Od

**Arguments**

None

**Default**

OFF  
The compiler performs default optimizations.

**Description**

This option disables all optimizations. It can be used for selective optimizations, such as a combination of /Od and /Ob1 (disables all optimizations, but enables inlining).
This option also causes certain /warn options to be ignored.
On IA-32 architecture, this option sets the /Oy- option.

**IDE Equivalent**
None

**Alternate Options**
Linux and OS X: `-O0`
Windows: `/optimize:0`

**See Also**
- `O` compiler option (see `O0`)

**Ofast**
*Sets certain aggressive options to improve the speed of your application.*

**Syntax**

**Linux OS and OS X:**

```
-Ofast
```

**Windows OS:**

None

**Arguments**
None

**Default**
OFF  
The aggressive optimizations that improve speed are not enabled.

**Description**
This option improves the speed of your application.
It sets compiler options `-O3`, `-no-prec-div`, and `-fp-model fast=2`.
On Linux* systems, this option is provided for compatibility with gcc.

**IDE Equivalent**
None

**Alternate Options**
None

**See Also**
- `O` compiler option
- `prec-div`, `Qprec-div` compiler option
- `fast` compiler option
- `fp-model`, `fp` compiler option
Os

*Enables optimizations that do not increase code size; it produces smaller code size than O2.*

Syntax

Linux OS and OS X:
- `-Os`

Windows OS:
- `/Os`

Arguments

None

Default

OFF

Optimizations are made for code speed. However, if `O1` is specified, `Os` is the default.

Description

This option enables optimizations that do not increase code size; it produces smaller code size than `O2`. It disables some optimizations that increase code size for a small speed benefit.

This option tells the compiler to favor transformations that reduce code size over transformations that produce maximum performance.

IDE Equivalent

Visual Studio: **Optimization > Favor Size or Speed**

Eclipse: None

Xcode: None

Alternate Options

None

Code Generation Options

arch
_Tells the compiler which features it may target, including which instruction sets it may generate._

Architecture Restrictions
Not available on Intel® 64 architecture targeting the Intel® Xeon Phi™ coprocessor x100 product family (formerly code name Knights Corner)

Syntax

Linux OS and OS X:
-arch code

Windows OS:
/Arch:code

Arguments

code
Indicates to the compiler a feature set that it may target, including which instruction sets it may generate. Many of the following descriptions refer to Intel® Streaming SIMD Extensions (Intel® SSE) and Supplemental Streaming SIMD Extensions (SSSE). Possible values are:

CORE-AVX2 May generate Intel® Advanced Vector Extensions 2 (Intel® AVX2), Intel® AVX, SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions.
CORE-AVX-I  May generate the RDRND instruction, Intel® Advanced Vector Extensions (Intel® AVX), Intel® SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions.

AVX  May generate Intel® Advanced Vector Extensions (Intel® AVX), Intel® SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions.

SSE4.2  May generate Intel® SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions.

SSE4.1  May generate Intel® SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions.

SSSE3  May generate SSSE3 instructions and Intel® SSE3, SSE2, and SSE instructions.

SSE3  May generate Intel® SSE3, SSE2, and SSE instructions.

SSE2  May generate Intel® SSE2 and SSE instructions. This value is only available on Linux* and Windows* systems.

SSE  This option has been deprecated; it is now the same as specifying IA32.

IA32  Generates x86/x87 generic code that is compatible with IA-32 architecture. Disables any default extended instruction settings, and any previously set extended instruction settings. It also disables all feature-specific optimizations and instructions. This value is only available on Linux* and Windows* systems using IA-32 architecture.

Default

Windows and Linux systems:  For more information on the default values, see Arguments above.
SSE2
OS X systems using IA-32  architecture:  SSE3
OS X systems using Intel® 64  architecture:  SSSE3

Description

This option tells the compiler which features it may target, including which instruction sets it may generate. Code generated with these options should execute on any compatible, non-Intel processor with support for the corresponding instruction set.

Options /arch and /Qx are mutually exclusive. If both are specified, the compiler uses the last one specified and generates a warning.

If you specify both the /Qax and /arch options, the compiler will not generate Intel-specific instructions.
For compatibility with Compaq* Visual Fortran, the compiler allows the following keyword values. However, you should use the suggested replacements.

<table>
<thead>
<tr>
<th>Compatibility Value</th>
<th>Suggested Replacement</th>
</tr>
</thead>
<tbody>
<tr>
<td>pn1</td>
<td>-mia32 or /arch:IA32</td>
</tr>
<tr>
<td>pn2</td>
<td>-mia32 or /arch:IA32</td>
</tr>
<tr>
<td>pn3</td>
<td>-mia32 or /arch:IA32</td>
</tr>
<tr>

arch compiler option

march compiler option

m compiler option

m32, m64, Qm32, Qm64 compiler option

**ax, Qax**

* Tells the compiler to generate multiple, feature-specific auto-dispatch code paths for Intel® processors if there is a performance benefit.

**Architecture Restrictions**

Not available on Intel® 64 architecture targeting the Intel® Xeon Phi™ coprocessor x100 product family (formerly code name Knights Corner)

**Syntax**

**Linux OS and OS X:**

`-axcode`

**Windows OS:**

`/Qaxcode`

**Arguments**

*code* Indicates to the compiler a feature set that it may target, including which instruction sets it may generate. The following descriptions refer to Intel® Streaming SIMD Extensions (Intel® SSE) and Supplemental Streaming SIMD Extensions (SSSE). Possible values are:
COMMON-AVX512 May generate Intel® Advanced Vector Extensions 512 (Intel® AVX-512) Foundation instructions, Intel® AVX-512 Conflict Detection instructions, as well as the instructions enabled with CORE-AVX2.

CORE-AVX512 May generate Intel® Advanced Vector Extensions 512 (Intel® AVX-512) Foundation instructions, Intel® AVX-512 Conflict Detection instructions, Intel® AVX-512 Doubleword and Quadword instructions, Intel® AVX-512 Byte and Word instructions and Intel® AVX-512 Vector Length extensions, as well as the instructions enabled with CORE-AVX2.

CORE-AVX2 May generate Intel® Advanced Vector Extensions 2 (Intel® AVX2), Intel® AVX, SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions for Intel® processors.

CORE-AVX-I May generate the RDRND instruction, Intel® Advanced Vector Extensions (Intel® AVX), Intel® SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions for Intel® processors.

AVX May generate Intel® Advanced Vector Extensions (Intel® AVX), Intel® SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions for Intel® processors.

SSE4.2 May generate Intel® SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions for Intel® processors.

SSE4.1 May generate Intel® SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions for Intel® processors.

SSSE3 May generate SSSE3 instructions and Intel® SSE3, SSE2, and SSE instructions for Intel® processors. For OS X* systems, this value is only supported on Intel® 64 architecture. This replaces value T, which is deprecated.

SSE3 May generate Intel® SSE3, SSE2, and SSE instructions for Intel® processors. For OS X* systems, this value is only supported on IA-32 architecture.

SSE2 May generate Intel® SSE2 and SSE instructions for Intel® processors. This value is not available on OS X* systems.
Default

OFF  No auto-dispatch code is generated. Feature-specific code is generated and is controlled by the setting of the following compiler options:

- Linux* OS: -m and -x
- Windows* OS: /arch and /Qx
- OS X*: -x

Description

This option tells the compiler to generate multiple, feature-specific auto-dispatch code paths for Intel® processors if there is a performance benefit. It also generates a baseline code path. The Intel feature-specific auto-dispatch path is usually more optimized than the baseline path. Other options, such as O3, control how much optimization is performed on the baseline path.

The baseline code path is determined by the architecture specified by options -m or -x (Linux* OS and OS X*) or options /arch or /Qx (Windows* OS). While there are defaults for the [Q|x] option that depend on the operating system being used, you can specify an architecture and optimization level for the baseline code that is higher or lower than the default. The specified architecture becomes the effective minimum architecture for the baseline code path.

If you specify both the [Q]ax and [Q]x options, the baseline code will only execute on Intel® processors compatible with the setting specified for the [Q]x.

If you specify both the -ax and -m options (Linux OS and OS X) or the /Qax and /arch options (Windows OS), the baseline code will execute on non-Intel processors compatible with the setting specified for the -m or /arch option.

If you specify both the -ax and -march options (Linux OS and OS X), or the /Qax and /arch options (Windows OS), the compiler will not generate Intel-specific instructions.

The [Q]ax option tells the compiler to find opportunities to generate separate versions of functions that take advantage of features of the specified instruction features.

If the compiler finds such an opportunity, it first checks whether generating a feature-specific version of a function is likely to result in a performance gain. If this is the case, the compiler generates both a feature-specific version of a function and a baseline version of the function. At run time, one of the versions is chosen to execute, depending on the Intel® processor in use. In this way, the program can benefit from performance gains on more advanced Intel processors, while still working properly on older processors and non-Intel processors. A non-Intel processor always executes the baseline code path.

You can use more than one of the feature values by combining them. For example, you can specify -axSSE4.1,SSSE3 (Linux OS and OS X) or /QaxSSE4.1,SSSE3 (Windows OS). You cannot combine the old style, deprecated options and the new options. For example, you cannot specify -axSSE4.1,T (Linux OS and OS X) or /QaxSSE4.1,T (Windows OS).

Optimization Notice

Intel’s compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

fasynchronous-unwind-tables
Determines whether unwind information is precise at an instruction boundary or at a call boundary.

Syntax
Linux OS and OS X:
-fasynchronous-unwind-tables
-fno-asynchronous-unwind-tables

Windows OS:
None

Arguments
None

Default

Intel® 64 architecture: -fasynchronous-unwind-tables
The unwind table generated is precise at an instruction boundary, enabling accurate unwinding at any instruction.

IA-32 architecture: -fno-asynchronous-unwind-tables
The unwind table generated is precise at call boundaries only.

Description
This option determines whether unwind information is precise at an instruction boundary or at a call boundary. The compiler generates an unwind table in DWARF2 or DWARF3 format, depending on which format is supported on your system.

If -fno-asynchronous-unwind-tables is specified, the unwind table is precise at call boundaries only. In this case, the compiler will avoid creating unwind tables for routines such as the following:

- A C++ routine that does not declare objects with destructors and does not contain calls to routines that might throw an exception.
- A C/C++ or Fortran routine compiled without -fexceptions, and on Intel® 64 architecture, without -traceback.
• A C/C++ or Fortran routine compiled with `-fexceptions` that does not contain calls to routines that might throw an exception.

**IDE Equivalent**

None

**Alternate Options**

None

**See Also**

`fexceptions` compiler option

**fexceptions**

*Enables exception handling table generation.*

**Syntax**

Linux OS and OS X:

- `-fexceptions`
- `-fno-exceptions`

Windows OS:

None

**Arguments**

None

**Default**

`-fno-exceptions`  
Exception handling table generation is disabled.

**Description**

This option enables C++ exception handling table generation, preventing Fortran routines in mixed-language applications from interfering with exception handling between C++ routines. The `-fno-exceptions` option disables C++ exception handling table generation, resulting in smaller code. When this option is used, any use of C++ exception handling constructs (such as try blocks and throw statements) when a Fortran routine is in the call chain will produce an error.

**IDE Equivalent**

None

**Alternate Options**

None

`fomit-frame-pointer, Oy`

*Determines whether EBP is used as a general-purpose register in optimizations.*

**Architecture Restrictions**

Option `/Oy[-]` is only available on IA-32 architecture
Syntax

Linux OS and OS X:
- `fomit-frame-pointer`
- `fno-omit-frame-pointer`

Windows OS:
/`Oy`
/`Oy-`

Arguments
None

Default
- `fomit-frame-pointer` or `/Oy`

EBP is used as a general-purpose register in optimizations. However, on Linux* and OS X* systems, the default is `-fno-omit-frame-pointer` if option `-O0` or `-g` is specified. On Windows* systems, the default is `/Oy-` if option `/Od` is specified.

Description
These options determine whether EBP is used as a general-purpose register in optimizations. Options `-fomit-frame-pointer` and `/Oy` allow this use. Options `-fno-omit-frame-pointer` and `/Oy-` disallow it.

Some debuggers expect EBP to be used as a stack frame pointer, and cannot produce a stack backtrace unless this is so. The `-fno-omit-frame-pointer` and `/Oy-` options direct the compiler to generate code that maintains and uses EBP as a stack frame pointer for all functions so that a debugger can still produce a stack backtrace without doing the following:

- For `-fno-omit-frame-pointer`: turning off optimizations with `-O0`
- For `/Oy-`: turning off `/O1`, `/O2`, or `/O3` optimizations

The `-fno-omit-frame-pointer` option is set when you specify option `-O0` or the `-g` option. The `-fomit-frame-pointer` option is set when you specify option `-O1`, `-O2`, or `-O3`.

The `/Oy` option is set when you specify the `/O1`, `/O2`, or `/O3` option. Option `/Oy-` is set when you specify the `/Od` option.

Using the `-fno-omit-frame-pointer` or `/Oy-` option reduces the number of available general-purpose registers by 1, and can result in slightly less efficient code.

IDE Equivalent
Visual Studio: **Optimization > Omit Frame Pointers**
Eclipse: None
Xcode: **Optimization > Provide Frame Pointer**

Alternate Options
Linux and OS X: `-fp` (this is a deprecated option)
Windows: None

**hotpatch**
*Tells the compiler to prepare a routine for hotpatching.*
Syntax

Linux OS:
-`-hotpatch[=n]`

OS X:
None

Windows OS:
-/hotpatch[:=n]

Arguments

\( n \)

An integer specifying the number of bytes the compiler should add before the function entry point.

Default

OFF

The compiler does not prepare routines for hotpatching.

Description

This option tells the compiler to prepare a routine for hotpatching. The compiler inserts nop padding around function entry points so that the resulting image is hot patchable.

Specifically, the compiler adds nop bytes after each function entry point and enough nop bytes before the function entry point to fit a direct jump instruction on the target architecture.

If \( n \) is specified, it overrides the default number of bytes that the compiler adds before the function entry point.

IDE Equivalent

None

Alternate Options

None

\( m \)

Tell the compiler which features it may target, including which instruction sets it may generate.

Architecture Restrictions

Not available on Intel® 64 architecture targeting the Intel® Xeon Phi™ coprocessor x100 product family (formerly code name Knights Corner)

Syntax

Linux OS and OS X:

-\( -mcode \)

Windows OS:

None
Arguments

code Indicates to the compiler a feature set that it may target, including which instruction sets it may generate. Many of the following descriptions refer to Intel® Streaming SIMD Extensions (Intel® SSE) and Supplemental Streaming SIMD Extensions (SSSE). Possible values are:

- **avx** May generate Intel® Advanced Vector Extensions (Intel® AVX), SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions.
- **sse4.2** May generate Intel® SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions.
- **sse4.1** May generate Intel® SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions.
- **ssse3** May generate SSSE3 instructions and Intel® SSE3, SSE2, and SSE instructions.
- **sse3** May generate Intel® SSE3, SSE2, and SSE instructions.
- **sse2** May generate Intel® SSE2 and SSE instructions. This value is only available on Linux systems.
- **sse** This option has been deprecated; it is now the same as specifying ia32.
- **ia32** Generates x86/x87 generic code that is compatible with IA-32 architecture. Disables any default extended instruction settings, and any previously set extended instruction settings. It also disables all feature-specific optimizations and instructions. This value is only available on Linux* systems using IA-32 architecture.

Default

**Linux* systems:** `-msse2`  
**OS X* systems using IA-32 architecture:** `-msse3`  
**OS X* systems using Intel® 64 architecture:** `-mssse3`  

For more information on the default values, see Arguments above.

Description

This option tells the compiler which features it may target, including which instruction sets it may generate. Code generated with these options should execute on any compatible, non-Intel processor with support for the corresponding instruction set.

Options `-x` and `-m` are mutually exclusive. If both are specified, the compiler uses the last one specified and generates a warning.

**Linux* systems:** For compatibility with gcc, the compiler allows the following options but they have no effect. You will get a warning error, but the instructions associated with the name will not be generated. You should use the suggested replacement options.
gcc Compatibility Option (Linux OS)  |  Suggested Replacement Option
---|---
-mfma  |  -march=core-avx2
-mbmi, -mavx2, -mlzcnt  |  -march=core-avx2
-mmovbe  |  -march=atom -minstruction=movbe
-mcrc32, -maes, -mpclmul, -mpopcnt  |  -march=corei7
-mvzeroupper  |  -march=corei7-avx
-mfsgsbase, -mrdrnd, -mf16c  |  -march=core-avx-i

Many of the above gcc options are not available on Intel® MIC Architecture.

IDE Equivalent
None

m32, m64, Qm32, Qm64
Tell the compiler to generate code for a specific architecture.

Architecture Restrictions
Not available on Intel® 64 architecture targeting the Intel® Xeon Phi™ coprocessor x100 product family (formerly code name Knights Corner)

Syntax

Linux OS and OS X:

-m32
-m64

Windows OS:

/Qm32
/Qm64

Arguments
None
Default
OFF

The compiler's behavior depends on the host system.

Description
These options tell the compiler to generate code for a specific architecture.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-m32 or /Qm32</td>
<td>Tells the compiler to generate code for IA-32 architecture.</td>
</tr>
<tr>
<td>-m64 or /Qm64</td>
<td>Tells the compiler to generate code for Intel® 64 architecture.</td>
</tr>
</tbody>
</table>

The -m32 and -m64 options are the same as OS X* options -arch i386 and -arch x86_64, respectively. These options are not related to the Intel® Fortran Compiler option arch.

On Linux* systems, these options are provided for compatibility with gcc.

IDE Equivalent
None

Alternate Options
None

march
_Tells the compiler to generate code for processors that support certain features._

Architecture Restrictions
Not available on Intel® 64 architecture targeting the Intel® Xeon Phi™ coprocessor x100 product family (formerly code name Knights Corner)

Syntax
Linux OS and OS X:
-march=processor

Windows OS:
None

Arguments
processor
Indicates to the compiler the code it may generate. Possible values are:

- generic
  Generates code for the compiler's default behavior.
- core-avx2
  Generates code for processors that support Intel® Advanced Vector Extensions 2 (Intel® AVX2), Intel® AVX, SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions.
Generates code for processors that support the RDRND instruction, Intel® Advanced Vector Extensions (Intel® AVX), Intel® SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions.

Generates code for processors that support Intel® Advanced Vector Extensions (Intel® AVX), Intel® SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions.

Generates code for processors that support Intel® SSE4 Efficient Accelerated String and Text Processing instructions. May also generate code for Intel® SSE4 Vectorizing Compiler and Media Accelerator, Intel® SSE3, SSE2, SSE, and SSSE3 instructions.

Generates code for processors that support MOVBE instructions, depending on the setting of option -minstruction (Linux* OS and OS X*) or /Qinstruction (Windows* OS). May also generate code for SSSE3 instructions and Intel® SSE3, SSE2, and SSE instructions.

Generates code for the Intel® Core™ 2 processor family.

Generates for Intel® Pentium® with MMX technology.

Generates for Intel® Pentium® Pro, Intel Pentium II, and Intel Pentium III processors.

Generates for Intel® Pentium® 4 processors with MMX technology.

Generates code for Intel® Pentium® processors. Value pentium3 is only available on Linux* OS.

If no architecture option is specified, value pentium4 is used by the compiler to generate code.

This option tells the compiler to generate code for processors that support certain features.
If you specify both the -ax and -march options, the compiler will not generate Intel-specific instructions.
Specifying -march=pentium4 sets -mtune=pentium4.
For compatibility, a number of historical processor values are also supported, but the generated code will not differ from the default.
### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

**masm**

_Tells the compiler to generate the assembler output file using a selected dialect._

### Syntax

**Linux OS:**

- `masm=dialect`

**OS X:**

None

**Windows OS:**

None
Arguments

dialect  
Is the dialect to use for the assembler output file. Possible values are:

att  
Tells the compiler to generate the assembler output file using AT&T* syntax.

intel  
Tells the compiler to generate the assembler output file using Intel syntax.

Default

-masm=att  
The compiler generates the assembler output file using AT&T* syntax.

Description

This option tells the compiler to generate the assembler output file using a selected dialect.

IDE Equivalent

None

Alternate Options

None

minstruction, Qinstruction  
Determines whether MOVBE instructions are generated for certain Intel processors.

Architecture Restrictions

Not available on Intel® 64 architecture targeting the Intel® Xeon Phi™ coprocessor x100 product family (formerly code name Knights Corner)

Syntax

Linux OS and OS X:

-minstruction=[no]movbe

Windows OS:

/Qinstruction:[no]movbe

Arguments

None

Default

-minstruction=nomovbe  
/or/Qinstruction:nomovbe  
The compiler does not generate MOVBE instructions for Intel® Atom™ processors.

Description

This option determines whether MOVBE instructions are generated for Intel® Atom™ processors. To use this option, you must also specify [Q]xATOM_SSSE3 or [Q]xATOM_SSE4.2.

If -minstruction=movbe or /Qinstruction:movbe is specified, the following occurs:
• MOVBE instructions are generated that are specific to the Intel® Atom™ processor.
• Generated executables can only be run on Intel® Atom™ processors or processors that support Supplemental Streaming SIMD Extensions 3 (Intel® SSSE3) or Intel® Streaming SIMD Extensions 4.2 (Intel® SSE4.2) and MOVBE.

If -minstruction=nomovbe or /Qinstruction:nomovbe is specified, the following occurs:

• The compiler optimizes code for the Intel® Atom™ processor, but it does not generate MOVBE instructions.
• Generated executables can be run on non-Intel® Atom™ processors that support Intel® SSE3 or Intel® SSE4.2.

IDE Equivalent
None

Alternate Options
None

See Also
x, Qx compiler option

mtune
Performs optimizations for specific processors.

Architecture Restrictions
Not available on Intel® 64 architecture targeting the Intel® Xeon Phi™ coprocessor x100 product family (formerly code name Knights Corner)

Syntax
Linux OS and OS X:
-mtune=processor

Windows OS:
None

Arguments

processor
Is the processor for which the compiler should perform optimizations. Possible values are:

- generic
  Optimizes code for the compiler's default behavior.

- core-avx2
  Optimizes code for processors that support Intel® Advanced Vector Extensions 2 (Intel® AVX2), Intel® AVX, SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions.

- core-avx-i
  Optimizes code for processors that support the RDRND instruction, Intel® Advanced Vector Extensions (Intel® AVX), Intel® SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions.
corei7-avx Optimizes code for processors that support Intel® Advanced Vector Extensions (Intel® AVX), Intel® SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions.

corei7 Optimizes code for processors that support Intel® SSE4 Efficient Accelerated String and Text Processing instructions. May also generate code for Intel® SSE4 Vectorizing Compiler and Media Accelerator, Intel® SSE3, SSE2, SSE, and SSSE3 instructions.

atom Optimizes code for processors that support MOVBE instructions, depending on the setting of option -minstruction (Linux* OS and OS X*) or /Qinstruction (Windows* OS). May also generate code for SSSE3 instructions and Intel® SSE3, SSE2, and SSE instructions.

core2 Optimizes for the Intel® Core™ 2 processor family, including support for MMX™, Intel® SSE, SSE2, SSE3 and SSSE3 instruction sets.

pentium-mmx Optimizes for Intel® Pentium® with MMX technology.
pentiumpro Optimizes for Intel® Pentium® Pro, Intel Pentium II, and Intel Pentium III processors.
pentium4m Optimizes for Intel® Pentium® 4 processors with MMX technology.
pentium-m Optimizes code for Intel® Pentium® processors. Value pentium3 is only available on Linux* OS.
pentium4 pentium3 pentium

Default
generic Code is generated for the compiler's default behavior.

Description
This option performs optimizations for specific processors.
The resulting executable is backwards compatible and generated code is optimized for specific processors. For example, code generated with -mtune=pentium4 will run correctly on Core2 processors, but it might not run as fast as if it had been generated using -mtune=core2.

The following table shows on which architecture you can use each value.

## Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

## IDE Equivalent

## Qpatchable-addresses

_Tells the compiler to generate code such that references to statically assigned addresses can be patched._

## Architecture Restrictions

Only available on Intel® 64 architecture

## Syntax

**Linux OS and OS X:**

None

**Windows OS:**

/Qpatchable-addresses

## Arguments

None
The compiler does not generate patchable addresses.

**Description**
This option tells the compiler to generate code such that references to statically assigned addresses can be patched with arbitrary 64-bit addresses.

Normally, the Windows* OS compiler that runs on Intel® 64 architecture uses 32-bit relative addressing to reference statically allocated code and data. That assumes the code or data is within 2GB of the access point, an assumption that is enforced by the Windows object format.

However, in some patching systems, it is useful to have the ability to replace a global address with some other arbitrary 64-bit address, one that might not be within 2GB of the access point.

This option causes the compiler to avoid 32-bit relative addressing in favor of 64-bit direct addressing so that the addresses can be patched in place without additional code modifications. This option causes code size to increase, and since 32-bit relative addressing is usually more efficient than 64-bit direct addressing, you may see a performance impact.

\texttt{x, Qx}

\textit{Tells the compiler which processor features it may target, including which instruction sets and optimizations it may generate.}

**Architecture Restrictions**
Not available on Intel® 64 architecture targeting the Intel® Xeon Phi™ coprocessor x100 product family (formerly code name Knights Corner)

**Syntax**

- \textbf{Linux OS and OS X:}

  \texttt{-xcode}

- \textbf{Windows OS:}

  \texttt{/Qxcode}

**Arguments**

\textit{code}

Indicates to the compiler a feature set that it may target, including which instruction sets and optimizations it may generate. Many of the following descriptions refer to Intel® Streaming SIMD Extensions (Intel® SSE) and Supplemental Streaming SIMD Extensions (Intel® SSSE). Possible values are:

\texttt{COMMON-AVX512}  May generate Intel® Advanced Vector Extensions 512 (Intel® AVX-512) Foundation instructions, Intel® AVX-512 Conflict Detection instructions, as well as
the instructions enabled with CORE-AVX2. Optimizes for Intel® processors that support Intel® AVX-512 instructions.

**MIC-AVX512**

**CORE-AVX512**

May generate Intel® Advanced Vector Extensions 512 (Intel® AVX-512) Foundation instructions, Intel® AVX-512 Conflict Detection instructions, Intel® AVX-512 Doubleword and Quadword instructions, Intel® AVX-512 Byte and Word instructions and Intel® AVX-512 Vector Length extensions, as well as the instructions enabled with CORE-AVX2. Optimizes for Intel® processors that support Intel® AVX-512 instructions.

**CORE-AVX2**

May generate Intel® Advanced Vector Extensions 2 (Intel® AVX2), Intel® AVX, SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions for Intel® processors. Optimizes for Intel® processors that support Intel® AVX2 instructions.

**CORE-AVX-1**

May generate the RDRND instruction, Intel® Advanced Vector Extensions (Intel® AVX), Intel® SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions for Intel® processors. Optimizes for Intel® processors that support the RDRND instruction.

**AVX**

May generate Intel® Advanced Vector Extensions (Intel® AVX), Intel® SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions for Intel® processors. Optimizes for Intel processors that support Intel® AVX instructions.

**SSE4.2**

May generate Intel® SSE4 Efficient Accelerated String and Text Processing instructions, Intel® SSE4 Vectorizing Compiler and Media Accelerator, and Intel® SSE3, SSE2, SSE, and SSSE3 instructions for Intel® processors. Optimizes for Intel processors that support Intel® SSE4.2 instructions.

**SSE4.1**

May generate Intel® SSE4 Vectorizing Compiler and Media Accelerator instructions for Intel® processors. May generate Intel® SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions for Intel processors that support Intel® SSE4.1 instructions.
ATOM_SSE4.2 May generate MOVBE instructions for Intel® processors, depending on the setting of option \(\text{minstruction}\) (Linux* OS and OS X*) or \(\text{Qinstruction}\) (Windows* OS). May also generate Intel® SSE4.2, SSE3, SSE2, and SSE instructions for Intel processors. Optimizes for Intel® Atom™ processors that support Intel® SSE4.2 and MOVBE instructions.

ATOM_SSSE3 May generate MOVBE instructions for Intel® processors, depending on the setting of option \(\text{minstruction}\) (Linux* OS and OS X*) or \(\text{Qinstruction}\) (Windows* OS). May also generate SSSE3, Intel® SSE3, SSE2, and SSE instructions for Intel processors. Optimizes for Intel® Atom™ processors that support Intel® SSE3 and MOVBE instructions.

SSE3_ATOM and SSSE3_ATOM These option settings are deprecated. They have the same effect as specifying ATOM_SSSE3.

SSSE3 May generate SSSE3 and Intel® SSE3, SSE2, and SSE instructions for Intel® processors. Optimizes for Intel processors that support SSSE3 instructions. For OS X* systems, this value is only supported on Intel® 64 architecture. This replaces value T, which is deprecated.

SSE3 May generate Intel® SSE3, SSE2, and SSE instructions for Intel® processors. Optimizes for Intel processors that support Intel® SSE3 instructions. For OS X* systems, this value is only supported on IA-32 architecture.

SSE2 May generate Intel® SSE2 and SSE instructions for Intel® processors. Optimizes for Intel processors that support Intel® SSE2 instructions. This value is not available on OS X* systems.

You can also specify \text{Host}. For more information, see option \(\text{Q}x\text{Host}\).

\textbf{Default}

Windows* systems: None
Linux* systems: None
OS X* systems using IA-32 architecture: SSE3
OS X* systems using Intel® 64 architecture: SSSE3

On Windows systems, if neither \(\text{/Qx}\) nor \(\text{/arch}\) is specified, the default is \(\text{/arch:SSE2}\).

On Linux systems, if neither \(-x\) nor \(-m\) is specified, the default is \(-\text{msse2}\).

\textbf{Description}

This option tells the compiler which processor features it may target, including which instruction sets and optimizations it may generate. It also enables optimizations in addition to Intel feature-specific optimizations. The specialized code generated by this option may only run on a subset of Intel® processors.
The resulting executables created from these option values can only be run on Intel® processors that support the indicated instruction set.

The binaries produced by these code values will run on Intel® processors that support the specified features.

Do not use code values to create binaries that will execute on a processor that is not compatible with the targeted processor. The resulting program may fail with an illegal instruction exception or display other unexpected behavior.

Compiling the main program with any of the code values produces binaries that display a fatal run-time error if they are executed on unsupported processors, including all non-Intel processors.

Compiler options \texttt{m} and \texttt{arch} produce binaries that should run on processors not made by Intel that implement the same capabilities as the corresponding Intel® processors.

The \texttt{-x} and \texttt{/Qx} options enable additional optimizations not enabled with options \texttt{-m} or \texttt{/arch} (nor with options \texttt{-ax} and \texttt{/Qax}).

On Windows* systems, options \texttt{/Qx} and \texttt{/arch} are mutually exclusive. If both are specified, the compiler uses the last one specified and generates a warning. Similarly, on Linux* and OS X* systems, options \texttt{-x} and \texttt{-m} are mutually exclusive. If both are specified, the compiler uses the last one specified and generates a warning.

\textbf{NOTE}

All settings except SSE2 do a CPU check.

Interprocedural Optimization (IPO) Options

ffat-lto-objects
Determines whether a fat link-time optimization (LTO) object, containing both intermediate language and object code, is generated during an interprocedural optimization compilation (-c -ipo).
Syntax

Linux OS:
-ffat-lto-objects
-fno-fat-lto-objects

OS X:
None

Windows OS:
None

Arguments
None

Default
-ffat-lto-objects

When \(-c \ -ipo\) is specified, the compiler generates a fat link-time optimization (LTO) object that has both a true object and a discardable intermediate language section.

Description

This option determines whether a fat link time optimization (LTO) object, containing both intermediate language and object code, is generated during an interprocedural optimization compilation \((-c \ -ipo)\).

During an interprocedural optimization compilation \((-c \ -ipo)\), the following occurs:

- If you specify \(-ffat-lto-objects\), the compiler generates a fat link-time optimization (LTO) object that has both a true object and a discardable intermediate language section. This enables both link-time optimization (LTO) linking and normal linking.
- If you specify \(-fno-fat-lto-objects\), the compiler generates a fat link-time optimization (LTO) object that only has a discardable intermediate language section; no true object is generated. This option may improve compilation time.

Note that these files will be inserted into archives in the form in which they were created.

This option is provided for compatibility with gcc. For more information about this option, see the gcc documentation.

NOTE

Intel's intermediate language representation is not compatible with gcc's intermediate language representation.

IDE Equivalent

None

Alternate Options

None

See Also

ipo, Qipo compiler option
ip, Qip
Determines whether additional interprocedural optimizations for single-file compilation are enabled.

Syntax

Linux OS and OS X:
- -ip
- -no-ip

Windows OS:
- /Qip
- /Qip-

Arguments
None

Default
OFF

Some limited interprocedural optimizations occur, including inline function expansion for calls to functions defined within the current source file. These optimizations are a subset of full intra-file interprocedural optimizations. Note that this setting is not the same as -no-ip (Linux* OS and OS X*) or /Qip- (Windows* OS).

Description
This option determines whether additional interprocedural optimizations for single-file compilation are enabled.

The [Q]ip option enables additional interprocedural optimizations for single-file compilation.

Options -no-ip (Linux OS and OS X) and /Qip- (Windows OS) may not disable inlining. To ensure that inlining of user-defined functions is disabled, specify -inline-level=0 or -fno-inline (Linux OS and OS X), or specify /Ob0 (Windows OS).

IDE Equivalent
Visual Studio: Optimization > Interprocedural Optimization
Eclipse: None
Xcode: None

None

See Also
finline-functions compiler option

ip-no-inlining, Qip-no-inlining
Disables full and partial inlining enabled by interprocedural optimization options.

Syntax

Linux OS and OS X:
- -ip-no-inlining
Windows OS:
/Qip-no-inlining

**Arguments**
None

**Default**
OFF

**Description**
Inlining enabled by interprocedural optimization options is performed.

This option disables full and partial inlining enabled by the following interprocedural optimization options:

- On Linux* and OS X* systems: `-ip` or `-ipo`
- On Windows* systems: `/Qip`, `/Qipo`, or `/Ob2`

It has no effect on other interprocedural optimizations.

On Windows systems, this option also has no effect on user-directed inlining specified by option `/Ob1`.

**IDE Equivalent**
None

**Alternate Options**
None

**ip-no-pinlining, Qip-no-pinlining**
Disables partial inlining enabled by interprocedural optimization options.

**Syntax**

**Linux OS and OS X:**
- `-ip-no-pinlining`

**Windows OS:**
- `/Qip-no-pinlining`

**Arguments**
None

**Default**
OFF

**Description**
Inlining enabled by interprocedural optimization options is performed.

This option disables partial inlining enabled by the following interprocedural optimization options:

- On Linux* and OS X* systems: `-ip` or `-ipo`
- On Windows* systems: `/Qip` or `/Qipo`

It has no effect on other interprocedural optimizations.

**IDE Equivalent**
None
Alternate Options
None

ipo, Qipo
Enables interprocedural optimization between files.

Syntax
Linux OS and OS X:
-ipo[n]
-no-ipo

Windows OS:
/Qipo[n]
/Qipo-

Arguments

\( n \) Is an optional integer that specifies the number of object files the compiler should create. The integer must be greater than or equal to 0.

Default
-no-ipo or /Qipo- Multifile interprocedural optimization is not enabled.

Description
This option enables interprocedural optimization between files. This is also called multifile interprocedural optimization (multifile IPO) or Whole Program Optimization (WPO).

When you specify this option, the compiler performs inline function expansion for calls to functions defined in separate files.

You cannot specify the names for the files that are created.

If \( n \) is 0, the compiler decides whether to create one or more object files based on an estimate of the size of the application. It generates one object file for small applications, and two or more object files for large applications.

If \( n \) is greater than 0, the compiler generates \( n \) object files, unless \( n \) exceeds the number of source files \( m \), in which case the compiler generates only \( m \) object files.

If you do not specify \( n \), the default is 0.

IDE Equivalent
Visual Studio: Optimization > Interprocedural Optimization
General > Whole Program Optimization

Eclipse: None
Xcode: None

Alternate Options
None
**ipo-c, Qipo-c**
*Tells the compiler to optimize across multiple files and generate a single object file.*

**Syntax**

*Linux OS and OS X:*

- `-ipo-c`

*Windows OS:*

/`Qipo-c`

**Arguments**

None

**Default**

OFF  
The compiler does not generate a multifile object file.

**Description**

This option tells the compiler to optimize across multiple files and generate a single object file (named `ipo_out.o` on Linux* and OS X* systems; `ipo_out.obj` on Windows* systems).

It performs the same optimizations as the `[Q]ipo` option, but compilation stops before the final link stage, leaving an optimized object file that can be used in further link steps.

**IDE Equivalent**

None

**Alternate Options**

None

**See Also**

ipo, Qipo compiler option

**ipo-jobs, Qipo-jobs**
*Specifies the number of commands (jobs) to be executed simultaneously during the link phase of Interprocedural Optimization (IPO).*

**Syntax**

*Linux OS and OS X:*

- `-ipo-jobs n`

*Windows OS:*

/`Qipo-jobs:n`

**Arguments**

`n`  
Is the number of commands (jobs) to run simultaneously. The number must be greater than or equal to 1.
**Default**

-ipo-jobs1 or /Qipo-jobs:1

One command (job) is executed in an interprocedural optimization parallel build.

**Description**

This option specifies the number of commands (jobs) to be executed simultaneously during the link phase of Interprocedural Optimization (IPO). It should only be used if the link-time compilation is generating more than one object. In this case, each object is generated by a separate compilation, which can be done in parallel.

This option can be affected by the following compiler options:

- [Q]ipo when applications are large enough that the compiler decides to generate multiple object files.
- [Q]ipo:n when n is greater than 1.
- [Q]ipo-separate

---

**CAUTION**

Be careful when using this option. On a multi-processor system with lots of memory, it can speed application build time. However, if n is greater than the number of processors, or if there is not enough memory to avoid thrashing, this option can increase application build time.

**IDE Equivalent**

None

**Alternate Options**

None

**See Also**

ipo, Qipo compiler option

ipo-separate, Qipo-separate compiler option

ipo-S, Qipo-S

*Tells the compiler to optimize across multiple files and generate a single assembly file.*

**Syntax**

**Linux OS and OS X:**

-ipo-S

**Windows OS:**

/Qipo-S

**Arguments**

None

**Default**

OFF

The compiler does not generate a multfile assembly file.
**Description**

This option tells the compiler to optimize across multiple files and generate a single assembly file (named ipo_out.s on Linux* and OS X* systems; ipo_out.asm on Windows* systems).

It performs the same optimizations as the [Q]ipo option, but compilation stops before the final link stage, leaving an optimized assembly file that can be used in further link steps.

**IDE Equivalent**

None

**Alternate Options**

None

**See Also**

ipo, Qipo compiler option

ipo-separate, Qipo-separate

_Tells the compiler to generate one object file for every source file._

**Syntax**

**Linux OS:**

-ipo-separate

**OS X:**

None

**Windows OS:**

/Qipo-separate

**Arguments**

None

**Default**

OFF

The compiler decides whether to create one or more object files.

**Description**

This option tells the compiler to generate one object file for every source file. It overrides any [Q]ipo option specification.

**IDE Equivalent**

None

**Alternate Options**

None

**See Also**

ipo, Qipo compiler option

**Advanced Optimization Options**
ansi-alias, Qansi-alias
Tells the compiler to assume that the program adheres to Fortran Standard type aliasability rules.

**Syntax**

**Linux OS and OS X:**

- `-ansi-alias`
- `-no-ansi-alias`

**Windows OS:**

- `Qansi-alias`
- `Qansi-alias-`

**Arguments**

None

**Default**

- `-ansi-alias` or `/Qansi-alias`

**Description**

This option tells the compiler to assume that the program adheres to type aliasability rules defined in the Fortran Standard.

For example, an object of type real cannot be accessed as an integer. For information on the rules for data types and data type constants, see "Data Types, Constants, and Variables" in the Language Reference.

This option directs the compiler to assume the following:

- Arrays are not accessed out of arrays' bounds.
- Pointers are not cast to non-pointer types and vice-versa.
- References to objects of two different scalar types cannot alias. For example, an object of type integer cannot alias with an object of type real or an object of type real cannot alias with an object of type double precision.

If your program adheres to the Fortran Standard type aliasability rules, this option enables the compiler to optimize more aggressively. If it doesn't adhere to these rules, then you should disable the option with `-no-ansi-alias` (Linux* OS and OS X*) or `/Qansi-alias-` (Windows* OS) so the compiler does not generate incorrect code.

**IDE Equivalent**

None

**Alternate Options**

None

---

coarray, Qcoarray
Enables the coarray feature.

**Syntax**

**Linux OS:**

- `coarray[-keyword]`
OS X:
None

Windows OS:
/Qcoarray[:keyword]

Arguments

keyword Specifies the memory system where the coarrays will be implemented. Possible values are:

shared Indicates a shared memory system. This is the default.

distributed Indicates a distributed memory system.

coprocessor Indicates a configuration where image 1 is running on the host processor, and other images are run on host processors or Intel® MIC Architecture coprocessors. The configuration file is used to determine where the images will be run; that is, how many on the host processors and how many on the coprocessors. This results in an executable containing code that will replicate itself NUM.Images() more times, ultimately resulting in NUM.Images()+1 running images. This setting is only available on Linux* OS on Intel® 64 architecture.

This setting requires that option -coarray-config-file also be specified.

single Indicates a configuration where the image does not contain self-replication code. This results in an executable with a single running image. This configuration can be useful for debugging purposes, even though there are no inter-image interactions.

Default
OFF Coarrays are not enabled without specifying this option.

Description
This option enables the coarray feature of the Fortran 2008 Standard. It enables any coarray syntax in your program. If this option is not specified, coarray syntax is rejected.

It also tells the driver to link against appropriate libraries, and to create the appropriate executables.

Only one keyword can be in effect. If you specify more than one keyword, the last one specified takes precedence. However, if keyword single is specified anywhere on the command line, it takes precedence.

On Intel® MIC Architecture, this option is only available on Linux* OS.

You can specify option [Q]coarray-num-images to specify the default number of images that can be used to run a coarray executable. If you do not specify that option, you get the number of execution units on the current system.
You can specify the [Q]coarray-config-file option to specify the name of a Message Passing Interface (MPI) configuration file.

Options [Q]coarray-num-images and [Q]coarray-config-file are valid for all keyword values.

**IDE Equivalent**

Visual Studio: **Language > Enable Coarrays**

Eclipse: None

Xcode: None

**Alternate Options**

None

**Example**

The following command runs a coarray program on shared memory using $n$ images:

```plaintext
/Qcoarray /Qcoarray-num-images:n          ! Windows OS
-coarray -coarray-num-images=n           ! Linux OS
```

The following command runs a coarray program on distributed memory using $n$ images:

```plaintext
/Qcoarray:distributed /Qcoarray-num-images:n          ! Windows OS
-coarray=distributed -coarray-num-images=n           ! Linux OS
```

The following command runs a coarray program on shared memory using the MPI configuration file specified by `filename`:

```plaintext
/Qcoarray:shared /Qcoarray-config-file:filename        ! Windows OS
-coarray=shared -coarray-config-file=filename          ! Linux OS
```

The following commands illustrate precedence:

**Linux* OS:**

- `coarray=coprocessor -coarray=shared`          ! shared takes precedence (last one specified)
- `coarray=single -coarray=shared`               ! single takes precedence (single always takes precedence)

**Windows* OS:**

- `/Qcoarray:distributed /Qcoarray:shared`        ! shared takes precedence (last one specified)
- `/Qcoarray:single /Qcoarray:shared`             ! single takes precedence (single always takes precedence)

coarray-config-file, Qcoarray-config-file compiler option

Coarrays

Using Coarrays

coarray-config-file, Qcoarray-config-file

Specifies the name of a Message Passing Interface (MPI) configuration file.

**Syntax**

**Linux OS:**

- `-coarray-config-file=filename`
OS X:
None

Windows OS:
/Qcoarray-config-file:filename

**Arguments**

filename  
Is the name of the MPI configuration file. You can specify a path.

**Default**

OFF  
When coarrays are enabled, the compiler uses default settings for MPI.

**Description**

This option specifies the name of a Message Passing Interface (MPI) configuration file. This file is used by the compiler when coarrays are processed; it configures the MPI for multi-node operations.

On Intel® MIC Architecture, this option is only available on Linux* OS.

This option has no affect unless you also specify the [Q]coarray option, which is required to create the coarray executable.

Note that when a setting is specified in environment variable FOR_COARRAY_CONFIG_FILE, it overrides the compiler option setting.

**IDE Equivalent**

Visual Studio: **Language > MPI Configuration File**
Eclipse: None
Xcode: None

**Alternate Options**

None

**See Also**

cooparray, Qcoarray compiler option

cooparray-num-images, Qcoarray-num-images  
*Specifies the default number of images that can be used to run a coarray executable.*

**Syntax**

Linux OS:
- coarray-num-images=n

OS X:
None

Windows OS:
/Qcoarray-num-images:n
Arguments

n  

Is the default number of images. The limit is determined from the system configuration.

Default

OFF  

The number of images is determined at run-time.

Description

This option specifies the default number of images that can be used to run a coarray executable.

On Intel® MIC Architecture, this option is only available on Linux* OS.

This option has no affect unless you also specify the [Q]coarray option. This option is required to create the coarray executable.

You can specify option [Q]coarray-num-images to specify the default number of images that can be used to run a coarray executable. If you do not specify that option, you get the number of execution units on the current system.

Note that when a setting is specified in environment variable FOR_COARRAY_NUM_IMAGES, it overrides the compiler option setting.

IDE Equivalent

Visual Studio: Language > Coarray Images

Eclipse: None

Xcode: None

Alternate Options

None

See Also

c��array, Qcoarray compiler option

complex-limited-range, Qcomplex-limited-range

Determines whether the use of basic algebraic expansions of some arithmetic operations involving data of type COMPLEX is enabled.

Syntax

Linux OS and OS X:

-complex-limited-range

-no-complex-limited-range

Windows OS:

/Qcomplex-limited-range

/Qcomplex-limited-range-

Arguments

None
Default

-no-complex-limited-range  Basic algebraic expansions of some arithmetic operations involving data of type COMPLEX are disabled.

Description
This option determines whether the use of basic algebraic expansions of some arithmetic operations involving data of type COMPLEX is enabled.

When the option is enabled, this can cause performance improvements in programs that use a lot of COMPLEX arithmetic. However, values at the extremes of the exponent range may not compute correctly.

IDE Equivalent
Visual Studio: Floating point > Limit COMPLEX Range
Eclipse: None
Xcode: Floating point > Limit COMPLEX Range

Alternate Options
None

guide, Qguide
Lets you set a level of guidance for auto-vectorization, auto parallelism, and data transformation.

Syntax
Linux OS and OS X:
-guide [=n]

Windows OS:
/Qguide[:n]

Arguments

n  Is an optional value specifying the level of guidance to be provided.

The values available are 1 through 4. Value 1 indicates a standard level of guidance. Value 4 indicates the most advanced level of guidance. If n is omitted, the default is 4.

Default
OFF  You do not receive guidance about how to improve optimizations for parallelism, vectorization, and data transformation.

Description
This option lets you set a level of guidance (advice) for auto-vectorization, auto parallelism, and data transformation. It causes the compiler to generate messages suggesting ways to improve these optimizations.

When this option is specified, the compiler does not produce any objects or executables.

You must also specify the [Q]parallel option to receive auto parallelism guidance.

You can set levels of guidance for the individual guide optimizations by specifying one of the following options:
[Q]guide-par  Provides guidance for auto parallelism.
[Q]guide-vec  Provides guidance for auto-vectorization.

If you specify the [Q]guide option and also specify one of the options setting a level of guidance for an individual guide optimization, the value set for the individual guide optimization will override the setting specified in [Q]guide.

If you do not specify [Q]guide, but specify one of the options setting a level of guidance for an individual guide optimization, option [Q]guide is enabled with the greatest value passed among any of the three individual guide optimizations specified.

In debug mode, this option has no effect unless option 02 (or higher) is explicitly specified in the same command line.

**NOTE**
The compiler speculatively performs optimizations as part of guide analysis. As a result, when you use guided auto-parallelism options with options that produce vectorization or auto-parallelizer reports (such as option [q or Q]opt-report), the compiler generates "LOOP WAS VECTORIZED" or similar messages as if the compilation was performed with the recommended changes.

When compilation is performed with the [Q]guide option, you should use extra caution when interpreting vectorizer diagnostics and auto-parallelizer diagnostics.

**NOTE**
You can specify [Q]diag-disable to prevent the compiler from issuing one or more diagnostic messages.

**IDE Equivalent**
Visual Studio: Diagnostics > Guided Auto Parallelism Analysis
Eclipse: None
Xcode: Diagnostics > Enable Guided Auto Parallelism Analysis

**Alternate Options**
None

**See Also**
guide-data-trans, Qguide-data-trans compiler option
guide-par, Qguide-par compiler option
guide-vec, Qguide-vec compiler option
guide-file, Qguide-file compiler option
guide-file-append, Qguide-file-append compiler option
guide-opts, Qguide-opts compiler option
diag, Qdiag compiler option
qopt-report, Qopt-report compiler option

**guide-data-trans, Qguide-data-trans**
Lets you set a level of guidance for data transformation.
Syntax

Linux OS and OS X:
-guide-data-trans [=n]

Windows OS:
/Qguide-data-trans [=n]

Arguments

n
Is an optional value specifying the level of guidance to be provided.
The values available are 1 through 4. Value 1 indicates a standard level of
guidance. Value 4 indicates the most advanced level of guidance. If n is
omitted, the default is 4.

Default

OFF You do not receive guidance about how to improve optimizations for data
transformation.

Description

This option lets you set a level of guidance for data transformation. It causes the compiler to generate
messages suggesting ways to improve that optimization.

IDE Equivalent

None

Alternate Options

None

See Also

guide, Qguide compiler option
guide-par, Qguide-par compiler option
guide-vec, Qguide-vec compiler option
guide-file, Qguide-file compiler option

guide-file, Qguide-file
Causes the results of guided auto parallelism to be
output to a file.

Syntax

Linux OS and OS X:
-guide-file [=filename]

Windows OS:
/Qguide-file [=filename]

Arguments

filename
Is the name of the file for output. It can include a path.
Messages that are generated by guided auto parallelism are output to stderr.

This option causes the results of guided auto parallelism to be output to a file. This option is ignored unless you also specify one or more of the following options:

- [Q]guide
- [Q]guide-vec
- [Q]guide-data-trans
- [Q]guide-par

If you do not specify a path, the file is placed in the current working directory. If there is already a file named `filename`, it will be overwritten.

You can include a file extension in `filename`. For example, if `file.txt` is specified, the name of the output file is `file.txt`. If you do not provide a file extension, the name of the file is `filename.guide`.

If you do not specify `filename`, the name of the file is `name-of-the-first-source-file.guide`. This is also the name of the file if the name specified for `filename` conflicts with a source file name provided in the command line.

**NOTE**
If you specify the `[Q]guide-file` option and you also specify option `[Q]guide-file-append`, the last option specified on the command line takes precedence.

**IDE Equivalent**

Visual Studio: **Diagnostics > Emit Guided Auto Parallelism Diagnostics to File**

**Diagnostics > Guided Auto Parallelism Diagnostics File**

Eclipse: None

Xcode: **Diagnostics > Emit Guided Auto Parallelism diagnostics to File**

**Diagnostics > Guided Auto Parallelism Report File**

**Alternate Options**

None

**Example**

The following example shows how to cause guided auto parallelism messages to be output to a file named `my_guided_autopar.guide`:

```bash
-guide-file=my_guided_autopar       ! Linux and OS X systems
/Qguide-file:my_guided_autopar      ! Windows systems
```

**See Also**

guide, Qguide compiler option

guide-file-append, Qguide-file-append compiler option

**guide-file-append, Qguide-file-append**

Causes the results of guided auto parallelism to be appended to a file.
Syntax

Linux OS and OS X:
-guide-file-append[=filename]

Windows OS:
/Qguide-file-append[:filename]

Arguments

date

filename
Is the name of the file to be appended to. It can include a path.

Default

OFF
Messages that are generated by guided auto parallelism are output to stderr.

Description

This option causes the results of guided auto parallelism to be appended to a file.
This option is ignored unless you also specify one or more of the following options:

- [Q]guide
- [Q]guide-vec
- [Q]guide-data-trans
- [Q]guide-par

If you do not specify a path, the compiler looks for filename in the current working directory.
If filename is not found, then a new file with that name is created in the current working directory.
If you do not specify a file extension, the name of the file is filename.guide.
If the name specified for filename conflicts with a source file name provided in the command line, the name of the file is name-of-the-first-source-file.guide.

NOTE

If you specify the [Q]guide-file-append option and you also specify option [Q]guide-file, the last option specified on the command line takes precedence.

IDE Equivalent

None

Alternate Options

None

Example

The following example shows how to cause guided auto parallelism messages to be appended to a file named my_messages.txt:

-guide-file-append=my_messages.txt  ! Linux and OS X systems
/Qguide-file-append=my_messages.txt  ! Windows systems

See Also

guide, Qguide compiler option
guide-file, Qguide-file compiler option
guide-opts, Qguide-opts
Tells the compiler to analyze certain code and generate recommendations that may improve optimizations.

Syntax

Linux OS and OS X:
-guide-opts=string

Windows OS:
/Qguide-opts:string

Arguments

string
Is the text denoting the code to analyze. The string must appear within quotes. It can take one or more of the following forms:

<table>
<thead>
<tr>
<th>Form</th>
</tr>
</thead>
<tbody>
<tr>
<td>filename</td>
</tr>
<tr>
<td>filename, routine</td>
</tr>
<tr>
<td>filename, range [, range]...</td>
</tr>
<tr>
<td>filename, routine, range [, range]...</td>
</tr>
</tbody>
</table>

If you specify more than one of the above forms in a string, a semicolon must appear between each form. If you specify more than one range in a string, a comma must appear between each range. Optional blanks can follow each parameter in the forms above and they can also follow each form in a string.

filename
Specifies the name of a file to be analyzed. It can include a path.

If you do not specify a path, the compiler looks for filename in the current working directory.

routine
Specifies the name of a routine to be analyzed. You can include an identifying argument.

The name, including any argument, must be enclosed in single quotes.

The compiler tries to uniquely identify the routine that corresponds to the specified routine name. It may select multiple routines to analyze, especially if the following is true:

- More than one routine has the specified routine name, so the routine cannot be uniquely identified.
- No argument information has been specified to narrow the number of routines selected as matches.

range
Specifies a range of line numbers to analyze in the file or routine specified. The range must be specified in integers in the form:

first_line_number-last_line_number
Default

OFF

You do not receive guidance on how to improve optimizations. However, if you specify the \([Q]guide\) option, the compiler analyzes and generates recommendations for all the code in an application.

Description

This option tells the compiler to analyze certain code and generate recommendations that may improve optimizations.

This option is ignored unless you also specify one or more of the following options:

• \([Q]guide\)
• \([Q]guide-vec\)
• \([Q]guide-data-trans\)
• \([Q]guide-par\)

When the \([Q]guide-opts\) option is specified, a message is output that includes which parts of the input files are being analyzed. If a routine is selected to be analyzed, the complete routine name will appear in the generated message.

When inlining is involved, you should specify callee line numbers. Generated messages also use callee line numbers.

IDE Equivalent

Visual Studio: **Diagnostics > Guided Auto Parallelism Code Selection Options**

Eclipse: None

Xcode: **Diagnostics > Guided Auto Parallelism Code Selection**

Alternate Options

None

Example

Consider the following:

Linux* OS: -guide-opts="m.f, 1-10; m2.f90, 1-40, 50-90, 100-200; m5.f, 300-400; x.f, 'funca(j)', 22-44, 55-77, 88-99; y.f, 'subrb'"

Windows* OS: /Quide-opts="m.f, 1-10; m2.f90, 1-40, 50-90, 100-200; m5.f, 300-400; x.f, 'funca(j)', 22-44, 55-77, 88-99; y.f, 'subrb'"

The above command causes the following to be analyzed:

<table>
<thead>
<tr>
<th>line numbers 1 to 10</th>
<th>line numbers 1 to 40, 50 to 90, and 100 to 200</th>
</tr>
</thead>
<tbody>
<tr>
<td>file m.f</td>
<td>file m2.f90</td>
</tr>
<tr>
<td>file 300 to 400</td>
<td>file m5.f, line numbers 300 to 400</td>
</tr>
<tr>
<td>file 22 to 44</td>
<td>file x.f, function funca with argument (j)</td>
</tr>
<tr>
<td>file 55 to 77</td>
<td>line numbers 22 to 44, 55 to 77, and 88 to 99</td>
</tr>
<tr>
<td>file 88 to 99</td>
<td>file y.f, subroutine subrb</td>
</tr>
</tbody>
</table>

See Also

guide, Qguide compiler option

guide-data-trans, Qguide-data-trans compiler option

guide-par, Qguide-par compiler option
guide-par, Qguide-par

Lets you set a level of guidance for auto parallelism.

Syntax

Linux OS and OS X:
-guide-par[=n]

Windows OS:
/Qguide-par[=n]

Arguments

n

Is an optional value specifying the level of guidance to be provided.

The values available are 1 through 4. Value 1 indicates a standard level of guidance. Value 4 indicates the most advanced level of guidance. If n is omitted, the default is 4.

Default

OFF

You do not receive guidance about how to improve optimizations for parallelism.

Description

This option lets you set a level of guidance for auto parallelism. It causes the compiler to generate messages suggesting ways to improve that optimization.

You must also specify the [Q]parallel option to receive auto parallelism guidance.

IDE Equivalent

None

Alternate Options

None

See Also

guide, Qguide compiler option

guide-vec, Qguide-vec compiler option
guide-file, Qguide-file compiler option
guide-profile, Qguide-profile

Specifies a loop profiler data file (or a set of files)
when used with option -guide or /Qguide.

Syntax

Linux OS and OS X:

-guide-profile=filename|dir [, [filename|dir]...]

Windows OS:

/Qguide-profile:filename|dir [, [filename|dir]...]

guide-profile, Qguide-profile

Specifies a loop profiler data file (or a set of files)
when used with option -guide or /Qguide.
Arguments

filename
Is an .xml file created from a loop profiler run.

dir
Is a directory that contains one or more .xml files from a loop profiler run.

Default

OFF
When the [Q]guide option is specified, the guide region is the whole file or the region specified by option [Q]guide-opts.

Description

This option specifies a loop profiler data file (or a set of files) when used with the [Q]guide option.
This option has no effect unless the [Q]guide option has been specified. Option [Q]guide-profile helps you take advantage of the [Q]guide option to more efficiently optimize your applications for auto parallelism and/or vectorization.

The loop profile data file can be collected by using one of the following options:

- [Q]profile-loops
- [Q]profile-functions

When the data is from [Q]profile-loops, the setting of the guide regions will be based upon the hottest loops.
When the data is from [Q]profile-functions, the guide region will be the entire function containing the hottest functions.

If you specify options [Q]guide-opts and [Q]guide-profile, the compiler issues an error message.

IDE Equivalent

None

Alternate Options

None

`guide-par, Qguide-par` compiler option
`guide-file, Qguide-file` compiler option
`heap-arrays`

*Puts automatic arrays and arrays created for temporary computations on the heap instead of the stack.*

**Syntax**

**Linux OS and OS X:**

`-heap-arrays [size]`

`-no-heap-arrays`

**Windows OS:**

`/heap-arrays[:size]`

`/heap-arrays-`

**Arguments**

\( size \) Is an integer value representing the size of the arrays in kilobytes. Arrays smaller than \( size \) are put on the stack.

**Default**

`-no-heap-arrays` or `/heap-arrays-` The compiler puts automatic arrays and temporary arrays in the stack storage area.

**Description**

This option puts automatic arrays and arrays created for temporary computations on the heap instead of the stack.
When this option is specified, automatic (temporary) arrays that have a compile-time size greater than the value specified for size are put on the heap, rather than on the stack. If the compiler cannot determine the size at compile time, it always puts the automatic array on the heap.

If size is specified, the value is only used when the total size of the temporary array or automatic array can be determined at compile time, using compile-time constants. Any arrays known at compile-time to be larger than size are allocated on the heap instead of the stack. For example, if 10 is specified for size:

- All automatic and temporary arrays equal to or larger than 10 KB are put on the heap.
- All automatic and temporary arrays smaller than 10 KB are put on the stack.

If size is omitted, and the size of the temporary array or automatic array cannot be determined at compile time, it is assumed that the total size is greater than size and the array is allocated on the heap.

IDE Equivalent
Visual Studio: Optimization > Heap Arrays
Eclipse: None
Xcode: Optimization > Heap Arrays

Alternate Options
None

Example
In Fortran, an automatic array gets its size from a run-time expression. For example:

```fortran
RECURSIVE SUBROUTINE F(N)
INTEGER :: N
REAL :: X(N)  ! an automatic array
REAL :: Y(1000) ! an explicit-shape local array on the stack

Array X in the example above is affected by the heap-array option; array Y is not.

Temporary arrays are often created before making a routine call, or when an array operation detects overlap. For example:

integer a(10000)
a(2:) = a(1:ubound(a,dim=1)-1)

In this case, the array assignment uses a temporary intermediate array because there is clearly an overlap between the right hand side and the left hand side of the assignment.

If you specify the heap-arrays option, the compiler creates the temporary array on the heap.

If you specify the heap-arrays option with size 50, the compiler creates the temporary array on the stack. This is because the size of the temporary intermediate array can be determined at compile time (40Kb), and it's size is less than the size value.

In the following example, a contiguous array is created from the array slice declaration and passed on:

call somesub(a(1:10000:2))

If you specify the heap-arrays option, the compiler creates the temporary array on the heap.

If you specify the heap-arrays option with size 25, the compiler creates the temporary array on the stack. This is because the size of the temporary intermediate array at compile time is only 20Kb.

mkl, Qmkl
Tells the compiler to link to certain libraries in the Intel® Math Kernel Library (Intel® MKL). On Windows systems, you must specify this option at compile time.
Syntax

Linux OS and OS X:

-mkl[=lib]

Windows OS:

/Qmkl[=lib]

Arguments

lib Indicates which Intel® MKL library files should be linked. Possible values are:

parallel Tells the compiler to link using the threaded libraries in the Intel® MKL. This is the default if the option is specified with no lib.

sequential Tells the compiler to link using the sequential libraries in the Intel® MKL.

cluster Tells the compiler to link using the cluster-specific libraries and the sequential libraries in the Intel® MKL. Cluster-specific libraries are not available for OS X*.

Default

OFF The compiler does not link to the Intel® MKL.

Description

This option tells the compiler to link to certain libraries in the Intel® Math Kernel Library (Intel® MKL).

On Linux* OS and OS X*, dynamic linking is the default when you specify -mkl. To link with Intel® MKL statically, you must specify:

-mkl -static-intel

On Windows* OS, static linking is the default when you specify /Qmkl. To link with Intel® MKL dynamically, you must specify:

/Qmkl /libs:dll or /Qmkl /MD

For more information about using MKL libraries, see the article in Intel® Developer Zone titled Intel® Math Kernel Library Link Line Advisor.

NOTE

On Windows* OS, this option adds directives to the compiled code, which the linker then reads without further input from the driver. On Linux* OS and OS X, the driver must add the library names explicitly to the link command.
NOTE
If you specify option [Q]mkl or [Q]mkl=parallel, and you also specify option [Q]tbb, the compiler links to the standard threaded version of the Intel® MKL. However, if you specify [Q]mkl or [Q]mkl=parallel, and you also specify option [Q]tbb and option [q or Q]openmp, the compiler links to the OpenMP* threaded version of the Intel® MKL.

### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Notice revision #20110804

### IDE Equivalent

Visual Studio: Libraries > Use Intel(R) Math Kernel Library

Eclipse: None

Xcode: Libraries > Use Intel(R) Math Kernel Library

### Alternate Options

None

### See Also

- `static-intel` compiler option
- `MD` compiler option
- `libs` compiler option

- `pad`, `Qpad`
  *Enables the changing of the variable and array memory layout.*

### Syntax

**Linux OS and OS X:**

- `-pad`
- `-nopad`

**Windows OS:**

- `/Qpad`
- `/Qpad-`

### Arguments

None
Default

-`nopad` or `/Qpad-`

Variable and array memory layout is performed by default methods.

Description

This option enables the changing of the variable and array memory layout.

This option is effectively not different from the `align` option when applied to structures and derived types. However, the scope of `pad` is greater because it applies also to common blocks, derived types, sequence types, and structures.

IDE Equivalent

None

Alternate Options

None

See Also

`align` compiler option

`qopt-args-in-regs`, `Qopt-args-in-regs`

Determines whether calls to routines are optimized by passing arguments in registers instead of on the stack. Option `-qopt-args-in-regs` is the replacement option for `-opt-args-in-regs`, which is deprecated.

Architecture Restrictions

Only available on IA-32 architecture

Syntax

Linux OS and OS X:

-`qopt-args-in-regs[=keyword]`

Windows OS:

/Qopt-args-in-regs[=keyword]

Arguments

`keyword`

Specifies whether the optimization should be performed and under what conditions. Possible values are:

- **none**
  
The optimization is not performed. No arguments are passed in registers. They are put on the stack.

- **seen**
  
Causes arguments to be passed in registers when they are passed to routines whose definition can be seen in the same compilation unit.

- **all**
  
Causes arguments to be passed in registers, whether they are passed to routines whose definition can be seen in the same compilation unit, or not. This value is only available on Linux* systems.
Arguments are passed in registers when they are passed to routines whose definition is seen in the same compilation unit.

**Description**

This option determines whether calls to routines are optimized by passing arguments in registers instead of on the stack. It also indicates the conditions when the optimization will be performed.

This option can improve performance for Application Binary Interfaces (ABIs) that require arguments to be passed in memory and compiled without interprocedural optimization (IPO).

Note that on Linux* systems, if all is specified, a small overhead may be paid when calling "unseen" routines that have not been compiled with the same option. This is because the call will need to go through a "thunk" to ensure that arguments are placed back on the stack where the callee expects them.

**IDE Equivalent**

None

**Alternate Options**

None

**qopt-assume-safe-padding, Qopt-assume-safe-padding**

Determines whether the compiler assumes that variables and dynamically allocated memory are padded past the end of the object. This option only applies to Intel® MIC Architecture. Option -qopt-assume-safe-padding is the replacement option for -opt-assume-safe-padding, which is deprecated.

**Architecture Restrictions**

Only available on Intel® 64 architecture targeting Intel® MIC Architecture

**Syntax**

**Linux OS:**

- `qopt-assume-safe-padding`
- `qno-opt-assume-safe-padding`

**OS X:**

None

**Windows OS:**

/Qopt-assume-safe-padding
/Qopt-assume-safe-padding-

**Arguments**

None
**Default**

-`qno-opt-assume-safe-padding`

or`/Qopt-assume-safe-padding`

The compiler will not assume that variables and dynamically allocated memory are padded past the end of the object. It will adhere to the sizes specified in your program.

**Description**

This option determines whether the compiler assumes that variables and dynamically allocated memory are padded past the end of the object.

When you specify option `q or Q`opt-assume-safe-padding, the compiler assumes that variables and dynamically allocated memory are padded. This means that code can access up to 64 bytes beyond what is specified in your program.

The compiler does not add any padding for static and automatic objects when this option is used, but it assumes that code can access up to 64 bytes beyond the end of the object, wherever the object appears in the program. To satisfy this assumption, you must increase the size of static and automatic objects in your program when you use this option.

This option may improve performance of memory operations.

**IDE Equivalent**

None

**Alternate Options**

None

**qopt-block-factor, Qopt-block-factor**

*Lets you specify a loop blocking factor. Option -qopt-block-factor is the replacement option for -opt-block-factor, which is deprecated.*

**Syntax**

**Linux OS and OS X:**

-`-qopt-block-factor=n`

**Windows OS:**

`/Qopt-block-factor:n`

**Arguments**

`n`  
Is the blocking factor. It must be an integer. The compiler may ignore the blocking factor if the value is 0 or 1.

**Default**

OFF  
The compiler uses default heuristics for loop blocking.

**Description**

This option lets you specify a loop blocking factor.

**IDE Equivalent**

None
Alternate Options
None

qopt-dynamic-align, Qopt-dynamic-align
Enables or disables dynamic data alignment optimizations. Option -qopt-dynamic-align is the replacement option for -opt-dynamic-align, which is deprecated.

Syntax
Linux OS and OS X:
-qopt-dynamic-align
-qno-opt-dynamic-align
Windows OS:
/Qopt-dynamic-align
/Qopt-dynamic-align-

Arguments
None

Default
-qopt-dynamic-align or/Qopt-dynamic-align

The compiler may generate code dynamically dependent on alignment. It may do optimizations based on data location for the best performance. The result of execution on some algorithms may depend on data layout.

Description
This option enables or disables dynamic data alignment optimizations.

If you specify -qno-opt-dynamic-align or /Qopt-dynamic-align-, the compiler generates no code dynamically dependent on alignment. It will not do any optimizations based on data location and results will depend on the data values themselves.

When you specify [q or Q]qopt-dynamic-align, the compiler may implement conditional optimizations based on dynamic alignment of the input data. These dynamic alignment optimizations may result in different bitwise results for aligned and unaligned data with the same values.

Dynamic alignment optimizations can improve the performance of vectorized code, especially for long trip count loops. Disabling such optimizations can decrease performance, but it may improve bitwise reproducibility of results, factoring out data location from possible sources of discrepancy.

IDE Equivalent
None

Alternate Options
None

qopt-gather-scatter-unroll, Qopt-gather-scatter-unroll
Lets you specify an alternative loop unroll sequence for gather and scatter loops on Intel® MIC Architecture. This option only applies to Intel® MIC
Architecture. Option -qopt-gather-scatter-unroll is the replacement option for -opt-gather-scatter-unroll, which is deprecated.

Architecture Restrictions
Only available on Intel® 64 architecture targeting the Intel® Xeon Phi™ coprocessor x100 product family (formerly code name Knights Corner)

Syntax

**Linux OS:**
-qopt-gather-scatter-unroll=n
-qno-opt-gather-scatter-unroll

**OS X:**
None

**Windows OS:**
/Qopt-gather-scatter-unroll:n
/Qopt-gather-scatter-unroll-

**Arguments**

\[ n \]

Is the unroll factor for the gather and scatter loops. It must be an integer between 0 and 8. If you specify value 0 for \( n \), it is the same as specifying the negative form of the option.

**Default**

-qno-opt-gather-scatter-unroll or /Qopt-gather-scatter-unroll

The compiler uses default heuristics when unrolling gather and scatter loops.

**Description**

This option lets you specify an alternative loop unroll sequence for gather and scatter loops on Intel® MIC Architecture.

This option may improve performance of gather/scatter operations.

The value of \( n \) that provides the best performance is data-dependent.

In cases where the gather/scatter operation accesses data in a small number of cache-lines (such as 1 or 2), the default sequence (using a small value for \( n \)) works best. In cases where each individual data item falls in a different cache-line, it may be better to use a large value for \( n \).

**IDE Equivalent**

None

**Alternate Options**

None
Example

Normally, on Intel® MIC Architecture, there are no "one-shot" gather/scatter instructions, so the compiler generates a loop to perform complete gather/scatter. By default, the loop looks as follows:

```
L1:
   gather
   jkz L2
   gather
   jknz L1
L2:
```

For some applications, this loop would be faster if it was unrolled; and different applications may benefit from different unroll factors. Also, when the loop is unrolled, adding gather/scatter hint instructions before the loop provides additional benefits.

If you specify option \([-q or Q]opt-gather-scatter-unroll\), the compiler will generate a similar loop unrolled by the number specified in \(n\).

The following example shows what happens when the \(-qopt-gather-scatter-unroll=3 \) (Linux* OS) or \(/Qopt-gather-scatter-unroll:3 \) option (Windows* OS) is specified. Notice that the alternate sequence also generates two gather/scatter hint instructions preceding the loop:

```
gather hint
  gather hint
  nop
L1:
   gather
   jkz L2
   gather |
   gather |  -> the number of gathers specified by \(n\)
   gather |
   jknz L1
L2:
```

\textbf{qopt-jump-tables, Qopt-jump-tables}

Enables or disables generation of jump tables for switch statements. Option \(-qopt-jump-tables\) is the replacement option for \(-opt-jump-tables\), which is deprecated.

Syntax

\textbf{Linux OS and OS X:}

\[-qopt-jump-tables=keyword\]
\[-qno-opt-jump-tables\]

\textbf{Windows OS:}

\[/Qopt-jump-tables:keyword\]
\[/Qopt-jump-tables-\]

Arguments

\textit{keyword}  
Is the instruction for generating jump tables. Possible values are:
never  
Tells the compiler to never generate jump tables. All switch statements are implemented as chains of if-then-elses. This is the same as specifying -qno-opt-jump-tables (Linux* OS and OS X*) or /Qopt-jump-tables- (Windows* OS).

default  
The compiler uses default heuristics to determine when to generate jump tables.

large  
Tells the compiler to generate jump tables up to a certain pre-defined size (64K entries).

n  
Must be an integer. Tells the compiler to generate jump tables up to n entries in size.

Default

-qopt-jump-tables=default or/Qopt-jump-tables:default  
The compiler uses default heuristics to determine when to generate jump tables for switch statements.

Description

This option enables or disables generation of jump tables for switch statements. When the option is enabled, it may improve performance for programs with large switch statements.

IDE Equivalent

None

Alternate Options

None

qopt-malloc-options

Lets you specify an alternate algorithm for malloc(). Option -qopt-malloc-options is the replacement option for -opt-malloc-options, which is deprecated.

Syntax

Linux OS and OS X:
-qopt-malloc-options=n

Windows OS:

None

Arguments

n  
Specifies the algorithm to use for malloc(). Possible values are:

0  
Tells the compiler to use the default algorithm for malloc(). This is the default.
Causes the following adjustments to the malloc() algorithm: 
M_MMAP_MAX=2 and M_TRIM_THRESHOLD=0x10000000.

Causes the following adjustments to the malloc() algorithm: 
M_MMAP_MAX=2 and M_TRIM_THRESHOLD=0x40000000.

Causes the following adjustments to the malloc() algorithm: 
M_MMAP_MAX=0 and M_TRIM_THRESHOLD=-1.

Causes the following adjustments to the malloc() algorithm: 
M_MMAP_MAX=0, M_TRIM_THRESHOLD=-1, M_TOP_PAD=4096.

Default
-qopt-malloc-options=0  The compiler uses the default algorithm when malloc() is called. No call is made to mallopt().

Description
This option lets you specify an alternate algorithm for malloc().

If you specify a non-zero value for n, it causes alternate configuration parameters to be set for how malloc() allocates and frees memory. It tells the compiler to insert calls to mallopt() to adjust these parameters to malloc() for dynamic memory allocation. This may improve speed.

IDE Equivalent
None

Alternate Options
None

See Also
malloc(3) man page
mallopt function (defined in malloc.h)

qopt-matmul, Qopt-matmul
Enables or disables a compiler-generated Matrix Multiply (matmul) library call. Option -qopt-matmul is the replacement option for -opt-matmul, which is deprecated.

Architecture Restrictions
Not available on Intel® 64 architecture targeting the Intel® Xeon Phi™ coprocessor x100 product family (formerly code name Knights Corner)

Syntax
Linux OS:
-qopt-matmul
-qno-opt-matmul
OS X:
None

Windows OS:
/Qopt-matmul
/Qopt-matmul-

Arguments
None

Default
-qno-opt-matmul
/Qopt-matmul-

The matmul library call optimization does not occur unless this option is enabled or certain other compiler options are specified (see below).

Description
This option enables or disables a compiler-generated Matrix Multiply (MATMUL) library call. The [q or Q]opt-matmul option tells the compiler to identify matrix multiplication loop nests (if any) and replace them with a matmul library call for improved performance. The resulting executable may get additional performance gain on Intel® microprocessors than on non-Intel microprocessors.

This option is enabled by default if options 03 and [Q]parallel are specified. To disable this optimization, specify -qno-opt-matmul or /Qopt-matmul-.

This option has no effect unless option 02 or higher is set.

NOTE
Many routines in the MATMUL library are more highly optimized for Intel® microprocessors than for non-Intel microprocessors.

IDE Equivalent
Visual Studio: Optimization > Enable Matrix Multiply Library Call
Eclipse: None
Xcode: None

Alternate Options
None

See Also
O compiler option
qopt-mem-layout-trans, Qopt-mem-layout-trans
Controls the level of memory layout transformations performed by the compiler. Option -qopt-mem-layout-trans is the replacement option for -opt-mem-layout-trans, which is deprecated.

Architecture Restrictions
Not available on Intel® 64 architecture targeting the Intel® Xeon Phi™ coprocessor x100 product family (formerly code name Knights Corner)
Syntax

Linux OS and OS X:
- `qopt-mem-layout-trans[=n]`
- `qno-opt-mem-layout-trans`

Windows OS:
/`Qopt-mem-layout-trans[=n]`
/`Qopt-mem-layout-trans-`

Arguments

\( n \)

Is the level of memory layout transformations. Possible values are:

0
Disables memory layout transformations. This is the same as specifying `qno-opt-mem-layout-trans` (Linux* OS and OS X*) or `/Qopt-mem-layout-trans-` (Windows* OS).

1
Enables basic memory layout transformations.

2
Enables more memory layout transformations. This is the same as specifying `[q or Q]opt-mem-layout-trans` with no argument.

3
Enables aggressive memory layout transformations. You should only use this setting if your system has more than 4GB of physical memory per core.

Default

`qopt-mem-layout-trans=2`
The compiler performs moderate memory layout transformations.

or `/Qopt-mem-layout-trans: 2`

Description

This option controls the level of memory layout transformations performed by the compiler. This option can improve cache reuse and cache locality.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

IDE Equivalent

None
Alternate Options

None

**qopt-multi-version-aggressive, Qopt-multi-version-aggressive**

*Tells the compiler to use aggressive multi-versioning to check for pointer aliasing and scalar replacement. Option -qopt-multi-version-aggressive is the replacement option for -opt-multi-version-aggressive, which is deprecated.*

**Syntax**

**Linux OS and OS X:**

-qopt-multi-version-aggressive
-qno-opt-multi-version-aggressive

**Windows OS:**

/Qopt-multi-version-aggressive
/Qopt-multi-version-aggressive-

**Arguments**

None

**Default**

-qno-opt-multi-version-aggressive or/Qopt-multi-version-aggressive-

The compiler uses default heuristics when checking for pointer aliasing and scalar replacement.

**Description**

This option tells the compiler to use aggressive multi-versioning to check for pointer aliasing and scalar replacement. This option may improve performance.

The performance can be affected by certain options, such as /arch or /Qx (Windows OS) or -m or -x (Linux OS and OS X).

**IDE Equivalent**

None

**Alternate Options**

None

**qopt-prefetch, Qopt-prefetch**

*Enables or disables prefetch insertion optimization. Option -qopt-prefetch is the replacement option for -opt-prefetch, which is deprecated.*

**Syntax**

**Linux OS and OS X:**

-qopt-prefetch [=n]
-qno-opt-prefetch
Windows OS:
/Qopt-prefetch[:n]
/Qopt-prefetch-

Arguments

\( n \)  
Is the level of software prefetching optimization desired. Possible values are:

- \( 0 \)  
Disables software prefetching. This is the same as specifying \(-qno-opt-prefetch\) (Linux* OS and OS X*) or \(/Qopt-prefetch-\) (Windows* OS).

- 1 to 4  
Enables different levels of software prefetching. If you do not specify a value for \( n \), the default is 2. Use lower values to reduce the amount of prefetching.

Default

- \(-qno-opt-prefetch\) or \(/Qopt-prefetch-\)  
Prefetch insertion optimization is disabled.

Description

This option enables or disables prefetch insertion optimization. The goal of prefetching is to reduce cache misses by providing hints to the processor about when data should be loaded into the cache.

On Intel® 64 architecture targeting Intel® MIC Architecture, option \(-qopt-prefetch=3\) (Linux* OS and OS X*) and \(/Qopt-prefetch:3\) (Windows* OS) are enabled by default if option [O2 or higher is set. To disable prefetching at these optimization levels, specify option \(-qno-opt-prefetch\) or \(/Qopt-prefetch-\).

This option enables prefetching when higher optimization levels are specified.

IDE Equivalent

Visual Studio: Optimization > Prefetch Insertion
Eclipse: None
Xcode: Optimization > Enable Prefetch Insertion

Alternate Options

None

See Also

qopt-prefetch-distance, Qopt-prefetch-distance  
compiler option

qopt-prefetch-distance, Qopt-prefetch-distance  
Specifies the prefetch distance to be used for compiler-generated prefetches inside loops. This option only applies to Intel® MIC Architecture. Option -qopt-prefetch-distance is the replacement option for -opt-prefetch-distance, which is deprecated.

Architecture Restrictions

Only available on Intel® 64 architecture targeting Intel® MIC Architecture
Syntax

Linux OS:
-qopt-prefetch-distance=n1[, n2]

OS X:
None

Windows OS:
/Qopt-prefetch-distance:n1[, n2]

Arguments

n1, n2

Is the prefetch distance in terms of the number of (possibly-vectorized) iterations. Possible values are non-negative numbers \( \geq 0 \).

n2 is optional.

\( n1 = 0 \) turns off all compiler issued prefetches from memory to L2. \( n2 = 0 \) turns off all compiler issued prefetches from L2 to L1. If \( n2 \) is specified and \( n1 > 0 \), \( n1 \) should be \( \geq n2 \).

Default

OFF

The compiler uses default heuristics to determine the prefetch distance.

Description

This option specifies the prefetch distance to be used for compiler-generated prefetches inside loops. The unit (\( n1 \) and optionally \( n2 \)) is the number of iterations. If the loop is vectorized by the compiler, the unit is the number of vectorized iterations.

The value of \( n1 \) will be used as the distance for prefetches from memory to L2 (for example, the vprefetch1 instruction). If \( n2 \) is specified, it will be used as the distance for prefetches from L2 to L1 (for example, the vprefetch0 instruction).

This option is ignored if option -qopt-prefetch=0 (Linux* OS) or /Qopt-prefetch:0 (Windows* OS) is specified. On Intel® MIC Architecture, -qopt-prefetch=3 and /Qopt-prefetch:3 is the default at option levels O2 and above.

IDE Equivalent

None

Alternate Options

None

Example

Consider the following Linux* OS examples:
-qopt-prefetch-distance=64,32

The above causes the compiler to use a distance of 64 iterations for memory to L2 prefetches, and a distance of 32 iterations for L2 to L1 prefetches.
-qopt-prefetch-distance=24

The above causes the compiler to use a distance of 24 iterations for memory to L2 prefetches. The distance for L2 to L1 prefetches will be determined by the compiler.
-qopt-prefetch-distance=0,4
The above turns off all memory to L2 prefetches inserted by the compiler inside loops. The compiler will use a distance of 4 iterations for L2 to L1 prefetches.

-qopt-prefetch-distance=16,0

The above causes the compiler to use a distance of 16 iterations for memory to L2 prefetches. No L2 to L1 loop prefetches are issued by the compiler.

See Also
qopt-prefetch, Qopt-prefetch compiler option
PREFETCH and NOPREFETCH directive

qopt-prefetch-issue-excl-hint, Qopt-prefetch-issue-excl-hint
Supports the prefetchW instruction in Intel® microarchitecture code name Broadwell and later.

Architecture Restrictions
Not available on Intel® 64 architecture targeting Intel® MIC Architecture

Syntax
Linux OS:
-qopt-prefetch-issue-excl-hint
OS X:
None
Windows OS:
/Qopt-prefetch-issue-excl-hint

Arguments
None

Default
OFF

The compiler does not support the PREFETCHW instruction for this microarchitecture.

Description
This option supports the PREFETCHW instruction in Intel® microarchitecture code name Broadwell and later. When you specify this option, you must also specify option [q or Q]opt-prefetch.

The prefetch instruction is merely a hint and does not affect program behavior. If executed, this instruction moves data closer to the processor and invalidates any other cached copy in anticipation of the line being written to in the future.

IDE Equivalent
None

Alternate Options
None

See Also
qopt-prefetch, Qopt-prefetch compiler option
Selects the method that the register allocator uses to partition each routine into regions. Option -qopt-ra-region-strategy is the replacement option for -opt-ra-region-strategy, which is deprecated.

**Syntax**

**Linux OS and OS X:**

- `qopt-ra-region-strategy[=keyword]`

**Windows OS:**

/`Qopt-ra-region-strategy[:keyword]`

**Arguments**

`keyword` Is the method used for partitioning. Possible values are:

- `routine` Creates a single region for each routine.
- `block` Partitions each routine into one region per basic block.
- `trace` Partitions each routine into one region per trace.
- `loop` Partitions each routine into one region per loop.
- `default` The compiler determines which method is used for partitioning.

**Default**

- `qopt-ra-region-strategy=default` or `/Qopt-ra-region-strategy:default`

The compiler determines which method is used for partitioning. This is also the default if `keyword` is not specified.

**Description**

This option selects the method that the register allocator uses to partition each routine into regions. When setting `default` is in effect, the compiler attempts to optimize the tradeoff between compile-time performance and generated code performance. This option is only relevant when optimizations are enabled (option `01` or higher).

**IDE Equivalent**

None

**Alternate Options**

None

**See Also**

O compiler option
qopt-streaming-cache-evict, Qopt-streaming-cache-evict
Specifies the cache eviction level to be used by the compiler for streaming loads and stores. This option only applies to Intel® MIC Architecture. Option -qopt-streaming-cache-evict is the replacement option for -opt-streaming-cache-evict, which is deprecated.

Architecture Restrictions
Only available on Intel® 64 architecture targeting Intel® MIC Architecture

Syntax
Linux OS:
-qopt-streaming-cache-evict [=n]

OS X:
None

Windows OS:
/Qopt-streaming-cache-evict [=n]

Arguments

n
Is a value denoting the cache eviction (clevict) level to use for streaming loads and stores. Possible values are:

0
Tells the compiler to use no cache eviction level.

1
Tells the compiler to use the L1 cache eviction level.

2
Tells the compiler to use the L2 cache eviction level.

3
Tells the compiler to use the L1 and L2 cache eviction level. This is the default if you do not specify n.

Default
2
The compiler uses the L2 cache eviction level.

Description
This option specifies the cache eviction (clevict) level to be used by the compiler for streaming loads and stores.

Depending on the level used, the compiler will generate clevict0 and/or clevict1 instructions that evict the cache-line (corresponding to the load or the store) from the first-level and second-level caches. These cache eviction instructions will be generated after performing the corresponding load/store operation.

For more information on how to mark loads/stores as streaming, see the description of the VECTOR NONTEMPORAL directive.

IDE Equivalent

qopt-streaming-stores, Qopt-streaming-stores compiler option
VECTOR and NOVECTOR directive

qopt-streaming-stores, Qopt-streaming-stores
Enables generation of streaming stores for optimization. Option -qopt-streaming-stores is the replacement option for -opt-streaming-stores, which is deprecated.

Syntax
Linux OS and OS X:
-qopt-streaming-stores=keyword

Windows OS:
/Qopt-streaming-stores:keyword

Arguments
keyword
Specifies whether streaming stores are generated. Possible values are:

always
Enables generation of streaming stores for optimization. The compiler optimizes under the assumption that the application is memory bound.

never
Disables generation of streaming stores for optimization. Normal stores are performed.

auto
Lets the compiler decide which instructions to use.

Default
-qopt-streaming-stores=auto
/Qopt-streaming-stores:auto

The compiler decides whether to use streaming stores or normal stores.

Description
This option enables generation of streaming stores for optimization. This method stores data with instructions that use a non-temporal buffer, which minimizes memory hierarchy pollution.

This option may be useful for applications that can benefit from streaming stores.

IDE Equivalent
None

Alternate Options
None

See Also
ax, Qax compiler option
x, Qx compiler option
qopt-subscript-in-range, Qopt-subscript-in-range
Determines whether the compiler assumes that there are no "large" integers being used or being computed inside loops. Option -qopt-subscript-in-range is the replacement option for -opt-subscript-in-range, which is deprecated.

Syntax

Linux OS and OS X:
- -qopt-subscript-in-range
- -qno-opt-subscript-in-range

Windows OS:
/ Qopt-subscript-in-range
/Qopt-subscript-in-range-

Arguments
None

Default
- -qno-opt-subscript-in-range
_or/Qopt-subscript-in-range-

Description
This option determines whether the compiler assumes that there are no "large" integers being used or being computed inside loops.

If you specify [q or Q]opt-subscript-in-range, the compiler assumes that there are no "large" integers being used or being computed inside loops. A "large" integer is typically > $2^{31}$.

This feature can enable more loop transformations.

IDE Equivalent
None

Alternate Options
None

Example
The following example shows how these options can be useful. Variable m is declared as type integer(kind=8) (64-bits) and all other variables inside the subscript are declared as type integer(kind=4) (32-bits):

```plaintext
A[ i + j + ( n + k) * m ]
```

qopt-threads-per-core, Qopt-threads-per-core
Informs the compiler about the number of hardware threads per core that will be used for an application. This option only applies to Intel® MIC Architecture. Option -qopt-threads-per-core is the replacement option for -opt-threads-per-core, which is deprecated.
Architecture Restrictions
Only available on Intel® 64 architecture targeting Intel® MIC Architecture

Syntax
Linux OS:
-qopt-threads-per-core=n
OS X:
None
Windows OS:
/Qopt-threads-per-core: n

Arguments

n
Is the number of hardware threads per core that the compiler should assume that will be used while executing the application. Possible values are 1, 2, 3, or 4.

Default
4
Four hardware threads per core are used for the application.

Description
This option informs the compiler about the number of hardware threads per core that will be used for an application. This enables the compiler to perform better code optimizations (such as instruction scheduling).

You should choose a value for n that is based on how many threads will be used per core while executing the application. For example, if the application is parallelized using OpenMP* API, use the value of n that uses the same number of threads per core as the OpenMP* API affinity setting will use when executing the application code on the Intel® Xeon Phi™ coprocessor.

This option does not affect the number of threads per core that will be used at run time.
Code compiled with this option can run correctly on any (hardware-supported) number of threads per core.

IDE Equivalent
None

Alternate Options
None

OpenMP* Affinity Specifications

reentrancy
Tells the compiler to generate reentrant code to support a multithreaded application.

Syntax
Linux OS and OS X:
-reentrancy keyword
-noreentrancy
**Windows OS:**

/reentrancy: **keyword**

/noreentrancy

**Arguments**

**keyword**

Specifies details about the program. Possible values are:

- **none**
  Tells the run-time library (RTL) that the program does not rely on threaded or asynchronous reentrancy. The RTL will not guard against such interrupts inside its own critical regions. This is the same as specifying noreentrancy.

- **async**
  Tells the run-time library (RTL) that the program may contain asynchronous (AST) handlers that could call the RTL. This causes the RTL to guard against AST interrupts inside its own critical regions.

- **threaded**
  Tells the run-time library (RTL) that the program is multithreaded, such as programs using the POSIX threads library. This causes the RTL to use thread locking to guard its own critical regions.

**Default**

noreentrancy

The compiler does not generate reentrant code for applications.

**Description**

This option tells the compiler to generate reentrant code to support a multithreaded application. If you do not specify a keyword for reentrancy, it is the same as specifying reentrancy threaded.

To ensure that a threadsafe and/or reentrant run-time library is linked and correctly initialized, option reentrancy threaded should also be used for the link step and for the compilation of the main routine.

Note that if option threads is specified, it sets option reentrancy threaded, since multithreaded code must be reentrant.

**IDE Equivalent**

Visual Studio:  **Code Generation > Generate Reentrant Code**

Eclipse: None

Xcode:  **Code Generation > Generate Reentrant Code**

**Alternate Options**

None

**See Also**

threads compiler option

safe-cray-ptr, Qsafe-cray-ptr

*Tells the compiler that Cray* pointers do not alias other variables.*
Syntax

Linux OS and OS X:

-safecray-ptr

Windows OS:

/Qsafecray-ptr

Arguments

None

Default

OFF

The compiler assumes that Cray pointers alias other variables.

Description

This option tells the compiler that Cray pointers do not alias (that is, do not specify sharing memory with) other variables.

IDE Equivalent

Visual Studio: Data > Assume Cray Pointers Do Not Share Memory Locations

Eclipse: None

Xcode: Data > Assume Cray Pointers Do Not Share Memory Locations

Alternate Options

None

Example

Consider the following:

```fortran
pointer (pb, b)
pb = getstorage()
do i = 1, n
  b(i) = a(i) + 1
endo
```

By default, the compiler assumes that b and a are aliased. To prevent such an assumption, specify the -safecray-ptr (Linux* OS and OS X*) or /Qsafecray-ptr (Windows* OS) option, and the compiler will treat b(i) and a(i) as independent of each other.

However, if the variables are intended to be aliased with Cray pointers, using the option produces incorrect results. In the following example, you should not use the option:

```fortran
pointer (pb, b)
pb = loc(a(2))
do i=1, n
  b(i) = a(i) +1
endo
```

**scalar-rep, Qscalar-rep**

_Enables or disables the scalar replacement optimization done by the compiler as part of loop transformations._
**Syntax**

**Linux OS and OS X:**
- -scalar-rep
- -no-scalar-rep

**Windows OS:**
- /Qscalar-rep
- /Qscalar-rep-

**Arguments**
None

**Default**
- -scalar-rep
  or /Qscalar-rep

  Scalar replacement is performed during loop transformation at optimization levels of O2 and above.

**Description**
This option enables or disables the scalar replacement optimization done by the compiler as part of loop transformations. This option takes effect only if you specify an optimization level of O2 or higher.

**IDE Equivalent**
None

**Alternate Options**
None

**See Also**
O compiler option

**simd, Qsimd**
Enables or disables compiler interpretation of SIMD directives.

**Syntax**

**Linux OS and OS X:**
- -simd
- -no-simd

**Windows OS:**
- /Qsimd
- /Qsimd-

**Arguments**
None

**Default**
- -simd
  or /Qsimd

  SIMD directives are enabled.
Description
This option enables or disables compiler interpretation of SIMD directives.

To disable interpretation of SIMD directives, specify `-no-simd` (Linux* OS and OS X*) or `/Qsimd-` (Windows* OS). Note that the compiler may still vectorize loops based on its own heuristics (leading to generation of SIMD instructions) even when `-no-simd` (or `/Qsimd-`) is specified.

To disable all compiler vectorization, use the "-no-vec -no-simd" (Linux* OS and OS X*) or "/Qvec- / Qsimd-" (Windows* OS) compiler options. The option `-no-vec` (and `/Qvec-`) disables all auto-vectorization, including vectorization of array notation statements. The option `-no-simd` (and `/Qsimd-`) disables vectorization of loops that have SIMD directives.

NOTE
If you specify option `-mia32` or option `/arch:IA32`, SIMD directives are disabled by default. When you specify option `-mia32` or option `/arch:IA32`, vector instructions cannot be used. Therefore, you cannot explicitly enable SIMD directives by specifying option `/Qsimd`.

IDE Equivalent
None

Alternate Options
None

See Also
vec, Qvec compiler option
unroll, Qunroll
Tells the compiler the maximum number of times to unroll loops.

Syntax
Linux OS and OS X:
- `-unroll[=n]`

Windows OS:
- `/Qunroll[:n]`

Arguments

\[ n \]
Is the maximum number of times a loop can be unrolled. To disable loop unrolling, specify 0.

Default

```
-`unroll`
or `/Qunroll`
```

The compiler uses default heuristics when unrolling loops.

Description
This option tells the compiler the maximum number of times to unroll loops.

If you do not specify \( n \), the optimizer determines how many times loops can be unrolled.
IDE Equivalent
Visual Studio: **Optimization > Loop Unroll Count**
Eclipse: None
Xcode: **Optimization > Loop Unroll Count**

Alternate Options
Linux and OS X: `-funroll-loops`
Windows: `/unroll` (this is a deprecated option)

**unroll-aggressive, Qunroll-aggressive**
_Determines whether the compiler uses more aggressive unrolling for certain loops._

Syntax
Linux OS and OS X:
- `-unroll-aggressive`
- `-no-unroll-aggressive`

Windows OS:
- `/Qunroll-aggressive`
- `/Qunroll-aggressive-`

Arguments
None

Default
- `-no-unroll-aggressive` or `/Qunroll-aggressive-`
The compiler uses default heuristics when unrolling loops.

Description
This option determines whether the compiler uses more aggressive unrolling for certain loops. The positive form of the option may improve performance.
This option enables aggressive, complete unrolling for loops with small constant trip counts.

IDE Equivalent
None

Alternate Options
None

**vec, Qvec**
_Enables or disables vectorization._

Syntax
Linux OS and OS X:
- `-vec`
- `-no-vec`
Windows OS:
/Qvec
/Qvec-

**Arguments**
None

**Default**
-vec Vectorization is enabled if option O2 or higher is in effect.
or /Qvec

**Description**
This option enables or disables vectorization.
To disable vectorization, specify -no-vec (Linux* OS and OS X*) or /Qvec- (Windows* OS).
To disable interpretation of SIMD directives, specify -no-simd (Linux* OS and OS X*) or /Qsimd- (Windows* OS).
To disable all compiler vectorization, use the "-no-vec -no-simd" (Linux* OS and OS X*) or "/Qvec- /Qsimd-" (Windows* OS) compiler options. The option -no-vec (and /Qvec-) disables all auto-vectorization, including vectorization of array notation statements. The option -no-simd (and /Qsimd-) disables vectorization of loops that have SIMD directives.

**NOTE**
Using this option enables vectorization at default optimization levels for both Intel® microprocessors and non-Intel microprocessors. Vectorization may call library routines that can result in additional performance gain on Intel microprocessors than on non-Intel microprocessors. The vectorization can also be affected by certain options, such as /arch (Windows OS), -m (Linux OS and OS X), or [Q]x.

**IDE Equivalent**
None

**Alternate Options**
None

**See Also**
simd, Qsimd compiler option
ax, Qax compiler option
x, Qx compiler option
vec-guard-write, Qvec-guard-write compiler option
vec-threshold, Qvec-threshold compiler option

**vec-guard-write, Qvec-guard-write**
*Tell the compiler to perform a conditional check in a vectorized loop.*

**Syntax**

**Linux OS and OS X:**
-vec-guard-write
-no-vec-guard-write
Windows OS:
/Qvec-guard-write
/Qvec-guard-write-

Arguments
None

Default
-vec-guard-write
or /Qvec-guard-write

Description
This option tells the compiler to perform a conditional check in a vectorized loop. This checking avoids unnecessary stores and may improve performance.

IDE Equivalent
None

Alternate Options
None

vec-threshold, Qvec-threshold
Sets a threshold for the vectorization of loops.

Syntax
Linux OS and OS X:
-vec-threshold[n]

Windows OS:
/Qvec-threshold[[:]:n]

Arguments

$n$

Is an integer whose value is the threshold for the vectorization of loops. Possible values are 0 through 100.

If $n$ is 0, loops get vectorized always, regardless of computation work volume.

If $n$ is 100, loops get vectorized when performance gains are predicted based on the compiler analysis data. Loops get vectorized only if profitable vector-level parallel execution is almost certain.

The intermediate 1 to 99 values represent the percentage probability for profitable speed-up. For example, $n=50$ directs the compiler to vectorize only if there is a 50% probability of the code speeding up if executed in vector form.

Default
-vec-threshold100
or /Qvec-threshold100

Loops get vectorized only if profitable vector-level parallel execution is almost certain. This is also the default if you do not specify $n$. 
Description
This option sets a threshold for the vectorization of loops based on the probability of profitable execution of the vectorized loop in parallel.

This option is useful for loops whose computation work volume cannot be determined at compile-time. The threshold is usually relevant when the loop trip count is unknown at compile-time.

The compiler applies a heuristic that tries to balance the overhead of creating multiple threads versus the amount of work available to be shared amongst the threads.

IDE Equivalent
Visual Studio: Optimization > Threshold For Vectorization
Eclipse: None
Xcode: None

Alternate Options
None

vecabi, Qvecabi
Determines whether the compiler uses the compatibility or legacy vector function application binary interface (ABI).

Syntax
Linux OS and OS X:
-vecabi=keyword

Windows OS:
/Qvecabi:keyword

Arguments
keyword
Specifies which vector function ABI to use. Possible values are:

- legacy
  Tells the compiler to use the legacy vector function ABI.
- compat
  Tells the compiler to use the compatibility vector function ABI.

Default
-vecabi=compat
or/Qvecabi:compat

The compiler uses the compatibility vector function ABI.

Description
This option determines whether the compiler uses the compatibility or legacy vector function application binary interface (ABI).

On Linux* systems, by default, it provides compatibility with gcc's version of the vector function ABI. You must specify keyword legacy if you need to keep the generated vector function binary backward compatible with the vectorized binary generated by the previous version of Intel® compilers.
Profile Guided Optimization (PGO) Options

*finstrument-functions, Qinstrument-functions*

*Determines whether routine entry and exit points are instrumented.*

**Syntax**

**Linux OS and OS X:**

- `finstrument-functions`
- `fno-instrument-functions`

**Windows OS:**

/Qinstrument-functions
/Qinstrument-functions-

**Arguments**

None

**Default**

-fno-instrument-functions  Routine entry and exit points are not instrumented.
or/Qinstrument-functions-

**Description**

This option determines whether routine entry and exit points are instrumented. It may increase execution time.

The following profiling functions are called with the address of the current routine and the address of where the routine was called (its "call site"):  

- **This function is called upon routine entry:**
  - `void __cyg_profile_func_enter (void *this_fn, void *call_site);`
- **This function is called upon routine exit:**
  - `void __cyg_profile_func_exit (void *this_fn, void *call_site);`

These functions can be used to gather more information, such as profiling information or timing information. Note that it is the user's responsibility to provide these profiling functions.

If you specify *-finstrument-functions (Linux* OS and OS X*) or /Qinstrument-functions (Windows* OS), routine inlining is disabled. If you specify *-fno-instrument-functions or /Qinstrument-functions-, inlining is not disabled.

This option is provided for compatibility with gcc.
p
Compiles and links for function profiling with gprof(1).

Architecture Restrictions
Not available on Intel® 64 architecture targeting the Intel® Xeon Phi™ coprocessor x100 product family (formerly code name Knights Corner)

Syntax
Linux OS and OS X:
- p

Windows OS:
None

Arguments
None

Default
OFF
Files are compiled and linked without profiling.

Description
This option compiles and links for function profiling with gprof(1).
When you specify this option, inlining is disabled. However, you can override this by specifying directive FORCEINLINE, or a compiler option such as [Q]inline-forceinline.

IDE Equivalent
None

Alternate Options
Linux and OS X: -pg,-qp (this is a deprecated option)
Windows: None

prof-data-order, Qprof-data-order
Enables or disables data ordering if profiling information is enabled.

Architecture Restrictions
Not available on Intel® 64 architecture targeting the Intel® Xeon Phi™ coprocessor x100 product family (formerly code name Knights Corner)

Syntax
Linux OS:
- prof-data-order
-no-prof-data-order

OS X:
None

Windows OS:
/Qprof-data-order
/Qprof-data-order-

Arguments
None

Default
-no-prof-data-order Data ordering is disabled.
or/Qprof-data-order-

Description
This option enables or disables data ordering if profiling information is enabled. It controls the use of profiling information to order static program data items.

For this option to be effective, you must do the following:
• For instrumentation compilation, you must specify option [Q]prof-gen setting globdata.
• For feedback compilation, you must specify the [Q]prof-use option. You must not use multi-file optimization by specifying options such as [Q]ipo or [Q]ipo-c.

IDE Equivalent
None

Alternate Options
None

See Also
prof-gen, Qprof-gen compiler option
prof-use, Qprof-use compiler option
prof-func-order, Qprof-func-order compiler option

prof-dir, Qprof-dir
Specifies a directory for profiling information output files.

Architecture Restrictions
Not available on Intel® 64 architecture targeting Intel® MIC Architecture

Syntax

Linux OS and OS X:
-.prof-dir dir

Windows OS:
/Qprof-dir:dir
Arguments

dir

Is the name of the directory. You can specify a relative pathname or an absolute pathname.

Default

OFF

Profiling output files are placed in the directory where the program is compiled.

Description

This option specifies a directory for profiling information output files (*.dyn and *.dpi). The specified directory must already exist.

You should specify this option using the same directory name for both instrumentation and feedback compilations. If you move the .dyn files, you need to specify the new path.

Option /Qprof-dir is equivalent to option /Qcov-dir. If you specify both options, the last option specified on the command line takes precedence.

IDE Equivalent

Visual Studio: Output Files > Profile Directory

Eclipse: None

Xcode: None

Alternate Options

None

prof-file, Qprof-file

Specifies an alternate file name for the profiling summary files.

Architecture Restrictions

Not available on Intel® 64 architecture targeting Intel® MIC Architecture

Syntax

Linux OS and OS X:

-prof-file filename

Windows OS:

/Qprof-file:filename

Arguments

filename

Is the name of the profiling summary file.

Default

OFF

The profiling summary files have the file name pgopti.*

Description

This option specifies an alternate file name for the profiling summary files. The filename is used as the base name for files created by different profiling passes.
If you add this option to profmerge, the .dpi file will be named `filename.dpi` instead of `pgopti.dpi`.

If you specify this option with option `[Q]prof-use`, the .dpi file will be named `filename.dpi` instead of `pgopti.dpi`.

Option `/Qprof-file` is equivalent to option `/Qcov-file`. If you specify both options, the last option specified on the command line takes precedence.

**NOTE**
When you use option `[Q]prof-file`, you can only specify a file name. If you want to specify a path (relative or absolute) for `filename`, you must also use option `[Q]prof-dir`.

**IDE Equivalent**
None

**Alternate Options**
None

**See Also**
prof-gen, Qprof-gen compiler option
prof-use, Qprof-use compiler option
prof-dir, Qprof-dir compiler option

**prof-func-groups**
Enables or disables function grouping if profiling information is enabled.

**Architecture Restrictions**
Not available on Intel® 64 architecture targeting the Intel® Xeon Phi™ coprocessor x100 product family (formerly code name Knights Corner)

**Syntax**

**Linux OS:**
- `prof-func-groups`
- `no-prof-func-groups`

**OS X:**
None

**Windows OS:**
None

**Arguments**
None

**Default**
- `no-prof-func-groups` Function grouping is disabled.

**Description**
This option enables or disables function grouping if profiling information is enabled.
A "function grouping" is a profiling optimization in which entire routines are placed either in the cold code section or the hot code section.

If profiling information is enabled by option \texttt{-prof-use}, option \texttt{-prof-func-groups} is set and function grouping is enabled. However, if you explicitly enable \texttt{-prof-func-order}, function ordering is performed instead of function grouping.

If you want to disable function grouping when profiling information is enabled, specify \texttt{-no-prof-func-groups}.

To set the hotness threshold for function grouping, use option \texttt{-prof-hotness-threshold}.

**IDE Equivalent**

None

**See Also**

\texttt{prof-use, Qprof-use} compiler option  
\texttt{prof-func-order, Qprof-func-order} compiler option  
\texttt{prof-hotness-threshold, Qprof-hotness-threshold} compiler option

\texttt{prof-func-order, Qprof-func-order}

Enables or disables function ordering if profiling information is enabled.

**Architecture Restrictions**

Not available on Intel® 64 architecture targeting the Intel® Xeon Phi™ coprocessor x100 product family (formerly code name Knights Corner)

**Syntax**

**Linux OS:**

\texttt{-prof-func-order}  
\texttt{-no-prof-func-order}

**OS X:**

None

**Windows OS:**

\texttt{/Qprof-func-order}  
\texttt{/Qprof-func-order-}

**Arguments**

None

**Default**

\texttt{-no-prof-func-order} Function ordering is disabled.  
\texttt{or/Qprof-func-order-}

**Description**

This option enables or disables function ordering if profiling information is enabled.

For this option to be effective, you must do the following:

- For instrumentation compilation, you must specify option \texttt{[Q]prof-gen setting srcpos}.
- For feedback compilation, you must specify \texttt{[Q]prof-use}. You must not use multi-file optimization by specifying options such as \texttt{[Q]ipo} or \texttt{[Q]ipo-c}. 
If you enable profiling information by specifying option \( Q \)prof-use, option \( Q \)prof-func-groups is set and function grouping is enabled. However, if you explicitly enable the \( Q \)prof-func-order option, function ordering is performed instead of function grouping.

On Linux* systems, this option is only available for Linux linker 2.15.94.0.1, or later.

To set the hotness threshold for function grouping and function ordering, use option \( Q \)prof-hotness-threshold.

**IDE Equivalent**
None

**Alternate Options**
None

**Example**
The following example shows how to use this option on a Windows system:

```bash
ifort /Qprof-gen:globdata file1.f90 file2.f90 /exe:instrumented.exe
  ./instrumented.exe
ifort /Qprof-use /Qprof-func-order file1.f90 file2.f90 /exe:feedback.exe
```

The following example shows how to use this option on a Linux system:

```bash
ifort -prof-gen:globdata file1.f90 file2.f90 -o instrumented
  ./instrumented.exe
ifort -prof-use -prof-func-order file1.f90 file2.f90 -o feedback
```

**See Also**
prof-hotness-threshold, Qprof-hotness-threshold compiler option
prof-gen, Qprof-gen compiler option
prof-use, Qprof-use compiler option
prof-data-order, Qprof-data-order compiler option
prof-func-groups compiler option

**prof-gen, Qprof-gen**
*Produces an instrumented object file that can be used in profile guided optimization.*

**Syntax**

*Linux OS and OS X:*

```bash
-prof-gen[=keyword[, keyword],...]
-no-prof-gen
```

*Windows OS:*

```bash
/Qprof-gen[:keyword[,keyword],...]
/Qprof-gen-
```

**Arguments**

*keyword*  
Specifies details for the instrumented file. Possible values are:

*default*  
*Produces an instrumented object file. This is the same as specifying the \( Q \)prof-gen option with no keyword.*
srcpos Produces an instrumented object file that includes extra source position information.

globdata Produces an instrumented object file that includes information for global data layout.

[no]threadsafe Produces an instrumented object file that includes the collection of PGO data on applications that use a high level of parallelism. If [Q]prof-gen is specified with no keyword, the default is nothreadsafe.

On Intel® 64 architecture targeting the Intel® Xeon Phi™ coprocessor x100 product family (formerly code name Knights Corner), the only valid mode is keyword threadsafe.

Default

-no-prof-gen or /Qprof-gen- Profile generation is disabled.

Description

This option produces an instrumented object file that can be used in profile guided optimization. It gets the execution count of each basic block.

You can specify more than one setting for [Q]prof-gen. For example, you can specify the following:

-prof-gen=scrpos -prof-gen=threadsafe (Linux* OS and OS X*)
-prof-gen=scrpos, threadsafe (this is equivalent to the above)

/Qprof-gen:scrpos /Qprof-gen:threadsafe (Windows* OS)
/Qprof-gen:scrpos, threadsafe (this is equivalent to the above)

If you specify keyword srcpos or globdata, a static profile information file (.spi) is created. These settings may increase the time needed to do a parallel build using -prof-gen, because of contention writing the .spi file.

These options are used in phase 1 of the Profile Guided Optimizer (PGO) to instruct the compiler to produce instrumented code in your object files in preparation for instrumented execution.

When the [Q]prof-gen option is used to produce an instrumented binary file for profile generation, some optimizations are disabled. Those optimizations are not disabled for any subsequent profile-guided compilation with option [Q]prof-use that makes use of the generated profiles.

IDE Equivalent

None

Alternate Options

None

prof-hotness-threshold, Qprof-hotness-threshold

Lets you set the hotness threshold for function grouping and function ordering.

Architecture Restrictions

Not available on Intel® 64 architecture targeting the Intel® Xeon Phi™ coprocessor x100 product family (formerly code name Knights Corner)
Syntax

Linux OS:
- `prof-hotness-threshold=n`

OS X:
None

Windows OS:
/Qprof-hotness-threshold: n

Arguments

n Is the hotness threshold. n is a percentage having a value between 0 and 100 inclusive. If you specify 0, there will be no hotness threshold setting in effect for function grouping and function ordering.

Default

OFF The compiler’s default hotness threshold setting of 10 percent is in effect for function grouping and function ordering.

Description

This option lets you set the hotness threshold for function grouping and function ordering.

The "hotness threshold" is the percentage of functions in the application that should be placed in the application's hot region. The hot region is the most frequently executed part of the application. By grouping these functions together into one hot region, they have a greater probability of remaining resident in the instruction cache. This can enhance the application's performance.

For this option to take effect, you must specify option [Q]prof-use and one of the following:

- On Linux systems: `-prof-func-groups` or `-prof-func-order`
- On Windows systems: `/Qprof-func-order`

IDE Equivalent

None

Alternate Options

None

See Also

`prof-use`, `Qprof-use` compiler option
`prof-func-groups` compiler option
`prof-func-order`, `Qprof-func-order` compiler option

`prof-src-dir`, `Qprof-src-dir`  
Determines whether directory information of the source file under compilation is considered when looking up profile data records.

Architecture Restrictions

Not available on Intel® 64 architecture targeting the Intel® Xeon Phi™ coprocessor x100 product family (formerly code name Knights Corner)
Syntax

Linux OS and OS X:
- prof-src-dir
- no-prof-src-dir

Windows OS:
/Qprof-src-dir
/Qprof-src-dir-

Arguments
None

Default

[Q]prof-src-dir Directory information is used when looking up profile data records in the .dpi file.

Description

This option determines whether directory information of the source file under compilation is considered when looking up profile data records in the .dpi file. To use this option, you must also specify the [Q]prof-use option.

If the option is enabled, directory information is considered when looking up the profile data records within the .dpi file. You can specify directory information by using one of the following options:

- Linux and OS X: -prof-src-root or -prof-src-root-cwd
- Windows: /Qprof-src-root or /Qprof-src-root-cwd

If the option is disabled, directory information is ignored and only the name of the file is used to find the profile data record.

Note that option [Q]prof-src-dir controls how the names of the user’s source files get represented within the .dyn or .dpi files. Option [Q]prof-dir specifies the location of the .dyn or the .dpi files.

IDE Equivalent
None

Alternate Options
None

See Also
prof-use, Qprof-use compiler option
prof-src-root, Qprof-src-root compiler option
prof-src-root-cwd, Qprof-src-root-cwd compiler option

prof-src-root, Qprof-src-root
Lets you use relative directory paths when looking up profile data and specifies a directory as the base.

Architecture Restrictions
Not available on Intel® 64 architecture targeting Intel® MIC Architecture
**Syntax**

**Linux OS and OS X:**
- `prof-src-root=dir`

**Windows OS:**
/`Qprof-src-root:dir`

**Arguments**

`dir`  
Is the base for the relative paths.

**Default**

OFF  
The setting of relevant options determines the path used when looking up profile data records.

**Description**

This option lets you use relative directory paths when looking up profile data in .dpi files. It lets you specify a directory as the base. The paths are relative to a base directory specified during the [Q]prof-gen compilation phase.

This option is available during the following phases of compilation:

- Linux OS and OS X: `-prof-gen` and `-prof-use` phases
- Windows OS: `/Qprof-gen` and `/Qprof-use` phases

When this option is specified during the [Q]prof-gen phase, it stores information into the .dyn or .dpi file. Then, when .dyn files are merged together or the .dpi file is loaded, only the directory information below the root directory is used for forming the lookup key.

When this option is specified during the [Q]prof-use phase, it specifies a root directory that replaces the root directory specified at the [Q]prof-gen phase for forming the lookup keys.

To be effective, this option or option `[Q]prof-src-root-cwd` must be specified during the [Q]prof-gen phase. In addition, if one of these options is not specified, absolute paths are used in the .dpi file.

**IDE Equivalent**

None

**Alternate Options**

None

Consider the initial [Q]prof-gen compilation of the source file `c:\user1\feature_foo\myproject\common\glob.f90` shown below:

**Windows** OS: `ifort /Qprof-gen /Qprof-src-root=c:\user1\feature_foo\myproject -c common\glob.f90`

**Linux** and OS X*: `ifort -prof-gen -prof-src-root=c:\user1\feature_foo\myproject -c common\glob.f90`

For the [Q]prof-use phase, the file `glob.f90` could be moved into the directory `c:\user2\feature_bar\myproject\common\glob.f90` and profile information would be found from the .dpi when using the following:

**Windows** OS: `ifort /Qprof-use /Qprof-src-root=c:\user2\feature_bar\myproject -c common\glob.f90`

**Linux** and OS X*: `ifort -prof-use -prof-src-root=c:\user2\feature_bar\myproject -c common\glob.f90`

If you do not use option `[Q]prof-src-root` during the [Q]prof-gen phase, by default, the [Q]prof-use compilation can only find the profile data if the file is compiled in the `c:\user1\feature_foo\my_project\common` directory.
See Also
prof-gen, Qprof-gen compiler option

prof-src-dir, Qprof-src-dir compiler option
prof-src-root-cwd, Qprof-src-root-cwd compiler option

prof-src-root-cwd, Qprof-src-root-cwd
Let you use relative directory paths when looking up profile data and specifies the current working directory as the base.

Architecture Restrictions
Not available on Intel® 64 architecture targeting Intel® MIC Architecture

Syntax
Linux OS and OS X:
-prof-src-root-cwd

Windows OS:
/Qprof-src-root-cwd

Arguments
None

Default
OFF

The setting of relevant options determines the path used when looking up profile data records.

Description
This option lets you use relative directory paths when looking up profile data in .dpi files. It specifies the current working directory as the base. To use this option, you must also specify option [Q]prof-use.

This option is available during the following phases of compilation:

- Linux OS and OS X: -prof-gen and -prof-use phases
- Windows OS: /Qprof-gen and /Qprof-use phases

When this option is specified during the [Q]prof-gen phase, it stores information into the .dyn or .dpi file. Then, when .dyn files are merged together or the .dpi file is loaded, only the directory information below the root directory is used for forming the lookup key.

When this option is specified during the [Q]prof-use phase, it specifies a root directory that replaces the root directory specified at the [Q]prof-gen phase for forming the lookup keys.

To be effective, this option or option [Q]prof-src-root must be specified during the [Q]prof-gen phase. In addition, if one of these options is not specified, absolute paths are used in the .dpi file.

IDE Equivalent
None

Alternate Options

prof-use, Qprof-use
Enables the use of profiling information during optimization.

Architecture Restrictions
Not available on Intel® 64 architecture targeting the Intel® Xeon Phi™ coprocessor x100 product family (formerly code name Knights Corner)

Syntax

Linux OS and OS X:
-prof-use[=keyword]
-no-prof-use

Windows OS:
/Qprof-use[::keyword]
/Qprof-use-

Arguments

keyword

- Specifies additional instructions. Possible values are:

  - weighted
    - Tells the profmerge utility to apply a weighting to the .dyn file values when creating the .dpi file to normalize the data counts when the training runs have different execution durations. This argument only has an effect when the compiler invokes the profmerge utility to create the .dpi file. This argument does not have an effect if the .dpi file was previously created without weighting.

  - [no]merge
    - Enables or disables automatic invocation of the profmerge utility. The default is merge. Note that you cannot specify both weighted and nomerge. If you try to specify both values, a warning will be displayed and nomerge takes precedence.

  - default
    - Enables the use of profiling information during optimization. The profmerge utility is invoked by default. This value is the same as specifying [Q]prof-use with no argument.

Default

-no-prof-use or /Qprof-use-

Profiling information is not used during optimization.
Description

This option enables the use of profiling information (including function splitting and function grouping) during optimization. It enables option /QfnSplit (Windows* OS).

This option instructs the compiler to produce a profile-optimized executable and it merges available profiling output files into a pgopti.dpi file.

Note that there is no way to turn off function grouping if you enable it using this option.

To set the hotness threshold for function grouping and function ordering, use option [Q]prof-hotness-threshold.

IDE Equivalent

None

Alternate Options

None

See Also

prof-hotness-threshold, Qprof-hotness-threshold compiler option

prof-value-profiling, Qprof-value-profiling
Controls which values are value profiled.

Architecture Restrictions

Not available on Intel® 64 architecture targeting Intel® MIC Architecture

Syntax

Linux OS and OS X:
- prof-value-profiling[=keyword]

Windows OS:
/Qprof-value-profiling[:keyword]

Arguments

keyword

Controls which type of value profiling is performed. Possible values are:

none Prevents all types of value profiling.

nodivide Prevents value profiling of non-compile time constants used in division or remainder operations.

noindcall Prevents value profiling of function addresses at indirect call sites.

all Enables all types of value profiling.

You can specify more than one keyword, but they must be separated by commas.

Default

all All value profile types are enabled and value profiling is performed.

Description

This option controls which features are value profiled.
If this option is specified with option \([Q]\)prof-gen, it turns off instrumentation of operations of the specified type. This also prevents feedback of values for the operations.

If this option is specified with option \([Q]\)prof-use, it turns off feedback of values collected of the specified type.

If you specify level 2 or higher for option \([q \text{ or } Q]\)opt-report, the value profiling specialization information will be reported within the PGO optimization report.

qopt-report, Qopt-report compiler option

**profile-functions, Qprofile-functions**

Inserts instrumentation calls at a function's entry and exit points.

**Architecture Restrictions**

Not available on Intel® 64 architecture targeting the Intel® Xeon Phi™ coprocessor x100 product family (formerly code name Knights Corner)

**Syntax**

**Linux OS and OS X:**

- `profile-functions`

**Windows OS:**

/Qprofile-functions

**Arguments**

None

**Default**

OFF

No instrumentation calls are inserted at a function's entry and exit points.

**Description**

This option inserts instrumentation calls at a function’s entry and exit points within a single-threaded application to collect the cycles spent within the function to produce reports that can help in identifying code hotspots.

When the instrumented application is run, this option causes the generation of a `loop_prof_funcs_<name>.dump` file, where `<name>` is a timestamp for the run.

The same data values are also dumped into the file `loop_prof_<name>.xml` for use with the data viewer application, unless you turn off the output format by setting the environment variable `INTEL_LOOP_PROF_XML_DUMP` to 0.

**IDE Equivalent**

None
Alternate Options
None

See Also
profile-loops, Qprofile-loops compiler option
profile-loops-report, Qprofile-loops-report compiler option

profile-loops, Qprofile-loops

Inserts instrumentation calls at a function’s entry and exit points, and before and after instrumentable loops.

Architecture Restrictions
Not available on Intel® 64 architecture targeting the Intel® Xeon Phi™ coprocessor x100 product family (formerly code name Knights Corner)

Syntax

Linux OS and OS X:

-profile-loops=keyword

Windows OS:

/Qprofile-loops:keyword

Arguments

keyword

Specifies which type of loops should have instrumentation. Possible values are:

inner

Inserts instrumentation before and after inner loops.

outer

Inserts instrumentation before and after outer loops.

all

Inserts instrumentation before and after all loops.

Default

OFF

No instrumentation calls are inserted at a function’s entry and exit points, or before and after instrumentable loop.

Description

This option inserts instrumentation calls at a function’s entry and exit points within a single-threaded application. For unthreaded applications, it also inserts instrumentation before and after instrumentable loops of the type listed in keyword.

When the instrumented application is run, this option causes the generation of a loop_prof_funcs_<name>.dump file and a loop_prof_funcs_<name>.dump file, where <name> is a timestamp for the run.

The same timestamp is used for the loop file and function file. This identifies that the loop data and function data were from the same program run.

The same data values are also dumped into the file loop_prof_<name>.xml for use with the data viewer application, unless you turn off the output format by setting the environment variable INTEL_LOOP_PROF_XML_DUMP to 0.
## IDE Equivalent
None

## Alternate Options
None

## See Also

- profile-loops-report, Qprofile-loops-report compiler option

### profile-loops-report, Qprofile-loops-report

Controls the level of detail for the data collected when instrumentation occurs before and after certain loops.

## Architecture Restrictions
Not available on Intel® 64 architecture targeting Intel® MIC Architecture

## Syntax

**Linux OS and OS X:**

```
-profile-loops-report[=n]
```

**Windows OS:**

```
/Qprofile-loops-report[:n]
```

## Arguments

\( n \)

Is a value denoting the level of detail to report. Possible values are:

1. \( n \) Reports the cycle counts on entry and exits of loops. This is the default if \( n \) is not specified.

2. \( n \) Reports the level 1 default details, but also includes the loop min/max and average loop iteration counts. To collect the loop iteration counts, additional instrumentation is inserted. This can increase overhead in the instrumented application and slow performance.

## Default
1

The report shows the cycle counts on entry and exits of loops.

## Description
This option controls the level of detail for the data collected when instrumentation occurs before and after certain loops. To use this option, you must also specify option [Q]profile-loops.

The report appears in file `loop_prof_loops_<name>.dump`, where `<name>` is a timestamp value for the run. The columns listed in the report will be based on the level of detail that was selected during instrumentation.

It is recommended that the same report level be used for all files that are instrumented for the application. If different files of the application were instrumented with different levels, the report will contain all the columns of the highest detail level, but with default values for unavailable fields for files that were instrumented at lower levels.
Qcov-dir
Specifies a directory for profiling information output files that can be used with the codecov or tselect tool.

Architecture Restrictions
Not available on Intel® 64 architecture targeting Intel® MIC Architecture

Syntax
Linux OS and OS X:
None

Windows OS:
/Qcov-dir:dir

Arguments
dir Is the name of the directory.

Default
OFF Profiling output files are placed in the directory where the program is compiled.

Description
This option specifies a directory for profiling information output files (*.dyn and *.dpi) that can be used with the code-coverage tool (codecov) or the test prioritization tool (tselect). The specified directory must already exist.

You should specify this option using the same directory name for both instrumentation and feedback compilations. If you move the .dyn files, you need to specify the new path.

Option /Qcov-dir is equivalent to option /Qprof-dir. If you specify both options, the last option specified on the command line takes precedence.

IDE Equivalent
None

Alternate Options
None

See Also
profile-functions, Qprofile-functions compiler option
profile-loops, Qprofile-loops compiler option
Qcov-gen compiler option
Qcov-file compiler option
Qcov-file
Specifies an alternate file name for the profiling summary files that can be used with the codecov or tselect tool.

Architecture Restrictions
Not available on Intel® 64 architecture targeting Intel® MIC Architecture

Syntax

Linux OS and OS X:
None

Windows OS:
/Qcov-file:filename

Arguments
filename Is the name of the profiling summary file.

Default
OFF The profiling summary files have the file name pgopti.*.

Description
This option specifies an alternate file name for the profiling summary files. The file name can be used with the code-coverage tool (codecov) or the test prioritization tool (tselect).

The filename is used as the base name for the set of files created by different profiling passes.

If you specify this option with option /Qcov-gen, the .spi and .spl files will be named filename.spi and filename.spl instead of pgopti.spi and pgopti.spl.

Option /Qcov-file is equivalent to option /Qprof-file. If you specify both options, the last option specified on the command line takes precedence.

IDE Equivalent
None

Alternate Options
None

See Also
Qcov-gen compiler option
Qcov-dir compiler option

Qcov-gen
Produces an instrumented object file that can be used with the codecov or tselect tool.

Architecture Restrictions
Not available on Intel® 64 architecture targeting Intel® MIC Architecture

Syntax

Linux OS and OS X:
None
Windows OS:
/Qcov-gen
/Qcov-gen-

Arguments
None

Default
/Qcov-gen- The instrumented object file is not produced.

Description
This option produces an instrumented object file that can be used with the code-coverage tool (codecov) or the test prioritization tool (tselect). The instrumented code is included in the object file in preparation for instrumented execution.

This option also creates a static profile information file (.spi) that can be used with the codecov or tselect tool.

Option /Qcov-gen should be used to minimize the instrumentation overhead if you are interested in using the instrumentation only for code coverage. You should use /Qprof-gen:srcpos if you intend to use the collected data for code coverage and profile feedback.

IDE Equivalent
None

Alternate Options
None

See Also
Qcov-dir compiler option
Qcov-file compiler option

Qfnsplit
Enables function splitting.

Architecture Restrictions
Not available on Intel® 64 architecture targeting Intel® MIC Architecture

Syntax

Linux OS:
None

OS X:
None

Windows OS:
/Qfnsplit
/Qfnsplit-

Arguments
None
Function splitting is not enabled unless option `/Qprof-use` is also specified.

Description
This option enables function splitting if `/Qprof-use` is also specified. Otherwise, this option has no effect.

It is enabled automatically if you specify `/Qprof-use`. Otherwise, the default is `/Qfnsplit-`, which disables function splitting but leaves function grouping enabled.

To disable function splitting when you use `/Qprof-use`, specify `/Qfnsplit-`.

IDE Equivalent
None

Alternate Options
None

Optimization Report Options

`qopt-report`, `Qopt-report`
*Tells the compiler to generate an optimization report. Option `-qopt-report` is the replacement option for `-opt-report`, which is deprecated.*

Syntax

**Linux OS and OS X:**

`-qopt-report[:n]`

**Windows OS:**

`/Qopt-report[:n]`

Arguments

`n` (Optional) Indicates the level of detail in the report. You can specify values 0 through 5. If you specify zero, no report is generated. For levels `n=1` through `n=5`, each level includes all the information of the previous level, as well as potentially some additional information. Level 5 produces the greatest level of detail. If you do not specify `n`, the default is level 2, which produces a medium level of detail.

Default

**OFF**
No optimization report is generated.

Description

This option tells the compiler to generate a collection of optimization report files, one per object; this is the same output produced by option `[q or Q]opt-report-per-object`. If you prefer another form of output, you can specify option `[q or Q]opt-report-file`.

If you specify a level (`n`) higher than 5, a warning will be displayed and you will get a level 5 report.

When optimization reporting is enabled, the default is `-qopt-report-phase=all` (Linux* OS and OS X*) or `/Qopt-report-phase:all` (Windows* OS).
For a description of the information that each n level provides, see the Example section in option [q or Q]opt-report-phase.

IDE Equivalent
Visual Studio: Diagnostics > Optimization Diagnostic Level
Eclipse: None
Xcode: None

Alternate Options
None

Example
If you only want reports about certain diagnostics, you can use this option with option [q or Q]opt-report-phase. The phase you specify determines which diagnostics you will receive.

For example, the following examples show how to get reports about certain specific diagnostics.

<table>
<thead>
<tr>
<th>To get this specific report</th>
<th>Specify</th>
</tr>
</thead>
<tbody>
<tr>
<td>Auto-parallelizer diagnostics</td>
<td>Linux* OS and OS X*: -qopt-report -qopt-report-phase=par</td>
</tr>
<tr>
<td></td>
<td>Windows* OS: /Qopt-report /Qopt-report-phase:par</td>
</tr>
<tr>
<td>OpenMP parallelizer diagnostics</td>
<td>Linux* OS and OS X*: -qopt-report -qopt-report-phase=openmp</td>
</tr>
<tr>
<td></td>
<td>Windows* OS: /Qopt-report /Qopt-report-phase:openmp</td>
</tr>
<tr>
<td>Vectorizer diagnostics</td>
<td>Linux* OS and OS X*: -qopt-report -qopt-report-phase=vec</td>
</tr>
<tr>
<td></td>
<td>Windows* OS: /Qopt-report /Qopt-report-phase:vec</td>
</tr>
</tbody>
</table>

qopt-report-embed, Qopt-report-embed
Determines whether special loop information annotations will be embedded in the object file and/or the assembly file when it is generated. Option -qopt-report-embed is the replacement option for -opt-report-embed, which is deprecated.

Syntax

Linux OS and OS X:
- qopt-report-embed
- qno-opt-report-embed

Windows OS:
/Qopt-report-embed
Arguments
None

Default
OFF

When an assembly file is being generated, special loop information annotations will not be embedded in the assembly file.

However, if option -g (Linux* OS and OS X*) or /zi (Windows* OS) is specified, special loop information annotations will be embedded in the assembly file unless option -qno-opt-report-embed (Linux OS and OS X) or /Qopt-report-embed- (Windows OS) is specified.

Description
This option determines whether special loop information annotations will be embedded in the object file and/or the assembly file when it is generated. Specify the positive form of the option to include the annotations in the assembly file.

If an object file (or executable) is being generated, the annotations will be embedded in the object file (or executable).

If you use this option, you do not have to specify option [q or Q]opt-report.

Alternate Options
None

See Also
qopt-report, Qopt-report compiler option
qopt-report-file, Qopt-report-file
Specifies that the output for the optimization report goes to a file, stderr, or stdout. Option -qopt-report-file is the replacement option for -opt-report-file, which is deprecated.

Syntax
Linux OS and OS X:
-qopt-report-file=keyword

Windows OS:
/Qopt-report-file:keyword

Arguments

\textit{keyword}

Specifies the output for the report. You can specify one of the following:

\begin{itemize}
  \item \textit{filename}
    \begin{itemize}
      \item Specifies the name of the file where the output should go.
    \end{itemize}
  \item \textit{stderr}
    \begin{itemize}
      \item Indicates that the output should go to stderr.
    \end{itemize}
  \item \textit{stdout}
    \begin{itemize}
      \item Indicates that the output should go to stdout.
    \end{itemize}
\end{itemize}
Default

OFF

No optimization report is generated.

Description

This option specifies that the output for the optimization report goes to a file, stderr, or stdout.

If you use this option, you do not have to specify option [q or Q]opt-report.

When optimization reporting is enabled, the default is -qopt-report-phase=all (Linux* OS and OS X*) or /Qopt-report-phase:all (Windows* OS).

IDE Equivalent

Visual Studio: Diagnostics > Emit Optimization Diagnostics to File

Diagnostics > Optimization Diagnostic File

Eclipse: None

Xcode: None

Alternate Options

None

See Also

qopt-report, Qopt-report compiler option

qopt-report-filter, Qopt-report-filter

Tells the compiler to find the indicated parts of your application, and generate optimization reports for those parts of your application. Option -qopt-report-filter is the replacement option for -opt-report-filter, which is deprecated.

Syntax

Linux OS and OS X:

-qopt-report-filter=string

Windows OS:

/Qopt-report-filter:string

Arguments

string

Is the information to search for. The string must appear within quotes. It can take one or more of the following forms:

- filename
- filename, routine
- filename, range [, range]...
- filename, routine, range [, range]...

If you specify more than one of the above forms in a string, a semicolon must appear between each form. If you specify more than one range in a string, a comma must appear between each range. Optional blanks can follow each parameter in the forms above and they can also follow each form in a string.
filename
Specifies the name of a file to be found. It can include a path.
If you do not specify a path, the compiler looks for the filename in the current working directory.

routine
Specifies the name of a routine to be found. You can include an identifying argument.
The name, including any argument, must be enclosed in single quotes.
The compiler tries to uniquely identify the routine that corresponds to the specified routine name.
It may select multiple routines to analyze, especially if more than one routine has the specified routine name, so the routine cannot be uniquely identified.

range
Specifies a range of line numbers to be found in the file or routine specified. The range must be specified in integers in the form:
first_line_number-last_line_number
The hyphen between the line numbers is required.

Default
OFF
No optimization report is generated.

Description
This option tells the compiler to find the indicated parts of your application, and generate optimization reports for those parts of your application. Optimization reports will only be generated for the routines that contain the specified string.
On Linux* OS and OS X*, if you specify both -qopt-report-routine=string1 and -qopt-report-filter=string2, it is treated as -qopt-report-filter=string1;string2. On Windows* OS, if you specify both /Qopt-report-routine:string1 and /Qopt-report-filter:string2, it is treated as /Qopt-report-filter:string1;string2.
If you use this option, you do not have to specify option [q or Q]opt-report.
When optimization reporting is enabled, the default is -qopt-report-phase=all (Linux* OS and OS X*) or /Qopt-report-phase:all (Windows* OS).

IDE Equivalent
None

Alternate Options
None

See Also
qopt-report, Qopt-report compiler option
qopt-report-format, Qopt-report-format
Specifies the format for an optimization report. Option -qopt-report-format is the replacement option for -opt-report-format, which is deprecated.

Syntax

Linux OS and OS X:
-qopt-report-format=keyword

Windows OS:
/Qopt-report-format:keyword

Arguments

keyword Specifies the format for the report. You can specify one of the following:

text Indicates that the report should be in text format.

vs Indicates that the report should be in Visual Studio* (IDE) format. The Visual Studio IDE uses the information to visualize the optimization report in the context of your program source code.

Default

OFF No optimization report is generated.

Description

This option specifies the format for an optimization report. If you use this option, you must specify either text or vs.

If you do not specify this option and another option causes an optimization report to be generated, the default format is text.

Specifying vs can change where the output goes in the following cases:

• If filename is specified for option [q or Q]opt-report-file, output goes to the specified file.
• If stdout is specified for option [q or Q]opt-report-file, output goes to stdout.
• If stderr is specified for option [q or Q]opt-report-file, output goes to stderr.

If you use this option, you do not have to specify option [q or Q]opt-report.

When optimization reporting is enabled, the default is -qopt-report-phase=all (Linux* OS and OS X*) or /Qopt-report-phase:all (Windows* OS).

IDE Equivalent

None

Alternate Options

None

See Also

qopt-report, Qopt-report compiler option
qopt-report-file, Qopt-report-file compiler option
**qopt-report-help, Qopt-report-help**

Displays the optimizer phases available for report generation and a short description of what is reported at each level. Option -qopt-report-help is the replacement option for -opt-report-help, which is deprecated.

**Syntax**

**Linux OS and OS X:**

-qopt-report-help

**Windows OS:**

/Qopt-report-help

**Arguments**

None

**Default**

OFF No optimization report is generated.

**Description**

This option displays the optimizer phases available for report generation using [q or Q]opt-report-phase, and a short description of what is reported at each level. No compilation is performed.

To indicate where output should go, you can specify one of the following options:

- [q or Q]opt-report-file
- [q or Q]opt-report-per-object

If you use this option, you do not have to specify option [q or Q]opt-report.

**IDE Equivalent**

None

**Alternate Options**

None

**See Also**

qopt-report, Qopt-report compiler option
qopt-report-phase, Qopt-report-phase compiler option
qopt-report-file, Qopt-report-file compiler option
qopt-report-per-object, Qopt-report-per-object compiler option

**qopt-report-per-object, Qopt-report-per-object**

Tells the compiler that optimization report information should be generated in a separate file for each object. Option -qopt-report-per-object is the replacement option for -opt-report-per-object, which is deprecated.

**Syntax**

**Linux OS and OS X:**

-qopt-report-per-object
Windows OS:
/Qopt-report-per-object

Arguments
None

Default
OFF No optimization report is generated.

Description
This option tells the compiler that optimization report information should be generated in a separate file for each object.

If you specify this option for a single-file Interprocedural Optimization (IPO) compilation, a file with a .optrpt extension is produced for every object file or assembly file that is generated by the compiler. For a single file compilation, one file is produced for each of the multiple true objects in the compilation. The names used are ipo_out1.optrpt, ipo_out2.optrpt, ...ipo_outn.optrpt.

The .optrpt files are written to the target directory of the compilation process. If an object or assembly file is explicitly generated, the corresponding .optrpt file is written to the same directory where the object file is generated. If the object file is just a temporary file and an executable is generated, the corresponding .optrpt files are placed in the directory in which the executable is placed.

If you use this option, you do not have to specify option [q or Q]opt-report.

When optimization reporting is enabled, the default is -qopt-report-phase=all (Linux* OS and OS X*) or /Qopt-report-phase:all (Windows* OS).

IDE Equivalent
None

Alternate Options
None

See Also
qopt-report, Qopt-report compiler option

qopt-report-phase, Qopt-report-phase
Specifies one or more optimizer phases for which optimization reports are generated. Option -qopt-report-phase is the replacement option for -opt-report-phase, which is deprecated.

Syntax

Linux OS and OS X:
-qopt-report-phase=[list]

Windows OS:
/Qopt-report-phase[:list]
Arguments

list  (Optional) Specifies one or more phases to generate reports for. If you specify more than one phase, they must be separated with commas. The values you can specify are:

cg The phase for code generation
ipo The phase for Interprocedural Optimization
loop The phase for loop nest optimization
offload The phase for Intel® MIC Architecture. This phase has no effect if option -no-qoffload or option /Qoffload- is specified. This phase only applies to Intel® MIC Architecture.
openmp The phase for OpenMP
par The phase for auto-parallelization
pgo The phase for Profile Guided Optimization
tcollect The phase for trace collection
vec The phase for vectorization
all All optimizer phases. This is the default if you do not specify list.

Default
OFF No optimization report is generated.

Description
This option specifies one or more optimizer phases for which optimization reports are generated. Note that phase offload causes the compiler to print a report of the input or output of variables that the host sends to the offload target and variables that the host receives from the target.

For certain phases, you also need to specify other options:
• If you specify phase par, you must also specify option [Q]parallel.
• If you specify phase openmp, you must also specify option [q or Q]openmp.

To find all phase possibilities, specify option [q or Q]opt-report-help.

If you use this option, you do not have to specify option [q or Q]opt-report.

However, if you want to get more details for each phase, specify option [q or Q]opt-report along with this option and indicate the level of detail you want by specifying an appropriate value for n. (See also the Example section below.)

When optimization reporting is enabled, the default is -qopt-report-phase=all (Linux* OS and OS X*) or /Qopt-report-phase:all (Windows* OS).

IDE Equivalent
Visual Studio: Diagnostics > Optimization Diagnostic Phase
Eclipse: None
### Example
The following shows examples of the details you may receive when you specify one of the optimizer phases and a particular level \((n)\) for option \([q\ or\ Q]\text{opt-report}\). Note that details may change in future releases.

<table>
<thead>
<tr>
<th>Optimizer phase</th>
<th>The level specified in option ([q\ or\ Q]\text{opt-report})</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cg</td>
<td>1</td>
<td>Generates a list of which intrinsics were lowered and which memcall optimizations were performed.</td>
</tr>
<tr>
<td></td>
<td>2</td>
<td>Generates level 1 details, values for important inlining command line options, and a list of the routines that were discovered to be dead and eliminated.</td>
</tr>
<tr>
<td></td>
<td>3</td>
<td>Generates level 2 details, whole program information, the sizes of inlined routines, and the reasons routines were not inlined.</td>
</tr>
<tr>
<td></td>
<td>4</td>
<td>Generates level 3 details, detailed footnotes on the reasons why routines are not inlined, and what action the user can take to get them inlined.</td>
</tr>
<tr>
<td>ipo</td>
<td>1</td>
<td>For each compiled routine, generates a list of the routines that were inlined into the routine, called directly by the routine, and whose calls were deleted.</td>

qopt-report, Qopt-report compiler option
qopt-report-help, Qopt-report-help compiler option

**qopt-report-routine, Qopt-report-routine**

*Tells the compiler to generate an optimization report for each of the routines whose names contain the specified substring. Option -qopt-report-routine is the replacement option for -opt-report-routine, which is deprecated.*

**Syntax**

**Linux OS and OS X:**

-qopt-report-routine=substring

**Windows OS:**

/Qopt-report-routine:substring
**Arguments**

*substring*  
Is the text (string) to look for.

**Default**

OFF  
No optimization report is generated.

**Description**

This option tells the compiler to generate an optimization report for each of the routines whose names contain the specified substring.

You can also specify a sequence of substrings separated by commas. If you do this, the compiler will generate an optimization report for each of the routines whose name contains one or more of these substrings.

If you use this option, you do not have to specify option \[q or Qopt-report\].

When optimization reporting is enabled, the default is `-qopt-report-phase=all` (Linux* OS and OS X*) or `/Qopt-report-phase:all` (Windows* OS).

**IDE Equivalent**

Visual Studio: *Diagnostics > Optimization Diagnostic Routine*

Eclipse: None

Xcode: None

**Alternate Options**

None

**See Also**

`qopt-report`, `Qopt-report` compiler option

`qopt-report-names`, `Qopt-report-names`  
*Specifies whether mangled or unmangled names should appear in the optimization report.*

**Syntax**

**Linux OS and OS X:**

- `-qopt-report-names=keyword`

**Windows OS:**

- `/Qopt-report-names:keyword`

**Arguments**

*keyword*  
Specifies the form for the names. You can specify one of the following:

- **mangled**  
  Indicates that the optimization report should contain mangled names.

- **unmangled**  
  Indicates that the optimization report should contain unmangled names.
Default

OFF No optimization report is generated.

Description
This option specifies whether mangled or unmangled names should appear in the optimization report. If you use this option, you must specify either mangled or unmangled. If this option is not specified, unmangled names are used by default.

If you specify mangled, encoding (also known as decoration) is added to names in the optimization report. This is appropriate when you want to match annotations with the assembly listing.

If you specify unmangled, no encoding (or decoration) is added to names in the optimization report. This is appropriate when you want to match annotations with the source listing.

If you use this option, you do not have to specify option [q or Q]opt-report.

When optimization reporting is enabled, the default is -qopt-report-phase=all (Linux* OS and OS X*) or /Qopt-report-phase:all (Windows* OS).

IDE Equivalent
None

Alternate Options
None

See Also
qopt-report, Qopt-report compiler option
tcheck, Qtcheck

Enables analysis of threaded applications in some older product versions. This option is not needed for analysis of threaded applications by Intel® Inspector.

Architecture Restrictions
Not available on Intel® 64 architecture targeting the Intel® Xeon Phi™ coprocessor x100 product family (formerly code name Knights Corner)

Syntax

Linux OS:
-tcheck

OS X:
None

Windows OS:
/Qtcheck

Arguments
None

Default

OFF Threaded applications are not instrumented by the compiler for analysis.
Description
This option enables analysis of threaded applications in some older product versions. This option is not needed for analysis of threaded applications by Intel® Inspector. This option will be removed in a future release.

For more information about the products that include Intel® Inspector, see Feature Requirements.

IDE Equivalent
None

Alternate Options
None

tcollect, Qtcollect
Inserts instrumentation probes calling the Intel® Trace Collector API.

Syntax
Linux OS:
-tcollect[lib]

OS X:
None

Windows OS:
/Qtcollect[:lib]

Arguments
lib
Is one of the Intel® Trace Collector libraries; for example, VT, VTcs, VTmc, or VTfs. If you do not specify lib, the default library is VT.

Default
OFF
Instrumentation probes are not inserted into compiled applications.

Description
This option inserts instrumentation probes calling the Intel® Trace Collector API.

This trace analyzing/collecting feature requires installation of another product. For more information, see Feature Requirements.

This option provides a flexible and convenient way of instrumenting functions of a compiled application. For every function, the entry and exit points are instrumented at compile time to let the Intel® Trace Collector record functions beyond the default MPI calls. For non-MPI applications (for example, threaded or serial), you must ensure that the Intel® Trace Collector is properly initialized (VT_initialize/VT_init).

CAUTION
Be careful with full instrumentation because this feature can produce very large trace files.

IDE Equivalent
None
Alternate Options

None

See Also
tcollect-filter, Qtcollect-filter compiler option

tcollect-filter, Qtcollect-filter

Lets you enable or disable the instrumentation of specified functions.

Syntax

Linux OS:

-tcollect-filter filename

OS X:

None

Windows OS:

/Qtcollect-filter:filename

Arguments

filename

Is a configuration file that lists filters, one per line. Each filter consists of a regular expression string and a switch. Strings with leading or trailing white spaces must be quoted. Other strings do not have to be quoted. The switch value can be ON, on, OFF, or off.

Default

OFF

Functions are not instrumented. However, if option -tcollect (Linux) or /Qtcollect (Windows) is specified, the filter setting is ".* ON" and all functions get instrumented.

Description

This option lets you enable or disable the instrumentation of specified functions.

During instrumentation, the regular expressions in the file are matched against the function names. The switch specifies whether matching functions are to be instrumented or not. Multiple filters are evaluated from top to bottom with increasing precedence.

The names of the functions to match against are formatted as follows:

• The source file name is followed by a colon-separated function name. Source file names should contain the full path, if available. For example:

/home/joe/src/file.f:FOO_bar

• Classes and function names are separated by double colons. For example:

/home/joe/src/file.fpp:app::foo::bar

You can use option [q or Q]opt-report to get a full list of file and function names that the compiler recognizes from the compilation unit. This list can be used as the basis for filtering in the configuration file.

This trace analyzing/collecting feature requires installation of another product. For more information, see Feature Requirements.

IDE Equivalent

None
Alternate Options

None

Consider the following filters in a configuration file:

'.*' OFF '.*vector.*' ON

The above will cause instrumentation of only those functions having the string 'vector' in their names. No other function will be instrumented. Note that reversing the order of the two lines will prevent instrumentation of all functions.

To get a list of the file or routine strings that can be matched by the regular expression filters, generate an optimization report with tcollect information. For example:

Windows OS: ifort /Qtcollect /Qopt-report /Qopt-report-phase:tcollect

Linux OS: ifort -tcollect -qopt-report -qopt-report-phase=tcollect

See Also
tcollect, Qtcollect compiler option
qopt-report, Qopt-report compiler option

OpenMP* Options and Parallel Processing Options

fmpc-privatize

*Enables or disables privatization of all static data for the MultiProcessor Computing environment (MPC) unified parallel runtime.*

Architecture Restrictions

Only available on Intel® 64 architecture

Syntax

Linux OS:
- fmpc-privatize
- fno-mpc-privatize

OS X:
None

Windows OS:
None

Arguments

None

Default

- fno-mpc-privatize

The privatization of all static data for the MPC unified parallel runtime is disabled.

Description

This option enables or disables privatization of all static data for the MultiProcessor Computing environment (MPC) unified parallel runtime.

Option -fmpc-privatize causes calls to extended thread-local-storage (TLS) resolution, run-time routines that are not supported on standard Linux* OS distributions.
This option requires installation of another product. For more information, see Feature Requirements.

**IDE Equivalent**
None

**Alternate Options**
None

**par-affinity, Qpar-affinity**
Specifies thread affinity.

**Syntax**

**Linux OS:**
- par-affinity={[modifier,...]type[,permut] [,offset]

**OS X:**
None

**Windows OS:**
/Qpar-affinity:[modifier,...]type[,permut] [,offset]

**Arguments**

- **modifier**
  Is one of the following values: granularity={fine|thread|core}, [no]respect, [no]verbose, [no]warnings, proclist=proc_list. The default is granularity=core, respect, and noverbose. For information on value proclist, see Thread Affinity Interface.

- **type**
  Indicates the thread affinity. This argument is required and must be one of the following values: compact, disabled, explicit, none, scatter, logical, physical. The default is none. Values logical and physical are deprecated. Use compact and scatter, respectively, with no permute value.

- **permut**
  Is a positive integer. You cannot use this argument with type setting explicit, none, or disabled. The default is 0.

- **offset**
  Is a positive integer. You cannot use this argument with type setting explicit, none, or disabled. The default is 0.

**Default**

OFF
The thread affinity is determined by the run-time environment.

**Description**
This option specifies thread affinity, which binds threads to physical processing units. It has the same effect as environment variable KMP_AFFINITY.

This option overrides the environment variable when both are specified.

This option only has an effect if the following is true:
- You have specified option [Q]parallel or option [q or Q]openmp (or both).
- You are compiling the main program.
IDE Equivalent
None

Alternate Options
None

See Also
parallel, Qparallel compiler option
qopt-report, Qopt-report compiler option
par-num-threads, Qpar-num-threads
Specifies the number of threads to use in a parallel region.

Syntax
Linux OS and OS X:
-par-num-threads=n
Windows OS:
/Qpar-num-threads:n

Arguments
n
Is the number of threads to use. It must be a positive integer.

Default
OFF
The number of threads to use is determined by the run-time environment.

Description
This option specifies the number of threads to use in a parallel region. It has the same effect as environment variable OMP_NUM_THREADS.
This option overrides the environment variable when both are specified.
This option only has an effect if the following is true:
• You have specified option [Q]parallel or option [q or Q]openmp (or both).
• You are compiling the main program.

IDE Equivalent
None

Alternate Options
None

See Also
parallel, Qparallel compiler option
qopt-report, Qopt-report compiler option
par-runtime-control, Qpar-runtime-control
Generates code to perform run-time checks for loops that have symbolic loop bounds.

Syntax
Linux OS and OS X:
-par-runtime-control[n]
-no-par-runtime-control
Windows OS:
/Qpar-runtime-control[n]
/Qpar-runtime-control-

Arguments
n Is a a value denoting what kind of runtime checking to perform. Possible values are:

0 Performs no runtime check based on auto-parallelization. This is the same as specifying \( -\text{no-par-runtime-control} \) (Linux* OS and OS X*) or \( /Q\text{par-runtime-control-} \) (Windows* OS).

1 Generates runtime check code under conservative mode. This is the default if you do not specify \( n \).

2 Generates runtime check code under heuristic mode.

3 Generates runtime check code under aggressive mode.

Default
-no-par-runtime-control or/\text{par-runtime-control-}
The compiler uses default heuristics when checking loops.

Description
This option generates code to perform run-time checks for loops that have symbolic loop bounds.
If the granularity of a loop is greater than the parallelization threshold, the loop will be executed in parallel.
If you do not specify this option, the compiler may not parallelize loops with symbolic loop bounds if the compile-time granularity estimation of a loop can not ensure it is beneficial to parallelize the loop.

NOTE
This option may behave differently on Intel® microprocessors than on non-Intel microprocessors.

IDE Equivalent
None
Alternate Options

None

par-schedule, Qpar-schedule
*Let's you specify a scheduling algorithm for loop iterations.*

Syntax

**Linux OS and OS X:**

```
-par-schedule-keyword[=n]
```

**Windows OS:**

```
/Qpar-schedule-keyword[[:n]]
```

Arguments

**keyword**

Specifies the scheduling algorithm or tuning method. Possible values are:

- **auto**
  - Lets the compiler or run-time system determine the scheduling algorithm.

- **static**
  - Divides iterations into contiguous pieces.

- **static-balanced**
  - Divides iterations into even-sized chunks.

- **static-steal**
  - Divides iterations into even-sized chunks, but allows threads to steal parts of chunks from neighboring threads.

- **dynamic**
  - Gets a set of iterations dynamically.

- **guided**
  - Specifies a minimum number of iterations.

- **guided-analytical**
  - Divides iterations by using exponential distribution or dynamic distribution.

- **runtime**
  - Defers the scheduling decision until run time.

**n**

Is the size of the chunk or the number of iterations for each chunk. This setting can only be specified for static, dynamic, and guided. For more information, see the descriptions of each keyword below.

Default

**static-balanced**

Iterations are divided into even-sized chunks and the chunks are assigned to the threads in the team in a round-robin fashion in the order of the thread number.

Description

This option lets you specify a scheduling algorithm for loop iterations. It specifies how iterations are to be divided among the threads of the team.

This option is only useful when specified with option [Q]parallel.

This option affects performance tuning and can provide better performance during auto-parallelization. It does nothing if it is used with option [q or Q]openmp.
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[Q]par-schedule-auto</td>
<td>Lets the compiler or run-time system determine the scheduling algorithm. Any possible mapping may occur for iterations to threads in the team.</td>
</tr>
<tr>
<td>[Q]par-schedule-static</td>
<td>Divides iterations into contiguous pieces (chunks) of size $n$. The chunks are assigned to threads in the team in a round-robin fashion in the order of the thread number. Note that the last chunk to be assigned may have a smaller number of iterations. If no $n$ is specified, the iteration space is divided into chunks that are approximately equal in size, and each thread is assigned at most one chunk.</td>
</tr>
<tr>
<td>[Q]par-schedule-static-balanced</td>
<td>Divides iterations into even-sized chunks. The chunks are assigned to the threads in the team in a round-robin fashion in the order of the thread number.</td>
</tr>
<tr>
<td>[Q]par-schedule-static-steal</td>
<td>Divides iterations into even-sized chunks, but when a thread completes its chunk, it can steal parts of chunks assigned to neighboring threads. Each thread keeps track of $L$ and $U$, which represent the lower and upper bounds of its chunks respectively. Iterations are executed starting from the lower bound, and simultaneously, $L$ is updated to represent the new lower bound.</td>
</tr>
<tr>
<td>[Q]par-schedule-dynamic</td>
<td>Can be used to get a set of iterations dynamically. Assigns iterations to threads in chunks as the threads request them. The thread executes the chunk of iterations, then requests another chunk, until no chunks remain to be assigned. As each thread finishes a piece of the iteration space, it dynamically gets the next set of iterations. Each chunk contains $n$ iterations, except for the last chunk to be assigned, which may have fewer iterations. If no $n$ is specified, the default is 1.</td>
</tr>
<tr>
<td>[Q]par-schedule-guided</td>
<td>Can be used to specify a minimum number of iterations. Assigns iterations to threads in chunks as the threads request them. The thread executes the chunk of iterations, then requests another chunk, until no chunks remain to be assigned. For a chunk of size 1, the size of each chunk is proportional to the number of unassigned iterations divided by the number of threads, decreasing to 1. For an $n$ with value $k$ (greater than 1), the size of each chunk is determined in the same way with the restriction that the chunks do not contain fewer than $k$ iterations (except for the last chunk to be assigned, which may have fewer than $k$ iterations). If no $n$ is specified, the default is 1.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>[Q]par-schedule-guided-analytical</td>
<td>Divides iterations by using exponential distribution or dynamic distribution. The method depends on run-time implementation. Loop bounds are calculated with faster synchronization and chunks are dynamically dispatched at run time by threads in the team.</td>
</tr>
<tr>
<td>[Q]par-schedule-runtime</td>
<td>Defers the scheduling decision until run time. The scheduling algorithm and chunk size are then taken from the setting of environment variable OMP_SCHEDULE.</td>
</tr>
</tbody>
</table>

**NOTE**
This option may behave differently on Intel® microprocessors than on non-Intel microprocessors.

**IDE Equivalent**
None

**Alternate Options**
None

**par-threshold, Qpar-threshold**
Sets a threshold for the auto-parallelization of loops.

**Syntax**

**Linux OS and OS X:**
-par-threshold[n]

**Windows OS:**
/Qpar-threshold[:][n]

**Arguments**

\( n \)

Is an integer whose value is the threshold for the auto-parallelization of loops. Possible values are 0 through 100.

If \( n \) is 0, loops get auto-parallelized always, regardless of computation work volume.

If \( n \) is 100, loops get auto-parallelized when performance gains are predicted based on the compiler analysis data. Loops get auto-parallelized only if profitable parallel execution is almost certain.

The intermediate 1 to 99 values represent the percentage probability for profitable speed-up. For example, \( n=50 \) directs the compiler to parallelize only if there is a 50% probability of the code speeding up if executed in parallel.
Loops get auto-parallelized only if profitable parallel execution is almost certain. This is also the default if you do not specify $n$.

**Description**

This option sets a threshold for the auto-parallelization of loops based on the probability of profitable execution of the loop in parallel. To use this option, you must also specify option \( Q \text{parallel} \).

This option is useful for loops whose computation work volume cannot be determined at compile-time. The threshold is usually relevant when the loop trip count is unknown at compile-time.

The compiler applies a heuristic that tries to balance the overhead of creating multiple threads versus the amount of work available to be shared amongst the threads.

**NOTE**

This option may behave differently on Intel® microprocessors than on non-Intel microprocessors.

**IDE Equivalent**

Visual Studio: **Optimization > Threshold For Auto-Parallelization**

Eclipse: None

Xcode: **Optimization > Threshold For Auto-Parallelization**

**Alternate Options**

None

**parallel, Qparallel**

*Tells the auto-parallelizer to generate multithreaded code for loops that can be safely executed in parallel.*

**Syntax**

**Linux OS and OS X:**

- `-parallel`

**Windows OS:**

- `/Qparallel` (or `/Qpar`)

**Arguments**

None

**Default**

*OFF* Multithreaded code is not generated for loops that can be safely executed in parallel.

**Description**

This option tells the auto-parallelizer to generate multithreaded code for loops that can be safely executed in parallel.

To use this option, you must also specify option `O2` or `O3`.

This option sets option `[q or Q]opt-matmul` if option `O3` is also specified.
NOTE
On OS X* systems, when you enable automatic parallelization, you must also set the
DYLD_LIBRARY_PATH environment variable within Xcode* or an error will be displayed.

NOTE
Using this option enables parallelization for both Intel® microprocessors and non-Intel
microprocessors. The resulting executable may get additional performance gain on Intel
microprocessors than on non-Intel microprocessors. The parallelization can also be affected by certain
options, such as /arch or /Qx (Windows OS) or -m or -x (Linux OS and OS X).

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for
optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and
SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or
effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-
dependent optimizations in this product are intended for use with Intel microprocessors. Certain
optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to
the applicable product User and Reference Guides for more information regarding the specific instruction
sets covered by this notice.

qopt-matmul, Qopt-matmul compiler option
O compiler option
parallel-source-info, Qparallel-source-info

Enables or disables source location emission when
OpenMP* or auto-parallelism code is generated.

Syntax

Linux OS and OS X:

-parallel-source-info[=n]
-no-parallel-source-info
**Windows OS:**

/Qparallel-source-info
/Qparallel-source-info-[:n]

**Arguments**

\( n \)  

Is the level of source location emission. Possible values are:

- **0**  
  Disables the emission of source location information when OpenMP* code or auto-parallelism code is generated. This is the same as specifying `-no-parallel-source-info` (Linux* OS and OS X*) or `/Qparallel-source-info-` (Windows* OS).

- **1**  
  Tells the compiler to emit routine name and line information. This is the same as specifying `[Q]parallel-source-info` with no \( n \).

- **2**  
  Tells the compiler to emit path, file, routine name, and line information.

**Default**

- `-parallel-source-info=1`  
  When OpenMP* code or auto-parallelism code is generated, the routine name and line information is emitted.

**Description**

This option enables or disables source location emission when OpenMP code or auto-parallelism code is generated. It also lets you set the level of emission.

**IDE Equivalent**

None

**Alternate Options**

None

**qopenmp, Qopenmp**

Enables the parallelizer to generate multi-threaded code based on OpenMP* directives. Option `-qopenmp` is the replacement option for `-openmp`, which is deprecated.

**Syntax**

**Linux OS and OS X:**

- `-qopenmp`
- `-qno-openmp`

**Windows OS:**

- `/Qopenmp`
- `/Qopenmp-`
**Arguments**

None

**Default**

- `–qno-openmp` or `/Qopenmp–`

No OpenMP* multi-threaded code is generated by the compiler.

**Description**

This option enables the parallelizer to generate multi-threaded code based on OpenMP* directives. The code can be executed in parallel on both uniprocessor and multiprocessor systems.

If you use this option, multithreaded libraries are used, but option `fpp` is not automatically invoked.

This option sets option automatic.

This option works with any optimization level. Specifying no optimization (`-00` on Linux* OS or `/Od` on Windows* OS) helps to debug OpenMP applications.

To ensure that a threadsafe and/or reentrant run-time library is linked and correctly initialized, option `[q` or `Q]openmp` should also be used for the link step and for the compilation of the main routine.

---

**NOTE**

On OS X* systems, when you enable OpenMP* API, you must also set the DYLD_LIBRARY_PATH environment variable within Xcode* or an error will be displayed.

---

**NOTE**

Options that use OpenMP* API are available for both Intel® microprocessors and non-Intel microprocessors, but these options may perform additional optimizations on Intel® microprocessors than they perform on non-Intel microprocessors. The list of major, user-visible OpenMP constructs and features that may perform differently on Intel® microprocessors versus non-Intel microprocessors include: locks (internal and user visible), the SINGLE construct, barriers (explicit and implicit), parallel loop scheduling, reductions, memory allocation, thread affinity, and binding.

---

**Optimization Notice**

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

**IDE Equivalent**

Visual Studio: **Language > Process OpenMP Directives**

Eclipse: None

Xcode: None
Alternate Options

Linux and OS X: -fopenmp
Windows: /openmp

See Also
qopenmp-stubs, Qopenmp-stubs compiler option

qopenmp-lib, Qopenmp-lib
Lets you specify an OpenMP* run-time library to use for linking. Option -qopenmp-lib is the replacement option for -openmp-lib, which is deprecated.

Syntax

Linux OS and OS X:
- qopenmp-lib=type

Windows OS:
/ Qopenmp-lib: type

Arguments

<table>
<thead>
<tr>
<th>type</th>
<th>Specifies the type of library to use; it implies compatibility levels. Currently, the only possible value is:</th>
</tr>
</thead>
<tbody>
<tr>
<td>compat</td>
<td>Tells the compiler to use the compatibility OpenMP* run-time library (libiomp). This setting provides compatibility with object files created using Microsoft* and GNU* compilers.</td>
</tr>
</tbody>
</table>

Default

- qopenmp-lib=compat or /Qopenmp-lib:compat

The compiler uses the compatibility OpenMP* run-time library (libiomp).

Description

This option lets you specify an OpenMP* run-time library to use for linking.

The compatibility OpenMP run-time libraries are compatible with object files created using the Microsoft* OpenMP run-time library (vcomp) or the GNU OpenMP run-time library (libgomp).

To use the compatibility OpenMP run-time library, compile and link your application using the compat setting for option [q or Q]openmp-lib. To use this option, you must also specify one of the following compiler options:

- Linux* OS: -qopenmp or -qopenmp-stubs
- Windows* OS: /Qopenmp or /Qopenmp-stubs

On Windows* systems, the compatibility OpenMP* run-time library lets you combine OpenMP* object files compiled with the Microsoft* C/C++ compiler with OpenMP* object files compiled with the Intel® C, Intel® C++, or Intel® Fortran compilers. The linking phase results in a single, coherent copy of the run-time library.

On Linux* systems, the compatibility Intel OpenMP* run-time library lets you combine OpenMP* object files compiled with the GNU* gcc or gfortran compilers with similar OpenMP* object files compiled with the Intel® C, Intel® C++, or Intel® Fortran compilers. The linking phase results in a single, coherent copy of the run-time library.
You cannot link object files generated by the Intel® Fortran compiler to object files compiled by the GNU Fortran compiler, regardless of the presence or absence of the [Q]openmp compiler option. This is because the Fortran run-time libraries are incompatible.

**NOTE**
The compatibility OpenMP run-time library is not compatible with object files created using versions of the Intel compilers earlier than 10.0.

**NOTE**
On Windows* OS, this option is processed by the compiler, which adds directives to the compiled object file that are processed by the linker. On Linux* OS and OS X*, this option is processed by the ifort command that initiates linking, adding library names explicitly to the link command.

**IDE Equivalent**
None

**Alternate Options**

**qopenmp-link**
Controls whether the compiler links to static or dynamic OpenMP* run-time libraries. Option -qopenmp-link is the replacement option for -openmp-link. Both options are deprecated. There is no replacement option.

**Syntax**

**Linux OS and OS X:**
-qopenmp-link=library

**Windows OS:**
None

**Arguments**

<table>
<thead>
<tr>
<th>library</th>
<th>Specifies the OpenMP library to use. Possible values are:</th>
</tr>
</thead>
<tbody>
<tr>
<td>static</td>
<td>Tells the compiler to link to static OpenMP run-time libraries. Note that static OpenMP libraries are deprecated.</td>
</tr>
<tr>
<td>dynamic</td>
<td>Tells the compiler to link to dynamic OpenMP run-time libraries.</td>
</tr>
</tbody>
</table>
Default
-qopenmp-link=dynamic  The compiler links to dynamic OpenMP* run-time libraries. However, if Linux* OS option -static is specified, the compiler links to static OpenMP run-time libraries.

Description
This option controls whether the compiler links to static or dynamic OpenMP* run-time libraries.
To link to the static OpenMP run-time library (RTL) and create a purely static executable, you must specify -qopenmp-link=static. However, we strongly recommend you use the default setting, -qopenmp-link=dynamic.

NOTE
Compiler options -static-intel and -shared-intel (Linux* OS and OS X*) have no effect on which OpenMP run-time library is linked.

NOTE
On Linux* systems, -qopenmp-link=dynamic cannot be used in conjunction with option -static. If you try to specify both options together, an error will be displayed.

NOTE
On Linux systems, the OpenMP runtime library depends on using libpthread and libc (libgcc when compiled with gcc). Libpthread and libc (libgcc) must both be static or both be dynamic. If both libpthread and libc (libgcc) are static, then the static version of the OpenMP runtime should be used. If both libpthread and libc (libgcc) are dynamic, then either the static or dynamic version of the OpenMP runtime may be used.

IDE Equivalent
None

Alternate Options
None

qopenmp-offload, Qopenmp-offload
Enables or disables OpenMP* offloading compilation for the TARGET directives. This option only applies to Intel® MIC Architecture. Option -qopenmp-offload is the replacement option for -openmp-offload, which is deprecated.

Architecture Restrictions
Only available on Intel® 64 architecture targeting Intel® MIC Architecture

Syntax
Linux OS:
-qopenmp-offload
-qno-openmp-offload
OS X:
None

Windows OS:
/Qopenmp-offload
/Qopenmp-offload-

Arguments
None

Default
-qno-openmp-offload or /Qopenmp-offload- OpenMP* offloading compilation is disabled. However, if option [q or Q]openmp is specified, the default is ON and OpenMP offloading compilation is enabled.

Description
This option enables or disables OpenMP* offloading compilation for the TARGET directives.
You can also use this option if you want to enable or disable the offloading feature with no impact on other OpenMP* features. In this case, no OpenMP runtime library is needed to link and the compiler does not need to generate OpenMP runtime initialization code.
If you specify this option with the [q or Q]openmp option, it can impact other OpenMP* features.

IDE Equivalent
None

Alternate Options
None

Example
Consider the following:
-qno-openmp -qopenmp-offload ! Linux OS
/Qopenmp- /Qopenmp-offload ! Windows OS

The above is equivalent to specifying only [q or Q]openmp-offload. In this case, only the offload library is linked, not the OpenMP* library, and only the !$OMP directives for TARGET are processed but no other !$OMP directives.

Consider the following:
-qopenmp -qopenmp-offload ! Linux OS
/Qopenmp /Qopenmp-offload ! Windows OS

In this case, the offload library is linked, the OpenMP library is linked, and OpenMP runtime initialization code is generated.

**qopenmp-simd, Qopenmp-simd**

*Enables or disables OpenMP* SIMD compilation.*

*Option -qopenmp-simd is the replacement option for -openmp-simd, which is deprecated.*

**Syntax**

**Linux OS:**
- `-qopenmp-simd`
- `-qno-openmp-simd`

**OS X:**
None

**Windows OS:**
- `/Qopenmp-simd`
- `/Qopenmp-simd-`

**Arguments**
None

**Default**

- `-qno-openmp-simd` or `/Qopenmp-simd-`

OpenMP* SIMD compilation is disabled. However, if option `[q or Q]openmp` is specified, the default is ON and OpenMP SIMD compilation is enabled.

**Description**

This option enables or disables OpenMP* SIMD compilation.

You can use this option if you want to enable or disable the SIMD support with no impact on other OpenMP features. In this case, no OpenMP runtime library is needed to link and the compiler does not need to generate OpenMP runtime initialization code.

If you specify this option with the `[q or Q]openmp` option, it can impact other OpenMP features.

**IDE Equivalent**
None

**Alternate Options**
None

**Example**

Consider the following:

```
-qno-openmp -qopenmp-simd    ! Linux OS
/Qopenmp- /Qopenmp-simd      ! Windows OS
```

The above is equivalent to specifying only `[q or Q]openmp-simd`. In this case, only SIMD support is provided, the OpenMP* library is not linked, and only the !$OMP directives related to SIMD are processed.

Consider the following:

```
-qopenmp -qopenmp-simd       ! Linux OS
/Qopenmp /Qopenmp-simd       ! Windows OS
```
In this case, SIMD support is provided, the OpenMP library is linked, and OpenMP runtime initialization code is generated.

**See Also**
qopenmp, Qopenmp compiler option
SIMD Directive (OpenMP* API) directive

**qopenmp-stubs, Qopenmp-stubs**
Enables compilation of OpenMP* programs in sequential mode. Option `-qopenmp-stubs` is the replacement option for `-openmp-stubs`, which is deprecated.

**Syntax**

**Linux OS and OS X:**
- `-qopenmp-stubs`

**Windows OS:**
- `/Qopenmp-stubs`

**Arguments**
None

**Default**
OFF
The library of OpenMP* function stubs is not linked.

**Description**
This option enables compilation of OpenMP* programs in sequential mode. The OpenMP directives are ignored and a stub OpenMP library is linked.

**IDE Equivalent**
Visual Studio: **Language > Process OpenMP Directives**
Eclipse: None
Xcode: **Language > Process OpenMP Directives**

**Alternate Options**
None

**See Also**
qopenmp, Qopenmp compiler option

**qopenmp-threadprivate, Qopenmp-threadprivate**
Lets you specify an OpenMP* threadprivate implementation. Option `-qopenmp-threadprivate` is the replacement option for `-openmp-threadprivate`, which is deprecated.

**Syntax**

**Linux OS:**
- `-qopenmp-threadprivate=type`
OS X:
None

Windows OS:
/Qopenmp-threadprivate:type

Arguments

type

Specifies the type of threadprivate implementation. Possible values are:

- **legacy**
  Tells the compiler to use the legacy OpenMP* threadprivate implementation used in the previous releases of the Intel® compiler. This setting does not provide compatibility with the implementation used by other compilers.

- **compat**
  Tells the compiler to use the compatibility OpenMP* threadprivate implementation based on applying the thread-local attribute to each threadprivate variable. This setting provides compatibility with the implementation provided by the Microsoft* and GNU* compilers.

Default

- `-qopenmp-threadprivate=legacy`
- `/Qopenmp-threadprivate:legacy`

The compiler uses the legacy OpenMP* threadprivate implementation used in the previous releases of the Intel compiler.

Description

This option lets you specify an OpenMP* threadprivate implementation.

The threadprivate implementation of the legacy OpenMP run-time library may not be compatible with object files created using OpenMP run-time libraries supported in other compilers.

To use this option, you must also specify one of the following compiler options:

- Linux* OS: `-qopenmp` or `-qopenmp-stubs`
- Windows* OS: `/Qopenmp` or `/Qopenmp-stubs`

The value specified for this option is independent of the value used for the `[q or Q]openmp-lib` option.

**NOTE**

On Windows* OS, if you specify option `/Qopenmp-threadprivate:compat`, the compiler does not generate threadsafe code for common blocks in an !$OMP THREADPRIVATE directive unless at least one element in the common block is explicitly initialized. For more information, see the article titled: `/Qopenmp-threadprivate:compat` doesn't work with uninitialized threadprivate common blocks, which is located in http://intel.ly/1aHhsjc

**NOTE**

On OS X* systems, legacy is the only type of threadprivate supported. Option `-qopenmp-threadprivate` is not recognized by the compiler.
**Qpar-adjust-stack**

*Tells the compiler to generate code to adjust the stack size for a fiber-based main thread.*

**Syntax**

**Linux OS and OS X:**

None

**Windows OS:**

/Qpar-adjust-stack: *n*

**Arguments**

*n*  
Is the stack size (in bytes) for the fiber-based main thread. It must be a number equal to or greater than zero.

**Default**

/Qpar-adjust-stack: 0  
No adjustment is made to the main thread stack size.

**Description**

This option tells the compiler to generate code to adjust the stack size for a fiber-based main thread. This can reduce the stack size of threads.  
For this option to be effective, you must also specify option /Qparallel.

**IDE Equivalent**

None

**Alternate Options**

None

**See Also**

parallel, Qparallel compiler option

**Floating-Point Options**

**fast-transcendentals, Qfast-transcendentals**

*Enables the compiler to replace calls to transcendental functions with faster but less precise implementations.*

**Syntax**

**Linux OS and OS X:**

-fast-transcendentals

-no-fast-transcendentals
Windows OS:
/Qfast-transcendentals
/Qfast-transcendentals-

Arguments
None

Default
depends on the setting of -fp- If you do not specify option -[no-]fast-transcendentals or option / Qfast-transcendentals [-]:
or /fp (Windows* OS)

- The default is ON if option -fp-model fast or /fp:fast is specified or is in effect.
- The default is OFF if a value-safe setting is specified for -fp-model or /fp (such as "precise", "source", etc.).

Description
This option enables the compiler to replace calls to transcendental functions with implementations that may be faster but less precise.

It allows the compiler to perform certain optimizations on transcendental functions, such as replacing individual calls to sine in a loop with a single call to a less precise vectorized sine library routine.

This option does not affect explicit Short Vector Math Library (SVML) intrinsics. It only affects scalar calls to the standard math library routines.

You cannot use option -fast-transcendentals with option -fp-model strict and you cannot use option /Qfast-transcendentals with option /fp:strict.

This option determines the setting for the maximum allowable relative error for math library function results (max-error) if none of the following options are specified:

- -fimf-accuracy-bits (Linux* OS and OS X*) or /Qimf-accuracy-bits (Windows* OS)
- -fimf-max-error (Linux OS and OS X) or /Qimf-max-error (Windows OS)
- -fimf-precision (Linux OS and OS X) or /Qimf-precision (Windows OS)

This option enables extra optimization that only applies to Intel® processors.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

fimf-max-error, Qimf-max-error compiler option
fimf-precision, Qimf-precision compiler option

fimf-absolute-error, Qimf-absolute-error
Defines the maximum allowable absolute error for math library function results.

Syntax
Linux OS and OS X:
-fimf-absolute-error=value[:funclist]

Windows OS:
/Qimf-absolute-error:value[:funclist]

Arguments
value
Is a positive, floating-point number. Errors in math library function results may exceed the maximum relative error (max-error) setting if the absolute-error is less than or equal to value.
The format for the number is [digits] [.digits] [ { e | E }[sign]digits]

funclist
Is an optional list of one or more math library functions to which the attribute should be applied. If you specify more than one function, they must be separated with commas. Precision-specific variants like sin and sinf are considered different functions, so you would need to use -fimf-absolute-error=0.00001: sin, sinf (or /Qimf-absolute-error: 0.00001: sin, sinf) to specify the maximum allowable absolute error for both the single-precision and double-precision sine functions.
You also can specify the symbol /f to denote single-precision divides, symbol / to denote double-precision divides, symbol /l to denote extended-precision divides, and symbol /q to denote quad-precision divides. For example you can specify -fimf-absolute-error=0.00001:/ or /Qimf-absolute-error: 0.00001:/.

Default
Zero ("0")
An absolute-error setting of 0 means that the function is bound by the relative error setting. This is the default behavior.

Description
This option defines the maximum allowable absolute error for math library function results.
This option can improve run-time performance, but it may decrease the accuracy of results.
This option only affects functions that have zero as a possible return value, such as log, sin, asin, etc.
The relative error requirements for a particular function are determined by options that set the maximum relative error (max-error) and precision. The return value from a function must have a relative error less than the max-error value, or an absolute error less than the absolute-error value.
If you need to define the accuracy for a math function of a certain precision, specify the function name of the precision that you need. For example, if you want double precision, you can specify :sin; if you want single precision, you can specify :sinf, as in -fimf-absolute-error=0.00001:sin or /Qimf-absolute-error:0.00001:sin, or -fimf-absolute-error=0.00001:sqrtf or /Qimf-absolute-error:0.00001:sqrtf.

If you do not specify any function names, then the setting applies to all functions (and to all precisions). However, as soon as you specify an individual function name, the setting applies only to the function of corresponding precision. So, for example, sinf applies only to the single-precision sine function, sin applies only to the double-precision sine function, sinl applies only to the extended-precision sine function, etc.

**NOTE**
Many routines in libraries LIBM (Math Library) and SVML (Short Vector Math Library) are more highly optimized for Intel® microprocessors than for non-Intel microprocessors.

---

fimf-precision, Qimf-precision compiler option

**fimf-accuracy-bits, Qimf-accuracy-bits**

*Defines the relative error for math library function results, including division and square root.*

### Syntax

**Linux OS and OS X:**

- `fimf-accuracy-bits=bits[:funclist]`

**Windows OS:**

/`Qimf-accuracy-bits:bits[:funclist]`
Arguments

bits
Is a positive, floating-point number indicating the number of correct bits the compiler should use.
The format for the number is [digits] [.digits] [ { e | E }[sign]digits].

funclist
Is an optional list of one or more math library functions to which the attribute should be applied. If you specify more than one function, they must be separated with commas. Precision-specific variants like sin and sinf are considered different functions, so you would need to use -fimf-accuracy-bits=23:sin,sinf (or /Qimf-accuracy-bits:23:sin,sinf) to specify the relative error for both the single-precision and double-precision sine functions.
You also can specify the symbol /f to denote single-precision divides, symbol / to denote double-precision divides, symbol /l to denote extended-precision divides, and symbol /q to denote quad-precision divides. For example you can specify -fimf-accuracy-bits=10.0:/f or /Qimf-accuracy-bits:10.0:/f.

Default

-fimf-precision=medium or /Qimf-precision:medium
The compiler uses medium precision when calling math library functions. Note that other options can affect precision; see below for details.

Description

This option defines the relative error, measured by the number of correct bits, for math library function results.
The following formula is used to convert bits into ulps: ulps = 2^{p-1-bits}, where p is the number of the target format mantissa bits (24, 53, and 113 for single, double, and quad precision, respectively).
This option can affect run-time performance and the accuracy of results.
If you need to define the accuracy for a math function of a certain precision, specify the function name of the precision that you need. For example, if you want double precision, you can specify :sin; if you want single precision, you can specify :sinf, as in the following:

- -fimf-accuracy-bits=23:sinf,cosf,logf or /Qimf-accuracy-bits:23:sinf,cosf,logf
- -fimf-accuracy-bits=52:sqrt,,trunc or /Qimf-accuracy-bits:52:sqrt,,trunc
- -fimf-accuracy-bits=10:powf or /Qimf-accuracy-bits:10:powf

If you do not specify any function names, then the setting applies to all functions (and to all precisions). However, as soon as you specify an individual function name, the setting applies only to the function of corresponding precision. So, for example, sinf applies only to the single-precision sine function, sin applies only to the double-precision sine function, sinl applies only to the extended-precision sine function, etc.
There are three options you can use to express the maximum relative error. They are as follows:

- -fimf-precision (Linux* OS and OS X*) or /Qimf-precision (Windows* OS)
- -fimf-max-error (Linux* OS and OS X*) or /Qimf-max-error (Windows* OS)
- -fimf-accuracy-bits (Linux OS and OS X*) or /Qimf-accuracy-bits (Windows OS)

If more than one of these options are specified, the default value for the maximum relative error is determined by the last one specified on the command line.
If none of the above options are specified, the default values for the maximum relative error are determined by the setting of the following options:
- [Q]fast-transcendentals
- [Q]prec-div
- [Q]prec-sqrt
- -fp-model (Linux OS and OS X) or /fp (Windows OS)

**NOTE**
Many routines in libraries LIBM (Math Library) and SVML (Short Vector Math Library) are more highly optimized for Intel® microprocessors than for non-Intel microprocessors.

fimf-precision, Qimf-precision compiler option

**fimf-arch-consistency, Qimf-arch-consistency**
Ensures that the math library functions produce consistent results across different microarchitectural implementations of the same architecture.

**Syntax**

**Linux OS and OS X:**

-`-fimf-arch-consistency=value[:funclist]`

**Windows OS:**

-/Qimf-arch-consistency:value[:funclist]

**Arguments**

`value` Is one of the logical values "true" or "false".
funclist

Is an optional list of one or more math library functions to which the attribute should be applied. If you specify more than one function, they must be separated with commas. Precision-specific variants like sin and sinf are considered different functions, so you would need to use -fimf-arch-consistency=true:sin,sinf (or /Qimf-arch-consistency:true:sin,sinf) to specify consistent results for both the single-precision and double-precision sine functions.

You also can specify the symbol /f to denote single-precision divides, symbol / to denote double-precision divides, symbol /l to denote extended-precision divides, and symbol /q to denote quad-precision divides. For example you can specify -fimf-arch-consistency=true:/ or /Qimf-arch-consistency:true:/.

Default
false

Implementations of some math library functions may produce slightly different results on implementations of the same architecture.

Description

This option ensures that the math library functions produce consistent results across different microarchitectural implementations of the same architecture (for example, across different microarchitectural implementations of IA-32 architecture). Consistency is only guaranteed for a single binary. Consistency is not guaranteed across different architectures. For example, consistency is not guaranteed across IA-32 architecture and Intel® 64 architecture.

If you need to define the accuracy for a math function of a certain precision, specify the function name of the precision that you need. For example, if you want double precision, you can specify :sin; if you want single precision, you can specify :sinf, as in -fimf-arch-consistency=true: sin or /Qimf-arch-consistency:true:sin or -fimf-arch-consistency=false:sqrtf or /Qimf-arch-consistency:false:sqrtf.

If you do not specify any function names, then the setting applies to all functions (and to all precisions). However, as soon as you specify an individual function name, the setting applies only to the function of corresponding precision. So, for example, sinf applies only to the single-precision sine function, sin applies only to the double-precision sine function, sinl applies only to the extended-precision sine function, etc.

The -fimf-arch-consistency (Linux® OS and OS X®) and /Qimf-arch-consistency (Windows® OS) option may decrease run-time performance, but the option will provide bit-wise consistent results on all Intel® processors and compatible, non-Intel processors, regardless of micro-architecture. This option may not provide bit-wise consistent results between different architectures, for example, between IA-32 and Intel® 64 architectures, or between Intel® 64 architecture and Intel® MIC Architecture.

NOTE

Many routines in libraries LIBM (Math Library) and SVML (Short Vector Math Library) are more highly optimized for Intel® microprocessors than for non-Intel microprocessors.

Optimization Notice

Intel’s compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain
### Optimization Notice

Optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

#### IDE Equivalent

None

#### Alternate Options

None

#### See Also

- `fimf-absolute-error, Qimf-absolute-error` compiler option
- `fimf-accuracy-bits, Qimf-accuracy-bits` compiler option
- `fimf-domain-exclusion, Qimf-domain-exclusion` compiler option
- `fimf-max-error, Qimf-max-error` compiler option
- `fimf-precision, Qimf-precision` compiler option

#### Syntax

**Linux OS and OS X:**

```
-fimf-domain-exclusion=classlist[:funclist]
```

**Windows OS:**

```
/Qimf-domain-exclusion:classlist[:funclist]
```

#### Arguments

`classlist`  

`classlist` is one of the following:

- One or more of the following floating-point value classes you can exclude from the function domain without affecting the correctness of your program. The supported class names are:

  - **extremes**: This class is for values which do not lie within the usual domain of arguments for a given function.
  - **nans**: This means "x=Nan".
  - **infinities**: This means "x=infinities".
  - **denormals**: This means "x=denormal".
  - **zeros**: This means "x=0".

  Each `classlist` element corresponds to a power of two. The exclusion attribute is the logical or of the associated powers of two (that is, a bitmask).
The following shows the current mapping from `classlist` mnemonics to numerical values:

<table>
<thead>
<tr>
<th>classlist</th>
<th>numerical value</th>
</tr>
</thead>
<tbody>
<tr>
<td>extremes</td>
<td>1</td>
</tr>
<tr>
<td>nans</td>
<td>2</td>
</tr>
<tr>
<td>infinities</td>
<td>4</td>
</tr>
<tr>
<td>denormals</td>
<td>8</td>
</tr>
<tr>
<td>zeros</td>
<td>16</td>
</tr>
<tr>
<td>none</td>
<td>0</td>
</tr>
<tr>
<td>all</td>
<td>31</td>
</tr>
<tr>
<td>common</td>
<td>15</td>
</tr>
<tr>
<td>other combinations</td>
<td>bitwise OR of the used values</td>
</tr>
</tbody>
</table>

You must specify the integer value that corresponds to the class that you want to exclude.

Note that on excluded values, unexpected results may occur.

- One of the following short-hand tokens:

  - **none**
    
    This means that none of the supported classes are excluded from the domain. To indicate this token, specify 0, as in `-fimf-domain-exclusion=0` (or `/Qimf-domain-exclusion:0`).

  - **all**
    
    This means that all of the supported classes are excluded from the domain. To indicate this token, specify 31, as in `-fimf-domain-exclusion=31` (or `/Qimf-domain-exclusion:31`).

  - **common**
    
    This is the same as specifying extremes, nans, infinities, denormals. To indicate this token, specify 15 \((1 + 2 + 4 + 8)\), as in `-fimf-domain-exclusion=15` (or `/Qimf-domain-exclusion:15`).

**funclist**

Is an optional list of one or more math library functions to which the attribute should be applied. If you specify more than one function, they must be separated with commas. Precision-specific variants like `sin` and `sinf` are considered different functions, so you would need to use `-fimf-domain-exclusion=4:sin,sinf` (or `/Qimf-domain-exclusion:4:sin,sinf`) to specify infinities for both the single-precision and double-precision sine functions.

You also can specify the symbol `/f` to denote single-precision divides, symbol `/` to denote double-precision divides, symbol `/l` to denote extended-precision divides, and symbol `/q` to denote quad-precision divides. For example, you can specify:

- `-fimf-domain-exclusion=4` or `/Qimf-domain-exclusion:4`
If you don’t specify argument funclist, the domain restrictions apply to all math library functions.

Default
Zero (“0”) The compiler uses default heuristics when calling math library functions.

Description
This option indicates the input arguments domain on which math functions must provide correct results. It specifies that your program will function correctly if the functions specified in funclist do not produce standard conforming results on the number classes.

This option can affect run-time performance and the accuracy of results. As more classes are excluded, faster code sequences can be used.

If you need to define the accuracy for a math function of a certain precision, specify the function name of the precision that you need. For example, if you want double precision, you can specify :sin; if you want single precision, you can specify :sinf, as in -fimf-domain-exclusion=denormals:sin or /Qimf-domain-exclusion:denormals:sin, or -fimf-domain-exclusion=extremes:sqrtf or /Qimf domain-exclusion:extremes:sqrtf.

If you do not specify any function names, then the setting applies to all functions (and to all precisions). However, as soon as you specify an individual function name, the setting applies only to the function of corresponding precision. So, for example, sinf applies only to the single-precision sine function, sin applies only to the double-precision sine function, sinl applies only to the extended-precision sine function, etc.

NOTE
Many routines in libraries LIBM (Math Library) and SVML (Short Vector Math Library) are more highly optimized for Intel® microprocessors than for non-Intel microprocessors.
Example

Consider the following single-precision sequence for function exp2f:

<table>
<thead>
<tr>
<th>Operation:</th>
<th>y = exp2f(x)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accuracy:</td>
<td>1.014 ulp</td>
</tr>
<tr>
<td>Instructions:</td>
<td>4 (2 without fix-up)</td>
</tr>
</tbody>
</table>

The following shows the 2-instruction sequence without the fix-up:

```
vcvtfxpntps2dq  zmm1 {k1}, zmm0, 0x50 // zmm1 <-- rndToInt(2^24 * x)
vexp223ps       zmm1 {k1}, zmm1            // zmm1 <-- exp2(x)
```

However, the above 2-instruction sequence will not correctly process NaNs. To process NaNs correctly, the following fix-up must be included following the above instruction sequence:

```
vpxord          zmm2, zmm2, zmm2             // zmm2 <-- 0
vfixupnanps     zmm1 {k1}, zmm0, zmm2 {aaaa} // zmm1 <-- QNaN(x) if x is NaN <F>
```

If the `vfixupnanps` instruction is not included, the sequence correctly processes any arguments except NaN values. For example, the following options generate the 2-instruction sequence:

```
-fimf-domain-exclusion=2:exp2f      <- NaN’s are excluded (2 corresponds to NaNs)
-fimf-domain-exclusion=6:exp2f      <- NaN’s and infinities are excluded (4 corresponds to infinities; 2 + 4 = 6)
-fimf-domain-exclusion=7:exp2f      <- NaN’s, infinities, and extremes are excluded (1 corresponds to extremes; 2 + 4 + 1 = 7)
-fimf-domain-exclusion=15:exp2f     <- NaN’s, infinities, extremes, and denormals are excluded (8 corresponds to denormals; 2 + 4 + 1 + 8=15)
```

If the `vfixupnanps` instruction is included, the sequence correctly processes any arguments including NaN values. For example, the following options generate the 4-instruction sequence:

```
-fimf-domain-exclusion=1:exp2f      <- only extremes are excluded (1 corresponds to extremes)
-fimf-domain-exclusion=4:exp2f      <- only infinities are excluded (4 corresponds to infinities)
-fimf-domain-exclusion=8:exp2f      <- only denormals are excluded (8 corresponds to denormals)
-fimf-domain-exclusion=13:exp2f     <- only extremes, infinities and denormals are excluded (1 + 4 + 8 = 13)
```

`fimf-precision`, `Qimf-precision` compiler option

`fimf-max-error`, `Qimf-max-error`

Defines the maximum allowable relative error for math library function results, including division and square root.

Syntax

Linux OS and OS X:

```
-fimf-max-error=ulps[:funclist]
```

Windows OS:

```
/Qimf-max-error:ulps[:funclist]
```
Arguments

ulps
Is a positive, floating-point number indicating the maximum allowable relative error the compiler should use.

The format for the number is [digits] [.digits] [ { e | E }[sign]digits].

funclist
Is an optional list of one or more math library functions to which the attribute should be applied. If you specify more than one function, they must be separated with commas. Precision-specific variants like sin and sinf are considered different functions, so you would need to use -fimf-max-error=4.0:sin,sinf (or /Qimf-max-error=4.0:sin,sinf) to specify the maximum allowable relative error for both the single-precision and double-precision sine functions.

You also can specify the symbol /f to denote single-precision divides, symbol / to denote double-precision divides, symbol /l to denote extended-precision divides, and symbol /q to denote quad-precision divides. For example you can specify -fimf-max-error=4.0:/ or /Qimf-max-error:4.0:/. 

Default

-fimf-precision=medium or /Qimf-precision:medium
The compiler uses medium precision when calling math library functions. Note that other options can affect precision; see below for details.

Description

This option defines the maximum allowable relative error, measured in ulps, for math library function results. This option can affect run-time performance and the accuracy of results.

If you need to define the accuracy for a math function of a certain precision, specify the function name of the precision that you need. For example, if you want double precision, you can specify :sin; if you want single precision, you can specify :sinf, as in -fimf-max-error=4.0:sin or /Qimf-max-error:4.0:sin, or -fimf-max-error=4.0:sqrtf or /Qimf-max-error:4.0:sqrtf.

If you do not specify any function names, then the setting applies to all functions (and to all precisions). However, as soon as you specify an individual function name, the setting applies only to the function of corresponding precision. So, for example, sinf applies only to the single-precision sine function, sin applies only to the double-precision sine function, sinl applies only to the extended-precision sine function, etc.

There are three options you can use to express the maximum relative error. They are as follows:

- -fimf-precision (Linux* OS and OS X*) or /Qimf-precision (Windows* OS)
- -fimf-max-error (Linux* OS and OS X*) or /Qimf-max-error (Windows* OS)
- -fimf-accuracy-bits (Linux OS and OS X*) or /Qimf-accuracy-bits (Windows OS)

If more than one of these options are specified, the default value for the maximum relative error is determined by the last one specified on the command line.

If none of the above options are specified, the default values for the maximum relative error are determined by the setting of the following options:

- [Q]fast-transcendentals
- [Q]prec-div
- [Q]prec-sqrt
- -fp-model (Linux OS and OS X) or /fp (Windows OS)
NOTE
Many routines in libraries LIBM (Math Library) and SVML (Short Vector Math Library) are more highly optimized for Intel® microprocessors than for non-Intel microprocessors.

fimf-precision, Qimf-precision compiler option

**fimf-precision, Qimf-precision**
Lets you specify a level of accuracy (precision) that the compiler should use when determining which math library functions to use.

Syntax

**Linux OS and OS X:**

```
-fimf-precision[=value[:funclist]]
```

**Windows OS:**

```
/Qimf-precision[:value[:funclist]]
```

Arguments

<table>
<thead>
<tr>
<th>value</th>
<th>Is one of the following values denoting the desired accuracy:</th>
</tr>
</thead>
<tbody>
<tr>
<td>high</td>
<td>This is equivalent to max-error = 0.6.</td>
</tr>
<tr>
<td>medium</td>
<td>This is equivalent to max-error = 4; this is the default setting if the option is specified and value is omitted.</td>
</tr>
</tbody>
</table>
This is equivalent to accuracy-bits = 11 for single-precision functions; accuracy-bits = 26 for double-precision functions.

In the above explanations, max-error means option -fimf-max-error (Linux* OS and OS X*) or /Qimf-max-error (Windows* OS); accuracy-bits means option -fimf-accuracy-bits (Linux* OS and OS X*) or /Qimf-accuracy-bits (Windows* OS).

funclist

Is an optional list of one or more math library functions to which the attribute should be applied. If you specify more than one function, they must be separated with commas. Precision-specific variants like sin and sinf are considered different functions, so you would need to use -fimf-precision=high:sin,sinf (or /Qimf-precision=high:sin,sinf) to specify high precision for both the single-precision and double-precision sine functions.

You also can specify the symbol /f to denote single-precision divides, symbol / to denote double-precision divides, symbol /l to denote extended-precision divides, and symbol /q to denote quad-precision divides. For example you can specify -fimf-precision=low:/ or /Qimf-precision:low:/ and -fimf-precision=low:/f or /Qimf-precision:low:/f.

Default

medium

The compiler uses medium precision when calling math library functions. Note that other options can affect precision; see below for details.

Description

This option lets you specify a level of accuracy (precision) that the compiler should use when determining which math library functions to use.

This option can be used to improve run-time performance if reduced accuracy is sufficient for the application, or it can be used to increase the accuracy of math library functions selected by the compiler.

In general, using a lower precision can improve run-time performance and using a higher precision may reduce run-time performance.

If you need to define the accuracy for a math function of a certain precision, specify the function name of the precision that you need. For example, if you want double precision, you can specify :sin; if you want single precision, you can specify :sinf, as in -fimf-precision=low:sin or /Qimf-precision=low:sin, or -fimf-precision=high:sqrtf or /Qimf-precision=high:sqrtf.

If you do not specify any function names, then the setting applies to all functions (and to all precisions). However, as soon as you specify an individual function name, the setting applies only to the function of corresponding precision. So, for example, sinf applies only to the single-precision sine function, sin applies only to the double-precision sine function, sinl applies only to the extended-precision sine function, etc.

There are three options you can use to express the maximum relative error. They are as follows:

- -fimf-precision (Linux* OS and OS X*) or /Qimf-precision (Windows* OS)
- -fimf-max-error (Linux* OS and OS X*) or /Qimf-max-error (Windows* OS)
- -fimf-accuracy-bits (Linux OS and OS X*) or /Qimf-accuracy-bits (Windows OS)

If more than one of these options are specified, the default value for the maximum relative error is determined by the last one specified on the command line.
If none of the above options are specified, the default values for the maximum relative error are determined by the setting of the following options:

- [Q]fast-transcendentals
- [Q]prec-div
- [Q]prec-sqrt
- -fp-model (Linux OS and OS X) or /fp (Windows OS)

**NOTE**

Many routines in libraries LIBM (Math Library) and SVML (Short Vector Math Library) are more highly optimized for Intel® microprocessors than for non-Intel microprocessors.

**fltconsistency**

Enables improved floating-point consistency.

**Architecture Restrictions**

Not available on Intel® 64 architecture targeting the Intel® Xeon Phi™ coprocessor x100 product family (formerly code name Knights Corner)

**Syntax**

**Linux OS and OS X:**

- -fltconsistency
-nofltconsistency

**Windows OS:**

/fltconsistency

/nofltconsistency

**Arguments**

None

**Default**

nofltconsistency  

Improved floating-point consistency is not enabled. This setting provides better accuracy and run-time performance at the expense of less consistent floating-point results.

**Description**

This option enables improved floating-point consistency and may slightly reduce execution speed. It limits floating-point optimizations and maintains declared precision. It also disables inlining of math library functions.

Floating-point operations are not reordered and the result of each floating-point operation is stored in the target variable rather than being kept in the floating-point processor for use in a subsequent calculation.

For example, the compiler can change floating-point division computations into multiplication by the reciprocal of the denominator. This change can alter the results of floating-point division computations slightly.

Floating-point intermediate results are kept in full 80 bits internal precision. Additionally, all spills/reloads of the X87 floating point registers are done using the internal formats; this prevents accidental loss of precision due to spill/reload behavior over which you have no control.

Specifying this option has the following effects on program compilation:

- Floating-point user variables are not assigned to registers.
- Floating-point arithmetic comparisons conform to IEEE 754.
- The exact operations specified in the code are performed. For example, division is never changed to multiplication by the reciprocal.
- The compiler performs floating-point operations in the order specified without reassociation.
- The compiler does not perform constant folding on floating-point values. Constant folding also eliminates any multiplication by 1, division by 1, and addition or subtraction of 0. For example, code that adds 0.0 to a number is executed exactly as written. Compile-time floating-point arithmetic is not performed to ensure that floating-point exceptions are also maintained.
- Whenever an expression is spilled, it is spilled as 80 bits (extended precision), not 64 bits (DOUBLE PRECISION). When assignments to type REAL and DOUBLE PRECISION are made, the precision is rounded from 80 bits down to 32 bits (REAL) or 64 bits (DOUBLE PRECISION). When you do not specify /fltconsistency, the extra bits of precision are not always rounded away before the variable is reused.
- Even if vectorization is enabled by the [Q]x option, the compiler does not vectorize reduction loops (loops computing the dot product) and loops with mixed precision types. Similarly, the compiler does not enable certain loop transformations. For example, the compiler does not transform reduction loops to perform partial summation or loop interchange.

This option causes performance degradation relative to using default floating-point optimization flags.

On Windows systems, an alternative is to use the /Qprec option, which should provide better than default floating-point precision while still delivering good floating-point performance.

The recommended method to control the semantics of floating-point calculations is to use option -fp-model (Linux* OS and OS X*) or /fp (Windows* OS).

mp1, Qprec compiler option
fp-model, fp compiler option

fma, Qfma
*Determine whether the compiler generates fused multiply-add (FMA) instructions if such instructions exist on the target processor.*

Syntax

**Linux OS and OS X:**

- `-fma`
- `-no-fma`

**Windows OS:**

- `/Qfma`
- `/Qfma-`

Arguments
None

Default

- `-fma`
- `/Qfma`

If the instructions exist on the target processor, the compiler generates fused multiply-add (FMA) instructions.

However, if you specify `-fp-model strict (Linux* OS and OS X*)` or `/fp:strict (Windows* OS), but do not explicitly specify `-fma` or `/Qfma`, the default is `-no-fma` or `/Qfma-`.

Description

This option determines whether the compiler generates fused multiply-add (FMA) instructions if such instructions exist on the target processor. When the `[Q]fma` option is specified, the compiler may generate FMA instructions for combining multiply and add operations. When the negative form of the `[Q]fma` option is specified, the compiler must generate separate multiply and add instructions with intermediate rounding.

This option has no effect unless setting CORE-AVX2 or higher is specified for option `[Q]x, -march (Linux OS and OS X), or /arch (Windows OS).
IDE Equivalent
None

fp-model, fp
Controls the semantics of floating-point calculations.

Syntax
Linux OS and OS X:
-fp-model keyword

Windows OS:
/fp:keyword

Arguments

keyword
Specifies the semantics to be used. Possible values are:

precise
Disables optimizations that are not value-safe on floating-point data and rounds intermediate results to source-defined precision.

fast[=1|2]
Enables more aggressive optimizations on floating-point data.

strict
Enables precise and except, disables contractions, and enables the property that allows modification of the floating-point environment.

source
Rounds intermediate results to source-defined precision.

[no-]except
Determines whether strict floating-point exception semantics are honored.

(Linux* OS and OS X*) or except[-]
(Windows* OS)

Default

-fp-model fast=1
or /fp:fast=1
The compiler uses more aggressive optimizations on floating-point calculations.

Description
This option controls the semantics of floating-point calculations.
The keywords can be considered in groups:

- Group A: precise, fast, strict
• Group B: source
• Group C: except (or the negative form)

You can use more than one keyword. However, the following rules apply:

• You cannot specify fast and except together in the same compilation. You can specify any other combination of group A, group B, and group C. Since fast is the default, you must not specify except without a group A or group B keyword.
• You should specify only one keyword from group A and only one keyword from group B. If you try to specify more than one keyword from either group A or group B, the last (rightmost) one takes effect.
• If you specify except more than once, the last (rightmost) one takes effect.

The floating-point (FP) environment is a collection of registers that control the behavior of FP machine instructions and indicate the current FP status. The floating-point environment may include rounding-mode controls, exception masks, flush-to-zero controls, exception status flags, and other floating-point related features.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-fp-model precise or /fp:precise</td>
<td>Tells the compiler to strictly adhere to value-safe optimizations when implementing floating-point calculations. It disables optimizations that can change the result of floating-point calculations. These semantics ensure the reproducibility of floating-point computations for serial code, including code vectorized or auto-parallelized by the compiler, but they may slow performance. They do not ensure value safety or run-to-run reproducibility of other parallel code. Run-to-run reproducibility for floating-point reductions in OpenMP* code may be obtained for a fixed number of threads through the KMP_DETERMINISTIC_REDUCTION environment variable. For more information about this environment variable, see topic &quot;Supported Environment Variables&quot;. The compiler assumes the default floating-point environment; you are not allowed to modify it. Note that option fp-model precise is converted to fp-model source and option fp:precise is converted to fp:source. Floating-point exception semantics are disabled by default. To enable these semantics, you must also specify -fp-model except or /fp:except. Note that option fp-model precise enables option assume protect-parens, which tells the optimizer to honor parentheses in REAL and COMPLEX expression evaluations by not reassociating operations.</td>
</tr>
<tr>
<td>-fp-model fast[=1</td>
<td>2] or /fp:fast[=1</td>
</tr>
</tbody>
</table>
Option | Description
--- | ---
Specifying fast is the same as specifying fast=1. fast=2 may produce faster and less accurate results.
Floating-point exception semantics are disabled by default and they cannot be enabled because you cannot specify fast and except together in the same compilation. To enable exception semantics, you must explicitly specify another keyword (see other keyword descriptions for details).

- **-fp-model strict or /fp:strict**
  Tells the compiler to strictly adhere to value-safe optimizations when implementing floating-point calculations and enables floating-point exception semantics. This is the strictest floating-point model.
  The compiler does not assume the default floating-point environment; you are allowed to modify it.
  Floating-point exception semantics can be disabled by explicitly specifying -fp-model no-except or /fp:except-.

- **-fp-model source or /fp:source**
  This option causes intermediate results to be rounded to the precision defined in the source code. It also implies keyword precise unless it is overridden by a keyword from Group A.
  The compiler assumes the default floating-point environment; you are not allowed to modify it.
  Note that option fp-model source enables option assume protect-parens, which tells the optimizer to honor parentheses in REAL and COMPLEX expression evaluations by not reassociating operations.

- **-fp-model except or /fp:except**
  Tells the compiler to follow strict floating-point exception semantics.

The **-fp-model** and **/fp** options determine the setting for the maximum allowable relative error for math library function results (max-error) if none of the following options are specified:
- `-fimf-accuracy-bits (Linux* OS and OS X*) or /Qimf-accuracy-bits (Windows* OS)`
- `-fimf-max-error (Linux OS and OS X) or /Qimf-max-error (Windows OS)`
- `-fimf-precision (Linux OS and OS X) or /Qimf-precision (Windows OS)`
- `[Q]fast-transcendentals

**NOTE**
This option cannot be used to change the default (source) precision for the calculation of intermediate results.
NOTE
On Windows and Linux operating systems on IA-32 architecture, the compiler, by default, implements floating-point (FP) arithmetic using SSE2 and SSE instructions. This can cause differences in floating-point results when compared to previous x87 implementations.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

The article titled: Consistency of Floating-Point Results using the Intel® Compiler, which is located in http://software.intel.com/en-us/articles/consistency-of-floating-point-results-using-the-intel-compiler/

fp-port, Qfp-port
Rounds floating-point results after floating-point operations.
Syntax

Linux OS and OS X:
- fp-port
- no-fp-port

Windows OS:
/Qfp-port
/Qfp-port-

Arguments
None

Default

-no-fp-port
or/Qfp-port-

The default rounding behavior depends on the compiler's code generation decisions and the precision parameters of the operating system.

Description
This option rounds floating-point results after floating-point operations.

This option is designed to be used with the -mia32 (Linux* OS and OS X*) or /arch:IA32 (Windows* OS) option on a 32-bit compiler. Under those conditions, the compiler implements floating-point calculations using the x87 instruction set, which uses an internal precision that may be higher than the precision specified in the program.

By default, the compiler may keep results of floating-point operations in this higher internal precision. Rounding to program precision occurs at unspecified points. This provides better performance, but the floating-point results are less deterministic. The [Q]fp-port option rounds floating-point results to user-specified precision at assignments and type conversions. This has some impact on speed.

When compiling for newer architectures, the compiler implements floating-point calculations with different instructions, such as Intel® SSE and SSE2. These Intel® Streaming SIMD Extensions round directly to single precision or double precision at every instruction. In these cases, option [Q]fp-port has no effect.

IDE Equivalent
Visual Studio: Floating-Point > Round Floating-Point Results
Eclipse: None
Xcode: Floating-Point > Round Floating-Point Results

Alternate Options
None

Understanding Floating-point Operations

fp-speculation, Qfp-speculation

Tells the compiler the mode in which to speculate on floating-point operations.

Syntax

Linux OS and OS X:
- fp-speculation=mode
Windows OS:
/Qfp-speculation:mode

Arguments

mode Is the mode for floating-point operations. Possible values are:

- fast Tells the compiler to speculate on floating-point operations.
- safe Tells the compiler to disable speculation if there is a possibility that the speculation may cause a floating-point exception.
- strict Tells the compiler to disable speculation on floating-point operations.
- off This is the same as specifying strict.

Default

-fp-speculation=fast or /Qfp-speculation:fast The compiler speculates on floating-point operations. This is also the behavior when optimizations are enabled. However, if you specify no optimizations (-00 on Linux* OS; /Od on Windows* OS), the default is -fp-speculation=safe (Linux* OS) or /Qfp-speculation:safe (Windows* OS).

Description

This option tells the compiler the mode in which to speculate on floating-point operations. Disabling speculation may prevent the vectorization of some loops containing conditionals. For an example, see this article.

IDE Equivalent

Visual Studio: Floating Point > Floating-Point Speculation
Eclipse: None
Xcode: Floating Point > Floating-Point Speculation

Alternate Options

None

fp-stack-check, Qfp-stack-check

Tells the compiler to generate extra code after every function call to ensure that the floating-point stack is in the expected state.

Syntax

Linux OS and OS X:
-fp-stack-check

Windows OS:
/Qfp-stack-check
Arguments
None

Default
OFF

There is no checking to ensure that the floating-point (FP) stack is in the expected state.

Description
This option tells the compiler to generate extra code after every function call to ensure that the floating-point (FP) stack is in the expected state.

By default, there is no checking. So when the FP stack overflows, a NaN value is put into FP calculations and the program's results differ. Unfortunately, the overflow point can be far away from the point of the actual bug. This option places code that causes an access violation exception immediately after an incorrect call occurs, thus making it easier to locate these issues.

IDE Equivalent
Visual Studio: Floating-Point > Check Floating-point Stack
Eclipse: None
Xcode: Floating-Point > Check Floating-point Stack

Alternate Options
None

fpe
Allows some control over floating-point exception handling for the main program at run-time.

Architecture Restrictions
Not available on Intel® 64 architecture targeting the Intel® Xeon Phi™ coprocessor x100 product family (formerly code name Knights Corner)

Syntax
Linux OS and OS X:
- fpe \( n \)

Windows OS:
/ fpe : \( n \)

Arguments
\( n \)

Specifies the floating-point exception handling level. Possible values are:

0
Floating-point invalid, divide-by-zero, and overflow exceptions are enabled throughout the application when the main program is compiled with this value. If any such exceptions occur, execution is aborted. This option causes denormalized floating-point results to be set to zero. Underflow results will also be set to zero, unless you override this by explicitly
specifying option -no-ftz or -fp-model precise (Linux* OS and OS X*) or option /Qftz- or /fp:precise (Windows* OS).

Underflow results from SSE instructions, as well as x87 instructions, will be set to zero. By contrast, option [Q]ftz only sets SSE underflow results to zero.

Sets option -fp-speculation=strict (Linux* and OS X*) or /Qfp-speculation:strict (Windows*) for any program unit compiled with -fpe0 (Linux* and OS X*) or /fpe:0 (Windows*). This disables certain optimizations in cases where speculative execution of floating-point operations could lead to floating-point exceptions that would not occur in the absence of speculation. For example, this may prevent the vectorization of some loops containing conditionals.

To get more detailed location information about where the error occurred, use option traceback.

1

All floating-point exceptions are disabled. Underflow results from SSE instructions, as well as x87 instructions, will be set to zero.

3

All floating-point exceptions are disabled. Floating-point underflow is gradual, unless you explicitly specify a compiler option that enables flush-to-zero, such as [Q]ftz, O3, or O2. This setting provides full IEEE support.

Default

-fpe3 or /fpe:3

All floating-point exceptions are disabled. Floating-point underflow is gradual, unless you explicitly specify a compiler option that enables flush-to-zero.

Description

This option allows some control over floating-point exception handling at run-time. This includes whether exceptional floating-point values are allowed and how precisely run-time exceptions are reported.

The fpe option affects how the following conditions are handled:

- When floating-point calculations result in a divide by zero, overflow, or invalid operation.
- When floating-point calculations result in an underflow.
- When a denormalized number or other exceptional number (positive infinity, negative infinity, or a NaN) is present in an arithmetic expression.

When enabled exceptions occur, execution is aborted and the cause of the abort reported to the user. If compiler option traceback is specified at compile time, detailed information about the location of the abort is also reported.

This option does not enable underflow exceptions, input denormal exceptions, or inexact exceptions.
IDE Equivalent

Visual Studio: Floating-Point > Floating-Point Exception Handling
Eclipse: None
Xcode: Floating-Point > Floating-Point Exception Handling

Alternate Options

None

fpe-all
Allows some control over floating-point exception handling for each routine in a program at run-time.

Architecture Restrictions

Not available on Intel® 64 architecture targeting the Intel® Xeon Phi™ coprocessor x100 product family (formerly code name Knights Corner)

Syntax

Linux OS and OS X:

-fpe-all=n

Windows OS:

/fpe-all:n

Arguments

n

Specifies the floating-point exception handling level. Possible values are:

0
Floating-point invalid, divide-by-zero, and overflow exceptions are enabled. If any such exceptions occur, execution is aborted. This option sets the [Q]ftz option; therefore underflow results will be set to zero unless you explicitly specify -no-ftz (Linux OS and OS X) or /Qftz- (Windows OS).

To get more detailed location information about where the error occurred, use option traceback.

1
All floating-point exceptions are disabled.

Underflow results from SSE instructions, as well as x87 instructions, will be set to zero.
All floating-point exceptions are disabled. Floating-point underflow is gradual, unless you explicitly specify a compiler option that enables flush-to-zero, such as [Q]ftz, O3, or O2. This setting provides full IEEE support.

**Default**

-fpe-all=3 or /fpe-all:3 or  

All floating-point exceptions are disabled. Floating-point underflow is gradual, unless you explicitly specify a compiler option that enables flush-to-zero.

**Description**

This option allows some control over floating-point exception handling for each routine in a program at runtime. This includes whether exceptional floating-point values are allowed and how precisely run-time exceptions are reported.

The `fpe-all` option affects how the following conditions are handled:

- When floating-point calculations result in a divide by zero, overflow, or invalid operation.
- When floating-point calculations result in an underflow.
- When a denormalized number or other exceptional number (positive infinity, negative infinity, or a NaN) is present in an arithmetic expression.

The current settings of the floating-point exception and status flags are saved on each routine entry and restored on each routine exit. This may incur some performance overhead.

When option `fpe-all` is applied to a main program, it has the same effect as when option `fpe` is applied to the main program.

When enabled exceptions occur, execution is aborted and the cause of the abort reported to the user. If compiler option `traceback` is specified at compile time, detailed information about the location of the abort is also reported.

This option does not enable underflow exceptions, input denormal exceptions, or inexact exceptions.

Option `fpe-all` sets option `assume ieee_fpe_flags`.

**IDE Equivalent**

None

**Alternate Options**

None

**See Also**

assume compiler option  
fpe compiler option  
ftz, Qftz compiler option  
traceback compiler option

**ftz, Qftz**

Flashes denormal results to zero.

**Syntax**

Linux OS and OS X:

-ftz
-no-ftz

Windows OS:
/Qftz
/Qftz-

Arguments
None

Default
-ftz or /Qftz

Denormal results are flushed to zero.
Every optimization option O level, except O0, sets [Q]ftz.
Value 0 for the [Q]fpe option sets [Q]ftz.

Description
This option flushes denormal results to zero when the application is in the gradual underflow mode. It may improve performance if the denormal values are not critical to your application’s behavior.
The [Q]ftz option has no effect during compile-time optimization.
The [Q]ftz option sets or resets the FTZ and the DAZ hardware flags. If FTZ is ON, denormal results from floating-point calculations will be set to the value zero. If FTZ is OFF, denormal results remain as is. If DAZ is ON, denormal values used as input to floating-point instructions will be treated as zero. If DAZ is OFF, denormal instruction inputs remain as is. Systems using Intel® 64 architecture have both FTZ and DAZ. FTZ and DAZ are not supported on all IA-32 architectures.

When the [Q]ftz option is used in combination with an SSE-enabling option on systems using IA-32 architecture (for example, the [Q]xSSE2 option), the compiler will insert code in the main routine to set FTZ and DAZ. When [Q]ftz is used without such an option, the compiler will insert code to conditionally set FTZ/DAZ based on a run-time processor check. The negative form of option [Q]ftz will prevent the compiler from inserting any code that might set FTZ or DAZ.

Option [Q]ftz only has an effect when the main program is being compiled. It sets the FTZ/DAZ mode for the process. The initial thread and any threads subsequently created by that process will operate in FTZ/DAZ mode.

If this option produces undesirable results of the numerical behavior of your program, you can turn the FTZ/DAZ mode off by using -no-ftz or /Qftz- in the command line while still benefiting from the O3 optimizations.

NOTE
Option [Q]ftz is a performance option. Setting this option does not guarantee that all denormals in a program are flushed to zero. The option only causes denormals generated at run time to be flushed to zero.

Setting the FTZ and DAZ Flags

Ge
Enables stack-checking for all functions. This is a deprecated option. The replacement option is /Gs0.

Syntax
Linux OS and OS X:
None

Windows OS:
/Ge

Arguments
None

Default
OFF Stack-checking for all functions is disabled.

Description
This option enables stack-checking for all functions.

IDE Equivalent
None

Alternate Options
Linux and OS X: None
Windows: /Gs0

mp1, Qprec
Improves floating-point precision and consistency.

Syntax
Linux OS and OS X:
-mp1

Windows OS:
/Qprec

Arguments
None
Default
OFF

The compiler provides good accuracy and run-time performance at the expense of less consistent floating-point results.

Description
This option improves floating-point consistency. It ensures the out-of-range check of operands of transcendental functions and improves the accuracy of floating-point compares.

This option prevents the compiler from performing optimizations that change NaN comparison semantics and causes all values to be truncated to declared precision before they are used in comparisons. It also causes the compiler to use library routines that give better precision results compared to the X87 transcendental instructions.

This option disables fewer optimizations and has less impact on performance than option fltconsistency.

This option disables fewer optimizations and has less impact on performance than option fltconsistency,-fp-model precise (Linux* OS and OS X*), or option /fp:precise (Windows* OS).

IDE Equivalent
None

Alternate Options
None

See Also
fltconsistency compiler option

pc, Qpc
Enables control of floating-point significand precision.

Syntax
Linux OS and OS X:
-pcn

Windows OS:
/Qpcn

Arguments

\( n \)

Is the floating-point significand precision. Possible values are:

- 32  Rounds the significand to 24 bits (single precision).
- 64  Rounds the significand to 53 bits (double precision).
- 80  Rounds the significand to 64 bits (extended precision).

Default
-pc80  
On Linux* and OS X* systems, the floating-point significand is rounded to 64 bits. On Windows* systems, the floating-point significand is rounded to 53 bits.
**Description**

This option enables control of floating-point significand precision.

Some floating-point algorithms are sensitive to the accuracy of the significand, or fractional part of the floating-point value. For example, iterative operations like division and finding the square root can run faster if you lower the precision with this option.

Note that a change of the default precision control or rounding mode, for example, by using the **[Q]pc32** option or by user intervention, may affect the results returned by some of the mathematical functions.

**IDE Equivalent**

None

**Alternate Options**

None

**prec-div, Qprec-div**

*Improves precision of floating-point divides.*

**Syntax**

**Linux OS and OS X:**

- `prec-div`
- `no-prec-div`

**Windows OS:**

/`Qprec-div`

/`Qprec-div-`

**Arguments**

None

**Default**

- `prec-div`
  
  The compiler uses this method for floating-point divides.

- `no-prec-div`

**Description**

This option improves precision of floating-point divides. It has a slight impact on speed.

With some optimizations, such as `-msse2` (Linux* OS) or `/arch:SSSE2` (Windows* OS), the compiler may change floating-point division computations into multiplication by the reciprocal of the denominator. For example, \( A/B \) is computed as \( A \times (1/B) \) to improve the speed of the computation.

However, sometimes the value produced by this transformation is not as accurate as full IEEE division. When it is important to have fully precise IEEE division, use this option to disable the floating-point division-to-multiplication optimization. The result is more accurate, with some loss of performance.

If you specify `-no-prec-div` (Linux* OS and OS X*) or `/Qprec-div-` (Windows* OS), it enables optimizations that give slightly less precise results than full IEEE division.

**IDE Equivalent**

None
Alternate Options

None

prec-sqrt, Qprec-sqrt

*Improves precision of square root implementations.*

Syntax

Linux OS and OS X:
-prec-sqrt
-no-prec-sqrt

Windows OS:
/Qprec-sqrt
/Qprec-sqrt-

Arguments

None

Default

-no-prec-sqrt
or /Qprec-sqrt-

The compiler uses a faster but less precise implementation of square root. However, the default is -prec-sqrt or /Qprec-sqrt if any of the following options are specified: /Od, /fltconsistency, or /Qprec on Windows* systems; -O0, -fltconsistency, or -mpl on Linux* and OS X* systems.

Description

This option improves precision of square root implementations. It has a slight impact on speed.

This option inhibits any optimizations that can adversely affect the precision of a square root computation. The result is fully precise square root implementations, with some loss of performance.

IDE Equivalent

None

Alternate Options

None

rcd, Qrcd

*Enables fast float-to-integer conversions.*

Syntax

Linux OS and OS X:
-rcd

Windows OS:
/Qrcd

Arguments

None
Floating-point values are truncated when a conversion to an integer is involved.

**Description**

This option enables fast float-to-integer conversions. It can improve the performance of code that requires floating-point-to-integer conversions.

The system default floating-point rounding mode is round-to-nearest. However, the Fortran language requires floating-point values to be truncated when a conversion to an integer is involved. To do this, the compiler must change the rounding mode to truncation before each floating-point-to-integer conversion and change it back afterwards.

This option disables the change to truncation of the rounding mode for all floating-point calculations, including floating point-to-integer conversions. This option can improve performance, but floating-point conversions to integer will not conform to Fortran semantics.

**IDE Equivalent**

None

**Alternate Options**

Linux and OS X: None

Windows: /QIfist (this is a deprecated option)

/recursive

*Tells the compiler that all routines should be compiled for possible recursive execution.*

**Syntax**

Linux OS and OS X:

- recursive
- -norecursive

Windows OS:

/recursive

/norecursive

**Arguments**

None

**Default**

norecursive

*Routines are not compiled for possible recursive execution.*

**Description**

This option tells the compiler that all routines should be compiled for possible recursive execution. It sets the automatic option.

**IDE Equivalent**

Visual Studio: Code Generation > Enable Recursive Routines

Eclipse: None
Xcode: Code Generation > Enable Recursive Routines

Alternate Options
None

auto compiler option

Inlining Options

finline
* Tells the compiler to inline functions declared with !DIR$ ATTRIBUTES FORCEINLINE. *

Syntax
Linux OS and OS X:
- finline
- fno-inline

Windows OS:
None

Arguments
None

Default
-fno-inline
The compiler does not inline functions declared with !DIR$ ATTRIBUTES FORCEINLINE.

Description
This option tells the compiler to inline functions declared with !DIR$ ATTRIBUTES FORCEINLINE.

IDE Equivalent
None

Alternate Options
Linux and OS X: -inline-level
Windows: /Ob

finline-functions
* Enables function inlining for single file compilation. *

Syntax
Linux OS and OS X:
- finline-functions
- fno-inline-functions

Windows OS:
None
Arguments
None

Default
-finline-functions  Interprocedural optimizations occur. However, if you specify -O0, the default is OFF.

Description
This option enables function inlining for single file compilation. It enables the compiler to perform inline function expansion for calls to functions defined within the current source file.

The compiler applies a heuristic to perform the function expansion. To specify the size of the function to be expanded, use the -finline-limit option.

IDE Equivalent
None

Alternate Options
Linux and OS X: -inline-level=2
Windows: /Ob2

See Also
ip, Qip compiler option
finline-limit compiler option

finline-limit
Lets you specify the maximum size of a function to be inlined.

Syntax
Linux OS and OS X:
-finline-limit=n

Windows OS:
None

Arguments
n  Must be an integer greater than or equal to zero. It is the maximum number of lines the function can have to be considered for inlining.

Default
OFF  The compiler uses default heuristics when inlining functions.

Description
This option lets you specify the maximum size of a function to be inlined. The compiler inlines smaller functions, but this option lets you inline large functions. For example, to indicate a large function, you could specify 100 or 1000 for n.

Note that parts of functions cannot be inlined, only whole functions.
This option is a modification of the -finline-functions option, whose behavior occurs by default.

**IDE Equivalent**
None

**Alternate Options**
None

**See Also**
finline-functions compiler option

**inline**
Specifies the level of inline function expansion.

**Syntax**
Linux OS and OS X:
None

Windows OS:
/inline[:keyword]

**Arguments**

finline-functions compiler option

**inline-factor, Qinline-factor**
Specifies the percentage multiplier that should be applied to all inlining options that define upper limits.

**Syntax**

**Linux OS and OS X:**
- -inline-factor=n
- -no-inline-factor

**Windows OS:**
- /Qinline-factor:n
- /Qinline-factor:

**Arguments**

n Is a positive integer specifying the percentage value. The default value is 100 (a factor of 1).

**Default**

- -inline-factor=100
- or/Qinline-factor:100

**Description**

This option specifies the percentage multiplier that should be applied to all inlining options that define upper limits:

- [Q]inline-max-size
- [Q]inline-max-total-size
- [Q]inline-max-per-routine
- [Q]inline-max-per-compile
The \texttt{inline-factor} option takes the default value for each of the above options and multiplies it by \( n \) divided by 100. For example, if 200 is specified, all inlining options that define upper limits are multiplied by a factor of 2. This option is useful if you do not want to individually increase each option limit.

If you specify \texttt{-no-inline-factor} (Linux* OS and OS X*) or \texttt{/Qinline-factor-} (Windows* OS), the following occurs:

- Every function is considered to be a small or medium function; there are no large functions.
- There is no limit to the size a routine may grow when inline expansion is performed.
- There is no limit to the number of times some routine may be inlined into a particular routine.
- There is no limit to the number of times inlining can be applied to a compilation unit.

To see compiler values for important inlining limits, specify option \texttt{[q or Q]opt-report}.

---

**CAUTION**

When you use this option to increase default limits, the compiler may do so much additional inlining that it runs out of memory and terminates with an "out of memory" message.

---

**IDE Equivalent**

None

**Alternate Options**

None

**See Also**

- \texttt{inline-max-per-compile}, \texttt{Qinline-max-per-compile} compiler option
- \texttt{qopt-report}, \texttt{Qopt-report} compiler option
- \texttt{inline-forceinline}, \texttt{Qinline-forceinline}

\textit{Instructs the compiler to force inlining of functions suggested for inlining whenever the compiler is capable doing so.}

**Syntax**

- **Linux OS and OS X:**
  - \texttt{inline-forceinline}

- **Windows OS:**
  - \texttt{/Qinline-forceinline}

**Default**

OFF

The compiler uses default heuristics for inline routine expansion.

**Description**

This option instructs the compiler to force inlining of functions suggested for inlining whenever the compiler is capable doing so.

Without this option, the compiler treats functions declared with an \texttt{INLINE} attribute as merely being recommended for inlining. When this option is used, it is as if they were declared with the directive \texttt{!DIR$ ATTRIBUTES FORCEINLINE}.  

---
To see compiler values for important inlining limits, specify option \([q\ or\ Q]\)opt-report.

**CAUTION**
When you use this option to change the meaning of inline to "forceinline", the compiler may do so much additional inlining that it runs out of memory and terminates with an "out of memory" message.

**IDE Equivalent**
None

**Alternate Options**
None

**See Also**
qopt-report, Qopt-report compiler option
inline-level, Ob
Specifies the level of inline function expansion.

**Syntax**

**Linux OS and OS X:**
- `inline-level=n`

**Windows OS:**
/Ob

**Arguments**

n
Is the inline function expansion level. Possible values are 0, 1, and 2.

**Default**

- `inline-level=2` or `/Ob2`
  This is the default if option O2 is specified or is in effect by default. On Windows* systems, this is also the default if option O3 is specified.

- `inline-level=0` or `/Ob0`
  This is the default if option -O0 (Linux* OS and OS X*) or /Od (Windows* OS) is specified.

**Description**
This option specifies the level of inline function expansion. Inlining procedures can greatly improve the run-time performance of certain programs.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>inline-level=0</code></td>
<td>Enables inlining of any function at the compiler's discretion.</td>

inline compiler option
inline-max-per-compile, Qinline-max-per-compile
Specifies the maximum number of times inlining may be applied to an entire compilation unit.

Syntax
Linux OS and OS X:
-inline-max-per-compile=n
-no-inline-max-per-compile
Windows OS:
/Qinline-max-per-compile=n
/Qinline-max-per-compile-

Arguments
n Is a positive integer that specifies the number of times inlining may be applied.

Default
-no-inline-max-per-compile The compiler uses default heuristics for inline routine expansion.
oR/Qinline-max-per-compile-

Description
This option the maximum number of times inlining may be applied to an entire compilation unit. It limits the number of times that inlining can be applied.

For compilations using Interprocedural Optimizations (IPO), the entire compilation is a compilation unit. For other compilations, a compilation unit is a file.

If you specify -no-inline-max-per-compile (Linux* OS and OS X*) or /Qinline-max-per-compile- (Windows* OS), there is no limit to the number of times inlining may be applied to a compilation unit.

To see compiler values for important inlining limits, specify option [q or Q]opt-report.

CAUTION
When you use this option to increase the default limit, the compiler may do so much additional inlining that it runs out of memory and terminates with an "out of memory" message.

IDE Equivalent
None
Alternate Options
None

inline-max-per-routine, Qinline-max-per-routine
Specifies the maximum number of times the inliner may inline into a particular routine.

Syntax

Linux OS and OS X:
-inline-max-per-routine=n
-no-inline-max-per-routine

Windows OS:
/Qinline-max-per-routine=n
/Qinline-max-per-routine-

Arguments

n Is a positive integer that specifies the maximum number of times the inliner may inline into a particular routine.

Default

-no-inline-max-per-routine The compiler uses default heuristics for inline routine expansion.
or/Qinline-max-per-routine-

Description

This option specifies the maximum number of times the inliner may inline into a particular routine. It limits the number of times that inlining can be applied to any routine.

If you specify -no-inline-max-per-routine (Linux* OS and OS X*) or /Qinline-max-per-routine- (Windows* OS), there is no limit to the number of times some routine may be inlined into a particular routine.

To see compiler values for important inlining limits, specify option [q or Q]opt-report.

CAUTION

When you use this option to increase the default limit, the compiler may do so much additional inlining that it runs out of memory and terminates with an "out of memory" message.

IDE Equivalent
None

Alternate Options
None
Specifies the lower limit for the size of what the inliner considers to be a large routine.

Syntax

Linux OS and OS X:
- `inline-max-size=n`
- `no-inline-max-size`

Windows OS:
/`Qinline-max-size=n`
/`Qinline-max-size-`

Arguments

`n` Is a positive integer that specifies the minimum size of what the inliner considers to be a large routine.

Default

`inline-max-size` or `/Qinline-max-size`
The compiler sets the maximum size (`n`) dynamically, based on the platform.

Description

This option specifies the lower limit for the size of what the inliner considers to be a large routine (a function or subroutine). The inliner classifies routines as small, medium, or large. This option specifies the boundary between what the inliner considers to be medium and large-size routines.

The inliner prefers to inline small routines. It has a preference against inlining large routines. So, any large routine is highly unlikely to be inlined.

If you specify `no-inline-max-size` (Linux* OS and OS X*) or `/Qinline-max-size-` (Windows* OS), there are no large routines. Every routine is either a small or medium routine.

To see compiler values for important inlining limits, specify option [q or Q]opt-report.

CAUTION

When you use this option to increase the default limit, the compiler may do so much additional inlining that it runs out of memory and terminates with an "out of memory" message.

IDE Equivalent

None

**inline-max-total-size, Qinline-max-total-size**  
Specifies how much larger a routine can normally grow when inline expansion is performed.

**Syntax**

**Linux OS and OS X:**
- `-inline-max-total-size=n`
- `-no-inline-max-total-size`

**Windows OS:**
- `/Qinline-max-total-size=n`
- `/Qinline-max-total-size-`

**Arguments**

`n`  
Is a positive integer that specifies the permitted increase in the routine's size when inline expansion is performed.

**Default**

`-no-inline-max-total-size`  
The compiler uses default heuristics for inline routine expansion.  
or `/Qinline-max-total-size-`

**Description**

This option specifies how much larger a routine can normally grow when inline expansion is performed. It limits the potential size of the routine. For example, if 2000 is specified for `n`, the size of any routine will normally not increase by more than 2000.

If you specify `-no-inline-max-total-size` (Linux* OS and OS X*) or `/Qinline-max-total-size-` (Windows* OS), there is no limit to the size a routine may grow when inline expansion is performed.

To see compiler values for important inlining limits, specify option [q or Q]opt-report.

---

**CAUTION**  
When you use this option to increase the default limit, the compiler may do so much additional inlining that it runs out of memory and terminates with an "out of memory" message.

**inline-min-size, Qinline-min-size**  
Specifies the upper limit for the size of what the inliner considers to be a small routine.
**Syntax**

**Linux OS and OS X:**
- `inline-min-size=n`
- `no-inline-min-size`

**Windows OS:**
- `/Qinline-min-size=n`
- `/Qinline-min-size-`

**Arguments**

`n` Is a positive integer that specifies the maximum size of what the inliner considers to be a small routine.

**Default**

- `no-inline-min-size`
  The compiler uses default heuristics for inline routine expansion.

**Description**

This option specifies the upper limit for the size of what the inliner considers to be a small routine (a function or subroutine). The inliner classifies routines as small, medium, or large. This option specifies the boundary between what the inliner considers to be small and medium-size routines.

The inliner has a preference to inline small routines. So, when a routine is smaller than or equal to the specified size, it is very likely to be inlined.

If you specify `no-inline-min-size` (Linux OS and OS X) or `/Qinline-min-size-` (Windows OS), there is no limit to the size of small routines. Every routine is a small routine; there are no medium or large routines.

To see compiler values for important inlining limits, specify option `[q or Q]opt-report`.

**CAUTION**

When you use this option to increase the default limit, the compiler may do so much additional inlining that it runs out of memory and terminates with an "out of memory" message.

Windows OS:
/bintext:string
/nobintext

Arguments
string
Is the text string to go into the object file.

Default
/nobintext
No text string is placed in the object file.

Description
This option places a text string into the object file (.obj) being generated by the compiler. The string also gets propagated into the executable file.
For example, this option is useful if you want to place a version number or copyright information into the object and executable.

If the string contains a space or tab, the string must be enclosed by double quotation marks ("."). A backslash (\) must precede any double quotation marks contained within the string.

If the command line contains multiple /bintext options, the last (rightmost) one is used.

**IDE Equivalent**

Visual Studio: **Code Generation > Object Text String**

Eclipse: None

Xcode: None

**Alternate Options**

Linux and OS X: None

Windows: /vstring

**c**

*Prevents linking.*

**Syntax**

Linux OS and OS X:

-c

Windows OS:

/c

**Arguments**

None

**Default**

OFF Linking is performed.

**Description**

This option prevents linking. Compilation stops after the object file is generated.

The compiler generates an object file for each Fortran source file.

**IDE Equivalent**

None

**Alternate Options**

Linux and OS X: None

Windows: /compile-only, /nolink

**debug (Linux* and OS X*)**

*Enables or disables generation of debugging information.*
Syntax

Linux OS and OS X:
-debug [keyword]

Windows OS:
None

Arguments

keyword

Is the type of debugging information to be generated. Possible values are:

none
Disables generation of debugging information.

full or all
Generates complete debugging information.

minimal
Generates line number information for debugging.

[no]emit_column
Determines whether the compiler generates column number information for debugging.

[no]inline-debug-info
Determines whether the compiler generates enhanced debug information for inlined code.

[no]pubnames
Determines whether the compiler generates a DWARF debug_pubnames section.

[no]semantic-stepping
Determines whether the compiler generates enhanced debug information useful for breakpoints and stepping.

[no]variable-locations
Determines whether the compiler generates enhanced debug information useful in finding scalar local variables.

extended
Sets keyword values semantic-stepping and variable-locations.

[no]parallel (Linux only)
Determines whether the compiler generates parallel debug code instrumentations useful for thread data sharing and reentrant call detection.

For information on the non-default settings for these keywords, see the Description section.

Default

varies

Normally, the default is -debug none and no debugging information is generated. However, on Linux* OS, the -debug inline-debug-info option will be enabled by default if you compile with optimizations (option -O2 or higher) and debugging is enabled (option -g).

Description

This option enables or disables generation of debugging information.

Note that if you turn debugging on, optimization is turned off.
Keywords `semantic-stepping`, `inline-debug-info`, `variable-locations`, and `extended` can be used in combination with each other. If conflicting keywords are used in combination, the last one specified on the command line has precedence.

<table>

<td>Generates column number information for debugging.</td>
</tr>
<tr>
<td>-debug inline-debug-info</td>
<td>Generates enhanced debug information for inlined code.</td>
</tr>
<tr>
<td></td>
<td>On inlined functions, symbols are (by default) associated with the caller. This option causes symbols for inlined functions to be associated with the source of the called function.</td>
</tr>
<tr>
<td>-debug pubnames</td>
<td>The compiler generates a DWARF debug_pubnames section. This provides a means to list the names of global objects and functions in a compilation unit.</td>
</tr>
<tr>
<td>-debug semantic-stepping</td>
<td>Generates enhanced debug information useful for breakpoints and stepping. It tells the debugger to stop only at machine instructions that achieve the final effect of a source statement.</td>
</tr>
<tr>
<td></td>
<td>For example, in the case of an assignment statement, this might be a store instruction that assigns a value to a program variable; for a function call, it might be the machine instruction that executes the call. Other instructions generated for those source statements are not displayed during stepping.</td>
</tr>
<tr>
<td></td>
<td>This option has no impact unless optimizations have also been enabled.</td>
</tr>
<tr>
<td>-debug variable-locations</td>
<td>Generates enhanced debug information useful in finding scalar local variables. It uses a feature of the Dwarf object module known as &quot;location lists&quot;.</td>
</tr>
<tr>
<td></td>
<td>This feature allows the run-time locations of local scalar variables to be specified more accurately; that is, whether, at a given position in the code, a variable value is found in memory or a machine register.</td>
</tr>
<tr>
<td>-debug extended</td>
<td>Sets keyword values <code>semantic-stepping</code> and <code>variable-locations</code>. It also tells the compiler to include column numbers in the line information.</td>
</tr>
<tr>
<td>-debug parallel</td>
<td>Generates parallel debug code instrumentations needed for the thread data sharing and reentrant call detection. For this setting to be effective, option <code>-qopenmp</code> must be set.</td>
</tr>
</tbody>
</table>

On Linux* systems, debuggers read debug information from executable images. As a result, information is written to object files and then added to the executable by the linker.

On OS X* systems, debuggers read debug information from object files. As a result, the executables don't contain any debug information. Therefore, if you want to be able to debug on these systems, you must retain the object files.

**IDE Equivalent**

None
**Alternate Options**

For `-debug full`, `-debug all`, **Linux and OS X**: `-g
or `-debug`  
**Windows**: `/debug:full, /debug:all, or /debug`

For `-debug variable-locations`  
**Linux and OS X**: `-fvar-tracking`  
**Windows**: None

For `-debug semantic-stepping`  
**Linux and OS X**: `-fvar-tracking-assignments`

dbglibs compiler option

Debugging Fortran Programs

debug (Linux* and OS X*) compiler option
**debug-parameters**
*Tells the compiler to generate debug information for PARAMETERs used in a program.*

**Syntax**

**Linux OS and OS X:**

- `debug-parameters [keyword]`
- `nodebug-parameters`

**Windows OS:**

`/debug-parameters[:keyword]`

`/nodebug-parameters`

**Arguments**

*keyword*  
Are the PARAMETERs to generate debug information for. Possible values are:

- *none*  
  Generates no debug information for any PARAMETERs used in the program. This is the same as specifying `nodebug-parameters`.

- *used*  
  Generates debug information for only PARAMETERs that have actually been referenced in the program. This is the default if you do not specify a *keyword*.

- *all*  
  Generates debug information for all PARAMETERs defined in the program.

**Default**

`nodebug-parameters`  
The compiler generates no debug information for any PARAMETERs used in the program. This is the same as specifying *keyword* `none`.

**Description**

This option tells the compiler to generate debug information for PARAMETERs used in a program.

Note that if a .mod file contains PARAMETERs, debug information is only generated for the PARAMETERs that have actually been referenced in the program, even if you specify *keyword* `all`.

**IDE Equivalent**

Visual Studio: **Debugging > Information for PARAMETER Constants**

Eclipse: None

Xcode: **Debug > Information for PARAMETER Constants**

**Alternate Options**

None

**exe**

*Specifies the name for a built program or dynamic-link library.*
Syntax

Linux OS and OS X:
None

Windows OS:
/exe:{filename | dir}

Arguments

filename Is the name for the built program or dynamic-link library.

dir Is the directory where the built program or dynamic-link library should be placed. It can include filename.

Default

OFF The name of the file is the name of the first source file on the command line with file extension .exe, so file.f becomes file.exe.

Description

This option specifies the name for a built program (.EXE) or a dynamic-link library (.DLL).

You can use this option to specify an alternate name for an executable file. This is especially useful when compiling and linking a set of input files. You can use the option to give the resulting file a name other than that of the first input file (source or object) on the command line.

You can use this option to specify an alternate name for an executable file. This is especially useful when compiling and linking a set of input files. You can use the option to give the resulting file a name other than that of the first input file (source or object) on the command line.

IDE Equivalent

None

Alternate Options

Linux and OS X: -o

Windows: /Fe

Example

The following example creates a dynamic-link library file named file.dll (note that you can use /LD in place of /dll):

ifort /dll /exe:file.dll a.f

In the following example (which uses the alternate option /Fe), the command produces an executable file named outfile.exe as a result of compiling and linking three files: one object file and two Fortran source files.

prompt> ifort /Feoutfile.exe file1.obj file2.for file3.for

By default, this command produces an executable file named file1.exe.

o compiler option

Fa
Specifies that an assembly listing file should be generated.
Syntax

**Linux OS and OS X:**

```
-Fa[filename|dir]
```

**Windows OS:**

```
/Fa[filename|dir]
```

**Arguments**

*filename*  
Is the name of the assembly listing file.

*dir*  
Is the directory where the file should be placed. It can include `filename`.

**Default**

OFF  
No assembly listing file is produced.

**Description**

This option specifies that an assembly listing file should be generated (optionally named `filename`).

If `filename` is not specified, the file name will be the name of the source file with an extension of `.asm`; the file is placed in the current directory.

**IDE Equivalent**

Visual Studio: **Output > ASM Listing Name**

Eclipse: None

Xcode: None

**Alternate Options**

Linux and OS X: `-S`

Windows: `/S`, `/asmfile` (this is a deprecated option)

**FA**

*Specifies the contents of an assembly listing file.*

**Syntax**

**Linux OS and OS X:**

None

**Windows OS:**

```
/FA[specifier]
```

**Arguments**

*specifier*  
Denotes the contents of the assembly listing file. Possible values are `c`, `s`, or `cs`. 
Default

OFF

No source or machine code annotations appear in the assembly listing file, if one is produced.

Description

These options specify what information, in addition to the assembly code, should be generated in the assembly listing file.

To use this option, you must also specify option `/Fa`, which causes an assembly listing to be generated.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>/FA</code></td>
<td>Produces an assembly listing without source or machine code annotations.</td>
</tr>
<tr>
<td><code>/FAc</code></td>
<td>Produces an assembly listing with machine code annotations. The assembly listing file shows the hex machine instructions at the beginning of each line of assembly code. The file cannot be assembled; the file name is the name of the source file with an extension of .cod.</td>
</tr>
<tr>
<td><code>/FAs</code></td>
<td>Produces an assembly listing with source code annotations. The assembly listing file shows the source code as interspersed comments. Note that if you use alternate option <code>-fsource-asm</code>, you must also specify the <code>-S</code> option.</td>
</tr>
<tr>
<td><code>/FAs</code></td>
<td>Produces an assembly listing with source and machine code annotations. The assembly listing file shows the source code as interspersed comments and shows the hex machine instructions at the beginning of each line of assembly code. This file cannot be assembled.</td>
</tr>
</tbody>
</table>

IDE Equivalent

Visual Studio: **Output > Assembler Output**
Eclipse: None
Xcode: None

Alternate Options

`/FAc`  
Linux and OS X: `-fcode-asm`  
Windows: None

`/FAs`  
Linux and OS X: `-fsource-asm`  
Windows: None

`fcode-asm`  
*Produces an assembly listing with machine code annotations.*

Syntax

Linux OS and OS X:  
`-fcode-asm`
Windows OS: None

Arguments
None

Default
OFF No machine code annotations appear in the assembly listing file, if one is produced.

Description
This option produces an assembly listing file with machine code annotations. The assembly listing file shows the hex machine instructions at the beginning of each line of assembly code. The file cannot be assembled; the file name is the name of the source file with an extension of .cod.

To use this option, you must also specify option -s, which causes an assembly listing to be generated.

IDE Equivalent
None

Alternate Options
Linux and OS X: None
Windows: /FAc

See Also
S compiler option

Fd
Lets you specify a name for a program database (PDB) file created by the compiler.

Syntax
Linux OS and OS X:
None

Windows OS:
/Fd[:filename]

Arguments
filename Is the name for the PDB file. It can include a path. If you do not specify a file extension, the extension .pdb is used.

Default
OFF No PDB file is created unless you specify option /zi. If you specify option /zi and /Fd, the default filename is vc\x\0.pdb, where x represents the version of Visual C++, for example vc100.pdb.

Description
This option lets you specify a name for a program database (PDB) file that is created by the compiler.
A program database (PDB) file holds debugging and project state information that allows incremental linking of a Debug configuration of your program. A PDB file is created when you build with option /Zi. Option /Fd has no effect unless you specify option /Zi.

**IDE Equivalent**

Visual Studio: **Output Files > Program Database File Name**

Eclipse: None

Xcode: None

**Alternate Options**

None

**See Also**

`g, Zi, Z7` compiler option

`pdbfile` compiler option

`feliminate-unused-debug-types, Qeliminate-unused-debug-types`

*Controls the debug information emitted for types declared in a compilation unit.*

**Syntax**

Linux OS and OS X:

- `-feliminate-unused-debug-types`
- `-fno-eliminate-unused-debug-types`

Windows OS:

- `/Qeliminate-unused-debug-types`
- `/Qeliminate-unused-debug-types-`

**Arguments**

None

**Default**

- `-feliminate-unused-debug-types`

or `/Qeliminate-unused-debug-types`

**Description**

This option controls the debug information emitted for types declared in a compilation unit.

If you specify `fno-eliminate-unused-debug-types` (Linux and OS X) or `/Qeliminate-unused-debug-types-`, it will cause the compiler to emit debug information for all types present in the sources. This option may cause a large increase in the size of the debug information.

**IDE Equivalent**

None

**Alternate Options**

None
fmerge-constants
Determines whether the compiler and linker attempt to merge identical constants (string constants and floating-point constants) across compilation units.

Syntax

Linux OS:
- fmerge-constants
- fno-merge-constants

OS X:
None

Windows OS:
None

Arguments
None

Default
- fmerge-constants

The compiler and linker attempt to merge identical constants across compilation units if the compiler and linker supports it.

Description

This option determines whether the compiler and linker attempt to merge identical constants (string constants and floating-point constants) across compilation units.

If you do not want the compiler and linker to attempt to merge identical constants across compilation units, specify -fno-merge-constants.

IDE Equivalent
None

Alternate Options
None

fmerge-debug-strings
Causes the compiler to pool strings used in debugging information.

Syntax

Linux OS:
- fmerge-debug-strings
- fno-merge-debug-strings

OS X:
None

Windows OS:
None
Arguments

None

Default

-fmerge-debug-strings The compiler will pool strings used in debugging information.

Description

This option causes the compiler to pool strings used in debugging information. The linker will automatically retain this pooling.

This option can reduce the size of debug information, but it may produce slightly slower compile and link times.

This option is only turned on by default if you are using gcc 4.3 or later, where this setting is also the default, since the generated debug tables require binutils version 2.17 or later to work reliably.

If you do not want the compiler to pool strings used in debugging information, specify option -fno-merge-debug-strings.

IDE Equivalent

None

Alternate Options

None

fsource-asm

Produces an assembly listing with source code annotations.

Syntax

Linux OS and OS X:

-fsource-asm

Windows OS:

None

Arguments

None

Default

OFF No source code annotations appear in the assembly listing file, if one is produced.

Description

This option produces an assembly listing file with source code annotations. The assembly listing file shows the source code as interspersed comments.

To use this option, you must also specify option -s, which causes an assembly listing to be generated.

IDE Equivalent

None
Alternate Options
Linux and OS X: None
Windows: /FAs

See Also
S compiler option

ftrapuv, Qtrapuv
*Initializes stack local variables to an unusual value to aid error detection.*

Syntax

Linux OS and OS X:
-ftrapuv

Windows OS:
/Qtrapuv

Arguments
None

Default
OFF  The compiler does not initialize local variables.

Description
This option initializes stack local variables to an unusual value to aid error detection. Normally, these local variables should be initialized in the application. It also unmasks the floating-point invalid exception. The option sets any uninitialized local variables that are allocated on the stack to a value that is typically interpreted as a very large integer or an invalid address. References to these variables are then likely to cause run-time errors that can help you detect coding errors.

This option sets option -g (Linux* OS and OS X*) and /Zi or /Z7 (Windows* OS), which changes the default optimization level from O2 to -O0 (Linux OS and OS X) or /Od (Windows OS). You can override this effect by explicitly specifying an O option setting.

This option sets option [Q]init snan.

If option O2 and option -ftrapuv (Linux OS and OS X) or /Qtrapuv (Windows OS) are used together, you should specify option -fp-speculation safe (Linux OS and OS X) or /Qfp-speculation:safe (Windows OS) to prevent exceptions resulting from speculated floating-point operations from being trapped.

For more details on using options -ftrapuv and /Qtrapuv with compiler option O, see the article in Intel® Developer Zone titled *Don’t optimize when using -ftrapuv for uninitialized variable detection.*

Another way to detect uninitialized local scalar variables is by specifying keyword uninit for option check.

IDE Equivalent
Visual Studio: Data > Initialize stack variables to an unusual value
Eclipse: None
Xcode: Run-Time > Initialize Stack Variables to an Unusual Value

Alternate Options
None
See Also
- g, Zi, Z7 compiler options
- O compiler option
- check compiler option (see setting uninit)
- init, Qinit compiler option (see setting snan)

Locating Run-Time Errors

**fverbose-asm**

*Produces an assembly listing with compiler comments, including options and version information.*

**Syntax**

**Linux OS and OS X:**

- `-fverbose-asm`
- `-fno-verbose-asm`

**Windows OS:**

None

**Arguments**

None

**Default**

- `-fno-verbose-asm`

  No source code annotations appear in the assembly listing file, if one is produced.

**Description**

This option produces an assembly listing file with compiler comments, including options and version information.

To use this option, you must also specify `-S`, which sets `-fverbose-asm`.

If you do not want this default when you specify `-S`, specify `-fno-verbose-asm`.

**IDE Equivalent**

None

**Alternate Options**

None

See Also

**S compiler option**

**g, Zi, Z7**

*Tells the compiler to generate full debugging information in the object file or a project database (PDB) file.*

**Syntax**

**Linux OS and OS X:**

- `-g`
Windows OS:
/zi
/z7

Arguments
None

Default
OFF No debugging information is produced in the object file or in a PDB file.

Description
Options -g (Linux* OS and OS X*) and /Z7 (Windows* OS) tell the compiler to generate symbolic debugging information in the object file, which increases the size of the object file. The /Zi option (Windows OS) tells the compiler to generate symbolic debugging information in a PDB file.

Two PDB files are created, one by the compiler, and one by the linker:

- vc\x.pdb, where \x represents the version of Visual C++, for example vc100.pdb.
  This file stores all debugging information for the individual OBJ files and resides in the same directory as the project makefile. If you want to change this name, use option /Fd.
- \executablename\pdb
  This file stores all debug information for the .exe file and resides in the debug subdirectory.

Each time it creates a .obj file, the compiler merges debug information into vc\x.pdb.

The linker creates \executablename\pdb, which contains debug information for the project's .exe file. The \executablename\pdb file contains full debug information, including function prototypes, not just the type information found in vc\x.pdb. Both PDB files allow incremental updates. The linker also embeds the path to the .pdb file in the .exe or .dll file that it creates.

The compiler does not support the generation of debugging information in assemblable files. If you specify these options, the resulting object file will contain debugging information, but the assemblable file will not.

These options turn off O2 and make O0 (Linux OS and OS X) or Od (Windows OS) the default unless O2 (or higher) is explicitly specified in the same command line.

On Linux* OS and OS X*, specifying the -g or -O0 option sets the -fno-omit-frame-pointer option. On Linux* OS, the -debug inline-debug-info option will be enabled by default if you compile with optimizations (option -O2 or higher) and debugging is enabled (option -g).

NOTE
When option -g is specified, debugging information is generated in the DWARF Version 3 format. Older versions of some analysis tools may require applications to be built with the -gdwarf-2 option to ensure correct operation.

IDE Equivalent
Visual Studio: General > Debug Information Format (/zi)
Eclipse: None
Xcode: General > Generate Debug Information (-g)
Alternate Options

/zi

Linux and OS X: None
Windows: /debug:full, /debug:all, or /debug

See Also
Fd compiler option
gdwarf compiler option

gdwarf
Lets you specify a DWARF Version format when generating debug information.

Syntax

Linux OS and OS X:
-gdwarf-n

Windows OS:
None

Arguments

n
Is a value denoting the DWARF Version format to use. Possible values are:

2 Generates debug information using the DWARF Version 2 format.

3 Generates debug information using the DWARF Version 3 format.

4 Generates debug information using the DWARF Version 4 format. This setting is only available on Linux* OS.

Default

OFF
No debug information is generated. However, if compiler option -g is specified, debugging information is generated in the DWARF Version 3 format.

Description

This option lets you specify a DWARF Version format when generating debug information.
Note that older versions of some analysis tools may require applications to be built with the -gdwarf-2 option to ensure correct operation.

IDE Equivalent

None

Alternate Options

None

See Also
g, Zi, Z7 compiler option
**grecord-gcc-switches**
*Causes the command line options that were used to invoke the compiler to be appended to the DW_AT_producer attribute in DWARF debugging information.*

**Syntax**

**Linux OS:**
- `grecord-gcc-switches`

**OS X:**
None

**Windows OS:**
None

**Arguments**
None

**Default**
OFF

The command line options that were used to invoke the compiler are not appended to the DW_AT_producer attribute in DWARF debugging information.

**Description**

This option causes the command line options that were used to invoke the compiler to be appended to the DW_AT_producer attribute in DWARF debugging information.

The options are concatenated with whitespace separating them from each other and from the compiler version.

**IDE Equivalent**
None

**Alternate Options**
None

**gsplit-dwarf**
*Creates a separate object file containing DWARF debug information.*

**Architectures**

Not available on Intel® 64 architecture targeting Intel® MIC Architecture

**Syntax**

**Linux OS:**
- `gsplit-dwarf`

**OS X:**
None

**Windows OS:**
None
Arguments
None

Default
OFF

No separate object file containing DWARF debug information is created.

Description
This option creates a separate object file containing DWARF debug information. It causes debug information to be split between the generated object (.o) file and the new DWARF object (.dwo) file. The DWARF object file is not used by the linker, so this reduces the amount of debug information the linker must process and it results in a smaller executable file.

For this option to perform correctly, you must use binutils-2.24 or later. To debug the resulting executable, you must use gdb-7.6.1 or later.

NOTE
If you use the split executable with a tool that does not support the split DWARF format, it will behave as though the DWARF debug information is absent.

IDE Equivalent
None

Alternate Options
None

list
Tells the compiler to create a listing of the source file.

Syntax

Linux OS and OS X:
-list[=filename]
-no-list

Windows OS:
/list[=filename]
/list-

Arguments

filename
Is the name of the file for output. It can include a path.

Default

-no-list or /list-
No listing is created for the source file.

Description
This option tells the compiler to create a listing of the source file. The listing contains the following:

- The contents of files included with INCLUDE statements
• A symbol list with a line number cross-reference for each routine
• A list of compiler options used for the current compilation

The contents of the listing can be controlled by specifying option `show`.
The line length of the listing can be specified by using option `list-line-len`.
The page length of the listing can be specified by using option `list-page-len`.
If you do not specify `filename`, the output is written to a file in the same directory as the source. The file name is the name of the source file with an extension of `.lst`.

**IDE Equivalent**

Visual Studio: **Output Files > Source Listing** (/list)
**Output Files > Source Listing File** (/list:[filename])
Eclipse: None
Xcode: None

**Alternate Options**
None

**See Also**
`show` compiler option
`list-line-len` compiler option
`list-page-len` compiler option

**`list-line-len`**

Specifies the line length for the listing generated when option `list` is specified.

**Syntax**

**Linux OS and OS X:**

- `-list-line-len=n`

**Windows OS:**

/`list-line-len:n`

**Arguments**

`n`  
Is a positive integer indicating the number of columns to show in the listing.

**Default**

80  
When a listing is generated, the default line length is 80 columns.

**Description**

This option specifies the line length for the listing generated when option `list` is specified.
If you specify option `list-line-len` and do not specify option `list`, the option is ignored.

**IDE Equivalent**

None
**Alternate Options**
None

**See Also**
list compiler option
list-page-len compiler option

**list-page-len**
Specifies the page length for the listing generated when option list is specified.

**Syntax**

Linux OS and OS X:
- list-page-len=n

Windows OS:
/ list-page-len:n

**Arguments**

n
Is a positive integer indicating the number of lines on a page to show in the listing.

**Default**

60
When a listing is generated, the default page length is 60 lines.

**Description**

This option specifies the page length for the listing generated when option list is specified.
If you specify option list-page-len and do not specify option list, the option is ignored.

**IDE Equivalent**
None

**Alternate Options**
None

**See Also**
list compiler option
list-line-len compiler option

**map-opts, Qmap-opts**
Maps one or more compiler options to their equivalent on a different operating system.

**Syntax**

Linux OS:
- map-opts

OS X:
None
Windows OS:
/Qmap-opts

Arguments
None

Default
OFF
No platform mappings are performed.

Description
This option maps one or more compiler options to their equivalent on a different operating system. The result is output to stdout.

On Windows systems, the options you provide are presumed to be Windows options, so the options that are output to stdout will be Linux equivalents.

On Linux systems, the options you provide are presumed to be Linux options, so the options that are output to stdout will be Windows equivalents.

The tool can be invoked from the compiler command line or it can be used directly.

No compilation is performed when the option mapping tool is used.

This option is useful if you have both compilers and want to convert scripts or makefiles.

NOTE
Compiler options are mapped to their equivalent on the architecture you are using. For example, if you are using a processor with IA-32 architecture, you will only see equivalent options that are available on processors with IA-32 architecture.

IDE Equivalent
None

Alternate Options
None

Example
The following command line invokes the option mapping tool, which maps the Linux options to Windows-based options, and then outputs the results to stdout:
ifort -map-opts -xP -O2

The following command line invokes the option mapping tool, which maps the Windows options to Linux-based options, and then outputs the results to stdout:
ifort /Qmap-opts /QxP /O2

See Also
Compiler Option Mapping Tool

o
Specifies the name for an output file.
Syntax

Linux OS and OS X:

-o filename

Windows OS:

None

Arguments

filename

Is the name for the output file. The space before filename is optional.

Default

OFF

The compiler uses the default file name for an output file.

Description

This option specifies the name for an output file as follows:

- If -c is specified, it specifies the name of the generated object file.
- If -S is specified, it specifies the name of the generated assembly listing file.
- If -preprocess-only or -P is specified, it specifies the name of the generated preprocessor file.

Otherwise, it specifies the name of the executable file.

IDE Equivalent

None

Alternate Options

Linux and OS X: None

Windows: /exe

See Also

object compiler option
exe compiler option

object

Specifies the name for an object file.

Syntax

Linux OS and OS X:

None

Windows OS:

/object:filename

Arguments

filename

Is the name for the object file. It can be a file name or a directory name. A directory name must be followed by a backslash (\). If a special character appears within the file name or directory name, the file name or directory name must appear within quotes. To be safe, you should consider any non-ASCII numeric character to be a special character.
Default

OFF

An object file has the same name as the name of the first source file and a file extension of .obj.

Description

This option specifies the name for an object file.

If you specify this option and you omit /c or /compile-only, the /object option gives the object file its name.

On Linux and OS X systems, this option is equivalent to specifying option -ofilename-c.

IDE Equivalent

Visual Studio: Output Files > Object File Name
Eclipse: None
Xcode: None

Alternate Options

Linux and OS X: None
Windows: /Fo

Example

The following command shows how to specify a directory:

ifort /object:directorya\ end.f

If you do not add the backslash following a directory name, an executable is created. For example, the following command causes the compiler to create directorya.exe:

ifort /object:directorya end.f

The following commands show how to specify a subdirectory that contains a special character:

ifort /object:"blank subdirectory"\ end.f

ifort /object:"c:\my_directory"\ end.f

See Also

do compiler option

dbfile

Lets you specify the name for a program database (PDB) file created by the linker.

Syntax

Linux OS and OS X:

None

Windows OS:

/pdbfile[:filename]

Arguments

filename Is the name for the PDB file. It can include a path. If you do not specify a file extension, the extension .pdb is used.
Default
OFF  No PDB file is created unless you specify option /zi. If you specify option /zi the default filename is `executablename`.pdb.

Description
This option lets you specify the name for a program database (PDB) file created by the linker. This option does not affect where the compiler outputs debug information.
To use this option, you must also specify option /debug:full or /zi.
If filename is not specified, the default file name used is the name of your file with an extension of .pdb.

IDE Equivalent
None

Alternate Options
None

See Also
g, Zi, Z7 compiler option
debug (Windows*) compiler option
Fd compiler option
print-multi-lib
Prints information about where system libraries should be found.

Architecture Restrictions
Not available on Intel® 64 architecture targeting Intel® MIC Architecture

Syntax
Linux OS and OS X:
-`print-multi-lib`

Windows OS:
None

Arguments
None

Default
OFF  No information is printed unless the option is specified.

Description
This option prints information about where system libraries should be found, but no compilation occurs. On Linux systems, it is provided for compatibility with gcc.

IDE Equivalent
None
Alternate Options
None

Quse-msasm-symbols
*Tells the compiler to use a dollar sign ("$") when producing symbol names.*

**Syntax**

**Linux OS and OS X:**
None

**Windows OS:**
/Quse-msasm-symbols

**Arguments**
None

**Default**
OFF

**Description**
This option tells the compiler to use a dollar sign ("$") when producing symbol names.
Use this option if you require symbols in your .asm files to contain characters that are accepted by the MS assembler.

**IDE Equivalent**
None

**Alternate Options**
None

**S**
*Causes the compiler to compile to an assembly file only and not link.*

**Syntax**

**Linux OS and OS X:**
-S

**Windows OS:**
/S

**Arguments**
None

**Default**
OFF

Normal compilation and linking occur.
Description
This option causes the compiler to compile to an assembly file only and not link.
On Linux* and OS X* systems, the assembly file name has a .s suffix. On Windows* systems, the assembly file name has an .asm suffix.

IDE Equivalent
None

Alternate Options
Linux and OS X: None
Windows: /Fa

See Also
Fa compiler option

show
Controls the contents of the listing generated when option list is specified.

Syntax
Linux OS and OS X:
/show=keyword[, keyword...]

Windows OS:
/show:keyword[, keyword...]

Arguments

keyword
Specifies the contents for the listing. Possible values are:

[n]include Controls whether contents of files added with INCLUDE statements are included when a listing is generated.

[n]map Controls whether a symbol listing with a line number cross-reference for each routine is included when a listing is generated.

[n]options Controls whether a list of compiler options used for the compilation is included when a listing is generated.

Default
include, map, and options When a listing is generated, it contains the contents of INCLUDEd files, a symbol list with a line number cross reference, and a list of compiler options used.

Description
This option controls the contents of the listing generated when option list is specified.
If you specify option show and do not specify option list, the option is ignored.
IDE Equivalent
None

Alternate Options
None

See Also
list compiler option

**use-assemble, Quse-assemble**
Tells the compiler to produce objects through the assembler. This is a deprecated option. There is no replacement option.

Syntax

Linux OS and OS X:
- **-use-assemble**
- **-no-use-assemble**

Windows OS:
- **/Quse-assemble**
- **/Quse-assemble-**

Arguments
None

Default
OFF
The compiler produces objects directly.

Description
This option tells the compiler to produce objects through the assembler.

IDE Equivalent
None

Alternate Options
None

Preprocessor Options

**B**
Specifies a directory that can be used to find include files, libraries, and executables.

Syntax

Linux OS and OS X:
- **Bdir**
Windows OS:
None

Arguments

*dir*  
Is the directory to be used. If necessary, the compiler adds a directory separator character at the end of *dir*.

Default

OFF  
The compiler looks for files in the directories specified in your PATH environment variable.

Description

This option specifies a directory that can be used to find include files, libraries, and executables. The compiler uses *dir* as a prefix.

For include files, the *dir* is converted to `-I/dir/include`. This command is added to the front of the includes passed to the preprocessor.

For libraries, the *dir* is converted to `-L/dir`. This command is added to the front of the standard `-L` inclusions before system libraries are added.

For executables, if *dir* contains the name of a tool, such as `ld` or `as`, the compiler will use it instead of those found in the default directories.

The compiler looks for include files in *dir*/include while library files are looked for in *dir*.

IDE Equivalent

None

Alternate Options

None

**D**

Defines a symbol name that can be associated with an optional value.

Syntax

Linux OS and OS X:

```
-Dname[=value]
```

Windows OS:

```
/Dname[=value]
```

Arguments

*name*  
Is the name of the symbol.

*value*  
Is an optional integer or an optional character string delimited by double quotes; for example, `Dname=string`.  

Intel® Fortran Compiler 16.0 User and Reference Guide
Default

noD

Only default symbols or macros are defined.

Description

Defines a symbol name that can be associated with an optional value. This definition is used during preprocessing.

If a value is not specified, name is defined as "1".

If you want to specify more than one definition, you must use separate D options.

If you specify noD, all preprocessor definitions apply only to fpp and not to Intel® Fortran conditional compilation directives. To use this option, you must also specify the fpp option.

CAUTION

On Linux* and OS X* systems, if you are not specifying a value, do not use D for name, because it will conflict with the -DD option.

IDE Equivalent

Visual Studio: General > Preprocessor Definitions
Preprocessor> Preprocessor Definitions
Preprocessor > Preprocessor Definitions to FPP only
Eclipse: None
Xcode: Preprocessor > Preprocessor Definitions
Preprocessor > Preprocessor Definitions to FPP only

Alternate Options

D

Windows: /define:name[=value]

noD

Windows: /nodefine

See Also

Using Predefined Preprocessor Symbols

d-lines, Qd-lines
Compiles debug statements.

Syntax

Linux OS and OS X:

-d-lines

-nod-lines

Windows OS:

/d-lines

/nod-lines

/Qd-lines
Arguments
None

Default

nod-lines

Debug lines are treated as comment lines.

Description
This option compiles debug statements. It specifies that lines in fixed-format files that contain a D in column 1 (debug statements) should be treated as source code.

IDE Equivalent
Visual Studio: **Language > Compile Lines With D in Column 1**
Eclipse: None
Xcode: **Language > Compile Lines With D in Column 1**

Alternate Options
Linux and OS X: `-DD`
Windows: None

E
_Causes the preprocessor to send output to stdout._

Syntax
Linux OS and OS X:

`-E`

Windows OS:

`/E`

Arguments
None

Default

OFF

Preprocessed source files are output to the compiler.

Description
This option causes the preprocessor to send output to stdout. Compilation stops when the files have been preprocessed.

When you specify this option, the compiler’s preprocessor expands your source module and writes the result to stdout. The preprocessed source contains #line directives, which the compiler uses to determine the source file and line number.

IDE Equivalent
None

Alternate Options
None
EP
Causes the preprocessor to send output to stdout, omitting #line directives.

Syntax
Linux OS and OS X:
-EP
Windows OS:
/EP

Arguments
None

Default
OFF
Preprocessed source files are output to the compiler.

Description
This option causes the preprocessor to send output to stdout, omitting #line directives.
If you also specify option preprocess-only, option F, or option E, the preprocessor will write the results (without #line directives) to a file instead of stdout.

IDE Equivalent
None

Alternate Options
None

fpp
Runs the Fortran preprocessor on source files before compilation.

Syntax
Linux OS and OS X:
-fpp
-nofpp
Windows OS:
/fpp
/fpp[:"fpp_option"]
/nofpp

Arguments
fpp_option
Is a Fortran preprocessor (fpp) option; it must start with a slash (/) and appear in quotes. This argument is only allowed on Windows* systems.
**Default**

nofpp  The Fortran preprocessor is not run on files before compilation.

**Description**

This option runs the Fortran preprocessor on source files before they are compiled. If you want to pass fpp options to the Fortran preprocessor, you can use any of the following methods:

- **Use option** `Qoption,fpp,"option"`. This is the recommended method.
- **On Windows* OS**, use this option (fpp) and include the argument `fpp_option` (for example, `fpp:="/macro=no"`).
- **On Linux* OS and OS X***, use option `-Wp,fpp_option` (for example, `-Wp,-macro=no`).

To see a list of all available fpp options, specify one of the following on the command line:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>fpp -help</code></td>
<td>Linux and OS X systems</td>
</tr>
<tr>
<td><code>fpp /help</code></td>
<td>Windows systems</td>
</tr>
</tbody>
</table>

**IDE Equivalent**

Visual Studio: **Preprocessor > Preprocess Source File**

Eclipse: None

Xcode: **Preprocessor > Preprocess Source File**

**Alternate Options**

Linux and OS X: `-cpp` (this is a deprecated option)

Windows: None

**Example**

The following examples show the recommended method of passing fpp options to the Fortran preprocessor:

```plaintext
ifort /fpp /Qoption,fpp,"/macro-no_com" file.f90  ! Disables macro expansion within comments (Windows OS)
ifort -fpp -Qoption,fpp,"-undef" file.f90         ! Undefines all predefined macros (Linux OS and OS X*)
```

**See Also**

- `Qoption` compiler option
- **Using Fortran Preprocessor Options**
- `Wp` compiler option

**fpp-name**

*Let you specify an alternate preprocessor to use with Fortran.*

**Syntax**

**Linux OS and OS X:**

- `-fpp-name=name`

**Windows OS:**

- `/fpp-name:name`
Arguments

name

Is the name of the preprocessor executable. It can include a path. See the description below for more details.

Default

OFF

No preprocessor is run on files before compilation.

Description

This option lets you specify an alternate preprocessor to use with Fortran.

The compiler invokes the user-specified Fortran preprocessor by spawning a command with the following signature:

```
alt_fpp [-D<define>..] [-I<include directory>..] inputfile
```

where `alt_fpp` is the name of the Fortran preprocessor you want to use. Output from the preprocessor goes to STDOUT and will be captured for any further processing.

You can use option `Qoption,fpp,...` to pass options, other than the definitions (`-D xxx`) or include directories (`-I xxx`), to the preprocessor.

You can use option `Qlocation,fpp,...` to specify a directory for supporting tools.

IDE Equivalent

None

Alternate Options

None

`Qlocation` compiler option

`gen-dep`

* Tells the compiler to generate build dependencies for the current compilation.*

Syntax

Linux OS and OS X:

```
-gen-dep[=filename]
-no-gen-dep
```

Windows OS:

```
/gen-dep[:filename]
/gen-dep-
```

Arguments

filename

Is the name of the file for output. It can include a path.
If you specify `filename`, it is similar to specifying option `[Q]MFfilename`. If you do not specify `filename`, it is similar to specifying option `[Q]MD or [Q]MMD.

**Default**

`-no-gen-dep` or `/gen-dep-` The compiler does not generate build dependencies for the compilation.

**Description**

This option tells the compiler to generate build dependencies for the current compilation. The build dependencies include a list of all files included with INCLUDE statements or .mod files accessed with USE statements.

If you do not specify `filename`, the dependencies are written to stdout.

You can use option `gen-depformat` to specify the form of the output for the build dependencies generated.

If you specify option `gen-dep` and you do not specify option `gen-depformat`, the output format is in a form acceptable to the make utility.

Note that if option `fpp` is used to process #include files, those files will also appear in the list of build dependencies.

If you want to generate build dependencies but you do not want to compile the sources, you must also specify option `syntax-only`.

**IDE Equivalent**

Visual Studio: **Output Files > Build Dependencies** (/gen-dep)

**Output Files > Emit Build Dependencies to File** (/gen-dep:filename)

**Output Files > Build Dependencies File** (/gen-dep:filename)

Eclipse: None

Xcode: None

**Alternate Options**

`gen-dep` with a `filename` Linux and OS X: `-MF`  
Windows: `/QMF`

`gen-dep` with no `filename` Linux and OS X: `-MD` or `-MMD`  
Windows: `/QMD` or `/QMMD`

**See Also**

gen-depformat compiler option

syntax-only compiler option

**gen-depformat**

Specifies the form for the output generated when option `gen-dep` is specified.

**Syntax**

**Linux OS and OS X:**

`-gen-depformat=form`
Windows OS:
/gen-depformat:form

Arguments

form Is the output form for the list of build dependencies. Possible values are make or nmake.

Default

make The output form for the list of build dependencies is in a form acceptable to the make utility.

Description

This option specifies the form for the output generated when option gen-dep is specified.

If you specify option gen-depformat and do not specify option gen-dep, the option is ignored.

IDE Equivalent

None

Alternate Options

None

See Also
gen-dep compiler option
gen-depshow

Determines whether certain features are excluded from dependency analysis. Currently, it only applies to intrinsic modules.

Syntax

Linux OS and OS X:
-gen-depshow=keyword

Windows OS:
/gen-depshow:keyword

Arguments

keyword Specifies inclusion or exclusion from dependency analysis. Possible values are:

[no]intr_mod Determines whether intrinsic modules are excluded from dependency analysis.

Default

nointr_mod Tells the compiler to exclude Fortran intrinsic modules in dependency analysis.
Description
This option determines whether certain features are excluded from dependency analysis. Currently, it only applies to intrinsic modules.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>gen-depshow</td>
<td>Tells the compiler to include Fortran intrinsic modules in dependency analysis.</td>
</tr>
</tbody>
</table>

If you do not specify option gen-dep, the compiler does not generate build dependencies for the compilation. If you specify option gen-depshow and do not specify option gen-dep, the option is ignored.

IDE Equivalent
None

gen-dep compiler option

Specifies an additional directory for the include path.

Syntax

Linux OS and OS X:

```
-1dir
```

Windows OS:

```
/I dir
```

Arguments

`dir` Is the directory to add to the include path.

Default

OFF The default include path is used.

Description

This option specifies an additional directory for the include path, which is searched for module files referenced in USE statements and include files referenced in INCLUDE statements. To specify multiple directories on the command line, repeat the option for each directory you want to add.

For all USE statements and for those INCLUDE statements whose file name does not begin with a device or directory name, the directories are searched in this order:

1. The directory containing the first source file.  
   Note that if `assume nosource_include` is specified, this directory will not be searched.
2. The current working directory where the compilation is taking place (if different from the above directory).
3. Any directory or directories specified using the I option. If multiple directories are specified, they are searched in the order specified on the command line, from left to right.

4. On Linux* and OS X* systems, any directories indicated using environment variable CPATH. On Windows* systems, any directories indicated using environment variable INCLUDE.

This option affects fpp preprocessor behavior and the USE statement.

**IDE Equivalent**

Visual Studio: General > Additional Include Directories (/include)

Preprocessor > Additional Include Directories (/include)

Eclipse: None

Xcode: Preprocessor > Additional Include Directories (/include)

**Alternate Options**

Linux and OS X: None

Windows: /include

**See Also**

X compiler option

assume compiler option

idirafter

*Adds a directory to the second include file search path.*

**Syntax**

Linux OS and OS X:

-idirafterdir

Windows OS:

None

**Arguments**

dir

Is the name of the directory to add.

**Default**

OFF

Include file search paths include certain default directories.

**Description**

This option adds a directory to the second include file search path (after \-I).

**IDE Equivalent**

None

**Alternate Options**

None
**isystem**
Specifies a directory to add to the start of the system include path.

**Architecture Restrictions**
Not available on Intel® 64 architecture targeting Intel® MIC Architecture

**Syntax**

Linux OS and OS X:
- `isystem` dir

Windows OS:
None

**Arguments**

`dir` Is the directory to add to the system include path.

**Default**

OFF The default system include path is used.

**Description**
This option specifies a directory to add to the system include path. The compiler searches the specified directory for include files after it searches all directories specified by the `-I` compiler option but before it searches the standard system directories.

On Linux* systems, this option is provided for compatibility with gcc.

**IDE Equivalent**
None

**Alternate Options**
None

**module**
Specifies the directory where module files should be placed when created and where they should be searched for.

**Syntax**

Linux OS and OS X:
- `module` path

Windows OS:
`/module:path`

**Arguments**

`path` Is the directory for module files.
The compiler places module files in the current directory.

**Description**
This option specifies the directory (path) where module (.mod) files should be placed when created and where they should be searched for (USE statement).

**IDE Equivalent**
Visual Studio: **Output > Module Path**
Eclipse: None
Xcode: **Output Files > Module Path**

**Alternate Options**
None

**preprocess-only**
*Causes the Fortran preprocessor to send output to a file.*

**Syntax**

**Linux OS and OS X:**
-preprocess-only

**Windows OS:**
/preprocess-only

**Arguments**
None

**Default**
OFF

Preprocessed source files are output to the compiler.

**Description**
This option causes the Fortran preprocessor to send output to a file.
The source file is preprocessed by the Fortran preprocessor, and the result for each source file is output to a corresponding .i or .i90 file.
Note that the source file is not compiled.

**IDE Equivalent**
None

**Alternate Options**

Linux and OS X: **-P**
Windows: **/P**
u (Windows*)
*Undefines all previously defined preprocessor values.*

**Syntax**

Linux OS and OS X:
None

Windows OS:
/\u

**Arguments**

None

**Default**

OFF  Defined preprocessor values are in effect until they are undefined.

**Description**

This option undefines all previously defined preprocessor values.
To undefine specific preprocessor values, use the /\U option.

**IDE Equivalent**

Visual Studio: **Preprocessor > Undefine All Preprocessor Definitions**
Eclipse: None
Xcode: None

**Alternate Options**

None

**See Also**

U compiler option

**U**
*Undefines any definition currently in effect for the specified symbol.*

**Syntax**

Linux OS and OS X:

- \U name

Windows OS:

/\U name

**Arguments**

name  Is the name of the symbol to be undefined.

**Default**

OFF  Symbol definitions are in effect until they are undefined.
Description
This option undefines any definition currently in effect for the specified symbol.
On Windows systems, use the /u option to undefine all previously defined preprocessor values.

IDE Equivalent
Visual Studio: **Preprocessor > Undefine Preprocessor Definitions**
Eclipse: None
Xcode: **Preprocessor > Undefine Preprocessor Definitions**

Alternate Options
Linux and OS X: None
Windows: /undefined:*name*

See Also
u (Windows*) compiler option

**undef**
*Disables all predefined symbols.*

Syntax
**Linux OS and OS X:**
- undefined

**Windows OS:**
None

Arguments
None

Default
OFF
*Defined symbols are in effect until they are undefined.*

Description
This option disables all predefined symbols.

IDE Equivalent
None

Alternate Options
None

**X**
*Removes standard directories from the include file search path.*

Syntax
**Linux OS and OS X:**
- x
Windows OS:

/X

Arguments
None

Default
OFF

Standard directories are in the include file search path.

Description
This option removes standard directories from the include file search path. It prevents the compiler from searching the default path specified by the CPATH environment variable.

On Linux* and OS X* systems, specifying -X (or -noinclude) prevents the compiler from searching in /usr/include for files specified in an INCLUDE statement.

You can use this option with the i option to prevent the compiler from searching the default path for include files and direct it to use an alternate path.

This option affects fpp preprocessor behavior and the USE statement.

IDE Equivalent
Visual Studio: Preprocessor > Ignore Standard Include Path (/noinclude)
Eclipse: None
Xcode: Preprocessor > Ignore Standard Include Path (/noinclude)

Alternate Options
Linux and OS X: -nostdinc
Windows: /noinclude

i compiler option

Component Control Options

Qinstall
Specifies the root directory where the compiler installation was performed.

Architecture Restrictions
Not available on Intel® 64 architecture targeting Intel® MIC Architecture

Syntax

Linux OS and OS X:

-Qinstall
dir

Windows OS:

None
Arguments

\textit{dir} \hspace{2cm} \text{Is the root directory where the installation was performed.}

Default

OFF \hspace{2cm} \text{The default root directory for compiler installation is searched for the compiler.}

Description

This option specifies the root directory where the compiler installation was performed. It is useful if you want to use a different compiler or if you did not use the compilervars shell script to set your environment variables.

IDE Equivalent

None

Alternate Options

None

\texttt{Qlocation}

\textit{Specifies the directory for supporting tools.}

Architecture Restrictions

Not available on Intel® 64 architecture targeting the Intel® Xeon Phi™ coprocessor x100 product family (formerly code name Knights Corner)

Syntax

Linux OS and OS X:

\texttt{-Qlocation,string,dir}

Windows OS:

\texttt{/Qlocation,string,dir}

Arguments

\textit{string} \hspace{2cm} \text{Is the name of the tool.}

\textit{dir} \hspace{2cm} \text{Is the directory (path) where the tool is located.}

Default

OFF \hspace{2cm} \text{The compiler looks for tools in a default area.}

Description

This option specifies the directory for supporting tools.

\textit{string} can be any of the following:

- \textit{f} - Indicates the Intel® Fortran compiler.
- \textit{fpp (or cpp)} - Indicates the Intel® Fortran preprocessor or a user-specified (alternate) Fortran preprocessor.
• asm - Indicates the assembler.
• link - Indicates the linker.
• prof - Indicates the profiler.

On Windows* systems, the following is also available:

• masm - Indicates the Microsoft assembler.

On Linux* and OS X* systems, the following are also available:

• as - Indicates the assembler.
• gas - Indicates the GNU assembler. This setting is for Linux* only.
• ld - Indicates the loader.
• gld - Indicates the GNU loader. This setting is for Linux* only.
• lib - Indicates an additional library.
• crt - Indicates the crt%.o files linked into executables to contain the place to start execution.

On Windows and OS X* systems, you can also specify a tool command name.

The following shows an example on OS X* systems:

- \texttt{-Qlocation,ld,\textasciitilde\textbackslash{}bin}  
  \texttt{\textasciitilde\textbackslash{}bin/ld} for the loader
- \texttt{-Qlocation,ld,\textasciitilde\textbackslash{}bin/gld}  
  \texttt{\textasciitilde\textbackslash{}bin/gld} as the loader

The following shows an example on Windows* systems:

- \texttt{/Qlocation,link,\textasciitilde\textbackslash{}Program Files\tools\link.exe}  
  \texttt{\textasciitilde\textbackslash{}Program Files\tools\link.exe} for the loader
- \texttt{/Qlocation,link,\textasciitilde\textbackslash{}Program Files\tools\my\_link.exe}  
  \texttt{\textasciitilde\textbackslash{}Program Files\tools\my\_link.exe} as the loader

**IDE Equivalent**

None

**Alternate Options**

None

**Example**

The following command provides the path for the fpp tool:

\texttt{ifort -Qlocation,fpp,\textasciitilde\textbackslash{}usr\preproc myprog.f}

**See Also**

Not available on Intel® 64 architecture targeting the Intel® Xeon Phi™ coprocessor x100 product family
(formerly code name Knights Corner)

**Syntax**

**Linux OS and OS X:**

\texttt{-Qoption,string,options}

**Windows OS:**

\texttt{/Qoption,string,options}
Arguments

**string**
Is the name of the tool.

**options**
Are one or more comma-separated, valid options for the designated tool.
Note that certain tools may require that options appear within quotation marks (" ").

Default
OFF
No options are passed to tools.

Description
This option passes options to a specified tool.
If an argument contains a space or tab character, you must enclose the entire argument in quotation marks (" "). You must separate multiple arguments with commas.

**string** can be any of the following:

- **fpp** (or **cpp**) - Indicates the Intel® Fortran preprocessor or a user-specified (alternate) Fortran preprocessor.
- **asm** - Indicates the assembler.
- **link** - Indicates the linker.
- **prof** - Indicates the profiler.
- On Windows* systems, the following is also available:
  - **masm** - Indicates the Microsoft assembler.
- On Linux* and OS X* systems, the following are also available:
  - **as** - Indicates the assembler.
  - **gas** - Indicates the GNU assembler.
  - **ld** - Indicates the loader.
  - **gld** - Indicates the GNU loader.
  - **lib** - Indicates an additional library.
  - **crt** - Indicates the crt%.o files linked into executables to contain the place to start execution.

IDE Equivalent
None

Alternate Options
None

Example

**Examples for Linux* and OS X* systems:**
The following example directs the linker to link with an alternative library:

```bash
ifort -Qoption,link,-L.,-Lmylib prog1.f
```

The following example passes a compiler option to the assembler to generate a listing file:

```bash
ifort -Qoption,as,"-as=myprogram.lst" -use-asmyprogram.f90
```

The following option passes an **fpp** option to the Fortran preprocessor:

```bash
ifort -Qoption,fpp,"-fpp=macro=no
```

**Examples for Windows* systems:**
The following example directs the linker to create a memory map when the compiler produces the executable file from the source being compiled:

```bash
ifort /Qoption,link,/map:prog1.map prog1.f
```

The following example passes a compiler option to the assembler:

```bash
ifort /Quse-asm /Qoption,masm,"/WX" myprogram.f90
```

The following option passes an `fpp` option to the Fortran preprocessor:

```bash
ifort /Qoption,fpp,"/fpp:macro=no"
```

**See Also**

`Qlocation` compiler option

**Language Options**

**allow**

*Determines whether the compiler allows certain behaviors.*

**Syntax**

Linux OS and OS X:

```
-allow keyword
```

Windows OS:

```
/allow:keyword
```

**Arguments**

`keyword`

Specifies the behaviors to allow or disallow. Possible values are:

- `[no]fpp_comments`
  
  Determines how the `fpp` preprocessor treats Fortran end-of-line comments in preprocessor directive lines.

**Default**

`fpp_comments`

The compiler recognizes Fortran-style end-of-line comments in preprocessor lines.

**Description**

This option determines whether the compiler allows certain behaviors.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>allow nofpp_comments</code></td>
<td>Tells the compiler to disallow Fortran-style end-of-line comments on preprocessor lines. Comment indicators have no special meaning.</td>
</tr>
</tbody>
</table>

**IDE Equivalent**

None

**Alternate Options**

None
**Example**

Consider the following:

```c
#define MAX_ELEMENTS 100  ! Maximum number of elements
```

By default, the compiler recognizes Fortran-style end-of-line comments on preprocessor lines. Therefore, the line above defines `MAX_ELEMENTS` to be "100" and the rest of the line is ignored. If `allow` `nofpp_comments` is specified, Fortran comment conventions are not used and the comment indicator "!" has no special meaning. So, in the above example, "! Maximum number of elements" is interpreted as part of the value for the `MAX_ELEMENTS` definition.

Option `allow` `nofpp_comments` can be useful when you want to have a Fortran directive as a define value; for example:

```c
#define dline(routname) !dir$ attributes alias:"_routname": routname
```

**altparam**

*Allows alternate syntax (without parentheses) for PARAMETER statements.*

**Syntax**

**Linux OS and OS X:**

- `altparam`
- `noaltparam`

**Windows OS:**

- `/altparam`
- `/noaltparam`

**Arguments**

None

**Default**

`altparam` The alternate syntax for PARAMETER statements is allowed.

**Description**

This option specifies that the alternate syntax for PARAMETER statements is allowed. The alternate syntax is:

```c
PARAMETER c = expr [, c = expr] ...
```

This statement assigns a name to a constant (as does the standard PARAMETER statement), but there are no parentheses surrounding the assignment list.

In this alternative statement, the form of the constant, rather than implicit or explicit typing of the name, determines the data type of the variable.

**IDE Equivalent**

Visual Studio: **Language > Enable Alternate PARAMETER Syntax**

Eclipse: None

Xcode: **Language > Enable Alternate PARAMETER Syntax**

**Alternate Options**

`altparam` Linux and OS X: None
assume
Tells the compiler to make certain assumptions.

Syntax

**Linux OS and OS X:**

```
-assume keyword[, keyword...]
```

**Windows OS:**

```
/assume:keyword[, keyword...]
```

Arguments

*keyword*  
Specifies the assumptions to be made. Possible values are:

- **none**  
  Disables all assume options.

- **[no]bscc**  
  Determines whether the backslash character is treated as a C-style control character syntax in character literals.

- **[no]buffered_io**  
  Determines whether data is immediately read from or written to disk or accumulated in a buffer. For variable length, unformatted files, determines whether data is buffered on input or read directly from disk to user variables.

- **[no]buffered_stdout**  
  Determines whether data is immediately written to the standard output device or accumulated in a buffer.

- **[no]byterecl**  
  Determines whether units for the OPEN statement RECL specifier (record length) value in unformatted files are in bytes or longwords (four-byte units).

- **[no]cc_omp**  
  Determines whether conditional compilation as defined by the OpenMP Fortran API is enabled or disabled.

- **[no]dummy_aliases**  
  Determines whether the compiler assumes that dummy arguments to procedures share memory locations with other dummy arguments or with COMMON variables that are assigned.

- **[no]fpe_summary**  
  Determines whether a floating-point exceptions summary is displayed when a STOP statement is encountered.
<table>
<thead>
<tr>

</tr>
<tr>
<td>source_include</td>
<td>Determines whether the compiler searches for USE modules and INCLUDE files in the default directory or in the directory where the source file is located.</td>
</tr>
<tr>
<td>std_intent_in</td>
<td>Determines whether the compiler assumes that dummy arguments with the INTENT(IN) attribute in a called procedure are not modified across a call, in accordance with the Fortran standard.</td>
</tr>
</tbody>
</table>
Determine whether to display a negative value that
is not zero but rounds to zero on output with a
leading minus sign.

Determines whether the names of module
procedures are allowed to conflict with user external
symbol names.

Determines whether the VALUE attribute has the
effect as if the actual argument is assigned to a
temporary, and the temporary is then passed to the
called procedure so that subsequent changes to the
value of the dummy argument do not affect the
actual argument, in accordance with the Fortran
standard.

Determines whether the compiler appends an
underscore character to external user-defined
names.

Determines whether the compiler appends two
underscore characters to external user-defined
names.

Determines whether character constants go into
non-read-only memory.

**Default**

**nobscc**

The backslash character is treated as a normal character in character
literals.

**nobuffered_io**

Data in the internal buffer is immediately read from or written (flushed) to
disk (OPEN specifier BUFFERED='NO'). Data read from variable length,
unformatted files is read directly from disk to a user's variables.

If you set the FORT_BUFFERED environment variable to true, the default is
assume buffered_io.

**nobuffered_stdout**

Data is not buffered for the standard output device but instead is written
immediately to the device.

**nobyterecl**

Units for OPEN statement RECL values with unformatted files are in four-
byte (longword) units.

**nocc_omp**

Conditional compilation as defined by the OpenMP Fortran API is disabled
unless option [q or Q]openmp is specified.

If compiler option [q or Q]openmp is specified, the default is assume
cc_omp.

**nodummy_aliases**

Dummy arguments to procedures do not share memory locations with other
dummy arguments or with variables shared through use association, host
association, or common block use.

**nofpe_summary**

Suppresses a summary of floating-point exceptions from being displayed
when a STOP statement is encountered.

</tr>
<tr>
<td>nostd_mod_proc_name</td>
<td>The compiler allows the names of module procedures to conflict with user external symbol names.</td>
</tr>
</tbody>
</table>
std_value

The compiler assumes that the VALUE attribute has the effect as if the actual argument is assigned to a temporary, and the temporary is then passed to the called procedure so that subsequent changes to the value of the dummy argument do not affect the actual argument, in accordance with the Fortran standard.

Windows: nounderscore
Linux and OS X: underscore

On Windows* systems, the compiler does not append an underscore character to external user-defined names. On Linux* and OS X* systems, the compiler appends an underscore character to external user-defined names.

no2underscores
(Linux and OS X)

The compiler does not append two underscore characters to external user-defined names that contain an embedded underscore.

nowritable-strings

The compiler puts character constants into read-only memory.

Description

This option specifies assumptions to be made by the compiler.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>assume none</td>
<td>Disables all the assume options.</td>
</tr>
<tr>
<td>assume bscc</td>
<td>Tells the compiler to treat the backslash character () as a C-style control (escape) character syntax in character literals. The &quot;bscc&quot; keyword means &quot;BackSlashControlCharacters.&quot;</td>
</tr>
<tr>
<td>assume buffered_io</td>
<td>Tells the compiler to accumulate records in a buffer. This sets the default for opening sequential files to BUFFERED='YES', which also occurs if the FORT_BUFFERED runtime environment variable is specified. When this option is specified, the internal buffer is filled, possibly by many record input statements (READ) or output statements (WRITE), before it is read from disk, or written to disk, by the Fortran run-time system. If a file is opened for direct access, I/O buffering is ignored. Using buffered reads and writes usually makes disk I/O more efficient by handling larger blocks of data on disk less often. However, if you request buffered writes, records not yet written to disk may be lost in the event of a system failure. The OPEN statement BUFFERED specifier applies to a specific logical unit. In contrast, the assume [no]buffered_io option and the FORT_BUFFERED environment variable apply to all Fortran units.</td>
</tr>
<tr>
<td>assume buffered_stdout</td>
<td>Tells the Fortran run-time system to accumulate data for the standard output device in a buffer. When the buffer is full or the user executes a FLUSH on OUTPUT_UNIT in intrinsic module ISO_FORTRAN_ENV, the data is displayed on the standard output unit. Using buffered writes may be a more efficient in time and space but use assume nobuffered_stdout if you want data displayed immediately on the standard output device, like for an input prompt. assume [no]buffered_stdout does not affect and is not affected by assume [no]buffered_io. After compiling with this option, the default blocksize for stdout is 8 KB.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>assume byterecl</td>
<td>Specifies that the units for the OPEN statement RECL specifier (record length) value are in bytes for unformatted data files, not longwords (four-byte units). For formatted files, the RECL value is always in bytes.</td>
</tr>
<tr>
<td></td>
<td>If a file is open for unformatted data and <strong>assume byterecl</strong> is specified, <strong>INQUIRE</strong> returns RECL in bytes; otherwise, it returns RECL in longwords. An <strong>INQUIRE</strong> returns RECL in bytes if the unit is not open.</td>
</tr>
<tr>
<td>assume cc_omp</td>
<td>Enables conditional compilation as defined by the OpenMP Fortran API. That is, when &quot;$space&quot; appears in free-form source or &quot;c$spaces&quot; appears in column 1 of fixed-form source, the rest of the line is accepted as a Fortran line.</td>
</tr>
<tr>
<td>assume dummy_aliases</td>
<td>Tells the compiler that dummy (formal) arguments to procedures share memory locations with other dummy arguments (aliases) or with variables shared through use association, host association, or common block use.</td>
</tr>
<tr>
<td></td>
<td>Specify the option when you compile the called subprogram. The program semantics involved with dummy aliasing do not strictly obey Standard Fortran and they slow performance, so you get better run-time performance if you do not use this option.</td>
</tr>
<tr>
<td></td>
<td>However, if a program depends on dummy aliasing and you do not specify this option, the run-time behavior of the program will be unpredictable. In such programs, the results will depend on the exact optimizations that are performed. In some cases, normal results will occur, but in other cases, results will differ because the values used in computations involving the offending aliases will differ.</td>
</tr>
<tr>
<td>assume fpe_summary</td>
<td>Causes a summary of floating-point exceptions that occurred during program execution to be displayed when a STOP statement is encountered. Counts will be shown for each exception. This is the behavior specified by the Fortran 2003 standard.</td>
</tr>
<tr>
<td></td>
<td>Note that if there is no STOP statement, no summary is displayed.</td>
</tr>
<tr>
<td>assume ieee_fpe_flags</td>
<td>Tells the compiler to save floating-point exception and status flags on routine entry and restore them on routine exit.</td>
</tr>
<tr>
<td></td>
<td>This option can slow runtime performance because it provides extra code to save and restore the floating-point exception and status flags (and the rounding mode) on entry to and exit from every routine compiled with the option.</td>
</tr>
<tr>
<td></td>
<td>This option can be used to get the full Fortran Standard behavior of intrinsic modules IEEE EXCEPTIONS, IEEE ARITHMETIC, and IEEE FEATURES, which require that if a flag is signaling on routine entry, the processor will set it to quiet on entry and restore it to signaling on return. If a flag signals while the routine is executing, it will not be set to quiet on routine exit.</td>
</tr>
<tr>
<td></td>
<td>Options <strong>fpe</strong> and <strong>fpe-all</strong> can be used to set the initial state for which floating-point exceptions will signal.</td>
</tr>
<tr>
<td>assume minus0</td>
<td>Tells the compiler to use Fortran 95 standard semantics for the treatment of the IEEE floating value -0.0 in the <strong>SIGN</strong> intrinsic, which distinguishes the difference between -0.0 and +0.0, and to write a value of -0.0 with a negative sign on formatted output.</td>
</tr>
<tr>
<td>assume old_boz</td>
<td>Tells the compiler that the binary, octal, and hexadecimal constant arguments in intrinsic functions <strong>INT</strong>, <strong>REAL</strong>, <strong>DBLE</strong>, and <strong>CMPLX</strong> should be treated as signed integer constants.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
</tr>
<tr>
<td><code>assume noold_ldout_for mat</code></td>
<td>Tells the compiler to use Fortran 2003 standard semantics for output of integer and real values in list-directed and namelist-directed output. Integers are written using an I0 format with a leading blank for spacing. Real and complex values are written using an E or F format with a leading blank for spacing. The format used depends on the magnitude of the value. Values that are zero are written using an F format.</td>
</tr>
<tr>
<td><code>assume old_logical_ldio</code></td>
<td>Logical values are allowed for numeric items and numeric values are allowed for logical items.</td>
</tr>
<tr>
<td><code>assume noold_maxminloc</code></td>
<td>Tells the compiler that MAXLOC and MINLOC should return 0 when given an empty array as an argument. Compared to the default setting (<code>old_maxminloc</code>), this behavior may slow performance because of the extra code needed to check for an empty array argument.</td>
</tr>
<tr>
<td><code>assume noold_unit_star</code></td>
<td>Tells the compiler that READs or WRITEs to UNIT=* go to the file to which UNIT=5 or 6 is connected.</td>
</tr>
<tr>
<td><code>assume noold_xor</code></td>
<td>Prevents the compiler from defining .XOR. as an intrinsic operator. This lets you use .XOR. as a user-defined operator. This is a Fortran 2003 feature.</td>
</tr>
<tr>
<td><code>assume protect_allocates</code></td>
<td>Memory allocation requests using the ALLOCATE statement are protected with critical sections to avoid random timing problems in a multi-threaded environment in some distributions and configurations.</td>
</tr>
<tr>
<td><code>assume noprotect_constants</code></td>
<td>Tells the compiler to pass a copy of a constant actual argument. This copy can be modified by the called routine, even though the Fortran standard prohibits such modification. The calling routine does not see any modification to the constant.</td>
</tr>
<tr>
<td><code>assume protect_parens</code></td>
<td>Tells the optimizer to honor parentheses in REAL and COMPLEX expression evaluations by not reassociating operations. For example, (A+B)+C would not be evaluated as A+(B+C). If <code>assume noprotect_parens</code> is specified, (A+B)+C would be treated the same as A+B+C and could be evaluated as A+(B+C) if it produced faster executing code. Such reassociation could produce different results depending on the sizes and precision of the arguments. For example, in (A+B)+C, if B and C had opposite signs and were very large in magnitude compared to A, A+B could result in the value as B; adding C would result in 0.0. With reassociation, B+C would be 0.0; adding A would result in a non-zero value.</td>
</tr>
<tr>
<td><code>assume realloc_lhs</code></td>
<td>Tells the compiler that when the left-hand side of an assignment is an allocatable object, it should be reallocated to the shape of the right-hand side of the assignment before the assignment occurs. This is the Fortran 2003 definition. This feature may cause extra overhead at run time.</td>
</tr>
<tr>
<td><code>assume nosource_includ e</code></td>
<td>Tells the compiler to search the default directory for module files specified by a USE statement or source files specified by an INCLUDE statement. This option affects fpp preprocessor behavior and the USE statement.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>assume nostd_intent_in</td>
<td>Tells the compiler to assume that dummy arguments with the INTENT(IN) attribute in a called procedure may be modified across a call. This is not in accordance with the Fortran standard.</td>
</tr>
<tr>
<td></td>
<td>If you specify option standard_semantics, it sets option assume std_intent_in.</td>
</tr>
<tr>
<td>assume nostd_minus0_ rounding</td>
<td>Tells the compiler to use pre-Fortran 2008 standard semantics for the treatment of IEEE floating values that are negative, non-zero, and when rounded for display are zero. The value should be printed without a leading minus sign.</td>
</tr>
<tr>
<td></td>
<td>For example, the floating value -0.00000001 when rounded in F5.1 format will be displayed as 0.0. Use assume std_minus0_rounding to use Fortran 2008 standard semantics to display this value as -0.0 when rounded in F5.1 format.</td>
</tr>
<tr>
<td>assume std_mod_proc_name</td>
<td>Tells the compiler to revise the names of module procedures so they do not conflict with user external symbol names. For example, procedure proc in module m would be named m_MP_proc. The Fortran 2003 Standard requires that module procedure names not conflict with other external symbols.</td>
</tr>
<tr>
<td></td>
<td>By default, procedure proc in module m would be named m_mp_proc, which could conflict with a user-defined external name m_mp_proc.</td>
</tr>
<tr>
<td>assume nostd_value</td>
<td>Tells the compiler to use pre-Fortran 2003 standard semantics for the VALUE attribute so that the value of the actual argument is passed to the called procedure, not the address of the actual argument nor the address of a copy of the actual argument.</td>
</tr>
<tr>
<td>assume underscore</td>
<td>Tells the compiler to append an underscore character to external user-defined names: the main program name, named common blocks, BLOCK DATA blocks, global data names in MODULEs, and names implicitly or explicitly declared EXTERNAL. The name of a blank (unnamed) common block remains <em>BLNK</em>_, and Fortran intrinsic names are not affected.</td>
</tr>
<tr>
<td>assume 2underscores (Linux and OS X)</td>
<td>Tells the compiler to append two underscore characters to external user-defined names that contain an embedded underscore: the main program name, named common blocks, BLOCK DATA blocks, global data names in MODULEs, and names implicitly or explicitly declared EXTERNAL. The name of a blank (unnamed) common block remains <em>BLNK</em>_, and Fortran intrinsic names are not affected.</td>
</tr>
<tr>
<td></td>
<td>This option does not affect external names that do not contain an embedded underscore. By default, the compiler only appends one underscore to those names. For example, if you specify assume 2underscores for external names my_program and myprogram, my_program becomes my_program__, but myprogram becomes myprogram_.</td>
</tr>
<tr>
<td>assume writeable-strings</td>
<td>Tells the compiler to put character constants into non-read-only memory.</td>
</tr>
</tbody>
</table>

Rules for Unformatted Sequential READ Statements

ccdecl
Specifies the type of carriage control used when a file is displayed at a terminal screen.

Syntax
Linux OS and OS X:
-ccdefault keyword
Windows OS:
/ccdefault:keyword

Arguments

Keyword Specifies the carriage-control setting to use. Possible values are:

- none: Tells the compiler to use no carriage control processing.
- default: Tells the compiler to use the default carriage-control setting.
- fortran: Tells the compiler to use normal Fortran interpretation of the first character. For example, the character 0 causes output of a blank line before a record.
- list: Tells the compiler to output one line feed between records.

Default

/ccdefault default The compiler uses the default carriage control setting.

Description

This option specifies the type of carriage control used when a file is displayed at a terminal screen (units 6 and *). It provides the same functionality as using the CARRIAGECONTROL specifier in an OPEN statement.

The default carriage-control setting can be affected by the vms option. If option vms is specified with /ccdefault default, carriage control defaults to normal Fortran interpretation (/ccdefault fortran) if the file is formatted and the unit is connected to a terminal. If option novms (the default) is specified with /ccdefault default, carriage control defaults to list (/ccdefault list).

IDE Equivalent

Visual Studio: Run-time > Default Output Carriage Control
Eclipse: None
Xcode: Run-time > Default Output Carriage Control

Alternate Options

None

check

Checks for certain conditions at run time.

Syntax

Linux OS and OS X:

- -check [keyword[, keyword...]]
- -nocheck

Windows OS:

/(check[:keyword[, keyword...]]

<tr>
<td>[no]assume</td>
<td>Determines whether checking occurs to test that the scalar-Boolean-expression in the ASSUME directive is true, or that the addresses in the ASSUME_ALIGNED directive are aligned on the specified byte boundaries.</td>
</tr>
<tr>
<td>[no]bounds</td>
<td>Determines whether checking occurs for array subscript and character substring expressions.</td>
</tr>
<tr>
<td>[no]format</td>
<td>Determines whether checking occurs for the data type of an item being formatted for output.</td>
</tr>
<tr>
<td>[no]output_conversion</td>
<td>Determines whether checking occurs for the fit of data items within a designated format descriptor field.</td>
</tr>
<tr>
<td>[no]pointers</td>
<td>Determines whether checking occurs for certain disassociated or uninitialized pointers or unallocated allocatable objects.</td>
</tr>
<tr>
<td>[no]stack</td>
<td>Determines whether checking occurs on the stack frame.</td>
</tr>
<tr>
<td>[no]uninit</td>
<td>Determines whether checking occurs for uninitialized variables.</td>
</tr>
<tr>
<td>all</td>
<td>Enables all check options.</td>
</tr>
</tbody>
</table>

Default

nocheck

No checking is performed for run-time failures. Note that if option vms is specified, the defaults are check format and check output_conversion.

Description

This option checks for certain conditions at run time.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>check none</td>
<td>Disables all check options (same as nocheck).</td>
</tr>
<tr>
<td>check arg_temp_created</td>
<td>Enables run-time checking on whether actual arguments are copied into temporary storage before routine calls. If a copy is made at run-time, an informative message is displayed.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>check assume</td>
<td>Enables run-time checking on whether the scalar-Boolean-expression in the ASSUME directive is true and that the addresses in the ASSUME_ALIGNED directive are aligned on the specified byte boundaries. If the test is .FALSE., a run-time error is reported and the execution terminates.</td>
</tr>
<tr>
<td>check bounds</td>
<td>Enables compile-time and run-time checking for array subscript and character substring expressions. An error is reported if the expression is outside the dimension of the array or the length of the string.</td>
</tr>
<tr>
<td></td>
<td>For array bounds, each individual dimension is checked. For arrays that are dummy arguments, only the lower bound is checked for a dimension whose upper bound is specified as * or where the upper and lower bounds are both 1.</td>
</tr>
<tr>
<td></td>
<td>For some intrinsics that specify a DIM= dimension argument, such as LBOUND, an error is reported if the specified dimension is outside the declared rank of the array being operated upon.</td>
</tr>
<tr>
<td></td>
<td>Once the program is debugged, omit this option to reduce executable program size and slightly improve run-time performance.</td>
</tr>
<tr>
<td></td>
<td>It is recommended that you do bounds checking on unoptimized code. If you use option check bounds on optimized code, it may produce misleading messages because registers (not memory locations) are used for bounds values.</td>
</tr>
<tr>
<td>check format</td>
<td>Issues the run-time FORVARMIS fatal error when the data type of an item being formatted for output does not match the format descriptor being used (for example, a REAL*4 item formatted with an I edit descriptor).</td>
</tr>
<tr>
<td></td>
<td>With check noformat, the data item is formatted using the specified descriptor unless the length of the item cannot accommodate the descriptor (for example, it is still an error to pass an INTEGER*2 item to an E edit descriptor).</td>
</tr>
<tr>
<td>check output_conversion</td>
<td>Issues the run-time OUTCONERR continuable error message when a data item is too large to fit in a designated format descriptor field without loss of significant digits. Format truncation occurs, the field is filled with asterisks (*), and execution continues.</td>
</tr>
<tr>
<td>check pointers</td>
<td>Enables run-time checking for disassociated or uninitialized Fortran pointers, unallocated allocatable objects, and integer pointers that are uninitialized.</td>
</tr>
<tr>
<td>check stack</td>
<td>Enables checking on the stack frame. The stack is checked for buffer overruns and buffer underruns. This option also enforces local variables initialization and stack pointer verification.</td>

extend-source

Specifies the length of the statement field in a fixed-form source file.
Syntax

Linux OS and OS X:
-extend-source [size]
-noextend-source

Windows OS:
/extend-source[:size]
/noextend-source

Arguments

size

Is the length of the statement field in a fixed-form source file. Possible values are: 72, 80, or 132.

Default

72

If you do not specify this option or you specify noextend-source, the statement field ends at column 72.

132

If you specify extend_source without size, the statement field ends at column 132.

Description

This option specifies the size (column number) of the statement field of a source line in a fixed-form source file. This option is valid only for fixed-form files; it is ignored for free-form files.

When size is specified, it is the last column parsed as part of the statement field. Any columns after that are treated as comments.

If you do not specify size, it is the same as specifying extend_source 132.

</table>
fixed
Specifies source files are in fixed format.

Syntax
Linux OS and OS X:
- fixed
  - nofixed
Windows OS:
/fixed
/nofixed

Arguments
None

Default
OFF

The source file format is determined from the file extension.

Description
This option specifies source files are in fixed format. If this option is not specified, format is determined as follows:

- Files with an extension of .f90, .F90, or .i90 are free-format source files.
- Files with an extension of .f, .for, .FOR, .ftn, .FTN, .fpp, .FPP, or .i are fixed-format files.

Note that on Linux* and OS X* systems, file names and file extensions are case sensitive.

IDE Equivalent
Visual Studio: Language > Source File Format (/free, /fixed)
Eclipse: None
Xcode: Language > Source File Format (/free, /fixed)

Alternate Options
Linux and OS X: -FI
Windows: /nofree, /FI, /4Nf

free
Specifies source files are in free format.

Syntax
Linux OS and OS X:
- free
-nofree

**Windows OS:**
/free
/nofree

**Arguments**
None

**Default**
OFF  The source file format is determined from the file extension.

**Description**
This option specifies source files are in free format. If this option is not specified, format is determined as follows:

- Files with an extension of .f90, .F90, or .i90 are free-format source files.
- Files with an extension of .f, .for, .FOR, .ftn, or .i are fixed-format files.

**IDE Equivalent**
Visual Studio: **Language > Source File Format (/free, /fixed)**
Eclipse: None
Xcode: **Language > Source File Format (/free, /fixed)**

**Alternate Options**
Linux and OS X: `-FR`
Windows: `/nofixed`, `/FR`, `/4Yf`

**See Also**
`fixed` compiler option

**iface**
Specifies the default calling convention and argument-passing convention for an application.

**Syntax**

**Linux OS and OS X:**
None

**Windows OS:**
`/iface:keyword`

**Arguments**

- **keyword**
  Specifies the calling convention or the argument-passing convention. Possible values are:

  - `default`
    Tells the compiler to use the default calling conventions.
Tells the compiler to use calling conventions C, REFERENCE.

Tells the compiler to use calling conventions compatible with Compaq Visual Fortran*. This value is only available on Windows* systems.

Determines the argument-passing convention for hidden-length character arguments.

Tells the compiler to use calling convention STDCALL.

Tells the compiler to use calling conventions STDCALL, REFERENCE.

The default calling convention is used.

This option specifies the default calling convention and argument-passing convention for an application. The aspects of calling and argument passing controlled by this option are as follows:

- The calling mechanism (C or STDCALL): On IA-32 architecture, these mechanisms differ in how the stack register is adjusted when a procedure call returns. On Intel® 64 architecture, the only calling mechanism available is C; requests for the STDCALL mechanism are ignored.
- The argument passing mechanism (by value or by reference)
- Character-length argument passing (at the end of the argument list or after the argument address)
- The case of external names (uppercase or lowercase)
- The name decoration (prefix and suffix)

You can also use the ATTRIBUTES compiler directive to modify these conventions on an individual basis. Note that the effects of the ATTRIBUTES directive do not always match that of the iface option of the same name.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/iface:default</td>
<td>Tells the compiler to use the default calling conventions. These conventions are as follows:</td>
</tr>
<tr>
<td></td>
<td>• The calling mechanism: C</td>
</tr>
<tr>
<td></td>
<td>• The argument passing mechanism: by reference</td>
</tr>
<tr>
<td></td>
<td>• Character-length argument passing: at end of argument list</td>
</tr>
<tr>
<td></td>
<td>• The external name case: uppercase</td>
</tr>
<tr>
<td></td>
<td>• The name decoration: Underscore prefix on IA-32 architecture, no prefix on Intel® 64 architecture; no suffix</td>
</tr>
<tr>
<td>/iface:cref</td>
<td>Tells the compiler to use the same conventions as /iface:default except that external names are lowercase.</td>
</tr>
<tr>
<td>/iface:cvf</td>
<td>Tells the compiler to use calling conventions compatible with Compaq Visual Fortran* and Microsoft Fortran PowerStation. This option is only available on Windows* systems. These conventions are as follows:</td>
</tr>
<tr>
<td></td>
<td>• The calling mechanism: STDCALL on Windows* systems using IA-32 architecture</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>/iface:mixed_str</td>
<td>Specifies argument-passing conventions for hidden-length character arguments. This option tells the compiler that the hidden length passed for a character argument is to be placed immediately after its corresponding character argument in the argument list. This is the method used by Compaq Visual Fortran®. When porting mixed-language programs that pass character arguments, either this option must be specified correctly or the order of hidden length arguments must be changed in the source code. This option can be used in addition to other /iface options.</td>
</tr>
<tr>
<td>/iface:stdcall</td>
<td>Tells the compiler to use the following conventions:</td>
</tr>
<tr>
<td></td>
<td>• The calling mechanism: STDCALL</td>
</tr>
<tr>
<td></td>
<td>• The argument passing mechanism: by value</td>
</tr>
<tr>
<td></td>
<td>• Character-length argument passing: at the end of the argument list</td>
</tr>
<tr>
<td></td>
<td>• The external name case: uppercase</td>
</tr>
<tr>
<td></td>
<td>• The name decoration: Underscore prefix on IA-32 architecture, no prefix on Intel® 64 architecture. On Windows* systems using IA-32 architecture, @n suffix where n is the number of bytes to be removed from the stack on exit from the procedure. No suffix on other systems.</td>
</tr>
<tr>
<td>/iface:stdref</td>
<td>Tells the compiler to use the same conventions as /iface:stdcall except that argument passing is by reference.</td>
</tr>
</tbody>
</table>

**CAUTION**

On Windows systems, if you specify option /iface:cref, it overrides the default for external names and causes them to be lowercase. It is as if you specified "!dir$ attributes c, reference“ for the external name.

If you specify option /iface:cref and want external names to be uppercase, you must explicitly specify option /names:uppercase.

**CAUTION**

On systems using IA-32 architecture, there must be agreement between the calling program and the called procedure as to which calling mechanism (C or STDCALL) is used, or unpredictable errors may occur. If you change the default mechanism to STDCALL, you must use the ATTRIBUTES DEFAULT directive to reset the calling conventions for any procedure that is:

• Specified as a FINAL procedure for a derived type
• Specified as a USEROPEN procedure in an OPEN statement
• Referenced in a variable format expression
• Specified as a comparison routine passed to the QSORT library routine from module IFPORT
• Used as a dialog callback procedure with the IFLOGM module
• Used as a callback procedure in a call to the IMSL* library
• Called from other contexts or languages that assume the C calling convention

Note that Visual Studio projects that are imported using the Extract Compaq Visual Fortran project items wizard have /iface:cvf applied automatically; this establishes STDCALL as the default convention.

**IDE Equivalent**

Visual Studio: **External Procedures > Calling Convention (/iface:{cref|stdref|stdcall|cvf|default})**

**External Procedures > String Length Argument Passing (/iface:[no]mixed_str_len_arg)**

Eclipse: None

Xcode: None

**Alternate Options**

```

**See Also**

Language Reference: **ATTRIBUTES**

**names**

Specifies how source code identifiers and external names are interpreted.

**Syntax**

Linux OS and OS X:

- `names keyword`

Windows OS:

`/names:keyword`

**Arguments**

`keyword`

Specifies how to interpret the identifiers and external names in source code. Possible values are:

- `lowercase` Causes the compiler to ignore case differences in identifiers and to convert external names to lowercase.
<table>
<thead>
<tr>
<th>Case Sensitivity</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>uppercase</strong></td>
<td>Causes the compiler to ignore case differences in identifiers and to convert external names to uppercase.</td>
</tr>
<tr>
<td><strong>as_is</strong></td>
<td>Causes the compiler to distinguish case differences in identifiers and to preserve the case of external names.</td>
</tr>
</tbody>
</table>

### Default
- **lowercase**
  This is the default on Linux* and OS X* systems. The compiler ignores case differences in identifiers and converts external names to lowercase.
- **uppercase**
  This is the default on Windows* systems. The compiler ignores case differences in identifiers and converts external names to uppercase.

### Description
This option specifies how source code identifiers and external names are interpreted. It can be useful in mixed-language programming.

This naming convention applies whether names are being defined or referenced.

You can use the ALIAS directive to specify an alternate external name to be used when referring to external subprograms.

**CAUTION**
On Windows systems, if you specify option `/iface:cref`, it overrides the default for external names and causes them to be lowercase. It is as if you specified "dir$ attributes c, reference" for the external name.

If you specify option `/iface:cref` and want external names to be uppercase, you must explicitly specify option `/names:uppercase`.

### IDE Equivalent
- **Visual Studio:** *External Procedures > Name Case Interpretation*
- **Eclipse:** None
- **Xcode:** *External Procedures > Name Case Interpretation*

### Alternate Options
None

### See Also
- `iface` compiler option
- ALIAS Directive
- `pad-source`, `Qpad-source`
  *Specifies padding for fixed-form source records.*

### Syntax
**Linux OS and OS X:**
- `-pad-source`
- `-nopad-source`
Windows OS:
/pad-source
/nopad-source
/Qpad-source
/Qpad-source-

Arguments
None

Default
-nopad-source or /Qpad-source

Fixed-form source records are not padded.

Description
This option specifies padding for fixed-form source records. It tells the compiler that fixed-form source lines shorter than the statement field width are to be padded with spaces to the end of the statement field. This affects the interpretation of character and Hollerith literals that are continued across source records.

The default value setting causes a warning message to be displayed if a character or Hollerith literal that ends before the statement field ends is continued onto the next source record. To suppress this warning message, specify setting nousage for option warn.

Specifying [Q]pad-source can prevent warning messages associated with setting usage for option warn.

IDE Equivalent
Visual Studio: Language > Pad Fixed Form Source Lines
Eclipse: None
Xcode: Language > Pad Fixed Form Source Lines

Alternate Options
None

See Also
warn compiler option
stand
Tells the compiler to issue compile-time messages for nonstandard language elements.

Syntax
Linux OS and OS X:
-stand [keyword]
-nostand

Windows OS:
/stand[:keyword]
/nostand
Arguments

*keyword* Specifies the language to use as the standard. Possible values are:

- **none** Issues no messages for nonstandard language elements.
- **f90** Issues messages for language elements that are not standard in Fortran 90.
- **f95** Issues messages for language elements that are not standard in Fortran 95.
- **f03** Issues messages for language elements that are not standard in Fortran 2003.
- **f08** Issues messages for language elements that are not standard in Fortran 2008.
- **f15** Issues messages for language elements that are not standard in draft Fortran 2015.

Default

**nostand** The compiler issues no messages for nonstandard language elements.

Description

This option tells the compiler to issue compile-time messages for nonstandard language elements.

If you do not specify a keyword for `stand`, it is the same as specifying `stand f08`.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>

warn compiler option

standard-semantics
Determines whether the current Fortran Standard behavior of the compiler is fully implemented.

Syntax

Linux OS and OS X:
-std-segmentation

Windows OS:
/standard-segmentation

Arguments
None

Default
OFF

The compiler implements most but not all of the current Fortran Standard behavior.

Description

This option determines whether the current Fortran Standard behavior of the compiler is fully implemented.

If you specify option standard-semantics, it enables all of the options that implement the current Fortran Standard behavior of the compiler, which is Fortran 2003 with some Fortran 2008 features.

Option standard-semantics enables option fpscomp logicals and the following settings for option assume: byterecl, fpe_summary, ieee_fpe_flags (if the fp-model option setting is strict or precise), minus0, noold_ldout_format, noold_maxminloc, noold_unit_star, noold_xor, protect_parens, realloc_lhs, std_intent_in, std_minus0_rounding\(^1\), std_mod_proc_name, and std_value\(^1\).
If you specify option standard-semantics and also explicitly specify a different setting for an affected assume option, the value you specify takes effect. It overrides the settings enabled by option standard-semantics.

**IDE Equivalent**

Visual Studio: Language > Enable F2003 Semantics

Eclipse: None

Xcode: None

**Alternate Options**

None

**See Also**

assume compiler option

stand compiler option

syntax-only

*Tells the compiler to check only for correct syntax.*

**Syntax**

**Linux OS and OS X:**

- `-syntax-only`

**Windows OS:**

`/syntax-only`

**Arguments**

None

**Default**

OFF

Normal compilation is performed.

**Description**

This option tells the compiler to check only for correct syntax. It lets you do a quick syntax check of your source file.

Compilation stops after the source file has been parsed. No code is generated, no object file is produced, and some error checking done by the optimizer is bypassed.

Warnings and messages appear on `stderr`.

**IDE Equivalent**

None

**Alternate Options**

Linux: `-y`, `-fsyntax-only`, `-syntax` *(this is a deprecated option)*

OS X: `-y`, `-fsyntax-only`

Windows: `/Zs`

---

¹ This is the default setting for this assume option.
**wrap-margin**

*Provides a way to disable the right margin wrapping that occurs in Fortran list-directed output.*

**Syntax**

**Linux OS:**
- `--wrap-margin`
- `--no-wrap-margin`

**OS X:**
None

**Windows OS:**
- `/wrap-margin`
- `/wrap-margin-`

**Arguments**

None

**Default**

`wrap-margin` The right margin wraps at column 80 if the record length is greater than 80 characters.

**Description**

This option provides a way to disable the right margin wrapping that occurs in Fortran list-directed output. By default, when the record being written becomes longer than 80 characters, the record is wrapped to a new record at what is called the "right margin".

Specify `--no-wrap-margin` (*Linux* OS) or `/wrap-margin-` (*Windows* OS) to disable this behavior.

**IDE Equivalent**

None

**Alternate Options**

None

**Data Options**

**align**

*Tells the compiler how to align certain data items.*

**Syntax**

**Linux OS and OS X:**
- `--align [keyword[, keyword...]]`
- `--noalign`

**Windows OS:**
- `/align[:keyword[, keyword...]]`
- `/noalign`
Arguments

*keyword*

Specifies the data items to align. Possible values are:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>Prevents padding bytes anywhere in common blocks and structures.</td>
</tr>
<tr>
<td>array<em>byte</em></td>
<td>Specifies a starting boundary for arrays.</td>
</tr>
<tr>
<td>[no]commons</td>
<td>Affects alignment of common block entities.</td>
</tr>
<tr>
<td>[no]dcommons</td>
<td>Affects alignment of common block entities.</td>
</tr>
<tr>
<td>[no]qcommons</td>
<td>Affects alignment of common block entities.</td>
</tr>
<tr>
<td>[no]zcommons</td>
<td>Affects alignment of common block entities.</td>
</tr>
<tr>
<td>[no]records</td>
<td>Affects alignment of derived-type components and fields of record structures.</td>
</tr>
<tr>
<td>rec<em>nbyte</em></td>
<td>Specifies a size boundary for derived-type components and fields of record structures.</td>
</tr>
<tr>
<td>[no]sequence</td>
<td>Affects alignment of sequenced derived-type components.</td>
</tr>
<tr>
<td>all</td>
<td>Adds padding bytes whenever possible to data items in common blocks and structures.</td>
</tr>
</tbody>
</table>

Default

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nocommons</td>
<td>Adds no padding bytes for alignment of common blocks.</td>
</tr>
<tr>
<td>nodcommons</td>
<td>Adds no padding bytes for alignment of common blocks.</td>
</tr>
<tr>
<td>noqcommons</td>
<td>Adds no padding bytes for alignment of common blocks.</td>
</tr>
<tr>
<td>nozcommons</td>
<td>Adds no padding bytes for alignment of common blocks.</td>
</tr>
<tr>
<td>records</td>
<td>Aligns derived-type components and record structure fields on default natural boundaries.</td>
</tr>
<tr>
<td>nosequence</td>
<td>Causes derived-type components declared with the SEQUENCE statement to be packed, regardless of current alignment rules set by the user.</td>
</tr>
</tbody>
</table>

By default, no padding is added to common blocks but padding is added to structures.

Description

This option specifies the alignment to use for certain data items. The compiler adds padding bytes to perform the alignment.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>align none</td>
<td>Tells the compiler not to add padding bytes anywhere in common blocks or structures. This is the same as specifying noalign.</td>

  Linux and OS X: -Zp1, -align rec1byte  
  Windows: /Zp1, /align:rec1byte  
- **align recnbyte**  
  Linux and OS X: -Zp{1|2|4|8|16}  
  Windows: /Zp{1|2|4|8|16}
align all

Linux and OS X: -align commons-align dcommons-align records-align nosequence

Windows: /align:nocommons,dcommons,records,nosequence

auto
Causes all local, non-SAVEd variables to be allocated to the run-time stack.

Syntax

Linux OS and OS X:
- auto
- noauto

Windows OS:
/auto
/noauto

Arguments
None

Default
-auto-scalar
or /Qauto-scalar

Scalar variables of intrinsic types INTEGER, REAL, COMPLEX, and LOGICAL are allocated to the run-time stack. Note that the default changes to auto if one of the following options are specified:
- recursive
- [q or Q]openmp

Description
This option places local variables (scalars and arrays of all types), except those declared as SAVE, on the run-time stack. It is as if the variables were declared with the AUTOMATIC attribute.

It does not affect variables that have the SAVE attribute or ALLOCATABLE attribute, or variables that appear in an EQUIVALENCE statement or in a common block.

This option may provide a performance gain for your program, but if your program depends on variables having the same value as the last time the routine was invoked, your program may not function properly.

If you want to cause variables to be placed in static memory, specify option [Q]save. If you want only scalar variables of certain intrinsic types to be placed on the run-time stack, specify option auto-scalar.

NOTE
On Windows NT* systems, there is a performance penalty for addressing a stack frame that is too large. This penalty may be incurred with /[Q]auto, because arrays are allocated on the stack along with scalars. However, with /Qauto-scalar, you would have to have more than 32K bytes of local scalar variables before you incurred the performance penalty. /Qauto-scalar enables the compiler to make better choices about which variables should be kept in registers during program execution.

IDE Equivalent
Visual Studio: Data > Local Variable Storage
**Alternate Options**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
</table>
| `auto`   | Linux and OS X: None  
Windows: `/Qauto, /4Ya` |
| `noauto` | Linux and OS X: `-save`  
Windows: `/Qsave, /4Na` |

**See Also**

- `auto-scalar`, `Qauto-scalar` compiler option
- `save`, `Qsave` compiler option

**auto-scalar, Qauto-scalar**

*Causes scalar variables of intrinsic types INTEGER, REAL, COMPLEX, and LOGICAL that do not have the SAVE attribute to be allocated to the run-time stack.*

**Syntax**

**Linux OS and OS X:**

- `-auto-scalar`

**Windows OS:**

- `/Qauto-scalar`

**Arguments**

None

**Default**

- `-auto-scalar` or `/Qauto-scalar`

Scalar variables of intrinsic types INTEGER, REAL, COMPLEX, and LOGICAL that do not have the SAVE attribute are allocated to the run-time stack. Note that the default changes to `auto` if one of the following options are specified:

- `recursive`
- `[q or Q]openmp`

**Description**

This option causes allocation of scalar variables of intrinsic types INTEGER, REAL, COMPLEX, and LOGICAL to the run-time stack. It is as if they were declared with the AUTOMATIC attribute.

It does not affect variables that have the SAVE attribute (which include initialized locals) or that appear in an EQUIVALENCE statement or in a common block.

This option may provide a performance gain for your program, but if your program depends on variables having the same value as the last time the routine was invoked, your program may not function properly. Variables that need to retain their values across subroutine calls should appear in a SAVE statement.

You cannot specify option `save` or `auto` with this option.
NOTE
On Windows NT* systems, there is a performance penalty for addressing a stack frame that is too large. This penalty may be incurred with /Qauto because arrays are allocated on the stack along with scalars. However, with /Qauto-scalar, you would have to have more than 32K bytes of local scalar variables before you incurred the performance penalty. /Qauto-scalar enables the compiler to make better choices about which variables should be kept in registers during program execution.

IDE Equivalent
Visual Studio: Data > Local Variable Storage (/Qsave, /Qauto, /Qauto_scalar)
Eclipse: None
Xcode: None

Alternate Options
None

convert
Specifies the format of unformatted files containing numeric data.

Syntax
Linux OS and OS X:
-convert keyword

Windows OS:
/convert:keyword

Arguments

keyword
Specifies the format for the unformatted numeric data. Possible values are:

native
Specifies that unformatted data should not be converted.

big_endian
Specifies that the format will be big endian for integer data and big endian IEEE floating-point for real and complex data.

cray
Specifies that the format will be big endian for integer data and CRAY* floating-point for real and complex data.

fdx
(Linux* OS, OS X*)
Specifies that the format will be little endian for integer data, and VAX processor floating-point format F_floating, D_floating, and X_floating for real and complex data.
fgx (Linux OS, OS X) Specifies that the format will be little endian for integer data, and VAX processor floating-point format F_floating, G_floating, and X_floating for real and complex data.

ibm Specifies that the format will be big endian for integer data and IBM* System\370 floating-point format for real and complex data.

little_endian Specifies that the format will be little endian for integer data and little endian IEEE floating-point for real and complex data.

vaxd Specifies that the format will be little endian for integer data, and VAX* processor floating-point format F_floating, D_floating, and H_floating for real and complex data.

vaxg Specifies that the format will be little endian for integer data, and VAX processor floating-point format F_floating, G_floating, and H_floating for real and complex data.

Default

convert native No conversion is performed on unformatted files containing numeric data.

Description

This option specifies the format of unformatted files containing numeric data.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>convert native</td>
<td>Specifies that unformatted data should not be converted.</td>
</tr>
<tr>
<td>convert big_endian</td>

</tr>
<tr>
<td>convert cray</td>
<td>Specifies that the format will be big endian for INTEGER<em>1, INTEGER</em>2, INTEGER<em>4, or INTEGER</em>8, and CRAY* floating-point for REAL<em>8 or COMPLEX</em>16.</td>
</tr>
<tr>
<td>convert fdx</td>
<td>Specifies that the format will be little endian for INTEGER<em>1, INTEGER</em>2, INTEGER<em>4, or INTEGER</em>8, and VAX processor floating-point format F_floating for REAL<em>4 or COMPLEX</em>8, D_floating for REAL<em>8 or COMPLEX</em>16, and X_floating for REAL<em>16 or COMPLEX</em>32.</td>
</tr>
<tr>
<td>convert fgx</td>
<td>Specifies that the format will be little endian for INTEGER<em>1, INTEGER</em>2, INTEGER<em>4, or INTEGER</em>8, and VAX processor floating-point format F_floating for REAL<em>4 or COMPLEX</em>8, G_floating for REAL<em>8 or COMPLEX</em>16, and X_floating for REAL<em>16 or COMPLEX</em>32.</td>
</tr>
<tr>
<td>convert ibm</td>
<td>Specifies that the format will be big endian for INTEGER<em>1, INTEGER</em>2, or INTEGER<em>4, and IBM</em> System\370 floating-point format for REAL<em>4 or COMPLEX</em>8 (IBM short 4) and REAL<em>8 or COMPLEX</em>16 (IBM long 8).</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
</tr>
<tr>
<td>convert little_endian</td>
<td>Specifies that the format will be little endian for INTEGER<em>1, INTEGER</em>2, INTEGER<em>4, or INTEGER</em>8 and little endian IEEE floating-point for REAL<em>4, REAL</em>8, REAL<em>16, COMPLEX</em>8, COMPLEX<em>16, or COMPLEX</em>32.</td>
</tr>
<tr>
<td>convert vaxd</td>
<td>Specifies that the format will be little endian for INTEGER<em>1, INTEGER</em>2, INTEGER<em>4, or INTEGER</em>8, and VAX processor floating-point format F_floating for REAL<em>4 or COMPLEX</em>8, D_floating for REAL<em>8 or COMPLEX</em>16, and H_floating for REAL<em>16 or COMPLEX</em>32.</td>
</tr>
<tr>
<td>convert vaxg</td>
<td>Specifies that the format will be little endian for INTEGER<em>1, INTEGER</em>2, INTEGER<em>4, or INTEGER</em>8, and VAX processor floating-point format F_floating for REAL<em>4 or COMPLEX</em>8, G_floating for REAL<em>8 or COMPLEX</em>16, and H_floating for REAL<em>16 or COMPLEX</em>32.</td>
</tr>
</tbody>
</table>

Non-native data conversion works on scalars and arrays of intrinsic types: INTEGER*1, INTEGER*2, INTEGER*4, INTEGER*8, including LOGICAL*1, LOGICAL*2, LOGICAL*4, LOGICAL*8, and REAL*4, REAL*8, REAL*16, including COMPLEX*8, COMPLEX*16, and COMPLEX*32. Conversion does not work inside defined type records on their individual fields. For example:

```fortran
type REC
  integer(8) :: K
  real(8)    :: X
end type REC

type (REC) :: R

write (17) R%K, R%X ! conversion will work on these objects
write (17) R     ! conversion will not work on the fields of this object
```

**IDE Equivalent**

Visual Studio: *Compatibility > Unformatted File Conversion*

Eclipse: None

Xcode: *Compatibility > Unformatted File Conversion*

**Alternate Options**

None

**double-size**

Specifies the default KIND for DOUBLE PRECISION and DOUBLE COMPLEX declarations, constants, functions, and intrinsics.

**Syntax**

**Linux OS and OS X:**

- `double-size` size

**Windows OS:**

`/double-size:size`
Arguments

\textit{size} Specifies the default KIND for DOUBLE PRECISION and DOUBLE COMPLEX declarations, constants, functions, and intrinsics. Possible values are: 64 (KIND=8) or 128 (KIND=16).

Default

64 DOUBLE PRECISION variables are defined as REAL*8 and DOUBLE COMPLEX variables are defined as COMPLEX*16.

Description

This option defines the default KIND for DOUBLE PRECISION and DOUBLE COMPLEX declarations, constants, functions, and intrinsics.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>double-size 64</td>
<td>Defines DOUBLE PRECISION declarations, constants, functions, and intrinsics as REAL(KIND=8) (REAL<em>8) and defines DOUBLE COMPLEX declarations, functions, and intrinsics as COMPLEX(KIND=8) (COMPLEX</em>16).</td>
</tr>
<tr>
<td>double-size 128</td>
<td>Defines DOUBLE PRECISION declarations, constants, functions, and intrinsics as REAL(KIND=16) (REAL<em>16) and defines DOUBLE COMPLEX declarations, functions, and intrinsics as COMPLEX(KIND=16) (COMPLEX</em>32).</td>
</tr>
</tbody>
</table>

The \textit{real-size} option overrides the \textit{double-size} option; for example, on Linux* systems, "-double-size 64 -real-size 128" acts like "-double-size 128 -real-size 128".

IDE Equivalent

Visual Studio: \textbf{Data > Default Double Precision KIND}

Eclipse: None

Xcode: \textbf{Data > Default Double Precision KIND}

Alternate Options

None

dyncom, Qdyncom

Enables dynamic allocation of common blocks at runtime.

Syntax

\textbf{Linux OS and OS X:}

\texttt{-dyncom "common1,common2,..."}

\textbf{Windows OS:}

\texttt{/Qdyncom "common1,common2,..."}

Arguments

\textit{common1,common2,...} Are the names of the common blocks to be dynamically allocated. The list of names must be within quotes.
Default
OFF
Common blocks are not dynamically allocated at run time.

Description
This option enables dynamic allocation of the specified common blocks at run time. For example, to enable
dynamic allocation of common blocks a, b, and c at run time, use this syntax:
The following are some limitations that you should be aware of when using this option:
• An entity in a dynamic common cannot be initialized in a DATA statement.
• Only named common blocks can be designated as dynamic COMMON.
• An entity in a dynamic common block must not be used in an EQUIVALENCE expression with an entity in a
  static common block or a DATA-initialized variable.

IDE Equivalent
Visual Studio: Data > Dynamic Common Blocks
Eclipse: None
Xcode: Data > Dynamic Common Blocks

Alternate Options
None

See Also
Allocating Common Blocks
FOR__SET_FTN_ALLOC

falign-functions, Qfnalign
Tell the compiler to align functions on an optimal
byte boundary.

Syntax
Linux OS and OS X:
-falign-functions=[n]
-fno-align-functions

Windows OS:
/Qfnalign[:n]
/Qfnalign-

Arguments
n
Is the byte boundary for function alignment. Possible values are 2 or 16.

Default
-fno-align-functions or /Qfnalign-
The compiler aligns functions on 2-byte boundaries. This is the same as
specifying -falign-functions=2 (Linux* OS and OS X*) or /Qfnalign:2
(Windows* OS).
**Description**

This option tells the compiler to align functions on an optimal byte boundary. If you do not specify *n*, the compiler aligns the start of functions on 16-byte boundaries.

**IDE Equivalent**

None

**Alternate Options**

None

**falign-stack**

*Tells the compiler the stack alignment to use on entry to routines.*

**Architecture Restrictions**

Only available on IA-32 architecture

**Syntax**

**Linux OS:**

- `falign-stack=mode`

**OS X:**

None

**Windows OS:**

None

**Arguments**

*mode*

Is the method to use for stack alignment. Possible values are:

- `assume-4-byte`
  
  Tells the compiler to assume the stack is aligned on 4-byte boundaries. The compiler can dynamically adjust the stack to 16-byte alignment if needed.

- `maintain-16-byte`
  
  Tells the compiler to not assume any specific stack alignment, but attempt to maintain alignment in case the stack is already aligned. The compiler can dynamically align the stack if needed. This setting is compatible with gcc.

- `assume-16-byte`
  
  Tells the compiler to assume the stack is aligned on 16-byte boundaries and to continue to maintain 16-byte alignment. This setting is compatible with gcc.

**Default**

- `falign-stack=assume-16-byte`

  The compiler assumes the stack is aligned on 16-byte boundaries and continues to maintain 16-byte alignment.

**Description**

This option tells the compiler the stack alignment to use on entry to routines.
IDE Equivalent
None

Alternate Options
None

**fcommon**
*Determines whether the compiler treats common symbols as global definitions.*

**Syntax**

**Linux OS and OS X:**
- `-fcommon`
- `-fno-common`

**Windows OS:**
None

**Arguments**
None

**Default**
- `-fcommon`
  The compiler does not treat common symbols as global definitions.

**Description**
This option determines whether the compiler treats common symbols as global definitions and to allocate memory for each symbol at compile time.

Option `-fno-common` tells the compiler to treat common symbols as global definitions. When using this option, you can only have a common variable declared in one module; otherwise, a link time error will occur for multiple defined symbols.

IDE Equivalent
None

Alternate Options
None

**fkeep-static-consts, Qkeep-static-consts**
*Tells the compiler to preserve allocation of variables that are not referenced in the source.*

**Syntax**

**Linux OS and OS X:**
- `-fkeep-static-consts`
- `-fno-keep-static-consts`

**Windows OS:**
/`Qkeep-static-consts`
/Qkeep-static-consts-

**Arguments**
None

**Default**
-no-keep-static-consts

If a variable is never referenced in a routine, the variable is discarded unless optimizations are disabled by option -O0 (Linux* OS and OS X*) or /Od (Windows* OS).

**Description**
This option tells the compiler to preserve allocation of variables that are not referenced in the source.
The negated form can be useful when optimizations are enabled to reduce the memory usage of static data.

**IDE Equivalent**
None

**Alternate Options**
None

**fmath-errno**
* Tells the compiler that errno can be reliably tested after calls to standard math library functions.*

**Syntax**

**Linux OS and OS X:**

-fmath-errno

-fno-math-errno

**Windows OS:**

None

**Arguments**
None

**Default**

-fno-math-errno

The compiler assumes that the program does not test errno after calls to standard math library functions.

**Description**
This option tells the compiler to assume that the program tests errno after calls to math library functions. This restricts optimization because it causes the compiler to treat most math functions as having side effects.

Option -fno-math-errno tells the compiler to assume that the program does not test errno after calls to math library functions. This frequently allows the compiler to generate faster code. Floating-point code that relies on IEEE exceptions instead of errno to detect errors can safely use this option to improve performance.

**IDE Equivalent**
None
Alternate Options
None

**fminshared**
Specifies that a compilation unit is a component of a main program and should not be linked as part of a shareable object.

Architecture Restrictions
Not available on Intel® 64 architecture targeting Intel® MIC Architecture

Syntax

**Linux OS and OS X:**
-fminshared

**Windows OS:**
None

Arguments
None

Default
OFF Source files are compiled together to form a single object file.

Description
This option specifies that a compilation unit is a component of a main program and should not be linked as part of a shareable object.

This option allows the compiler to optimize references to defined symbols without special visibility settings. To ensure that external and common symbol references are optimized, you need to specify visibility hidden or protected by using the `-fvisibility`, `-fvisibility-hidden`, or `-fvisibility-protected` option.

Also, the compiler does not need to generate position-independent code for the main program. It can use absolute addressing, which may reduce the size of the global offset table (GOT) and may reduce memory traffic.

IDE Equivalent
None

Alternate Options
None

See Also
fvisibility compiler option

**fpconstant**
Tells the compiler that single-precision constants assigned to double-precision variables should be evaluated in double precision.
**Syntax**

Linux OS and OS X:
- `-fpconstant`
- `-nofpconstant`

Windows OS:
- `/fpconstant`
- `/nofpconstant`

**Arguments**

None

**Default**

`nofpconstant`

Single-precision constants assigned to double-precision variables are evaluated in single precision according to Fortran 2003 Standard rules.

**Description**

This option tells the compiler that single-precision constants assigned to double-precision variables should be evaluated in double precision.

This is extended precision. It does not comply with the Fortran 2003 standard, which requires that single-precision constants assigned to double-precision variables be evaluated in single precision.

It allows compatibility with FORTRAN 77, where such extended precision was allowed. If this option is not used, certain programs originally created for FORTRAN 77 compilers may show different floating-point results because they rely on the extended precision for single-precision constants assigned to double-precision variables.

**IDE Equivalent**

Visual Studio: **Floating-Point > Extend Precision of Single-Precision Constants**

Eclipse: None

Xcode: **Floating-Point > Extend Precision of Single-Precision Constants**

**Alternate Options**

None

**Example**

In the following example, if you specify `fpconstant`, identical values are assigned to D1 and D2. If you omit `fpconstant`, the compiler will obey the Fortran 2003 Standard and assign a less precise value to D1:

```fortran
REAL (KIND=8) D1, D2
DATA D1 /2.71828182846182/ ! REAL (KIND=4) value expanded to double
DATA D2 /2.71828182846182D0/ ! Double value assigned to double
```

**fpic**

Determines whether the compiler generates position-independent code.
Syntax

Linux OS and OS X:
- *-fpic
- *-fno-pic

Windows OS:
None

Arguments
None

Default
- *-fno-pic

The compiler does not generate position-independent code.

Description

This option determines whether the compiler generates position-independent code.

Option `-fpic` specifies full symbol preemption. Global symbol definitions as well as global symbol references get default (that is, preemptable) visibility unless explicitly specified otherwise.

Option `-fpic` must be used when building shared objects.

This option can also be specified as `-fPIC`.

IDE Equivalent
None

Alternate Options
None

**fpie**

_Tells the compiler to generate position-independent code. The generated code can only be linked into executables._

Syntax

Linux OS:
- `-fpie`

OS X:
None

Windows OS:
None

Arguments
None
The compiler does not generate position-independent code for an executable-only object.

Description
This option tells the compiler to generate position-independent code. It is similar to `-fpic`, but code generated by `-fpie` can only be linked into an executable.

Because the object is linked into an executable, this option causes better optimization of some symbol references.

To ensure that run-time libraries are set up properly for the executable, you should also specify option `-pie` to the compiler driver on the link command line.

Option `-fpie` can also be specified as `-fPIE`.

IDE Equivalent
None

Alternate Options
None

See Also
`fpic` compiler option
`pie` compiler option

`fstack-protector`
Enables or disables stack overflow security checks for certain (or all) routines.

Syntax
Linux OS and OS X:
`-fstack-protector[-keyword]`
`-fno-stack-protector[-keyword]`

Windows OS:
None

Arguments
`keyword`
Possible values are:

- `strong`
  When option `-fstack-protector-strong` is specified, it enables stack overflow security checks for routines with any type of buffer.

- `all`
  When option `-fstack-protector-all` is specified, it enables stack overflow security checks for every routine.

If no `-keyword` is specified, option `-fstack-protector` enables stack overflow security checks for routines with a string buffer.
Default

-fno-stack-protector, -fno-stack-protector-strong
-fno-stack-protector-all

No stack overflow security checks are enabled for the relevant routines.
No stack overflow security checks are enabled for any routines.

Description

This option enables or disables stack overflow security checks for certain (or all) routines. A stack overflow occurs when a program stores more data in a variable on the execution stack than is allocated to the variable. Writing past the end of a string buffer or using an index for an array that is larger than the array bound could cause a stack overflow and security violations.

The -fstack-protector options are provided for compatibility with gcc. They use the gcc/glibc implementation when possible. If the gcc/glibc implementation is not available, they use the Intel implementation.

For an Intel-specific version of this feature, see option -fstack-security-check.

IDE Equivalent

None

Alternate Options

None

See Also

fstack-security-check compiler option
GS compiler option

fstack-security-check
Determines whether the compiler generates code that detects some buffer overruns.

Syntax

Linux OS and OS X:
-fstack-security-check
-fno-stack-security-check

Windows OS:

None

Arguments

None

Default

-fno-stack-security-check The compiler does not detect buffer overruns.

Description

This option determines whether the compiler generates code that detects some buffer overruns that overwrite the return address. This is a common technique for exploiting code that does not enforce buffer size restrictions.

This option always uses an Intel implementation.
For a gcc-compliant version of this feature, see option \texttt{fstack-protector}.

**IDE Equivalent**

None

**Alternate Options**

None

**See Also**

\texttt{fstack-protector} compiler option

\texttt{GS} compiler option

\texttt{fvisibility}

\textit{Specifies the default visibility for global symbols or the visibility for symbols in a file.}

**Syntax**

\textbf{Linux OS and OS X:}

- \texttt{-fvisibility=keyword}
- \texttt{-fvisibility-\textit{keyword}=filename}

\textbf{Windows OS:}

None

**Arguments**

\textit{keyword} \hspace{1cm} Specifies the visibility setting. Possible values are:

- \texttt{default} \hspace{1cm} Sets visibility to default.
- \texttt{extern} \hspace{1cm} Sets visibility to extern.
- \texttt{hidden} \hspace{1cm} Sets visibility to hidden.
- \texttt{internal} \hspace{1cm} Sets visibility to internal.
- \texttt{protected} \hspace{1cm} Sets visibility to protected. This value is not available on OS X* systems.

\textit{filename} \hspace{1cm} Is the pathname of a file containing the list of symbols whose visibility you want to set. The symbols must be separated by whitespace (spaces, tabs, or newlines).

**Default**

\texttt{-fvisibility=default} \hspace{1cm} The compiler sets visibility of symbols to default.

**Description**

This option specifies the default visibility for global symbols (syntax \texttt{-fvisibility=\textit{keyword}}) or the visibility for symbols in a file (syntax \texttt{-fvisibility-\textit{keyword}=filename}).

Visibility specified by \texttt{-fvisibility-\textit{keyword}=filename} overrides visibility specified by \texttt{-fvisibility=\textit{keyword}} for symbols specified in a file.
<table>
<thead>

</tr>
<tr>
<td>-fvisibility-hidden=filename</td>
<td></td>
</tr>
<tr>
<td>-fvisibility=internal</td>
<td>Sets visibility of symbols to internal. This means that the symbol cannot be referenced outside its defining component, either directly or indirectly. The affected functions can never be called from another module, including through function pointers.</td>
</tr>
<tr>
<td>-fvisibility-internal=filename</td>
<td></td>
</tr>
<tr>
<td>-fvisibility=protected</td>
<td>Sets visibility of symbols to protected. This means other components can reference the symbol, but it cannot be overridden by a definition of the same name in another component. This value is not available on OS X* systems.</td>
</tr>
<tr>
<td>-fvisibility-protected=filename</td>
<td></td>
</tr>
</tbody>
</table>

If an -fvisibility option is specified more than once on the command line, the last specification takes precedence over any others.

If a symbol appears in more than one visibility filename, the setting with the least visibility takes precedence.

The following shows the precedence of the visibility settings (from greatest to least visibility):

- extern
- default
- protected
- hidden
- internal

Note that extern visibility only applies to functions. If a variable symbol is specified as extern, it is assumed to be default.

**IDE Equivalent**
None

**Alternate Options**
None

**Example**
A file named prot.txt contains symbols a, b, c, d, and e. Consider the following:

- -fvisibility-protected=prot.txt
This option sets protected visibility for all the symbols in the file. It has the same effect as specifying \texttt{fvisibility=protected} in the declaration for each of the symbols.

\textbf{fzero-initialized-in-bss, Qzero-initialized-in-bss}

\textit{Determines whether the compiler places in the DATA section any variables explicitly initialized with zeros.}

\textbf{Syntax}

\textbf{Linux OS and OS X:}

- \texttt{-fzero-initialized-in-bss}
- \texttt{-fno-zero-initialized-in-bss}

\textbf{Windows OS:}

- \texttt{/Qzero-initialized-in-bss}
- \texttt{/Qzero-initialized-in-bss-}

\textbf{Arguments}

None

\textbf{Default}

- \texttt{-fno-zero-initialized-in-bss} or \texttt{/Qzero-initialized-in-bss-}

\textbf{Variables explicitly initialized with zeros are placed in the BSS section. This can save space in the resulting code.}

\textbf{Description}

This option determines whether the compiler places in the DATA section any variables explicitly initialized with zeros.

If option \texttt{-fno-zero-initialized-in-bss (Linux* OS and OS X*)} or \texttt{/Qzero-initialized-in-bss- (Windows* OS)} is specified, the compiler places in the DATA section any variables that are initialized to zero.

\textbf{IDE Equivalent}

Visual Studio: None

Eclipse: None

Xcode: \textbf{Data > Place Zero-Initialized Variables in .bss}

\textbf{Alternate Options}

None

\textbf{Gs}

\textit{Lets you control the threshold at which the stack checking routine is called or not called.}

\textbf{Syntax}

\textbf{Linux OS and OS X:}

None

\textbf{Windows OS:}

- \texttt{/Gs[n]}

\texttt{n}
Arguments

\( n \)  
Is the number of bytes that local variables and compiler temporaries can occupy before stack checking is activated. This is called the *threshold*.

Default

\( /Gs \)  
Stack checking occurs for routines that require more than 4KB (4096 bytes) of stack space. This is also the default if you do not specify \( n \).

Description

This option lets you control the threshold at which the stack checking routine is called or not called. If a routine's local stack allocation exceeds the threshold \( (n) \), the compiler inserts a \( \_\_\text{chkstk}() \) call into the prologue of the routine.

IDE Equivalent

None

Alternate Options

None

GS

Determines whether the compiler generates code that detects some buffer overruns.

Syntax

Linux OS and OS X:

None

Windows OS:

\( /GS \)

\( /GS- \)

Arguments

None

Default

\( /GS- \)  
The compiler does not detect buffer overruns.

Description

This option determines whether the compiler generates code that detects some buffer overruns that overwrite a function's return address, exception handler address, or certain types of parameters.

This option has been added for Microsoft compatibility. It uses the Microsoft implementation.

For more details about option \( /GS \), see the Microsoft documentation.

homeparams
Tell the compiler to store parameters passed in
registers to the stack.

Architecture Restrictions
Only available on Intel® 64 architecture

Syntax
Linux OS and OS X:
None

Windows OS:
/homeparams

Arguments
None

Default
OFF
Register parameters are not written to the stack.

Description
This option tells the compiler to store parameters passed in registers to the stack.

IDE Equivalent
None

Alternate Options
None

init, Qinit
Lets you initialize a class of variables to zero or to
signaling NaN.

Architecture Restrictions
[]init keyword snan: Not available on Intel® 64 architecture targeting the Intel® Xeon Phi™ coprocessor
x100 product family (formerly code name Knights Corner)

Syntax
Linux OS and OS X:
-init=keyword

Windows OS:
/Qinit:keyword
Arguments

keyword Specifies the initial value for a class of variables. Possible values are:

[no]arrays Determines whether the compiler initializes variables that are arrays or scalars. Specifying arrays initializes variables that are arrays or scalars. Specifying noarrays initializes only variables that are scalars. You must also specify either [Q]init snan or [Q]init zero when you specify [Q]init [no]arrays.

[no]snan Determines whether the compiler initializes to signaling NaN all uninitialized variables of intrinsic type REAL or COMPLEX that are saved, local, automatic, or allocated variables.

[no]zero Determines whether the compiler initializes to zero all uninitialized variables of intrinsic type REAL, COMPLEX, INTEGER, or LOGICAL that are saved, local, automatic, or allocated variables.

Option /Qinit:[no]zero replaces option /Qzero[-] (Windows*), and option -init=[no]zero replaces option -[no]zero (Linux* and OS X*).

Default OFF No initializations are performed by default if you do not specify any of these options.

Description

This option lets you initialize a class of variables to zero or to signaling NaN.

If you only specify option -init=zero or -init=snan (Linux* OS and OS X*) or /Qinit:zero or /Qinit:snan (Windows* OS), it affects only scalar variables. To apply the initialization to arrays as well, you must also specify option -init=arrays (Linux* OS and OS X*) or Qinit:arrays (Windows* OS).

If you specify both [Q]init snan and [Q]init zero, then certain variables of REAL and COMPLEX type are initialized to signaling NaN and certain variables of INTEGER and LOGICAL type are initialized to zero.

The following classes of variables are affected by the [Q]init option:

- Variables of intrinsic numeric type, that is, of type COMPLEX, INTEGER, LOGICAL, or REAL, of any KIND
- SAVED scalar or array variables, not in the main program, that are not initialized in the source code
- Local scalars and arrays
- Module variables that are not initialized in the source code
- Automatic arrays
- Variables with the POINTER or ALLOCATABLE attribute
- In a user-defined type, components that have the POINTER or ALLOCATABLE attribute may be initialized with option [Q]init

The following are general restrictions for this option:

- [Q]init snan only affects certain variables of REAL or COMPLEX type.
- You cannot initialize variables in equivalence groups to signaling NaN values.
In an equivalence group, if no member of that equivalence group has an explicit initialization or a default initialization (in the case of a derived type), a variable in that equivalence group can be initialized to zero.

- Derived types, arrays of derived types, and their components will not be initialized.
- Dummy arguments including adjustable arrays will not be initialized.
- Variables in COMMON will not be initialized.

If you specify [Q]init snan, the floating-point exception handling flags will be set to trap signaling NaN and halt so that when such a value is trapped at run-time, the Fortran library can catch the usage, display an error message about a possible uninitialized variable, display a traceback, and stop execution. You can use the debugger to determine where in your code this uninitialized variable is being referenced when execution stops.

Setting the option [Q]init snan implicitly sets the option fpe 0. A compile time warning will occur if you specify both option fpe 3 and option [Q]init snan on the command line. In this case, fpe 3 is ignored.

NOTE
If you build with optimization, the compiler may speculate floating-point operations, assuming the default floating-point environment in which floating-point exceptions are masked. When you add [Q]init snan, this speculation may result in exceptions, unrelated to uninitialized variables, that now get trapped. To avoid this, reduce the optimization level to /O1 or /Od (Windows*), or -O1 or -O0 (Linux* and OS X*) when doing uninitialized variable detection.

If you wish to maintain optimization, you should add option [Q]fp-speculation safe to disable speculation when there is a possibility that the speculation may result in a floating-point exception.

On Intel® 64 architecture targeting the Intel® Xeon Phi™ coprocessor x100 product family (formerly code name Knights Corner), you cannot specify [Q]init [no]snan, since trapping signaling snan is not available.

Use option [Q]save if you wish all variables to be specifically marked as SAVE.

IDE Equivalent

Visual Studio: Data > Initialize Variables to Signaling NaN
Data > Initialize Variables to Zero
Data > Initialize Arrays as well as Scalars
Eclipse: None
Xcode: Data > Initialize Variables to Signaling NaN
Data > Initialize Variables to Zero
Data > Initialize Arrays as well as Scalars

Alternate Options
None

Example

The following example shows how to initialize scalars of intrinsic type REAL and COMPLEX to signaling NaN, and scalars of intrinsic type INTEGER and LOGICAL to zero:

- init=snan,zero               ! Linux and OS X systems
/Qinit:snan,zero              ! Windows systems

The following example shows how to initialize scalars and arrays of intrinsic type REAL and COMPLEX to signaling NaN, and scalars and arrays of intrinsic type INTEGER and LOGICAL to zero:

- init=zero -init=snan -init=arrays       ! Linux and OS X systems
/Qinit:zero /Qinit:snan /Qinit:arrays       ! Windows systems
To see an example of how to use option \texttt{Q\_init} for detection of uninitialized floating-point variables at runtime, see the article titled \textit{Detection of Uninitialized Floating-point Variables in Intel\textsuperscript{\textregistered} Fortran}, which is located in https://software.intel.com/articles/detection-of-uninitialized-floating-point-variables-in-intel-fortran

\texttt{intconstant}

\textit{Tells the compiler to use FORTRAN 77 semantics to determine the kind parameter for integer constants.}

\textbf{Syntax}

\texttt{Linux OS and OS X:}

\texttt{-intconstant}

\texttt{-nointconstant}

\texttt{Windows OS:}

\texttt{/intconstant}

\texttt{/nointconstant}

\textbf{Arguments}

None

\textbf{Default}

\texttt{nointconstant} \hspace{1cm} The compiler uses the Fortran 2003 default INTEGER type.

\textbf{Description}

This option tells the compiler to use FORTRAN 77 semantics to determine the kind parameter for integer constants.

With FORTRAN 77 semantics, the kind is determined by the value of the constant. All constants are kept internally by the compiler in the highest precision possible. For example, if you specify option \texttt{intconstant}, the compiler stores an integer constant of 14 internally as INTEGER(KIND=8) and converts the constant upon reference to the corresponding proper size. Fortran 2003 specifies that integer constants with no explicit KIND are kept internally in the default INTEGER kind (KIND=4 by default).

Note that the internal precision for floating-point constants is controlled by option \texttt{fpconstant}.

\textbf{IDE Equivalent}

\texttt{Visual Studio: Compatibility > Use F77 Integer Constants}

\texttt{Eclipse: None}

\texttt{Xcode: Compatibility > Use F77 Integer Constants}

\textbf{Alternate Options}

None

\texttt{integer-size}

\textit{ Specifies the default KIND for integer and logical variables.}

Syntax

Linux OS and OS X:
-integer-size size

Windows OS:
/integer-size:size

Arguments

size

Is the size for integer and logical variables. Possible values are: 16, 32, or 64.

Default

integer-size 32

Integer and logical variables are 4 bytes long (INTEGER(KIND=4) and LOGICAL(KIND=4)).

Description

This option specifies the default size (in bits) for integer and logical variables.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer-size 16</td>
<td>Makes default integer and logical declarations, constants, functions, and intrinsics 2 bytes long. INTEGER and LOGICAL declarations are treated as (KIND=2). Integer and logical constants of unspecified KIND are evaluated in INTEGER (KIND=2) and LOGICAL(KIND=2)respectively.</td>
</tr>
<tr>
<td>integer-size 32</td>
<td>Makes default integer and logical declarations, constants, functions, and intrinsics 4 bytes long. INTEGER and LOGICAL declarations are treated as (KIND=4). Integer and logical constants of unspecified KIND are evaluated in INTEGER (KIND=4) and LOGICAL(KIND=4)respectively.</td>
</tr>
<tr>
<td>integer-size 64</td>
<td>Makes default integer and logical declarations, constants, functions, and intrinsics 8 bytes long. INTEGER and LOGICAL declarations are treated as (KIND=8). Integer and logical constants of unspecified KIND are evaluated in INTEGER (KIND=8) and LOGICAL(KIND=8)respectively.</td>
</tr>
</tbody>
</table>

</table>
**mcmodel**
*Tells the compiler to use a specific memory model to generate code and store data.*

**Architecture Restrictions**
Only available on Intel® 64 architecture

**Syntax**

Linux OS:

- `mcmodel=mem_model`

OS X:
None

Windows OS:
None

**Arguments**

`mem_model` Is the memory model to use. Possible values are:

- **small**
  Tells the compiler to restrict code and data to the first 2GB of address space. All accesses of code and data can be done with Instruction Pointer (IP)-relative addressing.

- **medium**
  Tells the compiler to restrict code to the first 2GB; it places no memory restriction on data. Accesses of code can be done with IP-relative addressing, but accesses of data must be done with absolute addressing.

- **large**
  Places no memory restriction on code or data. All accesses of code and data must be done with absolute addressing.

**Default**

`-mcmodel=small` On systems using Intel® 64 architecture, the compiler restricts code and data to the first 2GB of address space. Instruction Pointer (IP)-relative addressing can be used to access code and data.

**Description**

This option tells the compiler to use a specific memory model to generate code and store data. It can affect code size and performance. If your program has COMMON blocks and local data with a total size smaller than 2GB, `-mcmodel=small` is sufficient. COMMONs larger than 2GB require `-mcmodel=medium` or `-mcmodel=large`. Allocation of memory larger than 2GB can be done with any setting of `-mcmodel`.

IP-relative addressing requires only 32 bits, whereas absolute addressing requires 64-bits. IP-relative addressing is somewhat faster. So, the small memory model has the least impact on performance.
NOTE
When you specify option -mcmodel=medium or -mcmodel=large, it sets option -shared-intel. This ensures that the correct dynamic versions of the Intel run-time libraries are used.
If you specify option -static-intel while -mcmodel=medium or -mcmodel=large is set, an error will be displayed.

IDE Equivalent
None

Alternate Options
None

Example
The following example shows how to compile using -mcmodel:
ifort -shared-intel -mcmodel=medium -o prog prog.f

See Also
shared-intel compiler option
fPIC compiler option
mdynamic-no-pic
Generates code that is not position-independent but has position-independent external references.

Architecture Restrictions
Not available on Intel® 64 architecture targeting Intel® MIC Architecture

Syntax
Linux OS:
None
OS X:
-mdynamic-no-pic
Windows OS:
None

Arguments
None

Default
OFF All references are generated as position independent.

Description
This option generates code that is not position-independent but has position-independent external references.
The generated code is suitable for building executables, but it is not suitable for building shared libraries.
This option may reduce code size and produce more efficient code. It overrides the -fPIC compiler option.
IDE Equivalent
None

Alternate Options
None

See Also
fpic compiler option

no-bss-init, Qnobss-init
*Tells the compiler to place in the DATA section any uninitialized variables and explicitly zero-initialized variables.*

Syntax

Linux OS and OS X:
-no-bss-init

Windows OS:
/Qnobss-init

Arguments
None

Default
OFF

Uninitialized variables and explicitly zero-initialized variables are placed in the BSS section.

Description
This option tells the compiler to place in the DATA section any uninitialized variables and explicitly zero-initialized variables.

IDE Equivalent
None

Alternate Options
None

Qsfalign
*Specifies stack alignment for functions.*

Architecture Restrictions
Only available on IA-32 architecture

Syntax

Linux OS and OS X:
None

Windows OS:
/Qsfalign[n]
Arguments

\textit{n} \hspace{1cm} \text{Is the byte size of aligned variables. Possible values are:}

\begin{itemize}
\item \textbf{8} \hspace{1cm} Specifies that alignment should occur for functions with 8-byte aligned variables. At this setting the compiler aligns the stack to 16 bytes if there is any 16-byte or 8-byte data on the stack. For 8-byte data, the compiler only aligns the stack if the alignment will produce a performance advantage.
\item \textbf{16} \hspace{1cm} Specifies that alignment should occur for functions with 16-byte aligned variables. At this setting, the compiler only aligns the stack for 16-byte data. No attempt is made to align for 8-byte data.
\end{itemize}

Default

/\textit{Qsfalign8} \hspace{1cm} \text{Alignment occurs for functions with 8-byte aligned variables.}

Description

This option specifies stack alignment for functions. It lets you disable the normal optimization that aligns a stack for 8-byte data.

If you do not specify \textit{n}, stack alignment occurs for all functions. If you specify /\textit{Qsfalign8}, no stack alignment occurs for any function.

IDE Equivalent

None

Alternate Options

None

\textit{real-size} \hspace{1cm} \textit{Specifies the default KIND for real and complex declarations, constants, functions, and intrinsics.}

Syntax

\textbf{Linux OS and OS X:}

- \textit{-real-size} \textit{size}

\textbf{Windows OS:}

/\textit{real-size:} \textit{size}

Arguments

\textit{size} \hspace{1cm} \text{Is the size for real and complex declarations, constants, functions, and intrinsics. Possible values are: 32, 64, or 128.}

Default

\textit{real-size} 32 \hspace{1cm} \text{Default real and complex declarations, constants, functions, and intrinsics are 4 bytes long (REAL(KIND=4) and COMPLEX(KIND=4)).}
Description
This option specifies the default size (in bits) for real and complex declarations, constants, functions, and intrinsics.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>real-size 32</td>
<td>Makes default real and complex declarations, constants, functions, and intrinsics 4 bytes long. REAL declarations are treated as single precision REAL (REAL(KIND=4)) and COMPLEX declarations are treated as COMPLEX (COMPLEX(KIND=4)). Real and complex constants of unspecified KIND are evaluated in single precision (KIND=4).</td>
</tr>
<tr>
<td>real-size 64</td>
<td>Makes default real and complex declarations, constants, functions, and intrinsics 8 bytes long. REAL declarations are treated as DOUBLE PRECISION (REAL(KIND=8)) and COMPLEX declarations are treated as DOUBLE COMPLEX (COMPLEX(KIND=8)). Real and complex constants of unspecified KIND are evaluated in double precision (KIND=8).</td>
</tr>
<tr>
<td>real-size 128</td>
<td>Makes default real and complex declarations, constants, functions, and intrinsics 16 bytes long. REAL declarations are treated as extended precision REAL (REAL(KIND=16)); COMPLEX and DOUBLE COMPLEX declarations are treated as extended precision COMPLEX (COMPLEX(KIND=16)). Real and complex constants of unspecified KIND are evaluated in extended precision (KIND=16).</td>
</tr>
</tbody>
</table>

These compiler options can affect the result type of intrinsic procedures, such as CMPLX, FLOAT, REAL, SNGL, and AIMAG, which normally produce single-precision REAL or COMPLEX results. To prevent this effect, you must explicitly declare the kind type for arguments of such intrinsic procedures.

For example, if real-size 64 is specified, the CMPLX intrinsic will produce a result of type DOUBLE COMPLEX (COMPLEX(KIND=8)). To prevent this, you must explicitly declare any real argument to be REAL(KIND=4), and any complex argument to be COMPLEX(KIND=4).

IDE Equivalent
Visual Studio: **Data > Default Real KIND**
Eclipse: None
Xcode: **Data > Default Real KIND**

Alternate Options
real-size 64
Linux and OS X: -r8,-autodouble
Windows: /4R8,/Qautodouble
real-size 128
Linux and OS X: -r16
Windows: /4R16

**save, Qsave**
*Causes variables to be placed in static memory.*

**Syntax**

**Linux OS and OS X:**
-save

**Windows OS:**
/Qsave
### Arguments

None

### Default

- `auto-scalar` or `/Qauto-scalar`

Scalar variables of intrinsic types INTEGER, REAL, COMPLEX, and LOGICAL are allocated to the run-time stack. Note that the default changes to `auto` if one of the following options are specified:

- recursive
- `[q or Q]openmp`

### Description

This option saves all variables in static allocation except local variables within a recursive routine and variables declared as AUTOMATIC.

If you want all local, non-SAVEd variables to be allocated to the run-time stack, specify option `automatic`.

### IDE Equivalent

**Visual Studio:** Data > Local Variable Storage

**Eclipse:** None

**Xcode:** Data > Local Variable Storage

### Alternate Options

- **Linux and OS X:** `-noauto`
- **Windows:** `/noauto`, `/4Na`

### See Also

- **auto** compiler option
- **auto-scalar, Qauto-scalar** compiler option
- **zero, Qzero**
  
  Initializes to zero variables of intrinsic type INTEGER, REAL, COMPLEX, or LOGICAL that are not yet initialized. This is a deprecated option. The replacement option is `/Qinit:[no]zero` or `-init=[no]zero`.

### Syntax

**Linux OS and OS X:**

- `-zero`
- `-nozero`

**Windows OS:**

- `/Qzero`
- `/Qzero-`

### Arguments

None
Default

-nozero or /Qzero-  Variables are not initialized to zero.

Description

This option initializes to zero variables of intrinsic type INTEGER, REAL, COMPLEX, or LOGICAL that are not yet initialized.

Use option [Q]save on the command line to make all local variables specifically marked as SAVE.

IDE Equivalent

None

Alternate Options

None

See Also

init, Qinit compiler option (see setting zero)
save, Qsave compiler option

Compiler Diagnostic Options

diag, Qdiag

Controls the display of diagnostic information.

Syntax

Linux OS and OS X:

-diag-type=diag-list

Windows OS:

/Qdiag-type=diag-list

Arguments

type  Is an action to perform on diagnostics. Possible values are:

enable  Enables a diagnostic message or a group of messages. If you specify -diag-enable=all (Linux* OS and OS X*) or /Qdiag-enable:all (Windows* OS), all diagnostic messages shown in diag-list are enabled.

disable  Disables a diagnostic message or a group of messages. If you specify -diag-disable=all (Linux* OS and OS X*) or /Qdiag-disable:all (Windows* OS), all diagnostic messages shown in diag-list are disabled.

error  Tells the compiler to change diagnostics to errors.

warning  Tells the compiler to change diagnostics to warnings.
remark      Tells the compiler to change diagnostics to remarks (comments).

diag-list  Is a diagnostic group or ID value. Possible values are:

driver     Specifies diagnostic messages issued by the compiler driver.

vec        Specifies diagnostic messages issued by the vectorizer.

par        Specifies diagnostic messages issued by the auto-parallelizer (parallel optimizer).

openmp     Specifies diagnostic messages issued by the OpenMP* parallelizer.

warn       Specifies diagnostic messages that have a "warning" severity level.

error      Specifies diagnostic messages that have an "error" severity level.

remark     Specifies diagnostic messages that are remarks or comments.

cpu-dispatch Specifies the CPU dispatch remarks for diagnostic messages. These remarks are enabled by default.

id[,id,...] Specifies the ID number of one or more messages. If you specify more than one message number, they must be separated by commas. There can be no intervening white space between each id.

tag[,tag,...] Specifies the mnemonic name of one or more messages. If you specify more than one mnemonic name, they must be separated by commas. There can be no intervening white space between each tag.

The diagnostic messages generated can be affected by certain options, such as [Q]x, /arch (Windows) or -m (Linux and OS X).

Default

OFF         The compiler issues certain diagnostic messages by default.

Description

This option controls the display of diagnostic information. Diagnostic messages are output to stderr unless the [Q]diag-file option is specified.

To control the diagnostic information reported by the vectorizer, use options [q or Q]opt-report and [q or Q]opt-report-phase, phase vec.

To control the diagnostic information reported by the auto-parallelizer, use options [q or Q]opt-report and [q or Q]opt-report-phase, phase par.
IDE Equivalent

Visual Studio: **Diagnostics > Disable Specific Diagnostics** (/Qdiag-disable:id)

Eclipse: None

Xcode: **Diagnostics > Disable Specific Diagnostics** (-diag-disable id)

Alternate Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Linux and OS X:</th>
<th>Windows:</th>
</tr>
</thead>
</table>

Example

The following example shows how to enable diagnostic IDs 117, 230 and 450:

- `diag-enable=117,230,450` ! Linux and OS X systems
- `/Qdiag-enable:117,230,450` ! Windows systems

The following example shows how to change vectorizer diagnostic messages to warnings:

- `diag-enable=vec -diag-warning=vec` ! Linux and OS X systems
- `/Qdiag-enable:vec /Qdiag-warning:vec` ! Windows systems

Note that you need to enable the vectorizer diagnostics before you can change them to warnings.

The following example shows how to disable all auto-parallelizer diagnostic messages:

- `diag-disable=par` ! Linux and OS X systems
- `/Qdiag-disable:par` ! Windows systems

The following example shows how to change all diagnostic warnings and remarks to errors:

- `diag-error=warn,remark` ! Linux and OS X systems
- `/Qdiag-error:warn,remark` ! Windows systems

The following example shows how to get a list of only vectorization diagnostics:

- `diag-dump diag-disable=all diag-enable=vec` ! Linux and OS X systems
- `/Qdiag-dump /Qdiag-disable:all /Qdiag-enable:vec` ! Windows systems

See Also

diag-dump, Qdiag-dump compiler option
diag-id-numbers, Qdiag-id-numbers compiler option
diag-file, Qdiag-file compiler option
qopt-report, Qopt-report compiler option
x, Qx compiler option
diag-dump, Qdiag-dump
Tells the compiler to print all enabled diagnostic messages and stop compilation.

Syntax

Linux OS and OS X:
-diag-dump

Windows OS:
/Qdiag-dump

Arguments
None

Default
OFF

The compiler issues certain diagnostic messages by default.

Description
This option tells the compiler to print all enabled diagnostic messages and stop compilation. The diagnostic messages are output to stdout.

This option prints the enabled diagnostics from all possible diagnostics that the compiler can issue, including any default diagnostics.

If diag-list is specified for the [Q]diag-enable option, the print out will include the diag-list diagnostics.

IDE Equivalent
None

Alternate Options
None

Example
The following example adds vectorizer diagnostic messages to the printout of default diagnostics:

```
-diag-enable vec -diag-dump
/Qdiag-enable:vec /Qdiag-dump
```

! Linux and OS X systems

! Windows systems

See Also
diag, Qdiag compiler option
diag-error-limit, Qdiag-error-limit
Specifies the maximum number of errors allowed before compilation stops.

Syntax

Linux OS and OS X:
-diag-error-limit=n
-no-diag-error-limit

Windows OS:
/Qdiag-error-limit:n
/Qdiag-error-limit-
Arguments

$n$  
Is the maximum number of error-level or fatal-level compiler errors allowed.

Default

30  
A maximum of 30 error-level and fatal-level messages are allowed.

Description

This option specifies the maximum number of errors allowed before compilation stops. It indicates the maximum number of error-level or fatal-level compiler errors allowed for a file specified on the command line.

If you specify the negative form of the \texttt{[Q]diag-error-limit} option on the command line, there is no limit on the number of errors that are allowed.

If the maximum number of errors is reached, a warning message is issued and the next file (if any) on the command line is compiled.

IDE Equivalent

Visual Studio: \textbf{Diagnostics > Error Limit}  
Eclipse: None  
Xcode: \textbf{Diagnostics > Error Limit}

Alternate Options

Linux and OS X: \texttt{-error-limit} and \texttt{-noerror-limit}  
Windows: \texttt{/error-limit} and \texttt{/noerror-limit}

\texttt{diag-file, Qdiag-file}  
\textit{Causes the results of diagnostic analysis to be output to a file.}

Syntax

Linux OS:

\texttt{-diag-file [=filename]}

OS X:

None

Windows OS:

\texttt{/Qdiag-file[=filename]}

Arguments

\texttt{filename}  
Is the name of the file for output.

Default

OFF  
Diagnostic messages are output to stderr.
Description
This option causes the results of diagnostic analysis to be output to a file. The file is placed in the current working directory.

You can include a file extension in filename. For example, if file.txt is specified, the name of the output file is file.txt. If you do not provide a file extension, the name of the file is filename.diag.

If filename is not specified, the name of the file is name-of-the-first-source-file.diag. This is also the name of the file if the name specified for file conflicts with a source file name provided in the command line.

NOTE
If you specify the [Q]diag-file option and you also specify the [Q]diag-file-append option, the last option specified on the command line takes precedence.

IDE Equivalent
Visual Studio: Diagnostics > Diagnostics File
Eclipse: None
Xcode: Diagnostics > Diagnostics File

Alternate Options
None

Example
The following example shows how to cause diagnostic analysis to be output to a file named my_diagnostics.diag:

Linux systems
-diafile=my_diagnostics

Windows systems
/Qdiafile:my_diagnostics

See Also
diag-file-append, Qdiag-file-append compiler option

diag-file-append, Qdiag-file-append
Causes the results of diagnostic analysis to be appended to a file.

Syntax
Linux OS:
-diafile-append=[filename]

OS X:
None

Windows OS:
/Qdiafile-append[=filename]

Arguments
filename
Is the name of the file to be appended to. It can include a path.
Default

OFF Diagnostic messages are output to stderr.

Description

This option causes the results of diagnostic analysis to be appended to a file. If you do not specify a path, the driver will look for filename in the current working directory.

If filename is not found, then a new file with that name is created in the current working directory. If the name specified for file conflicts with a source file name provided in the command line, the name of the file is name-of-the-first-source-file.diag.

**NOTE**

If you specify the [Q]diag-file-append option and you also specify the [Q]diag-file option, the last option specified on the command line takes precedence.

IDE Equivalent

None

Alternate Options

None

Example

The following example shows how to cause diagnostic analysis to be appended to a file named my_diagnostics.txt:

```bash
-diag-file-append=my_diagnostics.txt       ! Linux systems
/Qdiag-file-append:my_diagnostics.txt      ! Windows systems
```

See Also
diag-file, Qdiag-file compiler option
diag-id-numbers, Qdiag-id-numbers

_Determines whether the compiler displays diagnostic messages by using their ID number values._

Syntax

Linux OS and OS X:

- -diag-id-numbers
- -no-diag-id-numbers

Windows OS:

- /Qdiag-id-numbers
- /Qdiag-id-numbers-

Arguments

None
**Default**

- **-diag-id-numbers**
  The compiler displays diagnostic messages by using their ID number values.

  or/Qdiag-id-numbers

**Description**

This option determines whether the compiler displays diagnostic messages by using their ID number values. If you specify the negative form of the `Qdiag-id-numbers` option, mnemonic names are output for driver diagnostics only.

**IDE Equivalent**

None

**Alternate Options**

None

**See Also**

diag, Qdiag compiler option

diag-once, Qdiag-once
*Tells the compiler to issue one or more diagnostic messages only once.*

**Syntax**

**Linux OS and OS X:**

- `diag-once id[,id,...]`

  **Windows OS:**

  /Qdiag-once:id[,id,...]

**Arguments**

*id*  
Is the ID number of the diagnostic message. If you specify more than one message number, they must be separated by commas. There can be no intervening white space between each *id*.

**Default**

OFF  
The compiler issues certain diagnostic messages by default.

**Description**

This option tells the compiler to issue one or more diagnostic messages only once.

**IDE Equivalent**

None

**Alternate Options**

None
**gen-interfaces**
*Tells the compiler to generate an interface block for each routine in a source file.*

**Syntax**

**Linux OS and OS X:**

- `gen-interfaces [[no]source]`
- `nogen-interfaces`

**Windows OS:**

/`gen-interfaces[:][no]source`

/`nogen-interfaces`

**Arguments**

None

**Default**

`nogen-interfaces`  
The compiler does not generate interface blocks for routines in a source file.

**Description**

This option tells the compiler to generate an interface block for each routine (that is, for each SUBROUTINE and FUNCTION statement) defined in the source file. The compiler generates two files for each routine, a .mod file and a .f90 file, and places them in the current directory or in the directory specified by the include (-I) or -module option. The .f90 file is the text of the interface block; the .mod file is the interface block compiled into binary form. The .f90 file is for reference only and may not completely represent the generated interface used by the compiler.

If `source` is specified, the compiler creates the `procedure-name__GENmod.f90` as well as the `procedure-name__GENmod.mod` files. If `nosource` is specified, the compiler creates the `procedure-name__GENmod.mod` but not the `procedure-name__GENmod.f90` files. If neither is specified, it is the same as specifying setting `source` for the `gen-interfaces` option.

On Windows* OS, for a Debug configuration in a Visual Studio project, the default is `/warn:interfaces`.

**IDE Equivalent**

None

**Alternate Options**

None

**traceback**
*Tells the compiler to generate extra information in the object file to provide source file traceback information when a severe error occurs at run time.*

**Syntax**

**Linux OS and OS X:**

- `traceback`
- `notraceback`

**Windows OS:**

/`traceback`
/notraceback

**Arguments**
None

**Default**

/notraceback

No extra information is generated in the object file to produce traceback information.

**Description**
This option tells the compiler to generate extra information in the object file to provide source file traceback information when a severe error occurs at run time.

When the severe error occurs, source file, routine name, and line number correlation information is displayed along with call stack hexadecimal addresses (program counter trace).

Note that when a severe error occurs, advanced users can also locate the cause of the error using a map file and the hexadecimal addresses of the stack displayed when the error occurs.

This option increases the size of the executable program, but has no impact on run-time execution speeds. It functions independently of the debug option.

On Windows* systems, `traceback` sets the `/Oy-` option, which forces the compiler to use EBP as the stack frame pointer.

On Windows* systems, the linker places the traceback information in the executable image, in a section named ".trace". To see which sections are in an image, use the command:

```
link -dump -summary your_app_name.exe
```

To see more detailed information, use the command:

```
link -dump -headers your_app_name.exe
```

On Windows* systems, when requesting traceback, you must set Enable Incremental Linking in the VS .NET* IDE Linker Options to No. You must also set Omit Frame Pointers (the `/Oy` option) in the Optimization Options to "No."

On Linux* systems, to display the section headers in the image (including the header for the .trace section, if any), use the command:

```
objdump -h your_app_name.exe
```

On OS X* systems, to display the section headers in the image, use the command:

```
otool -l your_app_name.exe
```

**IDE Equivalent**

Visual Studio: **Run-time > Generate Traceback Information**

Eclipse: None

Xcode: **Run-time > Generate Traceback Information**

**Alternate Options**
None

**warn**

Specifies diagnostic messages to be issued by the compiler.
Syntax

Linux OS and OS X:
- warn [keyword[, keyword...]]
- nowarn

Windows OS:
/warn[:keyword[, keyword...]]
/nowarn

Arguments

_keyword

Specifies the diagnostic messages to be issued. Possible values are:

- none
  Disables all warning messages.
- [no]alignments
  Determines whether warnings occur for data that is not naturally aligned.
- [no]declarations
  Determines whether warnings occur for any undeclared names.
- [no]errors
  Determines whether warnings are changed to errors.
- [no]general
  Determines whether warning messages and informational messages are issued by the compiler.
- [no]ignore_loc
  Determines whether warnings occur when %LOC is stripped from an actual argument.
- [no]interfaces
  Determines whether the compiler checks the interfaces of all SUBROUTINEs called and FUNCTIONs invoked in your compilation against an external set of interface blocks.
- [no]stderrors
  Determines whether warnings about Fortran standard violations are changed to errors.
- [no]truncated_source
  Determines whether warnings occur when source exceeds the maximum column width in fixed-format files.
- [no]uncalled
  Determines whether warnings occur when a statement function is never called
- [no]unused
  Determines whether warnings occur for declared variables that are never used.
- [no]usage
  Determines whether warnings occur for questionable programming practices.
- all
  Enables all warning messages except errors and stderrors.
### Default

- **alignments**
  - Warnings are issued about data that is not naturally aligned.
- **general**
  - All information-level and warning-level messages are enabled.
- **usage**
  - Warnings are issued for questionable programming practices.
- **nodeclarations**
  - No warnings are issued for undeclared names.
- **noerrors**
  - Warning-level messages are not changed to error-level messages.
- **noignore_loc**
  - No warnings are issued when %LOC is stripped from an argument.
- **nointerfaces**
  - The compiler does not check interfaces of SUBROUTINEs called and FUNCTIONs invoked in your compilation against an external set of interface blocks.
- **nostderrors**
  - Warning-level messages about Fortran standards violations are not changed to error-level messages.
- **notruncated_source**
  - No warnings are issued when source exceeds the maximum column width in fixed-format files.
- **nouncalled**
  - No warnings are issued when a statement function is not called.
- **nounused**
  - No warnings are issued for variables that are declared but never used.

### Description

This option specifies the diagnostic messages to be issued by the compiler.

<table>

<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>in the directory specified by the include (-I) or -module option. If interface mismatches occur, some will result in a compile-time error, others will only generate a warning.</td>
</tr>
<tr>
<td></td>
<td>By default, warn interfaces turns on option gen-interfaces. You can turn off that option by explicitly specifying option /gen-interfaces- (Windows* OS) or -no-gen-interfaces (Linux* OS and OS X*).</td>
</tr>
<tr>
<td>warn stderrors</td>
<td>Tells the compiler to change all warning-level messages about Fortran standards violations to error-level messages. This option sets the std03 option (Fortran 2003 standard). If you want Fortran 95 standards violations to become errors, you must specify options warn stderrors and std95.</td>
</tr>
<tr>
<td>warn truncated_source</td>
<td>Enables warnings when a source line exceeds the maximum column width in fixed-format source files. The maximum column width for fixed-format files is 72, 80, or 132, depending on the setting of the extend-source option. The warn truncated_source option has no effect on truncation; lines that exceed the maximum column width are always truncated. This option does not apply to free-format source files.</td>
</tr>
<tr>
<td>warn uncalled</td>
<td>Enables warnings when a statement function is never called.</td>
</tr>
<tr>
<td>warn unused</td>
<td>Enables warnings for variables that are declared but never used.</td>
</tr>
<tr>
<td>warn nousage</td>
<td>Disables warnings about questionable programming practices. Questionable programming practices, although allowed, often are the result of programming errors; for example: a continued character or Hollerith literal whose first part ends before the statement field and appears to end with trailing spaces. Note that the /pad-source option can prevent this error.</td>
</tr>
<tr>
<td>warn all</td>
<td>This is the same as specifying warn. This option does not set options warn errors or warn stderrors. To enable all the additional checking to be performed and force the severity of the diagnostic messages to be severe enough to not generate an object file, specify warn allwarn errors or warn allwarn stderrors.</td>
</tr>
</tbody>
</table>

**IDE Equivalent**

Diagnostics > Warn For Uncalled Routine (-warn [no]uncalled)

Diagnostics > Warn For Unused Variables (-warn [no]unused)

Diagnostics > Suppress Usage Messages (-warn [no]usage)

Alternate Options

warn none
Linux and OS X: -nowarn, -w, -W0, -warn nogeneral
Windows: /nowarn, /w, /W0, /warn:nogeneral

warn declarations
Linux and OS X: -implicitnone, -u
Windows: /4Yd

warn nodeclarations
Linux and OS X: None
Windows: /4Nd

warn general
Linux and OS X: -W1
Windows: /W1

warn nogeneral
Linux and OS X: -W0, -w, -nowarn, -warn none
Windows: /W0, /w, /nowarn, /warn:none

warn stderrors
Linux and OS X: -e90, -e95, -e03
Windows: None

warn all
Linux and OS X: -warn
Windows: /warn (this is a deprecated option)

**WB**

*Turns a compile-time bounds check into a warning.*

**Syntax**

Linux OS and OS X:

- -WB

Windows OS:

/ -WB
Arguments
None

Default
OFF Compile-time bounds checks are errors.

Description
This option turns a compile-time bounds check into a warning.

IDE Equivalent
None

Alternate Options
None

Winline
Warns when a function that is declared as inline is not inlined.

Syntax
Linux OS and OS X:
-Winline

Windows OS:
None

Arguments
None

Default
OFF No warning is produced when a function that is declared as inline is not inlined.

Description
This option warns when a function that is declared as inline is not inlined.

To see diagnostic messages, including a message about why a particular function was not inlined, you should generate an optimization report by specifying option -qopt-report=5.

IDE Equivalent
None

Alternate Options
None

See Also
qopt-report, Qopt-report compiler option

Compatibility Options
**f66**  
*Tells the compiler to apply FORTRAN 66 semantics.*

**Syntax**

*Linux OS and OS X:*

- `-f66`

*Windows OS:*

- `/f66`

**Arguments**

None

**Default**

OFF The compiler applies Fortran 95 semantics.

**Description**

This option tells the compiler to apply FORTRAN 66 semantics when interpreting language features. This causes the following to occur:

- DO loops are always executed at least once
- FORTRAN 66 EXTERNAL statement syntax and semantics are allowed
- If the OPEN statement STATUS specifier is omitted, the default changes to STATUS='NEW' instead of STATUS='UNKNOWN'
- If the OPEN statement BLANK specifier is omitted, the default changes to BLANK='ZERO' instead of BLANK='NULL'

**IDE Equivalent**

Visual Studio: **Language > Enable FORTRAN 66 Semantics**

Eclipse: None

Xcode: **Language > Enable FORTRAN 66 Semantics**

**Alternate Options**

None

---

**f77rtl**  
*Tells the compiler to use the run-time behavior of FORTRAN 77.*

**Syntax**

*Linux OS and OS X:*

- `-f77rtl`
- `-nof77rtl`

*Windows OS:*

- `/f77rtl`
- `/nof77rtl`

**Arguments**

None
Default

nof77rtl  

The compiler uses the run-time behavior of Intel® Fortran.

Description

This option tells the compiler to use the run-time behavior of FORTRAN 77.

Specifying this option controls the following run-time behavior:

• When the unit is not connected to a file, some INQUIRE specifiers will return different values:
  • NUMBER= returns 0
  • ACCESS= returns 'UNKNOWN'
  • BLANK= returns 'UNKNOWN'
  • FORM= returns 'UNKNOWN'
  • PAD= defaults to 'NO' for formatted input.
• NAMELIST and list-directed input of character strings must be delimited by apostrophes or quotes.
• When processing NAMELIST input:
  • Column 1 of each record is skipped.
  • The 's' or 'l' that appears prior to the group-name must appear in column 2 of the input record.

IDE Equivalent

Visual Studio: Compatibility > Enable F77 Run-Time Compatibility

Eclipse: None

Xcode: Compatibility > Enable F77 Run-Time Compatibility

Alternate Options

None

fpscomp

Controls whether certain aspects of the run-time system and semantic language features within the compiler are compatible with Intel® Fortran or Microsoft® Fortran PowerStation.

Syntax

Linux OS and OS X:

-fpscomp [keyword[, keyword...]]

-nofpscomp

Windows OS:

/fpscomp[:keyword[, keyword...]]

/nofpscomp

Arguments

keyword  

Specifies the compatibility that the compiler should follow. Possible values are:

none  

Specifies that no options should be used for compatibility.
[no]filesfromcmd  Determines what compatibility is used when the OPEN statement FILE= specifier is blank.

[no]general      Determines what compatibility is used when semantics differences exist between Fortran PowerStation and Intel® Fortran.

[no]ioformat     Determines what compatibility is used for list-directed formatted and unformatted I/O.

[no]libs         Determines whether the portability library is passed to the linker.

[no]ldio_spacing Determines whether a blank is inserted at run-time after a numeric value before a character value.

[no]logicals     Determines what compatibility is used for representation of LOGICAL values.

all             Specifies that all options should be used for compatibility.

Default

fpscomp libs    The portability library is passed to the linker.

Description

This option controls whether certain aspects of the run-time system and semantic language features within the compiler are compatible with Intel Fortran or Microsoft* Fortran PowerStation.

If you experience problems when porting applications from Fortran PowerStation, specify fpscomp (or fpscomp all). When porting applications from Intel Fortran, use fpscomp none or fpscomp libs (the default).

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fpscomp none</td>
<td>Specifies that no options should be used for compatibility with Fortran PowerStation. This is the same as specifying nofpscomp. Option fpscomp none enables full Intel® Fortran compatibility. If you omit fpscomp, the default is fpscomp libs. You cannot use the fpscomp and vms options in the same command.</td>
</tr>
</tbody>
</table>
| fpscomp filesfromcmd | Specifies Fortran PowerStation behavior when the OPEN statement FILE= specifier is blank (FILE=''). It causes the following actions to be taken at run time:  
  - The program reads a file name from the list of arguments (if any) in the command line that invoked the program. If any of the command-line arguments contain a null string ('"'), the program asks the user for the corresponding file name. Each additional OPEN statement with a blank FILE= specifier reads the next command-line argument.  
  - If there are more nameless OPEN statements than command-line arguments, the program prompts for additional file names.  
  - In a QuickWin application, a "File Select" dialog box appears to request file names. |
To prevent the run-time system from using the file name specified on the command line when the OPEN statement FILE specifier is omitted, specify **fpscomp nofilesfromcmd**. This allows the application of Intel Fortran defaults, such as the FORTn environment variable and the FORT. n file name (where n is the unit number).

The **fpscomp filesfromcmd** option affects the following Fortran features:

- **The OPEN statement FILE specifier**

  For example, assume a program OPENTEST contains the following statements:
  
  OPEN(UNIT = 2, FILE = ' ')
  OPEN(UNIT = 3, FILE = ' ')
  OPEN(UNIT = 4, FILE = ' ')

  The following command line assigns the file TEST.DAT to unit 2, prompts the user for a file name to associate with unit 3, then prompts again for a file name to associate with unit 4:
  
  opentest test.dat " "

- **Implicit file open statements such as the WRITE, READ, and ENDFILE statements**

  Unopened files referred to in READ or WRITE statements are opened implicitly as if there had been an OPEN statement with a name specified as all blanks. The name is read from the command line.

**fpscomp general** Specifies that Fortran PowerStation semantics should be used when a difference exists between Intel Fortran and Fortran PowerStation. The **fpscomp general** option affects the following Fortran features:

- **The BACKSPACE statement:**

  - It allows files opened with ACCESS='APPEND' to be used with the BACKSPACE statement.
  - It allows files opened with ACCESS='DIRECT' to be used with the BACKSPACE statement.

  **Note:** Allowing files that are not opened with sequential access (such as ACCESS='DIRECT') to be used with the BACKSPACE statement violates the Fortran 95 standard and may be removed in the future.

- **The READ statement:**

  - It causes a READ from a formatted file opened for direct access to read records that have the same record type format as Fortran PowerStation. This consists of accounting for the trailing Carriage Return/Line Feed pair (<CR><LF>) that is part of the record. It allows sequential reads from a formatted file opened for direct access.

  **Note:** Allowing files that are not opened with sequential access (such as ACCESS='DIRECT') to be used with the sequential READ statement violates the Fortran 95 standard and may be removed in the future.

  - It allows the last record in a file opened with FORM='FORMATTED' and a record type of STREAM_LF or STREAM_CR that does not end with a proper record terminator (<line feed> or <carriage return>) to be read without producing an error.
  - It allows sequential reads from an unformatted file opened for direct access.
The INQUIRE statement:

- The CARRIAGECONTROL specifier returns the value "UNDEFINED" instead of "UNKNOWN" when the carriage control is not known.
- The NAME specifier returns the file name "UNKNOWN" instead of filling the file name with spaces when the file name is not known.
- The SEQUENTIAL specifier returns the value "YES" instead of "NO" for a direct access formatted file.
- The UNFORMATTED specifier returns the value "NO" instead of "UNKNOWN" when it is not known whether unformatted I/O can be performed to the file.

Note: Returning the value "NO" instead of "UNKNOWN" for this specifier violates the Fortran 95 standard and may be removed in the future.

The OPEN statement:

- If a file is opened with an unspecified STATUS keyword value, and is not named (no FILE specifier), the file is opened as a scratch file.
  For example:
  ```fortran
  OPEN (UNIT = 4)
  ```
- In contrast, when fpscomp nogeneral is in effect with an unspecified STATUS value with no FILE specifier, the FORTn environment variable and the FORT.n file name are used (where n is the unit number).
- If the STATUS value was not specified and if the name of the file is "USER", the file is marked for deletion when it is closed.
- It allows a file to be opened with the APPEND and READONLY characteristics.
- If the default for the CARRIAGECONTROL specifier is assumed, it gives "LIST" carriage control to direct access formatted files instead of "NONE".
- If the default for the CARRIAGECONTROL specifier is assumed and the device type is a terminal file, the file is given the default carriage control value of "FORTRAN" instead of "LIST".
- It gives an opened file the additional default of write sharing.
- It gives the file a default block size of 1024 instead of 8192.
- If the default for the MODE and ACTION specifier is assumed and there was an error opening the file, try opening the file as read only, then write only.
- If a file that is being re-opened has a different file type than the current existing file, an error is returned.
- It gives direct access formatted files the same record type as Fortran PowerStation. This means accounting for the trailing Carriage Return/Line Feed pair (<CR><LF>) that is part of the record.

The STOP statement: It writes the Fortran PowerStation output string and/or returns the same exit condition values.

The WRITE statement:

- Writing to formatted direct files
  When writing to a formatted file opened for direct access, records are written in the same record type format as Fortran PowerStation. This consists of adding the trailing Carriage Return/Line Feed pair (<CR><LF>) that is part of the record.
Option | Description
---|---
| It ignores the CARRIAGECONTROL specifier setting when writing to a formatted direct access file.
| **Interpreting Fortran carriage control characters**
  - When interpreting Fortran carriage control characters during formatted I/O, carriage control sequences are written that are the same as Fortran PowerStation. This is true for the "Space, 0, 1 and + " characters.
| **Performing non-advancing I/O to the terminal**
  - When performing non-advancing I/O to the terminal, output is written in the same format as Fortran PowerStation.
| **Interpreting the backslash (\) and dollar ($) edit descriptors**
  - When interpreting backslash and dollar edit descriptors during formatted I/O, sequences are written the same as Fortran PowerStation.
| **Performing sequential writes**
  - It allows sequential writes from an unformatted file opened for direct access.
  - Note: Allowing files that are not opened with sequential access (such as ACCESS='DIRECT') to be read with the sequential WRITE statement violates the Fortran 95 standard and may be removed in the future.

Specifying `fpscomp general sets fpscomp ldio_spacing`.  
`fpscomp ioformat` specifies that Fortran PowerStation semantic conventions and record formats should be used for list-directed formatted and unformatted I/O. The `fpscomp ioformat` option affects the following Fortran features:

- **The WRITE statement:**
  - For formatted list-directed WRITE statements, formatted internal list-directed WRITE statements, and formatted namelist WRITE statements, the output line, field width values, and the list-directed data type semantics are determined according to the following sample for real constants (N below):
    - For $1 \leq N < 10^7$, use F15.6 for single precision or F24.15 for double.
    - For $N < 1$ or $N \geq 10^7$, use E15.6E2 for single precision or E24.15E3 for double.
    - See the Fortran PowerStation documentation for more detailed information about the other data types affected.
  - For unformatted WRITE statements, the unformatted file semantics are dictated according to the Fortran PowerStation documentation; these semantics are different from the Intel Fortran file format. See the Fortran PowerStation documentation for more detailed information.

The following table summarizes the default output formats for list-directed output with the intrinsic data types:

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Output Format with <code>fpscomp noioformat</code></th>
<th>Output Format with <code>fpscomp ioformat</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>BYTE</td>
<td>I5</td>
<td>I12</td>
</tr>
<tr>
<td>LOGICAL (all)</td>
<td>L2</td>
<td>L2</td>

The READ statement:

- For formatted list-directed READ statements, formatted internal list-directed READ statements, and formatted namelist READ statements, the field width values and the list-directed semantics are dictated according to the following sample for real constants (N below):
  - For $1 \leq N < 10^7$, use `F15.6` for single precision or `F24.15` for double.
  - For $N < 1$ or $N \geq 10^7$, use `E15.6E2` for single precision or `E24.15E3` for double.
  - See the Fortran PowerStation documentation for more detailed information about the other data types affected.
- For unformatted READ statements, the unformatted file semantics are dictated according to the Fortran PowerStation documentation; these semantics are different from the Intel Fortran file format. See the Fortran PowerStation documentation for more detailed information.

</tbody>
</table>
The default is fpscomp nologicals, which specifies that odd integer values (low bit one) are treated as true and even integer values (low bit zero) are treated as false.

The literal constant .TRUE. has an integer value of -1, and the literal constant .FALSE. has an integer value of 0. This representation is used by Compaq* Visual Fortran. The internal representation of LOGICAL values is not specified by the Fortran standard. Programs which use integer values in LOGICAL contexts, or which pass LOGICAL values to procedures written in other languages, are non-portable and may not execute correctly. Intel recommends that you avoid coding practices that depend on the internal representation of LOGICAL values.

The fpscomp logical option affects the results of all logical expressions and affects the return value for the following Fortran features:

- The INQUIRE statement specifiers OPENED, IOFOCUS, EXISTS, and NAMED
- The EOF intrinsic function
- The BTEST intrinsic function
- The lexical intrinsic functions LLT, LLE, LGT, and LGE

fpscomp all

Specifies that all options should be used for compatibility with Fortran PowerStation. This is the same as specifying fpscomp with no keyword. Option fpscomp all enables full compatibility with Fortran PowerStation.

IDE Equivalent

Visual Studio: Compatibility > Use Filenames from Command Line (/fpscomp:[no]filesfromcmd)
Compatibility > Use PowerStation I/O Format (/fpscomp:[no]ioformat)
Compatibility > Use PowerStation Portability Library (/fpscomp:[no]libs)
Compatibility > Use PowerStation List-Directed I/O Spacing (/fpscomp:[no]ldio_spacing)
Compatibility > Use PowerStation Logical Values (/fpscomp:[no]logicals)
Compatibility > Use Other PowerStation Run-Time Behavior (/fpscomp:[no]general)
Eclipse: None
Xcode: None

Alternate Options

None

gcc-name

Lets you specify the name of the gcc compiler that should be used to set up the link-time environment, including the location of standard libraries.

Syntax

Linux OS:
-gcc-name=name

OS X:
None

Windows OS:
None
Arguments

name

Is the name of the gcc compiler to use. It can include the path where the gcc compiler is located.

Default

OFF

The compiler uses the PATH setting to find the gcc compiler and resolve environment settings.

Description

This option lets you specify the name of the gcc compiler that should be used to set up the link-time environment, including the location of standard libraries. If you do not specify a path, the compiler will search the PATH settings for the compiler name you provide.

This option is helpful when you are referencing a non-standard gcc installation, or you have multiple gcc installations on your system. The compiler will match gcc version values to the gcc compiler you specify. The C++ equivalent to option -gcc-name is -gxx-name.

IDE Equivalent

None

Alternate Options

None

Example

If the following option is specified, the compiler looks for the gcc compiler named foobar in the PATH setting:

-gcc-name=foobar

If the following option is specified, the compiler looks for the gcc compiler named foobar in the path specified:

-gcc-name=/a/b/foobar

See Also

gxx-name compiler option

gxx-name

Lets you specify the name of the g++ compiler that should be used to set up the link-time environment, including the location of standard libraries.

Syntax

Linux OS:

-gxx-name=name

OS X:

None

Windows OS:

None
Arguments

name  Is the name of the g++ compiler to use. It can include the path where the g++ compiler is located.

Default

OFF  The compiler uses the PATH setting to find the g++ compiler and resolve environment settings.

Description

This option lets you specify the name of the g++ compiler that should be used to set up the link-time environment, including the location of standard libraries. If you do not specify a path, the compiler will search the PATH settings for the compiler name you provide.

This option is helpful if you have multiple gcc++ installations on your system. The compiler will match gcc++ version values to the gcc++ compiler you specify.

The C equivalent to option -gxx-name is -gcc-name.

NOTE

When compiling a C++ file with icc, g++ is used to get the environment.

IDE Equivalent

None

Alternate Options

None

Example

If the following option is specified, the compiler looks for the g++ compiler named foobar in the PATH setting:

-gxx-name=foobar

If the following option is specified, the compiler looks for the g++ compiler named foobar in the path specified:

-gxx-name=/a/b/foobar

gcc-name compiler option

Qvc

Specifies compatibility with Microsoft* Visual C++ or Microsoft* Visual Studio.

Architecture Restrictions

Not available on Intel® 64 architecture targeting Intel® MIC Architecture

Syntax

Linux OS and OS X:

None
Windows OS:
/Qvc14
/Qvc12
/Qvc11
/Qvc10

Arguments
None

Default
varies

When the compiler is installed, it detects which version of Visual Studio is on your system. Qvc defaults to the form of the option that is compatible with that version. When multiple versions of Visual Studio are installed, the compiler installation lets you select which version you want to use. In this case, Qvc defaults to the version you choose.

Description
This option specifies compatibility with Microsoft* Visual C++ or Microsoft* Visual Studio.

vms
*Causes the run-time system to behave like HP* Fortran on OpenVMS* Alpha systems and VAX* systems (VAX FORTRAN*).

Syntax

Linux OS and OS X:
- vms
- novms

Windows OS:
/vms
Arguments
None

Default
novms

The run-time system follows default Intel® Fortran behavior.

Description
This option causes the run-time system to behave like HP* Fortran on OpenVMS* Alpha systems and VAX* systems (VAX FORTRAN*).

It affects the following language features:

• Certain defaults
  In the absence of other options, vms sets the defaults as check format and check output_conversion.

• Alignment
  Option vms does not affect the alignment of fields in records or items in common blocks. For compatibility with HP Fortran on OpenVMS systems, use align norecords to pack fields of records on the next byte boundary.

• Carriage control default
  If option vms and option ccdefault default are specified, carriage control defaults to FORTRAN if the file is formatted and the unit is connected to a terminal.

• INCLUDE qualifiers
  /LIST and /NOLIST are recognized at the end of the file name in an INCLUDE statement at compile time. If the file name in the INCLUDE statement does not specify the complete path, the path used is the current directory. Note that if vms is not specified, the path used is the directory where the file that contains the INCLUDE statement resides.

• Quotation mark character
  A quotation mark ("”) character is recognized as starting an octal constant ("0..7) instead of a character literal ("...").

• Deleted records in relative files
  When a record in a relative file is deleted, the first byte of that record is set to a known character (currently '@’). Attempts to read that record later result in ATTACCNON errors. The rest of the record (the whole record, if vms is not specified) is set to nulls for unformatted files and spaces for formatted files.

• ENDFILE records
  When an ENDFILE is performed on a sequential unit, an actual 1-byte record containing a Ctrl/Z is written to the file. If vms is not specified, an internal ENDFILE flag is set and the file is truncated. The vms option does not affect ENDFILE on relative files: these files are truncated.

• Implied logical unit numbers
  The vms option enables Intel® Fortran to recognize certain environment variables at run time for ACCEPT, PRINT, and TYPE statements and for READ and WRITE statements that do not specify a unit number (such as READ (*,1000)).

• Treatment of blanks in input
  The vms option causes the defaults for the keyword BLANK in OPEN statements to become 'NULL' for an explicit OPEN and 'ZERO' for an implicit OPEN of an external or internal file.

• OPEN statement effects
Carriage control defaults to FORTRAN if the file is formatted, and the unit is connected to a terminal. Otherwise, carriage control defaults to LIST. The vms option affects the record length for direct access and relative organization files. The buffer size is increased by 1 to accommodate the deleted record character.

- Reading deleted records and ENDFILE records

The run-time direct access READ routine checks the first byte of the retrieved record. If this byte is '@' or NULL ("\0"), then an ATTACCNON error is returned. The run-time sequential access READ routine checks to see if the record it just read is one byte long and contains a Ctrl/Z. If this is true, it returns EOF.

**IDE Equivalent**

Visual Studio: **Compatibility > Enable VMS Compatibility**

Eclipse: None

Xcode: **Compatibility > Enable VMS Compatibility**

**Alternate Options**

None

**See Also**

align compiler option
ccdefault compiler option

**Linking or Linker Options**

4nportlib, 4yportlib

*Determine whether the compiler links to the library of portability routines.*

**Syntax**

**Linux OS and OS X:**

None

**Windows OS:**

/4nportlib
/4yportlib

**Arguments**

None

**Default**

/4yportlib

The library of portability routines is linked during compilation.

**Description**

Option /4yportlib causes the compiler to link to the library of portability routines. This also includes Intel's functions for Microsoft* compatibility.

Option /4nportlib prevents the compiler from linking to the library of portability routines.

**IDE Equivalent**

Visual Studio: **Libraries > Use Portlib Library**

Eclipse: None
**Bdynamic**

*Enables dynamic linking of libraries at run time.*

**Syntax**

**Linux OS:**

-Bdynamic

**OS X:**

None

**Windows OS:**

None

**Arguments**

None

**Default**

OFF  

Limited dynamic linking occurs.

**Description**

This option enables dynamic linking of libraries at run time. Smaller executables are created than with static linking.

This option is placed in the linker command line corresponding to its location on the user command line. It controls the linking behavior of any library that is passed using the command line.

All libraries on the command line following option -Bdynamic are linked dynamically until the end of the command line or until a -Bstatic option is encountered. The -Bstatic option enables static linking of libraries.

**IDE Equivalent**

None

**Alternate Options**

None

**See Also**

Bstatic compiler option

**Bstatic**

*Enables static linking of a user’s library.*

**Syntax**

**Linux OS:**

-Bstatic
OS X:
None

Windows OS:
None

Arguments
None

Default
OFF

Default static linking occurs.

Description
This option enables static linking of a user's library.

This option is placed in the linker command line corresponding to its location on the user command line. It controls the linking behavior of any library that is passed using the command line.

All libraries on the command line following option -Bstatic are linked statically until the end of the command line or until a -Bdynamic option is encountered. The -Bdynamic option enables dynamic linking of libraries.

IDE Equivalent
None

Alternate Options
None

See Also
Bdynamic compiler option

Bsymblic
Binds references to all global symbols in a program to the definitions within a user's shared library.

Syntax
Linux OS:
-Bsymbolic

OS X:
None

Windows OS:
None

Arguments
None

Default
OFF

When a program is linked to a shared library, it can override the definition within the shared library.
Description
This option binds references to all global symbols in a program to the definitions within a user's shared library.
This option is only meaningful on Executable Linkage Format (ELF) platforms that support shared libraries.

CAUTION
This option can have unintended side-effects of disabling symbol preemption in the shared library.

IDE Equivalent
None

Alternate Options
None

See Also
bsymbolic-functions compiler option

bsymbolic-functions
Binds references to all global function symbols in a program to the definitions within a user's shared library.

Syntax
Linux OS:
-Bsymbolic-functions

OS X:
None

Windows OS:
None

Arguments
None

Default
OFF

When a program is linked to a shared library, it can override the definition within the shared library.

Description
This option binds references to all global function symbols in a program to the definitions within a user's shared library.
This option is only meaningful on Executable Linkage Format (ELF) platforms that support shared libraries.

CAUTION
This option can have unintended side-effects of disabling symbol preemption in the shared library.
IDE Equivalent
None

Alternate Options
None

Bsymbolic compiler option

cxxlib
Determines whether the compiler links using the C++ run-time libraries provided by gcc.

Syntax
Linux OS and OS X:
-cxxlib
-no-cxxlib

Windows OS:
None

Arguments
None

Default
-no-cxxlib
The compiler uses the default run-time libraries and does not link to any additional C++ run-time libraries.

Description
This option determines whether the compiler links to the standard C++ run-time library (libc++.). It is useful for building mixed Fortran/C++ applications.

IDE Equivalent
None

Alternate Options
None

See Also
gcc-name compiler option

dbglibs
Tells the linker to search for unresolved references in a debug run-time library.

Syntax
Linux OS and OS X:
None

Windows OS:
/dbglibs
/nodbglibs

**Arguments**

None

**Default**

/nodbglibs

The linker does not search for unresolved references in a debug run-time library.

**Description**

This option tells the linker to search for unresolved references in a debug run-time library. This option is processed by the compiler, which adds directives to the compiled object file that are processed by the linker.

The following table shows which options to specify for a debug run-time library:

<table>
<thead>
<tr>
<th>Type of Library</th>
<th>Options Required</th>
<th>Alternate Option</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug single-threaded</td>
<td>/libs:static</td>
<td>/MLd <em>(this is a deprecated option)</em></td>
</tr>
<tr>
<td></td>
<td>/dbglibs</td>
<td></td>
</tr>
<tr>
<td>Debug multithreaded</td>
<td>/libs:static</td>
<td>/MTd</td>
</tr>
<tr>
<td></td>
<td>/threads</td>
<td></td>
</tr>
<tr>
<td></td>
<td>/dbglibs</td>
<td></td>
</tr>
<tr>
<td>Multithreaded debug DLLs</td>
<td>/libs:dll</td>
<td>/MDd</td>
</tr>
<tr>
<td></td>
<td>/threads</td>
<td></td>
</tr>
<tr>
<td></td>
<td>/dbglibs</td>
<td></td>
</tr>
<tr>
<td>Debug Fortran QuickWin multi-thread applications</td>
<td>/libs:qwin</td>
<td>None</td>
</tr>
<tr>
<td></td>
<td>/dbglibs</td>
<td></td>
</tr>
<tr>
<td>Debug Fortran standard graphics (QuickWin single-thread) applications</td>
<td>/libs:qwins</td>
<td>None</td>
</tr>
<tr>
<td></td>
<td>/dbglibs</td>
<td></td>
</tr>
</tbody>
</table>

**IDE Equivalent**

None

**Alternate Options**

None

**dll**

Specifies that a program should be linked as a dynamic-link (DLL) library.

**Syntax**

**Linux OS and OS X:**

None

**Windows OS:**

/dll
Arguments
None

Default
OFF
The program is not linked as a dynamic-link (DLL) library.

Description
This option specifies that a program should be linked as a dynamic-link (DLL) library instead of an executable (.exe) file. It overrides any previous specification of run-time routines to be used and enables the /libs:dll option.
If you use this option with the /libs:qwin or /libs:qwins option, the compiler issues a warning.

IDE Equivalent
None

Alternate Options
Linux and OS X: None
Windows: /LD

dynamic-linker
Specifies a dynamic linker other than the default.

Syntax
Linux OS:
-dynamic-linker file

OS X:
None

Windows OS:
None

Arguments
file
Is the name of the dynamic linker to be used.

Default
OFF
The default dynamic linker is used.

Description
This option lets you specify a dynamic linker other than the default.

IDE Equivalent
None

Alternate Options
None
**dynamiclib**
*Invokes the libtool command to generate dynamic libraries.*

**Architecture Restrictions**
Not available on Intel® 64 architecture targeting Intel® MIC Architecture

**Syntax**

*Linux OS:*
None

*OS X:*
-dynamiclib

*Windows OS:*
None

**Arguments**
None

**Default**
OFF The compiler produces an executable.

**Description**
This option invokes the `libtool` command to generate dynamic libraries.

When passed this option, the compiler uses the `libtool` command to produce a dynamic library instead of an executable when linking.

To build static libraries, you should specify option `-staticlib` or `libtool -static <objects>`.

**IDE Equivalent**
None

**Alternate Options**
None

**See Also**
*staticlib* compiler option

**extlnk**
*Specifies file extensions to be passed directly to the linker.*

**Syntax**

*Linux OS and OS X:*
None

*Windows OS:*
/exetlnk:ext
Arguments

`ext`  
Are the file extensions to be passed directly to the linker.

Default

OFF  
Only the file extensions recognized by the compiler are passed to the linker.

Description

This option specifies file extensions (`ext`) to be passed directly to the linker. It is useful if your source file has a nonstandard extension.

You can specify one or more file extensions. A leading period before each extension is optional; for example, `/extlnk:myobj` and `/extlnk:.myobj` are equivalent.

IDE Equivalent

None

Alternate Options

None

F (Windows*)

Specifies the stack reserve amount for the program.

Syntax

Linux OS and OS X:

None

Windows OS:

`/Fn`

Arguments

`n`  
Is the stack reserve amount. It can be specified as a decimal integer or by using a C-style convention for constants (for example, `/F0x1000`).

Default

OFF  
The stack size default is chosen by the operating system.

Description

This option specifies the stack reserve amount for the program. The amount (`n`) is passed to the linker.

Note that the linker property pages have their own option to do this.

IDE Equivalent

None

Alternate Options

None
**F (OS X*)**  
Adds a framework directory to the head of an include file search path.

**Architecture Restrictions**  
Not available on Intel® 64 architecture targeting Intel® MIC Architecture

**Syntax**  
**Linux OS:**  
None  

**OS X:**  
\(-F\textit{dir}\)  

**Windows OS:**  
None

**Arguments**  
\(\textit{dir}\)  
Is the name for the framework directory.

**Default**  
OFF  
The compiler does not add a framework directory to the head of an include file search path.

**Description**  
This option adds a framework directory to the head of an include file search path.

**IDE Equivalent**  
None

**Alternate Options**  
None

**l**  
*Tells the linker to search for a specified library when linking.*

**Syntax**  
**Linux OS and OS X:**  
\(-l\textit{string}\)  

**Windows OS:**  
None

**Arguments**  
\(\textit{string}\)  
Specifies the library (lib\textit{string}) that the linker should search.
**Default**

OFF The linker searches for standard libraries in standard directories.

**Description**

This option tells the linker to search for a specified library when linking.

When resolving references, the linker normally searches for libraries in several standard directories, in directories specified by the `L` option, then in the library specified by the `l` option.

The linker searches and processes libraries and object files in the order they are specified. So, you should specify this option following the last object file it applies to.

**IDE Equivalent**

None

**Alternate Options**

None

**See Also**

L compiler option

**L**

*Tells the linker to search for libraries in a specified directory before searching the standard directories.*

**Syntax**

Linux OS and OS X:

- `L dir`

Windows OS:

None

**Arguments**

*dir* Is the name of the directory to search for libraries.

**Default**

OFF The linker searches the standard directories for libraries.

**Description**

This option tells the linker to search for libraries in a specified directory before searching for them in the standard directories.

**IDE Equivalent**

None

**Alternate Options**

None

**See Also**

L compiler option
**libs**
*Tells the compiler which type of run-time library to link to.*

**Syntax**

**Linux OS and OS X:**
None

**Windows OS:**
/\libs[;keyword]

**Arguments**

*keyword*

Specifies the type of run-time library to link to. Possible values are:

- *dll* Specifies a multithreaded, dynamic-link (DLL) library.
- *qwin* Specifies the Fortran QuickWin library.
- *qwins* Specifies the Fortran Standard Graphics library.

**Default**

/\libs

The compiler links to a multithreaded library.

**Description**

This option tells the compiler which type of run-time library to link to.

This option is processed by the compiler, which adds directives to the compiled object file that are processed by the linker.

There are several types of libraries you can link to, depending on which compiler options you specify, as shown in the table below.

If you use the /\libs:dll option and an unresolved reference is found in the DLL, it gets resolved when the program is executed, during program loading, reducing executable program size.

If you use the /\libs:qwin or /\libs:qwins option with the /dll option, the compiler issues a warning.

You cannot use the /\libs:qwin option and options /\libs:dll /threads.

The following table shows which options to specify for different run-time libraries:

<table>
<thead>
<tr>
<th>Type of Library</th>
<th>Options Required</th>
<th>Alternate Option</th>
</tr>
</thead>
<tbody>
<tr>
<td>Multithreaded static</td>
<td>/\libs (or /threads)</td>
<td>/MT</td>
</tr>
<tr>
<td>Debug multithreaded static</td>
<td>/\libs (or /threads)</td>
<td>/MTd and /dbglibs</td>
</tr>
<tr>
<td>Multithreaded DLLs</td>
<td>/\libs:dll</td>
<td>/MD</td>
</tr>
<tr>
<td>Multithreaded debug DLLs</td>
<td>/\libs:dll and /dbglibs</td>
<td>/MDd</td>
</tr>
<tr>
<td>Type of Library</td>
<td>Options Required</td>
<td>Alternate Option</td>
</tr>
<tr>
<td>-----------------------------------------------------</td>
<td>------------------</td>
<td>------------------</td>
</tr>
<tr>
<td>Fortran QuickWin multi-doc applications</td>
<td>/libs:qwin</td>
<td>/MW</td>
</tr>
<tr>
<td>Fortran standard graphics (QuickWin single-doc)</td>
<td>/libs:qwins</td>
<td>/MWs</td>
</tr>
<tr>
<td>Debug Fortran QuickWin multi-doc applications</td>
<td>/libs:qwin</td>
<td>None</td>
</tr>
<tr>
<td>Debug Fortran standard graphics (QuickWin single-doc)</td>
<td>/libs:qwins</td>
<td>None</td>
</tr>
</tbody>
</table>

**NOTE**
This option adds directives to the compiled code, which the linker then reads without further input from the driver.

**NOTE**
Starting with the 13.0 release of the Intel compilers, the Intel® OpenMP* library is provided in DLL form only.

**IDE Equivalent**
- **Visual Studio:** Libraries > Runtime Library (/libs:{dll|qwin|qwins},/threads,/dbglibs)
- **Eclipse:** None
- **Xcode:** None

**Alternate Options**

- `/libs`  
  - Linux and OS X: -threads  
  - Windows: /threads

- `/libs:dll`  
  - Linux and OS X: None  
  - Windows: /MD

- `/libs:qwin`  
  - Linux and OS X: None  
  - Windows: /MW

- `/libs:qwins`  
  - Linux and OS X: None  
  - Windows: /MWs

**See Also**
- threads compiler option

**link**
*Passes user-specified options directly to the linker at compile time.*
Syntax

**Linux OS and OS X:**
None

**Windows OS:**
/link

**Arguments**
None

**Default**
OFF

No user-specified options are passed directly to the linker.

**Description**
This option passes user-specified options directly to the linker at compile time. All options that appear following /link are passed directly to the linker.

**IDE Equivalent**
None

**Alternate Options**
None

**See Also**
Xlinker compiler option

map
*Tells the linker to generate a link map file.*

Syntax

**Linux OS and OS X:**
None

**Windows OS:**
/map[:filename]
/nomap

**Arguments**

*filename* Is the name for the link map file. It can be a file name or a directory name.

**Default**
/nomap

No link map is generated.

**Description**
This option tells the linker to generate a link map file.

**IDE Equivalent**

Visual Studio: **Linker > Debug > Generate Map File**
MD
Tells the linker to search for unresolved references in a multithreaded, dynamic-link run-time library.

Syntax

Linux OS and OS X:
None

Windows OS:
/MD
/MDd

Arguments
None

Default
OFF
The linker searches for unresolved references in a single-threaded, static run-time library.

Description

This option tells the linker to search for unresolved references in a multithreaded, dynamic-link (DLL) run-time library. This is the same as specifying options /libs:dll /threads /dbglibs. You can also specify /MDd, where d indicates a debug version.

This option is processed by the compiler, which adds directives to the compiled object file that are processed by the linker.

IDE Equivalent

Visual Studio: Libraries > Runtime Library

Eclipse: None
Xcode: None

Alternate Options
None

MT
Tells the linker to search for unresolved references in a multithreaded, static run-time library.

Syntax

Linux OS and OS X:
None

Windows OS:
/MT
/MTd

Arguments
None
**Default**

Systems using Intel® 64 architecture: /MT /norentancy
IA-32 architecture: OFF

On systems using Intel® 64 architecture, the linker searches for unresolved references in a multithreaded, static run-time library.

On systems using IA-32 architecture, the linker searches for unresolved references in a single-threaded, static run-time library.

**Description**

This option tells the linker to search for unresolved references in a multithreaded, static run-time library. This is the same as specifying options /libs:static /threads /norentancy. You can also specify /MTd, where d indicates a debug version.

This option is processed by the compiler, which adds directives to the compiled object file that are processed by the linker.

**IDE Equivalent**

Visual Studio: **Libraries > Runtime Library**

Eclipse: None

Xcode: None

**Alternate Options**

None

**See Also**

nodefaultlibs
Prevents the compiler from using standard libraries when linking.

**Syntax**

Linux OS and OS X:

```
-nodefaultlibs
```

Windows OS:

None

**Arguments**

None

**Default**

OFF

The standard libraries are linked.

**Description**

This option prevents the compiler from using standard libraries when linking.
### nofor-main

Specifies that the main program is not written in Fortran.

**Syntax**

**Linux OS and OS X:**

```
-nofor-main
```

**Windows OS:**

None

**Arguments**

None

**Default**

**OFF**  
The compiler assumes the main program is written in Fortran.

**Description**

This option specifies that the main program is not written in Fortran. It is a link-time option that prevents the compiler from linking `for_main.o` into applications.

For example, if the main program is written in C and calls a Fortran subprogram, specify `-nofor-main` when compiling the program with the `ifort` command.

If you omit this option, the main program must be a Fortran program.

### nostartfiles

Prevents the compiler from using standard startup files when linking.

**Syntax**

**Linux OS and OS X:**

```
-nostartfiles
```

**Windows OS:**

None
Arguments
None

Default
OFF

The compiler uses standard startup files when linking.

Description
This option prevents the compiler from using standard startup files when linking.

IDE Equivalent
None

Alternate Options
None

See Also
nostdlib compiler option

nostdlib
Prevents the compiler from using standard libraries and startup files when linking.

Syntax

Linux OS and OS X:
-nostdlib

Windows OS:
None

Arguments
None

Default
OFF

The compiler uses standard startup files and standard libraries when linking.

Description
This option prevents the compiler from using standard libraries and startup files when linking.
This option is not related to option -stdlib.

IDE Equivalent
None

Alternate Options
None

See Also
nodefaultlibs compiler option
nostartfiles compiler option
pie
Determines whether the compiler generates position-independent code that will be linked into an executable.

Syntax
Linux OS and OS X:
- pie
- no-pie
Windows OS:
None

Arguments
None

Default
varies
On Linux* OS and on OS X* versions less than 10.7, the default is -no-pie.
On OS X* 10.7 or greater, the default is -pie.

Description
This option determines whether the compiler generates position-independent code that will be linked into an executable. To enable generation of position-independent code that will be linked into an executable, specify -pie.
To disable generation of position-independent code that will be linked into an executable, specify -no-pie.

IDE Equivalent
None

Alternate Options
None

See Also
fpic compiler option
pthread
Tells the compiler to use pthreads library for multithreading support.

Syntax
Linux OS and OS X:
- pthread
Windows OS:
None

Arguments
None
Default
OFF

The compiler does not use pthreads library for multithreading support.

Description
Tells the compiler to use pthreads library for multithreading support.

IDE Equivalent
None

Alternate Options
Linux and OS X: -reentrancy threaded
Windows: /reentrancy:threaded

Qimsl
Tells the compiler to link to the IMSL* Fortran Numerical Library*(IMSL* library).

Architecture Restrictions
Not available on Intel® 64 architecture targeting Intel® MIC Architecture

Syntax
Linux OS and OS X:
None

Windows OS:
/Qimsl

Arguments
None

Default
OFF

The compiler does not link to the IMSL* library.

Description
This option tells the compiler to link to the IMSL* Fortran Numerical Library* (IMSL* library). This option is applicable for users of editions of the Intel® Fortran Compiler product that include the IMSL* libraries.

This option is processed by the compiler, which adds directives to the compiled object file that are processed by the linker.

IDE Equivalent
None

Alternate Options
None
shared
Tells the compiler to produce a dynamic shared object instead of an executable.

Syntax

Linux OS:
-shared

OS X:
None

Windows OS:
None

Arguments
None

Default
OFF The compiler produces an executable.

Description
This option tells the compiler to produce a dynamic shared object (DSO) instead of an executable. This includes linking in all libraries dynamically and passing -shared to the linker.

You must specify option fpic for the compilation of each object file you want to include in the shared library.

IDE Equivalent
None

Alternate Options
None

See Also
dynamiclib compiler option
fpic compiler option
Xlinker compiler option

shared-intel
Causes Intel-provided libraries to be linked in dynamically.

Syntax

Linux OS and OS X:
-shared-intel

Windows OS:
None

Arguments
None
Default

OFF Intel® libraries are linked in statically, with the exception of Intel’s OpenMP* runtime support library, which is linked in dynamically.

Description
This option causes Intel-provided libraries to be linked in dynamically. It is the opposite of -static-intel. This option is processed by the ifort (icc/icpc) command that initiates linking, adding library names explicitly to the link command. If you specify option -mcmmodel=medium or -mcmmodel=large, it sets option -shared-intel.

NOTE
On OS X* systems, when you set "Intel Runtime Libraries" to "Dynamic", you must also set the DYLD_LIBRARY_PATH environment variable within Xcode* or an error will be displayed.

IDE Equivalent
Visual Studio: None
Eclipse: None
Xcode: Runtime > Intel Runtime Libraries

Alternate Options
None

See Also
static-intel compiler option
shared-libgcc
Links the GNU libgcc library dynamically.

Syntax
Linux OS:
-shared-libgcc

OS X:
None

Windows OS:
None

Arguments
None

Default
-shared-libgcc The compiler links the libgcc library dynamically.

Description
This option links the GNU libgcc library dynamically. It is the opposite of option static-libgcc.
This option is processed by the ifort (icc/icpc) command that initiates linking, adding library names explicitly to the link command.

This option is useful when you want to override the default behavior of the static option, which causes all libraries to be linked statically.

**IDE Equivalent**
None

**Alternate Options**
None

**See Also**
static-libgcc compiler option

**static**
Prevents linking with shared libraries.

**Syntax**

**Linux OS:**
- static

**OS X:**
None

**Windows OS:**
/static

**Arguments**
None

**Default**

Linux: OFF
Windows: varies

On Linux* systems, the compiler links with shared libraries. On Windows* systems, /static is equivalent to option /MT.

**Description**
This option prevents linking with shared libraries. It causes the executable to link all libraries statically.

**IDE Equivalent**
None

**Alternate Options**
None

**See Also**
MT compiler option
Qvc compiler option
static-intel compiler option

**static-intel**
Causes Intel-provided libraries to be linked in statically.
Syntax
Linux OS and OS X:
- static-intel
Windows OS:
None

Arguments
None

Default
ON

Description
Intel libraries are linked in statically, with the exception of Intel's OpenMP* runtime support library, which is linked in dynamically.

IDE Equivalent
Visual Studio: None
Eclipse: None
Xcode: Runtime > Intel Runtime Libraries

Alternate Options
None

See Also
shared-intel compiler option
static-libgcc
Links the GNU libgcc library statically.

Syntax
Linux OS:
- static-libgcc
OS X:
None
Windows OS:
None

Arguments
None
Default

OFF  The compiler links the GNU libgcc library dynamically.

Description
This option links the GNU libgcc library statically. It is the opposite of option -shared-libgcc.

This option is processed by the ifort (icc/icpc) command that initiates linking, adding library names explicitly
to the link command.

This option is useful when you want to override the default behavior, which causes the library to be linked
dynamically.

IDE Equivalent
None

Alternate Options
None

See Also
shared-libgcc compiler option
static-libstdc++ compiler option

static-libstdc++
Links the GNU libstdc++ library statically.

Syntax

Linux OS:
-<span class="highlight">static-libstdc++</span>

OS X:
None

Windows OS:
None

Arguments
None

Default

OFF  The compiler links the GNU libstdc++ library dynamically.

Description
This option links the GNU libstdc++ library statically. This option is processed by the ifort (icc/icpc)
command that initiates linking, adding library names explicitly to the link command.

This option is useful when you want to override the default behavior, which causes the library to be linked
dynamically.

IDE Equivalent
None
Alternate Options
None

See Also
static-libgcc compiler option

staticlib
Invokes the libtool command to generate static libraries.

Architecture Restrictions
Not available on Intel® 64 architecture targeting Intel® MIC Architecture

Syntax
Linux OS:
None

OS X:
staticlib

Windows OS:
None

Arguments
None

Default
OFF The compiler produces an executable.

Description
This option invokes the libtool command to generate static libraries. This option is processed by the command that initiates linking, adding library names explicitly to the link command.

When passed this option, the compiler uses the libtool command to produce a static library instead of an executable when linking.

To build dynamic libraries, you should specify option -dynamiclib or libtool -dynamic <objects>.

IDE Equivalent
None

Alternate Options
None

See Also
dynamiclib compiler option

T
Tells the linker to read link commands from a file.
Syntax
Linux OS:
-`T`filename

OS X:
None

Windows OS:
None

Arguments

`filename` Is the name of the file.

Default

OFF The linker does not read link commands from a file.

Description
This option tells the linker to read link commands from a file.

IDE Equivalent

None

Alternate Options

None

threads
*Tells the linker to search for unresolved references in a multithreaded run-time library.*

Syntax
Linux OS and OS X:
-`-threads`
-`-nothreads`

Windows OS:
/`threads`
/`nothreads`

Arguments

None

Default

Windows* OS: `threads` The linker searches for unresolved references in a library that supports enabling thread-safe operation when the `/reentrancy:threaded` option is also specified.
The linker searches for unresolved references in a library that does not support thread-safe operation.

**Description**

This option tells the linker to search for unresolved references in a multithreaded run-time library.

This option sets option reentrancy threaded.

**Windows systems:** The following table shows which options to specify for a multithreaded run-time library.

<table>
<thead>
<tr>
<th>Type of Library</th>
<th>Options Required</th>
<th>Alternate Option</th>
</tr>
</thead>
<tbody>
<tr>
<td>Multithreaded</td>
<td>/libs:static</td>
<td>/MT</td>
</tr>
<tr>
<td></td>
<td>/threads</td>
<td></td>
</tr>
<tr>
<td>Debug multithreaded</td>
<td>/libs:static</td>
<td>/MTd</td>
</tr>
<tr>
<td></td>
<td>/threads</td>
<td></td>
</tr>
<tr>
<td></td>
<td>/dbglibs</td>
<td></td>
</tr>
<tr>
<td>Multithreaded DLLs</td>
<td>/libs:dll</td>
<td>/MD</td>
</tr>
<tr>
<td></td>
<td>/threads</td>
<td></td>
</tr>
<tr>
<td>Multithreaded debug DLLs</td>
<td>/libs:dll</td>
<td>/MDd</td>
</tr>
<tr>
<td></td>
<td>/threads</td>
<td></td>
</tr>
<tr>
<td></td>
<td>/dbglibs</td>
<td></td>
</tr>
</tbody>
</table>

To ensure that a threadsafe and/or reentrant run-time library is linked and correctly initialized, option threads should also be used for the link step and for the compilation of the main routine.

**NOTE**

On Windows* OS, this option is processed by the compiler, which adds directives to the compiled object file that are processed by the linker. On Linux* OS and OS X*, this option is processed by the ifort command that initiates linking, adding library names explicitly to the link command.

**IDE Equivalent**

None

**Alternate Options**

None

**See Also**

reentrancy compiler option

v

*Specifies that driver tool commands should be displayed and executed.*

**Syntax**

**Linux OS and OS X:**

-v [filename]
Windows OS:
None

Arguments

filename Is the name of a source file to be compiled. A space must appear before the file name.

Default
OFF No tool commands are shown.

Description
This option specifies that driver tool commands should be displayed and executed.
If you use this option without specifying a source file name, the compiler displays only the version of the compiler.
If you want to display processing information (pass information and source file names), specify keyword all for the watch option.

IDE Equivalent
None

Alternate Options
Linux and OS X: -watch cmd
Windows: /watch:cmd

See Also
dryrun compiler option
watch compiler option

Wa
Passes options to the assembler for processing.

Syntax
Linux OS and OS X:
-Wa,option1[,option2,...]

Windows OS:
None

Arguments

option Is an assembler option. This option is not processed by the driver and is directly passed to the assembler.

Default
OFF No options are passed to the assembler.
Description
This option passes one or more options to the assembler for processing. If the assembler is not invoked, these options are ignored.

IDE Equivalent
None

Alternate Options
None

\texttt{winapp}
\textit{Tells the compiler to create a graphics or Fortran Windows application and link against the most commonly used libraries.}

Architecture Restrictions
Not available on Intel® 64 architecture targeting Intel® MIC Architecture

Syntax
Linux OS and OS X:
None

Windows OS:
\texttt{/winapp}

Arguments
None

Default
OFF No graphics or Fortran Windows application is created.

Description
This option tells the compiler to create a graphics or Fortran Windows application and link against the most commonly used libraries.
This option is processed by the compiler, which adds directives to the compiled object file that are processed by the linker.

IDE Equivalent
Visual Studio: Libraries > Use Common Windows Libraries
Eclipse: None
Xcode: None

Alternate Options
Linux and OS X: None
Windows: /MG

\texttt{Wl}
\textit{Passes options to the linker for processing.}
Syntax

Linux OS and OS X:
-\texttt{-Wl,option1[,option2,...]}

Windows OS:
None

Arguments

\texttt{option} \quad Is a linker option. This option is not processed by the driver and is directly passed to the linker.

Default

OFF \quad No options are passed to the linker.

Description

This option passes one or more options to the linker for processing. If the linker is not invoked, these options are ignored.

This option is equivalent to specifying option \texttt{-Qoption,link,\textit{options}}.

IDE Equivalent

None

Alternate Options

None

See Also

\texttt{Qoption} compiler option

Wp

Passes options to the preprocessor.

Syntax

Linux OS and OS X:
-\texttt{-Wp,option1[,option2,...]}

Windows OS:
None

Arguments

\texttt{option} \quad Is a preprocessor option. This option is not processed by the driver and is directly passed to the preprocessor.

Default

OFF \quad No options are passed to the preprocessor.

Description

This option passes one or more options to the preprocessor. If the preprocessor is not invoked, these options are ignored.
This option is equivalent to specifying option `-Qoption, fpp, options`.

**IDE Equivalent**
None

**Alternate Options**
None

**See Also**
Option compiler option

**Xlinker**
*Passes a linker option directly to the linker.*

**Syntax**

**Linux OS and OS X:**

- `-Xlinker option`

**Windows OS:**

None

**Arguments**

`option` Is a linker option.

**Default**
OFF No options are passed directly to the linker.

**Description**

This option passes a linker option directly to the linker. If `-Xlinker -shared` is specified, only `-shared` is passed to the linker and no special work is done to ensure proper linkage for generating a shared object. `-Xlinker` just takes whatever arguments are supplied and passes them directly to the linker.

If you want to pass compound options to the linker, for example "-L $HOME/lib", you must use the following method:

- `-Xlinker -L -Xlinker $HOME/lib`

**IDE Equivalent**
None

**Alternate Options**
None

**See Also**
shared compiler option
link compiler option

**Miscellaneous Options**
**bigobj**
*Increases the number of sections that an object file can contain.*

**Syntax**

**Linux OS and OS X:**
None

**Windows OS:**
`/bigobj`

**Arguments**
None

**Default**
OFF

An object file can hold up to 65,536 ($2^{16}$) addressable sections.

**Description**
This option increases the number of sections that an object file can contain. It increases the address capacity to 4,294,967,296 ($2^{32}$).

This option may be helpful for .obj files that can hold more sections, such as machine generated code.

**IDE Equivalent**
None

**Alternate Options**
None

**dryrun**
*Specifies that driver tool commands should be shown but not executed.*

**Syntax**

**Linux OS and OS X:**
`-dryrun`

**Windows OS:**
None

**Arguments**
None

**Default**
OFF

No tool commands are shown, but they are executed.

**Description**
This option specifies that driver tool commands should be shown but not executed.

**IDE Equivalent**
None
Alternate Options
None

See Also
v compiler option
dumpmachine

Displays the target machine and operating system configuration.

Syntax
Linux OS and OS X:
-dumpmachine

Windows OS:
None

Arguments
None

Default
OFF

The compiler does not display target machine or operating system information.

Description
This option displays the target machine and operating system configuration. No compilation is performed.

IDE Equivalent
None

Alternate Options
None

extfor

Specifies file extensions to be processed by the compiler as Fortran files.

Syntax
Linux OS and OS X:
None

Windows OS:
/extfor:ext

Arguments
ext

Are the file extensions to be processed as a Fortran file.
Default

OFF

Only the file extensions recognized by the compiler are processed as Fortran files.

Description

This option specifies file extensions (ext) to be processed by the compiler as Fortran files. It is useful if your source file has a nonstandard extension.

You can specify one or more file extensions. A leading period before each extension is optional; for example, /extfor:myf95 and /extfor:.myf95 are equivalent.

IDE Equivalent

None

Alternate Options

None

See Also

Tf Tells the compiler to compile the file as a Fortran source file.

extfpp

Specifies file extensions to be recognized as a file to be preprocessed by the Fortran preprocessor.

Syntax

Linux OS and OS X:

None

Windows OS:

/extfpp:ext

Arguments

ext

Are the file extensions to be preprocessed by the Fortran preprocessor.

Default

OFF

Only the file extensions recognized by the compiler are preprocessed by fpp.

Description

This option specifies file extensions (ext) to be recognized as a file to be preprocessed by the Fortran preprocessor (fpp). It is useful if your source file has a nonstandard extension.

You can specify one or more file extensions. A leading period before each extension is optional; for example, /extfpp:myfpp and /extfpp:.myfpp are equivalent.

IDE Equivalent

None

Alternate Options

None
**global-hoist, Qglobal-hoist**

*Enables certain optimizations that can move memory loads to a point earlier in the program execution than where they appear in the source.*

**Syntax**

**Linux OS and OS X:**

- `-global-hoist`
- `-no-global-hoist`

**Windows OS:**

- `/Qglobal-hoist`
- `/Qglobal-hoist-`

**Arguments**

None

**Default**

- `-global-hoist`
  
  Certain optimizations are enabled that can move memory loads.
  
  or
  
  `/Qglobal-hoist`

**Description**

This option enables certain optimizations that can move memory loads to a point earlier in the program execution than where they appear in the source. In most cases, these optimizations are safe and can improve performance.

The negative form of the option is useful for some applications, such as those that use shared or dynamically mapped memory, which can fail if a load is moved too early in the execution stream (for example, before the memory is mapped).

**IDE Equivalent**

None

**Alternate Options**

None

**help**

*Displays all available compiler options or a category of compiler options.*

**Syntax**

**Linux OS and OS X:**

- `-help[category]`

**Windows OS:**

- `/help[category]`

**Arguments**

*category*  

Is a category or class of options to display. Possible values are:
advanced Displays advanced optimization options that allow fine tuning of compilation or allow control over advanced features of the compiler.

codegen Displays Code Generation options.

compatibility Displays options affecting language compatibility.

component Displays options for component control.

data Displays options related to interpretation of data in programs or the storage of data.

deprecated Displays options that have been deprecated.

diagnostics Displays options that affect diagnostic messages displayed by the compiler.

float Displays options that affect floating-point operations.

help Displays all the available help categories.

inline Displays options that affect inlining.

ipo Displays Interprocedural Optimization (IPO) options.

language Displays options affecting the behavior of the compiler language features.

link Displays linking or linker options.

misc Displays miscellaneous options that do not fit within other categories.

openmp Displays OpenMP and parallel processing options.

opt Displays options that help you optimize code.

output Displays options that provide control over compiler output.

pgo Displays Profile Guided Optimization (PGO) options.

preproc Displays options that affect preprocessing operations.

reports Displays options for optimization reports.

**Default**

OFF No list is displayed unless this compiler option is specified.

**Description**

This option displays all available compiler options or a category of compiler options. If category is not specified, all available compiler options are displayed.
IDE Equivalent
None

Alternate Options
Linux and OS X: None
Windows: /?

libdir
*Controls whether linker options for search libraries are included in object files generated by the compiler.*

Syntax
Linux OS and OS X:
None

Windows OS:
/libdir[:keyword ]
/nolibdir

Arguments

keyword

Specifies the linker search options. Possible values are:

- none
  Prevents any linker search options from being included into the object file. This is the same as specifying /nolibdir.

- [no]automatic
  Determines whether linker search options for libraries automatically determined by the ifort command driver (default libraries) are included in the object file.

- [no]user
  Determines whether linker search options for libraries specified by the OBJCOMMENT source directives are included in the object file.

- all
  Causes linker search options for the following libraries:
  - Libraries automatically determined by the ifort command driver (default libraries)
  - Libraries specified by the OBJCOMMENT directive to be included in the object file
  
  This is the same as specifying /libdir.

Default
/libdir:all

Linker search options for libraries automatically determined by the ifort command driver (default libraries) and libraries specified by the OBJCOMMENT directive are included in the object file.
Description
This option controls whether linker options for search libraries (/DEFAULTLIB:library) are included in object files generated by the compiler.

The linker option /DEFAULTLIB:library adds one library to the list of libraries that the linker searches when resolving references. A library specified with /DEFAULTLIB:library is searched after libraries specified on the command line and before default libraries named in .obj files.

IDE Equivalent
Libraries > Disable OBJCOMMENT Library Name in Object (/libdir:[no]user)
Eclipse: None
Xcode: None

Alternate Options
/libdir:none Linux and OS X: None
Windows: /Zl

logo
Displays the compiler version information.

Syntax
Linux OS and OS X:
-Logo
-nologo

Windows OS:
/logo
/nologo

Arguments
None

Default
Linux* OS and OS X*: nologo The compiler version information is not displayed.
Windows* OS: logo The compiler version information is displayed.

Description
This option displays the startup banner, which contains the following compiler information:

- The name of the compiler and its applicable architecture
- The major and minor version of the compiler, the update number, and the package number (for example, Version 11.1.0.047)
- The specific build and build date (for example, Build <builddate>)
- The copyright date of the software

This option can be placed anywhere on the command line.
IDE Equivalent
Visual Studio: **General > Suppress Startup Banner** (/nologo)
Eclipse: None
Xcode: **General > Show Startup Banner** (-V)

Alternate Options
Linux and OS X: -V
Windows: None

**multiple-processes, MP**
*Creates multiple processes that can be used to compile large numbers of source files at the same time.*

**Syntax**

Linux OS and OS X:
- `multiple-processes=[n]`

Windows OS:
/MP[:n]

**Arguments**

\( n \)
Is the maximum number of processes that the compiler should create.

**Default**

OFF
A single process is used to compile source files.

**Description**
This option creates multiple processes that can be used to compile large numbers of source files at the same time. It can improve performance by reducing the time it takes to compile source files on the command line.

This option causes the compiler to create one or more copies of itself, each in a separate process. These copies simultaneously compile the source files.

If \( n \) is not specified for this option, the default value is as follows:

- On Windows* OS, the value is based on the setting of the NUMBER_OF_PROCESSORS environment variable.
- On Linux* OS and OS X*, the value is 2.

This option applies to compilations, but not to linking or link-time code generation.

**IDE Equivalent**
Visual Studio: **General > Multi-processor Compilation**
Eclipse: None
Xcode: None

Alternate Options
None
**print-sysroot**

*Prints the target sysroot directory that is used during compilation.*

**Architectures**

Not available on Intel® 64 architecture targeting Intel® MIC Architecture

**Syntax**

**Linux OS:**

- `print-sysroot`

**OS X:**

None

**Windows OS:**

None

**Arguments**

None

**Default**

OFF

*Nothing is printed.*

**Description**

This option prints the target sysroot directory that is used during compilation.

This is the target sysroot directory that is specified in an environment file or in option `--sysroot`. This option is only effective if a target sysroot has been specified.

**IDE Equivalent**

None

**Alternate Options**

None

**See Also**

sysroot compiler option

**save-temps, Qsave-temps**

*Tells the compiler to save intermediate files created during compilation.*

**Syntax**

**Linux OS and OS X:**

- `save-temps`
- `no-save-temps`

**Windows OS:**

/-save-temps
/-Qsave-temps/-
Arguments
None

Default
Linux* OS and OS X*: -no-save-temps
Windows* OS: .obj files are saved

On Linux and OS X systems, the compiler deletes intermediate files after compilation is completed. On Windows systems, the compiler saves only intermediate object files after compilation is completed.

Description
This option tells the compiler to save intermediate files created during compilation. The names of the files saved are based on the name of the source file; the files are saved in the current working directory.

If option [Q]save-temps is specified, the following occurs:

- The object .o file (Linux OS and OS X) or .obj file (Windows OS) is saved.
- The assembler .s file (Linux OS and OS X) or .asm file (Windows OS) is saved if you specified the [Q]use-asm option.
- The .i or .i90 file is saved if the fpp preprocessor is invoked.

If -no-save-temps is specified on Linux or OS X systems, the following occurs:

- The .o file is put into /tmp and deleted after calling ld.
- The preprocessed file is not saved after it has been used by the compiler.

If /Qsave-temps- is specified on Windows systems, the following occurs:

- The .obj file is not saved after the linker step.
- The preprocessed file is not saved after it has been used by the compiler.

NOTE
This option only saves intermediate files that are normally created during compilation.

IDE Equivalent
None

Alternate Options
None

Example
If you compile program my_foo.F on a Linux or OS X system and you specify option -save-temps and option -use-asm, the compilation will produce files my_foo.o, my_foo.s, and my_foo.i.

If you compile program my_foo.fpp on a Windows system and you specify option /Qsave-temps and option /Quse-asm, the compilation will produce files my_foo.obj, my_foo.asm, and my_foo.i.

sox
Tells the compiler to save the compilation options and version number in the executable file. It also lets you choose whether to include lists of certain routines.
Syntax

Linux OS:
- sox\[=keyword[,keyword]]
- no-sox

OS X:
None

Windows OS:
None

Arguments

\textit{keyword}

Is the routine information to include. Possible values are:

- \textit{inline}
  
  Includes a list of the routines that were inlined in each object.

- \textit{profile}
  
  Includes a list of the routines that were compiled with the \textit{-prof-use} option and for which the .dpi file had profile information, and an indication for each as to whether the profile information was USED (matched) or IGNORED (mismatched).

Default

- \textit{-no-sox}
  
  The compiler does not save these informational strings in the object file.

Description

This option tells the compiler to save the compilation options and version number in the executable file. It also lets you choose whether to include lists of certain routines. The information is embedded as a string in each object file or assembly output.

If you specify option \textit{sox} with no \textit{keyword}, the compiler saves the compiler options and version number used in the compilation of the objects that make up the executable.

When you specify this option, the size of the executable on disk is increased slightly. Each \textit{keyword} you specify increases the size of the executable. When you link the object files into an executable file, the linker places each of the information strings into the header of the executable. It is then possible to use a tool, such as a strings utility, to determine what options were used to build the executable file.

IDE Equivalent

None

Alternate Options

None

Example

The following commands are equivalent:

- sox=profile  no-sox=inline
- sox=profile,inline
You can use the negative form of the option to disable and reset the option. For example:

- sox=profile -no-sox -sox=inline  ! This means -sox=inline

**See Also**

prof-use, Qprof-use compiler option

docs

Specifies the root directory where headers and libraries are located.

**Architecture Restrictions**

Not available on Intel® 64 architecture targeting Intel® MIC Architecture

**Syntax**

**Linux OS:**

```bash
--sysroot=dir
```

**OS X:**

None

**Windows OS:**

None

**Arguments**

`dir`

Specifies the local directory that contains copies of target libraries in the corresponding subdirectories.

**Default**

Off

The compiler uses default settings to search for headers and libraries.

**Description**

This option specifies the root directory where headers and libraries are located.

For example, if the headers and libraries are normally located in `/usr/include` and `/usr/lib` respectively, `--sysroot=/mydir` will cause the compiler to search in `/mydir/usr/include` and `/mydir/usr/lib` for the headers and libraries.

**IDE Equivalent**

None

**Alternate Options**

None

**See Also**

**Tf**

*Tells the compiler to compile the file as a Fortran source file.*

**Syntax**

**Linux OS and OS X:**

```bash
-Tf filename
```
Windows OS:
/Tf filename

**Arguments**

*filename* Is the name of the file.

**Default**

OFF Files that do not end in standard Fortran file extensions are not compiled as Fortran files.

**Description**

This option tells the compiler to compile the file as a Fortran source file.

This option is useful when you have a Fortran file with a nonstandard file extension (that is, not one of .F, .FOR, or .F90).

This option assumes the file specified uses fixed source form. If the file uses free source form, you must also specify option `free`.

**IDE Equivalent**

None

**Alternate Options**

None

**See Also**

extfor compiler option
free compiler option

**watch**

*Tells the compiler to display certain information to the console output window.*

**Syntax**

Linux OS and OS X:

-`-watch[=keyword[, keyword...]]`
-`-nowatch`

Windows OS:

`/watch[::keyword[, keyword...]]`
`/nowatch`

**Arguments**

*keyword* Determines what information is displayed. Possible values are:

- `none` Disables cmd and source.
- `[no]cmd` Determines whether driver tool commands are displayed and executed.
Determines whether the name of the file being compiled is displayed.

`mic-cmd` Enables display of compiler options that are passed to the offload compilation. This keyword is only available on Intel® MIC Architecture.

`all` Enables `cmd` and `source`.

**Default**

`nowatch` Pass information and source file names are not displayed to the console output window.

**Description**

Tells the compiler to display processing information (pass information and source file names) to the console output window.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>watch</code></td>
<td>Tells the compiler to display pass information and source file names to the console output window. This is the same as specifying <code>nowatch</code>.</td>
</tr>
<tr>
<td><code>cmd</code></td>
<td>Tells the compiler to display and execute driver tool commands.</td>
</tr>
<tr>
<td><code>source</code></td>
<td>Tells the compiler to display the name of the file being compiled.</td>
</tr>
<tr>
<td><code>mic-cmd</code></td>
<td>Tells the compiler to display the compiler options that are passed to the offload compilation. Only the options that are automatically passed are displayed. If this keyword is specified on an architecture other than Intel® MIC Architecture, results vary. It may be ignored, have no effect, or produce an error.</td>
</tr>
<tr>
<td><code>all</code></td>
<td>Tells the compiler to display pass information and source file names to the console output window. This is the same as specifying <code>watch</code> with no <code>keyword</code>. For heterogeneous compilation, the tool commands for the host and the offload compilations will be displayed.</td>
</tr>
</tbody>
</table>

**IDE Equivalent**

Understanding Floating-point Operations

Programming Tradeoffs in Floating-point Applications

In general, the programming objectives for floating-point applications fall into the following categories:

- **Accuracy**: The application produces results that are close to the correct result.
- **Reproducibility and portability**: The application produces consistent results across different runs, different sets of build options, different compilers, different platforms, and different architectures.
- **Performance**: The application produces fast, efficient code.

Based on the goal of an application, you will need to make tradeoffs among these objectives. For example, if you are developing a 3D graphics engine, then performance may be the most important factor to consider, and reproducibility and accuracy may be your secondary concerns.

The Intel® Fortran Compiler provides several compiler options that allow you to tune your applications based on specific objectives. Broadly speaking, there are the floating-point specific options, such as the `-fp-model` (Linux* and OS X*) or `/fp` (Windows*) option, and the fast-but-low-accuracy options, such as the `[Q]imf-max-error` option. The compiler optimizes and generates code differently when you specify these different compiler options. You should select appropriate compiler options by carefully balancing your programming objectives and making tradeoffs among these objectives. Some of these options may influence the choice of math routines that will be invoked.

Many routines in the `libirc`, `libm`, and `svml` library are more highly optimized for Intel microprocessors than for non-Intel microprocessors.

Using Floating-point Options

Take the following code as an example:

```
Example

REAL(4):: t0, t1, t2
...
t0=t1+t2+4.0+0.1
```

If you specify the `-fp-model extended` (Linux* and OS X*) or `/fp:extended` (Windows*) option in favor of accuracy, the compiler generates the following assembly code:

```
fld  DWORD PTR _t1
fadd DWORD PTR _t2
fadd DWORD PTR _Cnst4.0
fadd DWORD PTR _Cnst0.1
fstp DWORD PTR _t0
```

The above code maximizes accuracy because it utilizes the highest mantissa precision available on the target platform. However, the code might suffer in performance due to the overhead of managing the x87 stack and it might yield results that cannot be reproduced on other platforms that do not have an equivalent extended precision type.
If you specify the `-fp-model source` (Linux* and OS X*) or `/fp:source` (Windows*) option in favor of reproducibility and portability, the compiler generates the following assembly code:

```
movss     xmm0, DWORD PTR _t1
addss     xmm0, DWORD PTR _t2
addss     xmm0, DWORD PTR _Cnst4.0
addss     xmm0, DWORD PTR _Cnst0.1
movss     DWORD PTR _t0, xmm0
```

The above code maximizes portability by preserving the original order of the computation and by using the well-defined IEEE single-precision type for all computations. It is not as accurate as the previous implementation because the intermediate rounding error is greater compared to extended precision. And it is not the highest performance implementation because it does not take advantage of the opportunity to pre-compute \(4.0 + 0.1\).

If you specify the `-fp-model fast` (Linux* and OS X*) or `/fp:fast` (Windows*) option in favor of performance, the compiler generates the following assembly code:

```
movss     xmm0, DWORD PTR _Cnst4.1
addss     xmm0, DWORD PTR _t1
addss     xmm0, DWORD PTR _t2
movss     DWORD PTR _t0, xmm0
```

The above code maximizes performance by using Intel® SSE instructions and pre-computing \(4.0 + 0.1\). It is not as accurate as the first implementation, again due to greater intermediate rounding error. It will not provide reproducible results like the second implementation because it must reorder the addition in order to pre-compute \(4.0 + 0.1\), and you cannot expect that all compilers, on all platforms, at all optimization levels will reorder the addition in the same way.

For many other applications, the considerations may be more complicated.

### Using Fast-but-low-accuracy Options

The fast-but-low-accuracy options provide an easy way to control the accuracy of mathematical functions and utilize performance/accuracy tradeoffs offered by the Intel® Math Libraries. You can specify accuracy, via a command line interface, for all math functions or a selected set of math functions at the level more precise than low, medium or high.

You specify the accuracy requirements as a set of function attributes that the compiler uses for selecting an appropriate function implementation in the math libraries. Examples using the attribute, `max-error`, is presented here. For example, use the following option:

```
-fimf-max-error=2
```

to specify relative error of two ulps (u nit in the l ast p lace) for all single, double, long double, and quad precision functions.

To specify twelve bits of accuracy for a \(\sin\) function, use:

```
-fimf-sin-accuracy-bits=12
```

To specify relative error of ten ulps for a \(\sin\) function, and four ulps for other math functions called in the source file you are compiling, use:

```
-fimf-sin-max-error=10-fimf-max-error=4
```

The Intel® Fortran Compiler defines the default value for the `max-error` attribute depending on the `/fp` option and `/Qfast-transcendentals` settings. In `/fp:fast` mode or if fast but less accurate math functions are explicitly enabled by `/Qfast-transcendentals-`, then the Intel® Fortran Compiler sets `max-error=4.0` for the call. Otherwise, it sets `max-error=0.6`.

Using the `-fp-model (/fp) Option

fimf-max-error, Qimf-max-error compiler option
Floating-point Optimizations

Application performance is an important goal of the Intel® Fortran Compiler, even at default optimization levels. A number of optimizations involve transformations that might affect the floating-point behavior of the application, such as evaluation of constant expressions at compile time, hoisting invariant expressions out of loops, or changes in the order of evaluation of expressions. These optimizations usually help the compiler to produce the most efficient code possible. However, the optimizations might be contrary to the floating-point requirements of the application.

Some optimizations are not consistent with strict interpretation of the ANSI or ISO standards for Fortran. Such optimizations can cause differences in rounding and small variations in floating-point results that may be more or less accurate than the ANSI-conformant result.

The Intel® Fortran Compiler provides the -fp-model (Linux* and OS X*) or /fp (Windows*) option, which allows you to control the optimizations performed when you build an application. The option allows you to specify the compiler rules for:

- **Value safety**: Whether the compiler may perform transformations that could affect the result. For example, in the SAFE mode, the compiler won't transform $x/x$ to 1.0 because the value of $x$ at runtime might be a zero or a NaN. The UNSAFE mode is the default.
- **Floating-point expression evaluation**: How the compiler should handle the rounding of intermediate expressions.
- **Floating-point contractions**: Whether the compiler should generate fused multiply-add (FMA) instructions on processors that support them. When enabled, the compiler may generate FMA instructions for combining multiply and add operations; when disabled, the compiler must generate separate multiply and add instructions with intermediate rounding.
- **Floating-point environment access**: Whether the compiler must account for the possibility that the program might access the floating-point environment, either by changing the default floating-point control settings or by reading the floating-point status flags. This is disabled by default. You can use the -fp-model:strict (Linux* and OS X*) or /fp:strict (Windows*) option to enable it.
- **Precise floating-point exceptions**: Whether the compiler should account for the possibility that floating-point operations might produce an exception. This is disabled by default. You can use -fp-model:strict (Linux* and OS X*) or /fp:strict (Windows*) or -fp-model:except (Linux* and OS X*) or /fp:except (Windows*) to enable it.

The following table describes the impact of different keywords of the option on compiler rules and optimizations:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Value Safety</th>
<th>Floating-Point Expression Evaluation</th>
<th>Floating-Point Contractions</th>
<th>Floating-Point Environment Access</th>
<th>Precise Floating-Point Exceptions</th>
</tr>
</thead>
<tbody>
<tr>
<td>precise source</td>
<td>Safe</td>
<td>Source</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>strict</td>
<td>Safe</td>
<td>Source</td>
<td>No</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>fast=1 (default)</td>
<td>Unsafe</td>
<td>Unknown</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>fast=2</td>
<td>Very unsafe</td>
<td>Unknown</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>except</td>
<td>Unaffected</td>
<td>Unaffected</td>
<td>Unaffected</td>
<td>Unaffected</td>
<td>Yes</td>
</tr>
<tr>
<td>except-</td>
<td>Unaffected</td>
<td>Unaffected</td>
<td>Unaffected</td>
<td>Unaffected</td>
<td>No</td>
</tr>
</tbody>
</table>

**NOTE**
It is illegal to specify the except keyword in an unsafe safety mode.

Based on the objectives of an application, you can choose to use different sets of compiler options and keywords to enable or disable certain optimizations, so that you can get the desired result.
Using the -fp-model (/fp) Option

The -fp-model (Linux* and OS X*) or /fp (Windows*) option allows you to control the optimizations on floating-point data. You can use this option to tune the performance, level of accuracy, or result consistency for floating-point applications across platforms and optimization levels.

For applications that do not require support for denormalized numbers, the -fp-model or /fp option can be combined with the [Q]ftz option to flush denormalized results to zero in order to obtain improved runtime performance on processors based on all Intel® architectures.

You can use keywords to specify the semantics to be used. The keywords specified for this option may influence the choice of math routines that are invoked. Many routines in the libirc, libm, and svml library are more highly optimized for Intel microprocessors than for non-Intel microprocessors. Possible values of the keywords are as follows:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>precise</td>
<td>Enables value-safe optimizations on floating-point data and rounds intermediate results to source-defined precision.</td>
</tr>
<tr>
<td>fast[=1</td>
<td>2]</td>
</tr>
<tr>
<td>strict</td>
<td>Enables precise and except, disables contractions, and enables the property that allows modification of the floating-point environment.</td>
</tr>
<tr>
<td>source</td>
<td>Enables value-safe optimizations on floating-point data and rounds intermediate results to source-defined precision (same as precise keyword).</td>
</tr>
<tr>
<td>[no-]except</td>
<td>Determines whether strict floating-point exception semantics are used. (Linux* and OS X*) or except[-] (Windows*)</td>
</tr>
</tbody>
</table>

The default value of the option is -fp-model fast=1 or /fp:fast=1, which means that the compiler uses more aggressive optimizations on floating-point calculations.

**NOTE**
Using the default option keyword -fp-model fast or /fp:fast, you may get significant differences in your result depending on whether the compiler uses x87 or SSE/AVX instructions to implement floating-point operations. Results are more consistent when the other option keywords are used.

Several examples are provided to illustrate the usage of the keywords. These examples show:

- A small example of source code.

**NOTE**
The same source code is considered in all the included examples.

- The semantics that are used to interpret floating-point calculations in the source code.
- One or more possible ways the compiler may interpret the source code.

**NOTE**
There are several ways the compiler may interpret the code; we show just some of these possibilities.

**-fp-model fast or /fp:fast**
Example source code:
When this option is specified, the compiler applies the following semantics:

- Additions may be performed in any order.
- Intermediate expressions may use single, double, or extended double precision.
- The constant addition may be pre-computed, assuming the default rounding mode.

Using these semantics, some possible ways the compiler may interpret the original code are given below:

### Example

```c
REAL T0, T1, T2;
...
T0 = 4.0E + 0.1E + T1 + T2;
```

### Example

```c
REAL T0, T1, T2;
...
T0 = (T1 + T2) + 4.1E;
```

### -fp-model source or /fp:source

This setting is equivalent to -fp-model precise or /fp:precise on systems based on the Intel® 64 architecture.

#### Source code example

```c
REAL T0, T1, T2;
...
T0 = 4.0E + 0.1E + T1 + T2;
```

When this option is specified, the compiler applies the following semantics:

- Additions are performed in program order.
- Intermediate expressions use the precision specified in the source code, that is, single-precision.
- The constant addition may be pre-computed, assuming the default rounding mode.

Using these semantics, a possible way the compiler may interpret the original code is shown below:

### Example

```c
REAL T0, T1, T2;
...
T0 = ((4.1E + T1) + T2);
```

### -fp-model strict or /fp:strict

#### Source code example

```c
REAL T0, T1, T2;
...
T0 = 4.0E + 0.1E + T1 + T2;
```

When this option is specified, the compiler applies the following semantics:
• Additions are performed in program order
• Intermediate expressions always use source precision in modes other than fast.
• The constant addition is not pre-computed because there is no way to tell what rounding mode will be
  active when the program runs.

Using these semantics, a possible way the compiler may interpret the original code is shown below:

```
Example

REAL T0, T1, T2;
...
T0 = REAL ((((REAL)4.0E + (REAL)0.1E) + (REAL)T1) + (REAL)T2);
```

Denormal Numbers

A normalized number is a number for which both the exponent (including bias) and the most significant bit of
the mantissa are non-zero. For such numbers, all the bits of the mantissa contribute to the precision of the
representation.

The smallest normalized single-precision floating-point number greater than zero is about 1.1754943^-38.
Smaller numbers are possible, but those numbers must be represented with a zero exponent and a mantissa
whose leading bit(s) are zero, which leads to a loss of precision. These numbers are called denormalized
numbers or denormals (newer specifications refer to these as subnormal numbers).

Denormal computations use hardware and/or operating system resources to handle denormals; these can
cost hundreds of clock cycles. Denormal computations take much longer to calculate than normal
computations.

There are several ways to avoid denormals and increase the performance of your application:
• Scale the values into the normalized range.
• Use a higher precision data type with a larger range.
• Flush denormals to zero.

floating-point standards and recommendations

Floating-Point Environment

The floating-point environment is a collection of registers that control the behavior of the floating-point
machine instructions and indicate the current floating-point status. The floating-point environment can
include rounding mode controls, exception masks, flush-to-zero (FTZ) controls, exception status flags, and
other floating-point related features.

For example, bit 15 of the MXCSR register enables the flush-to-zero mode, which controls the masked
response to an single-instruction multiple-data (SIMD) floating-point underflow condition.

The floating-point environment affects most floating-point operations; therefore, correct configuration to
meet your specific needs is important. For example, the exception mask bits define which exceptional
conditions will be raised as exceptions by the processor. In general, the default floating-point environment is
set by the operating system. You don’t need to configure the floating-point environment unless the default
floating-point environment does not suit your needs.
There are several methods available if you want to modify the default floating-point environment. For example, you can use inline assembly, compiler built-in functions, library functions, or command line options. Changing the default floating-point environment affects runtime results only. This does not affect any calculations that are pre-computed at compile time.

Setting the FTZ and DAZ Flags

In Intel® processors, the flush-to-zero (FTZ) and denormals-are-zero (DAZ) flags in the MXCSR register are used to control floating-point calculations. Intel® Streaming SIMD Extensions (Intel® SSE) and Intel® Advanced Vector Extensions (Intel® AVX) instructions, including scalar and vector instructions, benefit from enabling the FTZ and DAZ flags respectively. Floating-point computations using these Intel® SSE and Intel® AVX instructions are accelerated when the FTZ and DAZ flags are enabled and thus the performance of the application improves.

You can use the [Q]ftz option to flush denormal results to zero when the application is in the gradual underflow mode. This option may improve performance if the denormal values are not critical to your application’s behavior. The [Q]ftz option, when applied to the main program, set the FTZ and the DAZ hardware flags. The negative form of the [Q]ftz option leave the flags as they are.

The following table describes how the compiler processes denormal values based on the status of the FTZ and DAZ flags:

<table>
<thead>
<tr>
<th>Flag</th>
<th>When set to ON, the compiler...</th>
<th>When set to OFF, the compiler...</th>
<th>Supported on</th>
</tr>
</thead>
<tbody>
<tr>
<td>FTZ (flush-to-zero)</td>
<td>Sets denormal results from floating-point calculations to zero</td>
<td>Does not change the denormal results</td>
<td>Intel® 64 architectures, and some IA-32 architectures</td>
</tr>
<tr>
<td>DAZ (denormals-are-zero)</td>
<td>Treats denormal values used as input to floating-point instructions as zero</td>
<td>Does not change the denormal instruction inputs</td>
<td>Intel® 64 architecture and some IA-32 architecture</td>
</tr>
</tbody>
</table>

- FTZ and DAZ are not supported on all IA-32 architectures. The FTZ flag is supported only on IA-32 architectures that support Intel® SSE instructions.
- On systems based on the IA-32 and Intel® 64 architectures, FTZ only applies to Intel® SSE and Intel® AVX instructions. Hence, if your application happens to generate denormals using x87 instructions, FTZ does not apply.
- DAZ and FTZ flags are not compatible with IEEE Standard 754, so you should only consider enabling them when strict compliance to the IEEE standard is not required.

Options [Q]ftz are performance options. Setting these options does not guarantee that all denormals in a program are flushed to zero. They only cause denormals generated at run-time to be flushed to zero.

On Intel® 64 and IA-32 systems, the compiler, by default, inserts code into the main routine to set the FTZ and DAZ flags. When [Q]ftz option is used on IA-32 systems with the option –msse2 or /arch:sse2, the compiler will insert code to conditionally set FTZ/DAZ flags based on a run-time processor check. Using the negative form of [Q]ftz will prevent the compiler from inserting any code that might set FTZ or DAZ flags.

When the [Q]ftz option is used in combination with an Intel® SSE-enabling option on systems based on the IA-32 architecture (for example, –msse2 or /arch:sse2), the compiler will insert code in the main routine to set FTZ and DAZ. When option [Q]ftz is used without such an option, the compiler will insert code to conditionally set FTZ or DAZ based on a run-time processor check. The negative form of [Q]ftz will prevent the compiler from inserting any code that might set FTZ or DAZ.

The [Q]ftz option only has an effect when the main program is being compiled. It sets the FTZ/DAZ mode for the process. The initial thread and any threads subsequently created by that process will operate in the FTZ/DAZ mode.
On systems based on the IA-32 and Intel® 64 architectures, every optimization option o level, except o0, sets [Q]ftz.

If this option produces undesirable results of the numerical behavior of your program, you can turn the FTZ/DAZ mode off by using the negative form of [Q]ftz in the command line while still benefitting from the O3 optimizations.

You can set the flags manually by calling the following Intel® Fortran intrinsic:

```
Example
RESULT = FOR_SET_FPE (FOR_M_ABRUPT_UND)
```

**Checking the Floating-point Stack State**

On systems based on the IA-32 architecture, when an application calls a function that returns a floating-point value, the returned floating-point value is supposed to be on the top of the floating-point stack. If the return value is not used, the compiler must pop the value off of the floating-point stack in order to keep the floating-point stack in the correct state.

On systems based on Intel® 64 architecture, floating-point values are usually returned in the xmm0 register. The floating-point stack is used only when the return value is an internal 80-bit floating-point data type on Linux* and OS X* systems.

If the application calls a function without defining or incorrectly defining the function's prototype, the compiler cannot determine if the function must return a floating-point value. Consequently, the return value is not popped off the floating-point stack if it is not used. This can cause the floating-point stack to overflow.

The overflow of the stack results in two undesirable situations:

- A NaN value gets involved in the floating-point calculations
- The program results become unpredictable; the point where the program starts making errors can be arbitrarily far away from the point of the actual error.

For systems based on the IA-32 and Intel® 64 architectures, the [Q]fp-stack-check option checks whether a program makes a correct call to a function that should return a floating-point value. If an incorrect call is detected, the option places a code that marks the incorrect call in the program. The [Q]fp-stack-check option marks the incorrect call and makes it easy to find the error.

**NOTE**

The [Q]fp-stack-check option causes significant code generation after every function/subroutine call to ensure that the floating-point stack is maintained in the correct state. Therefore, using this option slows down the program being compiled. Use the option only as a debugging aid to find floating point stack underflow/overflow problems, which can be otherwise hard to find.

**Tuning Performance**

**Overview: Tuning Performance**

This section describes several programming guidelines that can help you improve the performance of floating-point applications:

- Avoid exceeding representable ranges during computation; handling these cases can have a performance impact.
• Use REAL variables in single precision format unless the extra precision obtained through DOUBLE or REAL*8 is required because a larger precision formation will also increase memory size and bandwidth requirements. See Using Efficient Data Types section.
• Reduce the impact of denormal exceptions for all supported architectures.
• Avoid mixed data type arithmetic expressions.

Avoiding Mixed Data Type Arithmetic Expressions
Reducing the Impact of Denormal Exceptions
Using Efficient Data Types

Handling Floating-point Array Operations in a Loop Body

Following the guidelines below will help auto-vectorization of the loop.
• Statements within the loop body may contain float or double operations (typically on arrays). The following arithmetic operations are supported: addition, subtraction, multiplication, division, negation, square root, MAX, MIN, and mathematical functions such as SIN and COS.
• Writing to a single-precision scalar/array and a double scalar/array within the same loop decreases the chance of auto-vectorization due to the differences in the vector length (that is, the number of elements in the vector register) between float and double types. If auto-vectorization fails, try to avoid using mixed data types.

See Also
Programming Guidelines for Vectorization

Reducing the Impact of Denormal Exceptions

Denormalized floating-point values are those that are too small to be represented in the normal manner; that is, the mantissa cannot be left-justified. Denormal values require hardware or operating system interventions to handle the computation, so floating-point computations that result in denormal values may have an adverse impact on performance.

There are several ways to handle denormals to increase the performance of your application:
• Scale the values into the normalized range
• Use a higher precision data type with a larger range
• Flush denormals to zero

For example, you can translate them to normalized numbers by multiplying them using a large scalar number, doing the remaining computations in the normal space, then scaling back down to the denormal range. Consider using this method when the small denormal values benefit the program design.

If you change the type declaration of a variable, you might also need to change associated library calls, unless these are generic. Another strategy that might result in increased performance is to increase the amount of precision of intermediate values using the -fp-model [double|extended] option. However, this strategy might not eliminate all denormal exceptions, so you must experiment with the performance of your application. You should verify that the gain in performance from eliminating denormals is greater than the overhead of using a data type with higher precision and greater dynamic range.

In many cases, denormal numbers can be treated safely as zero without adverse effects on program results. Depending on the target architecture, use flush-to-zero (FTZ) options.

IA-32 and Intel® 64 Architectures

These architectures take advantage of the FTZ (flush-to-zero) and DAZ (denormals-are-zero) capabilities of Intel® Streaming SIMD Extensions (Intel® SSE) instructions.

By default, the Intel® Fortran Compiler inserts code into the main routine to enable FTZ and DAZ at optimization levels higher than O0. To enable FTZ and DAZ at O0, compile the source file containing PROGRAM using compiler option [Q]ftz. When the [Q]ftz option is used on IA-32-based systems with the option -mia32 (Linux* and OS X*) or /arch:IA32 (Windows*), the compiler inserts code to conditionally enable FTZ and DAZ flags based on a run-time processor check.
NOTE
After using flush-to-zero, ensure that your program still gives correct results when treating
denormalized values as zero.

Avoiding Mixed Data Type Arithmetic Expressions
Avoid mixing integer and floating-point (REAL) data in the same computation. Expressing all numbers in a
floating-point arithmetic expression (assignment statement) as floating-point values eliminates the need to
convert data between fixed and floating-point formats. Expressing all numbers in an integer arithmetic
expression as integer values also achieves this. This improves run-time performance.

For example, assuming that I and J are both INTEGER variables, expressing a constant number (2.) as an
integer value (2) eliminates the need to convert the data. The following examples demonstrate inefficient
and efficient code.

Examples

<table>
<thead>
<tr>
<th>Inefficient Code Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER I, J</td>
</tr>
<tr>
<td>I = J / 2.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Efficient Code Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER I, J</td>
</tr>
<tr>
<td>I = J / 2</td>
</tr>
</tbody>
</table>

Special Considerations for Auto-Vectorization of the Innermost Loops
Auto-vectorization of an innermost loop packs multiple data elements from consecutive loop iterations into a
vector register, each of which is 128-bit (SSE) or 256 bit (AVX) in size.

Consider a loop that uses different sized data, for example, REAL and DOUBLE PRECISION. For REAL data,
the compiler tries to pack data elements from four (SSE) or eight (AVX) consecutive iterations (32 bits x 4 =
128 bits, 32 bits x 8 = 256 bits). For DOUBLE PRECISION data, the compiler tries to pack data elements
from two (SSE) or four (AVX) consecutive iterations (64 bits x 2 = 128 bits, 64 bits x 4 = 256 bits). Because
of the mismatched number of iterations, the compiler sometimes fails to perform auto-vectorization of the
loop, after trying to automatically remedy the situation.

If your attempt to auto-vectorize an innermost loop fails, it is a good practice to try using the same sized
data. INTEGER and REAL are considered same sized data since both are 32-bit in size.

Examples

<table>
<thead>
<tr>
<th>Example 1: Not auto-vectorizable code</th>
</tr>
</thead>
<tbody>
<tr>
<td>DOUBLE PRECISION A(N), B(N)</td>
</tr>
<tr>
<td>REAL C(N), D(N)</td>
</tr>
<tr>
<td>DO I=1, N</td>
</tr>
<tr>
<td>A(I)=D(I)</td>
</tr>
<tr>
<td>C(I)=B(I)</td>
</tr>
<tr>
<td>ENDDO</td>
</tr>
</tbody>
</table>

12 Intel® Fortran Compiler 16.0 User and Reference Guide

536
Example 2: Auto-vectorizable after automatic distribution into two loops

```fortran
DOUBLE PRECISION A(N), B(N)
REAL C(N), D(N)
DO I=1, N
   A(I)=B(I)
   C(I)=D(I)
ENDDO
```

Example 3: Auto-vectorizable as one loop

```fortran
REAL A(N), B(N)
REAL C(N), D(N)
DO I=1, N
   A(I)=B(I)
   C(I)=D(I)
ENDDO
```

Using Efficient Data Types

In cases where more than one data type can be used for a variable, consider selecting the data types based on the following hierarchy, listed from most to least efficient:

- Integer
- Single-precision real, expressed explicitly as `REAL`, `REAL (KIND=4)`, or `REAL*4`
- Double-precision real, expressed explicitly as `DOUBLE PRECISION`, `REAL (KIND=8)`, or `REAL*8`
- Extended-precision real, expressed explicitly as `REAL (KIND=16)` or `REAL*16`

**NOTE**

In an arithmetic expression, you should avoid mixing integer and floating-point data.
Creating Static Libraries

Executables generated using static libraries are no different than executables generated from individual source or object files. Because static libraries are not required at runtime, you do not need to include them when you distribute your executable. Linking to a static library is generally faster than linking to individual object files.

When building objects for a static library from the ifort command line, include option c to suppress linking. Without this option, the linker will run and generate an error because the object is not a complete program.

Building a static library (Linux*)

1. Use the c option to generate object files from the source files:
   ```
   ifort -c my_source1.f90 my_source2.f90 my_source3.f90
   ```
2. Use the Intel® xiar tool to create the library file from the object files:
   ```
   ar rc my_lib.a my_source1.o my_source2.o my_source3.o
   ```
3. Compile and link your project with your new library:
   ```
   ifort main.f90 my_lib.a
   ```

If your library file and source files are in different directories, use the -Ldir option to indicate where your library is located:
```
ifort -L/for/libs main.f90 my_lib.a
```  

Building a static library (OS X*)

1. Use the following command line to generate object files and create the library file:
   ```
   ifort -o my_lib.a -staticlib mysource1.f90 mysource2.f90 mysource3.f90
   ```
2. Compile and link your project with your new library:
   ```
   ifort main.f90 my_lib.a
   ```

If your library file and source files are in different directories, use the -Ldir option to indicate where your library is located:
```
ifort -L/for/libs main.f90 my_lib.a
```  

Building a static library (Windows*)

To build a static library from the integrated development environment (IDE), select the Fortran Static Library project type.

To build a static library using the command line:

1. Use option c to generate object files from the source files:
   ```
   ifort /c my_source1.f90 my_source2.f90
   ```
2. Use the Intel® xilib tool to create the library file from the object files:
   ```
   lib /out:my_lib.lib my_source1.obj my_source2.obj
   ```
3. Compile and link your project with your new library:
   ```
   ifort main.f90 my_lib.lib
   ```
Creating Shared Libraries

This topic applies to Linux* and OS X*.

Shared libraries, also referred to as dynamic libraries, are linked differently than static libraries. At compile time, the linker insures that all the necessary symbols are either linked into the executable, or can be linked at runtime from the shared library. Executables compiled from shared libraries are smaller, but the shared libraries must be included with the executable to function correctly. When multiple programs use the same shared library, only one copy of the library is required in memory.

To create a shared library from a Fortran source file, process the files using the ifort command:

- You must specify the -shared option (Linux*) or the -dynamiclib option (OS X*) to create the .so or .dylib file. On Linux* and OS X* operating systems using either IA-32 architecture or Intel® 64 architecture, you must also specify option -fpic for the compilation of each object file you want to include in the shared library.
- You can specify the -o output option to name the output file.
- If you omit the -c option, you will create a shared library (.so file) directly from the command line in a single step.
- If you also omit the -o output option, the file name of the first Fortran file on the command line is used to create the file name of the .so file. You can specify additional options associated with shared library creation.
- If you specify the -c option, you will create an object file (.o file) that you can name with the -o option. To create a shared library, process the .o file with ld, specifying certain options associated with shared library creation.

Creating a Shared Library

There are several ways to create a shared library.

You can create a shared library file with a single ifort command:

- You can create a shared library file with a single ifort command:

  ```
  ifort -shared -fpic octagon.f90 (Linux*)
  ifort -dynamiclib octagon.f90 (OS X*)
  ```

  The -shared or -dynamiclib option is required to create a shared library. The name of the source file is octagon.f90. You can specify multiple source files and object files.

  Because the -o option was omitted, the name of the shared library file is octagon.so (Linux*) or octagon.dylib (OS X*).

  You can use the -static-intel option to force the linker to use the static versions of the Intel-supplied libraries.

  You can also create a shared library file with a combination of ifort and ld (Linux*) or libtool (OS X*) commands:

  First, create the .o file, such as octagon.o in the following example:

  ```
  ifort -c -fpic octagon.f90
  ```

  The file octagon.o is then used as input to the ld (Linux*) or libtool (OS X*) command to create the shared library. The following example shows the command to create a shared library named octagon.so on a Linux* operating system:

  ```
  ld -shared octagon.o \
  -lifport -lifcoremt -lifm -lm -lcxa \
  -lpthread -lirc -lunwind -lc -lirc_s
  ```

  Note the following:

  - When you use ld, you need to list all Intel® Fortran libraries. It is easier and safer to use the ifort command. On OS X*, you would use libtool.
• The -shared option is required to create a shared library. On OS X*, use the -dynamiclib option, and also specify the following: -arch_only i386, -noall_load, -weak_references_mismatches non-weak.

• The name of the object file is octagon.o. You can specify multiple object (.o) files.

• The -lifport option and subsequent options are the standard list of libraries that the ifort command would have otherwise passed to ld or libtool. When you create a shared library, all symbols must be resolved.

It is recommended that you review the output of the -dryrun command to find the names of all the libraries used, to be able to specify them correctly.

If you are using the ifort command to link, you can use the -Qoption command to pass options to the ld linker. (You cannot use -Qoption on the ld command line.)

For more information on relevant compiler options, see the Compiler Options reference.

See also the ld(1) reference page.

Shared Library Restrictions

When creating a shared library with ld, be aware of the following restrictions:

• Shared libraries must not be linked with archive libraries.

  When creating a shared library, you can only depend on other shared libraries for resolving external references. If you need to reference a routine that currently resides in an archive library, put that routine in a separate shared library or include it in the shared library being created. You can specify multiple object (.o) files when creating a shared library.

  To put a routine in a separate shared library, obtain the source or object file for that routine, recompile if necessary, and create a separate shared library. You can specify an object file when recompiling with the ifort command or when creating the shared library with the ld command.

  To include a routine in the shared library being created, put the routine (source or object file) with other source files that make up the shared library and recompile if necessary.

  Now create the shared library, and specify the file containing that routine either during recompilation or when creating the shared library. You can specify an object file when recompiling with the ifort command or when creating the shared library with the ld or libtool command.

• When creating shared libraries, all symbols must be defined (resolved).

  Because all symbols must be defined to ld when you create a shared library, you must specify the shared libraries on the ld command line, including all standard Intel® Fortran libraries. The list of standard Intel® Fortran libraries can be specified by using the -lifport option.

Installing Shared Libraries

Once the shared library is created, it must be installed for private or system-wide use before you run a program that refers to it:

• To install a private shared library (when you are testing, for example), set the environment variable LD_LIBRARY_PATH, as described in ld(1). For OS X*, set the environment variable DYLD_LIBRARY_PATH.

• To install a system-wide shared library, place the shared library file in one of the standard directory paths used by ld or libtool.

Using Shared Libraries on OS X*

On OS X*, it is possible to store path information in shared libraries to perform library searches. The compiler installation changes the path to the installation directory, but you will need to modify these paths if you move the libraries elsewhere. For example, you may want to bundle redistributable Intel libraries with your application, which eliminates the dependency on libraries found on DYLD_LIBRARY_PATH.
If your compilations do not use `DYLD_LIBRARY_PATH` to find libraries, and you distribute executables that depend on shared libraries, then you will need to modify the Intel shared libraries (../lib/*.dylib) using the `install_name_tool` to set the correct path to the shared libraries. This also permits the end-user to launch the application by double-clicking on the executable. The code below will modify each library with the correct absolute path information:

```bash
for i in *.dylib
do
echo -change $i `pwd`/$i
done > changes
for i in *.dylib
do
install_name_tool `cat changes` $i
done
```

You can also use the `install_name_tool` command to set `@executable_path` to change path information for the libraries bundled in your application by changing the path appropriately.

Be sure to recompile your sources after modifying the libraries.

### Calling Library Routines

The following tables show Intel® Fortran library routine groups and the `USE` statement required to include the interface definitions for the routines in that group:

<table>
<thead>
<tr>
<th>Routines</th>
<th>USE statement</th>
</tr>
</thead>
<tbody>
<tr>
<td>Portability</td>
<td>USE IFPORT</td>
</tr>
<tr>
<td>POSIX*</td>
<td>USE IFPOSIX</td>
</tr>
<tr>
<td>Miscellaneous Run-Time</td>
<td>USE IFCORE</td>
</tr>
</tbody>
</table>

The following are Windows only:

<table>
<thead>
<tr>
<th>Routines</th>
<th>USE statement</th>
</tr>
</thead>
<tbody>
<tr>
<td>Automation (AUTO) (systems using IA-32 architecture only)</td>
<td>USE IFAUTO</td>
</tr>
<tr>
<td>Component Object Model (COM) (systems using IA-32 architecture only)</td>
<td>USE IFCOM</td>
</tr>
<tr>
<td>Dialog (systems using IA-32 architecture only)</td>
<td>USE IFLOGM</td>
</tr>
<tr>
<td>Graphics</td>
<td>USE IFQWIN</td>
</tr>
<tr>
<td>National Language Support</td>
<td>USE IFNLS</td>
</tr>
<tr>
<td>QuickWin</td>
<td>USE IFQWIN</td>
</tr>
<tr>
<td>Serial port I/O (SPORT) (systems using IA-32 architecture only)</td>
<td>USE IFPORT</td>
</tr>
</tbody>
</table>

**Module Routines Overview** lists topics that provide an overview of the different groups of library routines as well as calling syntax for the routines. For example, add the following `USE` statement before any data declaration statements, such as `IMPLICIT`, `NONE`, or `INTEGER`:

```fortran
USE IFPORT
```

If you want to minimize compile time for source files that use the Intel® Fortran library routines, add the `ONLY` keyword to the `USE` statement. For example:

```fortran
USE IFPORT, only: getenv
```
Using the ONLY keyword limits the number of interfaces for that group of library routines.

To view the actual interface definitions, view the .f90 file that corresponds to the .mod file. For example, if a routine requires a USE IFCORE, locate and use a text editor to view the file ifcore.f90 in the standard INCLUDE directory.

You should avoid copying the actual interface definitions contained in the ifport.f90 (or ifcore.f90, ...) into your program because future versions of Intel® Fortran might change these interface definitions.

Similarly, some of the library interface .f90 files contain USE statements for a subgrouping of routines. However, if you specify a USE statement for such a subgroup, this module name may change in future version of the Intel® Fortran Compiler. Although this will make compilation times faster, it might not be compatible with future versions of the Intel® Fortran Compiler.

Module Routines Overview

Comparison of Intel® Visual Fortran and Windows* API Routines

This topic only applies to Windows*.

Intel® Visual Fortran provides Fortran language elements (such as intrinsic procedures and statements) that conform to the Fortran Standard. The Intel® Visual Fortran Compiler also provides language elements that are language extensions, including library routines.

The library routines provided by the Intel® Visual Fortran Compiler:

- Are intended to be called from the Fortran language. For example, character arguments are assumed to be Fortran character variables, not null-terminated C strings.
- May have QQ appended at the end of their names to differentiate them from equivalent Windows* routines.
- Are described in the Intel® Visual Fortran Compiler Language Reference online documentation, in the A to Z Reference. The routine description lists the appropriate USE statement needed to include the interface definitions, such as USE IFPORT.
- Call appropriate Windows* system API routines provided with the operating system.
- Are specific to Windows* systems, with one exception: most of the Intel® Fortran Portability Library routines exist on most Linux* systems.

In contrast, the Windows* API routines provided by the Windows* operating system:

- Are intended to be called from the C language. For example, character arguments are assumed to be null-terminated C strings.
- Often have multiple words appended together in their names, such as GetSystemTime.
- Are described in the Platform SDK online documentation. To look up a specific routine, use the Index or Search tabs in HTML Help viewer. The calling format is listed near the top of the page, followed by a description of the routine's arguments. The QuickInfo at the bottom of the Windows* API routine documentation page lists the import library needed.
- Are also specific to Windows*.

Note that the Intel® Visual Fortran Compiler provides interface block definitions that simplify calling Windows* API routines from the Intel® Visual Fortran Compiler (such as allowing you to specify Fortran data arguments as being passed by reference). To obtain these interface definitions, add the USE IFQWIN statement to your program.

There are many groups of Windows* routines (see the Platform SDK and other resources). These routines provide sophisticated window management, memory management, graphics support, threading, security, and networking.

You can access many Windows* API routines from any Fortran application, including Fortran Console and Fortran QuickWin applications. Only the Fortran Windows* application Understanding Project Types provides access to the full set of Win32 routines needed to create GUI applications.

Fortran Console applications are text-only applications. Fortran QuickWin applications allow you to build Windows*-style applications easily, but access only a small subset of the available Windows* API features. Fortran QuickWin applications also allow you to use graphics.
Specifying Consistent Library Types

This topic only applies to Windows*.

There are a number of Visual C++* run-time libraries that offer the same entry points but have different characteristics. The default Visual C++* library is libc.lib, which is single-threaded, non-debug, and static.

The Intel® Visual Fortran and Microsoft* Visual C++* libraries must be the same types. The incompatible types are listed below.

- Mixing single-threaded with multi-threaded versions of the libraries.
- Mixing static and dynamic-link versions of the libraries.
- Mixing debug with non-debug versions of the libraries.

The default Intel® Visual Fortran libraries depend on the project type:

<table>
<thead>
<tr>
<th>Fortran Project Type</th>
<th>Default Libraries Used</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fortran Console</td>
<td>Static, single-threaded libraries ifcore.lib and libc.lib</td>
</tr>
<tr>
<td>Fortran Standard Graphics</td>
<td>Static, multithreaded libraries ifcoremt.lib and libcmt.lib</td>
</tr>
<tr>
<td>Fortran QuickWin</td>

</tr>
</tbody>
</table>

Pure Fortran applications can have mismatched types of libraries. One common scenario is a Fortran QuickWin application that links with a Fortran Static library. Fortran QuickWin (and Fortran Standard Graphics) applications must use the static, multithreaded libraries, and by default, Fortran Static libraries are built using static, single-threaded libraries. Because this causes a conflict, the Fortran Static library and the QuickWin application must both be built using static, multithreaded libraries.

Similarly, different C/C++ applications link against different C libraries. If you mix the different types of applications without modifying the defaults, you can get conflicts. The debug version of a library has a letter d appended to its base file name:

- Static, single-threaded: libc.lib and libcd.lib
- Static, multithreaded: libcmt.lib and libcmtd.lib
- Dynamic-link libraries: msvcrtd and msvcrtd.lib

When using a Debug configuration, Visual C++* selects the debug libraries.

The Intel® Visual Fortran Compiler does not select debug libraries for any configuration, but provides settings that allow you to request their use. To specify different types of Fortran libraries in the IDE, select Project > Properties, then select the Libraries category on the Fortran tab:

- To specify static libraries, select the appropriate type of static (non-DLL) library under Run-Time Library (see /libs:static).
- To specify dynamic-link libraries, select the appropriate type of DLL library under Run-Time Library (see /libs:dll).
- To specify multithreaded libraries, select the appropriate type of Multi-thread library under Run-Time Library (see /threads).
To specify the debug libraries, select the appropriate type of Debug library under Run-Time Library (see /[no]dbglibs). If you specify debug libraries (/dbglibs) and also request DLL libraries (/libs:dll), be aware that this combination selects the debug versions of the Fortran DLLs. These Fortran DLL files have been linked against the C debug DLLs.

When you specify QuickWin or Standard Graphics libraries under Run-Time Library, this selection implicitly requests multithreaded libraries.

Building Intel® Fortran/C Mixed-Language Programs (Windows*)

Redistributing Libraries When Deploying Applications
When you deploy your application to systems that do not have the Intel® Fortran Compiler installed, you need to redistribute certain Intel® libraries to which your application is linked. You can do so in one of the following ways:

• Statically link your application.
  An application built with statically-linked libraries eliminates the need to distribute runtime libraries with the application executable. By linking the application to the static libraries, you are not dependent on the Intel® Fortran or Intel® C/C++ dynamic shared libraries.

• Dynamically link your application.
  If you must build your application with dynamically linked (or shared) compiler libraries, you should address the following concerns:
  • You must build your application with shared or dynamic libraries that are redistributable.
  • Note the directory where the redistributables are installed and how the OS finds them.
  • You should determine which shared or dynamic libraries your application needs.

The information here is only introductory. See the Intel® Developer Zone articles at http://software.intel.com (search for “redistributable libraries”) for everything you need to know to redistribute these libraries.

The redistributable library installation package is available at:

Storing Object Code in Static Libraries
Another way to organize source code used by several projects is to build a static library (for Windows*, .lib and for Linux* and OS X*, .a) containing the object files for the reused procedures. You can create a static library by doing the following:

• From the Microsoft* Visual Studio* integrated development environment (IDE), create and build a Fortran Static Library project type.
From the command line, use the `ar` command (on Linux* and OS X*) or the `LIB` command (Windows*).

After you have created a static library, you can use it as input to other types of Intel® Fortran Compiler projects.

Using Fortran Static Library Projects

### Storing Routines in Shareable Libraries

You can organize the code in your application by storing the executable code for certain routines in a shareable library (.dll for Windows*, .so for Linux*, or .dylib for OS X*). You can then build your applications so that they call these routines from the shareable library.

When routines in a shareable library are called, the routines are loaded into memory at run-time as they are needed. This is most useful when several applications use a common group of routines. By storing these common routines in a shareable library, you reduce the size of each application that calls the library. In addition, you can update the routines in the library without having to rebuild any of the applications that call the library.

### Using the Windows* API Routines

**Including the Intel® Visual Fortran Interface Definitions for Windows* API Routines**

This topic only applies to Windows* OS.

Intel® Fortran provides interface definitions for both the Intel Fortran library routines and most of the Windows* API routines in the standard include directory. Documentation on the Windows API can be found at msdn.microsoft.com.

To include the Windows API interface definitions, do one of the following:

1. Add the statement `USE IFWIN` to include all Windows API routine definitions.
   
   The `USE IFWIN` statement makes all parameters and interfaces for most Windows routines available to your Intel Fortran program. Any program or subprogram that uses the Windows features can include the statement `USE IFWIN`, which is needed in each subprogram that makes Windows API calls.

   Add the `USE` statement before any declaration statements (such as `IMPLICIT NONE or INTEGER`).

2. You can limit the type of parameters and interfaces for Windows applications to make compilation times faster. To do this, include only the subsets of the Windows API needed in multiple `USE` statements (see the file `...\INCLUDE\IFWIN.F90`).

   To locate the specific libraries for the routines being called, view the QuickInfo at the bottom of the routine page in the Windows API documentation at msdn.microsoft.com, which lists the import library name. For example, to call only `GetSystemTime`, you need the interface definitions provided in `kernel32.mod` (binary form). To do this, add the following `USE` statement:

   ```fortran
   USE KERNEL32
   ```

   If you want to further minimize compile time, add the `ONLY` keyword to the `USE` statement. For example:

   ```fortran
   USE KERNEL32, only: GetSystemTime, GetLastError
   ```

### Calling Windows API Routines

This topic describes general information about calling Windows API routines from Intel® Fortran applications. It contains the following information:

- **Calling Windows API Routines Using the Intel Visual Fortran Interface Definitions**
- **Understanding Data Types Differences**
Calling Windows API Routines Using the Intel Visual Fortran Interface Definitions

To call the appropriate Windows API routine after including the Intel Visual Fortran interface definitions, follow these guidelines:

1. Examine the documentation for the appropriate routine in the Windows API (for example, GetSystemTime) to obtain the following information:
   - The number and order of arguments. You will need to declare and initialize each argument variable using the correct data type. In the case of the GetSystemTime routine, a structure (derived type) is passed by reference.
     If character arguments are present, add a null character as a terminator to the character variable before calling the Windows API routine.
   - Whether the routine returns a result (function) or not (subroutine). For example, because the GetSystemTime routine calling format starts with VOID, this routine should be called as a subroutine with a CALL statement.

2. If you are not sure about the data type of arguments or its function return value, you can examine the interface definitions in the appropriate .F90 file in .\INCLUDE\. For example, to view the interface definition for GetSystemTime:
   - In a text editor (such as Notepad), open the file kernel32.f90 from .\INCLUDE\.
   - Search (or Find) the routine name (such as GetSystemTime)
   - View the interface definition and compare it to the description in the Windows API documentation to see how the arguments are represented in Fortran. Take note of how arguments are passed; in some cases, such as when an arbitrary data type is passed by address, you must pass the address of a variable using the LOC intrinsic rather than the variable directly.

3. If one of the arguments is a structure, look up the definition in IFWINTY.F90 in .\INCLUDE\. For example, to view the data type definition for the T_SYSTEMTIME type used in GetSystemTime:
   - In a text editor (such as Notepad), open the file IFWINTY.F90 from .\INCLUDE\.
   - Search (or Find) the data type name (such as T_SYSTEMTIME).
   - View the data type definition and note the field names. In some cases, these will differ slightly from those listed in the Windows API documentation.
   - Define a variable name to use the derived-type definition in your program, such as:

```
TYPE (T_SYSTEMTIME) MYTIME
```

4. Many Windows API routines have an argument or return a value described as a “handle”. This is generally an address-sized integer and must be declared using an appropriate KIND value, typically HANDLE, which automatically provides the correct value for 32- and 64-bit platforms. For example:

```
Integer(HANDLE) :: hwnd
```

Use the variable definition to call the Win32 routine. For example, the completed program follows:

```
! Getsystime.f90 file shows how to call a Windows API routine
! Since the only routine called is GetSystemTime, only include
! interface definitions from kernel32.mod instead of all modules
! included by ifwin.f90. Type definitions are defined in IFWINT1,
! which is used within KERNEL32.
PROGRAM Getsystime
USE KERNEL32
TYPE (T_SYSTEMTIME) MYTIME
CALL GetSystemTime(MYTIME)
WRITE (*,'(A,2I4)') 'Current UTC time hour and minute:', Mytime.wHour, Mytime.wMinute
END PROGRAM
```

You can create a new Fortran Console (or QuickWin) application project, add the code shown above as a source file, build it, and view the result.
Understanding Data Type Differences

Module IFWINTY, which is used by IFWIN and the other Win32 API modules, defines a set of constants for INTEGER and REAL kinds that correspond to many of the type definitions provided in the Windows WINDOWS.H header file. Use these kind values in INTEGER and REAL declarations. The following table gives the correspondence of some of the more common Windows types:

<table>
<thead>
<tr>
<th>Windows Data Type</th>
<th>Equivalent Fortran Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BOOL, BOOLEAN</td>
<td>INTEGER(BOOL)</td>
</tr>
<tr>
<td>BYTE</td>
<td>INTEGER(BYTE)</td>
</tr>
<tr>
<td>CHAR, CCHAR, UCHAR</td>
<td>CHARACTER or INTEGER(UCHAR)</td>
</tr>
<tr>
<td>DWORD</td>
<td>INTEGER(DWORD)</td>
</tr>
<tr>
<td>ULONG</td>
<td>INTEGER(ULONG)</td>
</tr>
<tr>
<td>SHORT</td>
<td>INTEGER(SHORT)</td>
</tr>
<tr>
<td>LPHANDLE</td>
<td>INTEGER(LPHANDLE)</td>
</tr>
<tr>
<td>PLONG</td>
<td>INTEGER(PLONG)</td>
</tr>
<tr>
<td>DOUBLE</td>
<td>REAL(DOUBLE)</td>
</tr>
</tbody>
</table>

Use the kind constants instead of explicitly specifying the kind as a number, or assuming a default kind.

Note that the Windows BOOL type is not equivalent to Fortran LOGICAL and should not be used with Fortran LOGICAL operators and literal constants. Use the constants TRUE and FALSE, defined in IFWINTY, rather than the Fortran literals .TRUE. and .FALSE., and do not test BOOL values using LOGICAL expressions.

Additional notes about equivalent data types for arguments:

- If an argument is described in the Windows API documentation as a pointer, then the corresponding Fortran interface definition of that argument would have the REFERENCE property (see the ATTRIBUTES). Older interface definitions use the POINTER - Integer and pass the address of the argument, or the LOC intrinsic function.
- Pointer arguments on systems using IA-32 architecture are 32-bit (4 bytes) in length. Pointer arguments on systems using Intel® 64 architecture are 64 bits (8 bytes) in length.
- Be aware that Fortran character variables need to be null-terminated. You can do this by using the C string extension (see C Strings in Character Constants):
  
  ```fortran
  forstring = 'This is a null-terminated string.'//C
  
  You can also concatenate a null using the C_NULL_CHAR constant from intrinsic module ISO_C_BINDING, or CHAR(0):
  ```

  ```fortran
  use, intrinsic :: ISO_C_BINDING
  ...
  forstring = 'This is a null-terminated string'//C_NULL_CHAR
  forstring2 = 'This is another null-terminated string'//CHAR(0)
  
  The structures in WINDOWS.H have been converted to derived types in IFWINTY. Unions in structures are converted to union/maps within the derived type.

  Names of components are generally unchanged. C bitfields do not translate directly to Fortran; collections of bitfields are declared as Fortran INTEGER types and individual bitfields are noted as comments in the source (IFWINTY.F90). To see how a particular Windows declaration was translated to Fortran, read the corresponding declaration in the appropriate .F90 source file in the Include folder.
Supplied Windows* API Modules

The Intel Fortran Compiler provides the following Windows* API modules. These modules correspond to the Windows* import libraries of the same name.

<table>
<thead>
<tr>
<th>Module</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADVAPI32</td>
</tr>
<tr>
<td>COMCTL32</td>
</tr>
<tr>
<td>COMDLG32</td>
</tr>
<tr>
<td>GDI32</td>
</tr>
<tr>
<td>KERNEL32</td>
</tr>
<tr>
<td>LZ32</td>
</tr>
<tr>
<td>OLE32</td>
</tr>
<tr>
<td>OLEAUT32</td>
</tr>
<tr>
<td>PSAPI</td>
</tr>
<tr>
<td>SCRNSAVE</td>
</tr>
<tr>
<td>SHELL32</td>
</tr>
<tr>
<td>USER32</td>
</tr>
<tr>
<td>VERSION</td>
</tr>
<tr>

</tr>
<tr>
<td>WINSPool</td>
</tr>
<tr>
<td>WS2_32</td>
</tr>
<tr>
<td>WSOCK32</td>
</tr>
</tbody>
</table>

Additionally, the IFOPNGL module declares OpenGL routines for Windows OS, with Fortran-specific names.

Math Libraries

The Intel® Fortran Compiler includes these math libraries:

<table>
<thead>
<tr>
<th>Library name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>libimf.a (Linux* and OS X* )</td>
<td>Intel® Math Libraries, in addition to libm.a, the math library provided with gcc*</td>
</tr>
<tr>
<td></td>
<td>Both of these libraries are linked in by default because certain math functions supported by the GNU* math library are not available in the Intel® Math Library. This linking arrangement allows the GNU* users to have all functions available when using ifort, with Intel optimized versions available when supported.</td>
</tr>
<tr>
<td></td>
<td>libimf.a is linked in before libm.a. If you link in libm.a first, it will change the versions of the math functions that are used.</td>
</tr>
<tr>
<td></td>
<td>Many routines in the libimf library are more highly optimized for Intel® microprocessors than for non-Intel microprocessors.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Library name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>libm.lib (static library) and libmmd.dll (the DLL version) (Windows*)</td>
<td>Math Libraries provided by Intel. Many routines in the libm library are more highly optimized for Intel® microprocessors than for non-Intel microprocessors.</td>
</tr>
</tbody>
</table>

**NOTE**

It is strongly recommended to use the default rounding mode (round-to-nearest-even) when calling math library transcendental functions and compiling with default optimization or higher. Faster implementations (in terms of latency and/or throughput) of these functions are validated under the default round-to-nearest-even mode. Using other rounding modes may make results generated by these faster implementations less accurate, or set unexpected floating-point status flags. This behavior may be avoided by -no-fast-transcendentals, which disables calls to the faster implementations of math functions, or by -fp-model strict, which warns the compiler that it cannot assume default settings for the floating-point environment.

Many routines in the Intel® Math Library are more highly optimized for Intel® microprocessors than for non-Intel microprocessors.

Intel® Math Kernel Library (Intel® MKL) Math library of Fortran routines and functions that perform a wide variety of operations on vectors and matrices. The library also includes fast Fourier transform (fft) functions, as well as vector mathematical and vector statistical functions. For more information, see Using Intel® Performance Libraries and the Intel® Math Kernel Library documentation.

IMSL* Fortran Numerical Library (Windows*) Libraries provided only with certain editions of the Intel® Visual Fortran product. The IMSL* libraries provide a large collection of mathematical and statistical functions accessible from the visual and command line development environments. For more information, see Using the IMSL* Mathematical and Statistical Libraries Overview.

**Optimization Notice**

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804
Data Representation

Data Representation Overview

Intel® Fortran expects numeric data to be in native little endian order, in which the least-significant, right-most zero bit (bit 0) or byte has a lower address than the most-significant, left-most bit (or byte). For information on using nonnative big endian and VAX* floating-point formats, see Supported Native and Nonnative Numeric Formats.

The symbol :A in any figure specifies the address of the byte containing bit 0, which is the starting address of the represented data element.

The following table lists the intrinsic data types used by Intel® Fortran, the storage required, and valid ranges. For information on declaring Fortran intrinsic data types, see Type Declarations. For example, the declaration INTEGER(4) is the same as INTEGER(KIND=4) and INTEGER*4.

<table>

### Integer Data Representations

#### Integer Data Representations Overview

The Fortran numeric environment is flexible, which helps make Fortran a strong language for intensive numerical calculations. The Fortran standard purposely leaves the precision of numeric quantities and the method of rounding numeric results unspecified. This allows Fortran to operate efficiently for diverse applications on diverse systems.

The effect of math computations on integers is straightforward:

- **INTEGER(KIND=1) Representation** consist of a maximum positive integer (127), a minimum negative integer (-128), and all integers between them including zero.
- **INTEGER(KIND=2) Representation** consist of a maximum positive integer (32,767), a minimum negative integer (-32,768), and all integers between them including zero.
- **INTEGER(KIND=4) Representation** consist of a maximum positive integer (2,147,483,647), a minimum negative integer (-2,147,483,648), and all integers between them including zero.
- **INTEGER(KIND=8) Representation** consist of a maximum positive integer (9,223,372,036,854,775,807), a minimum negative integer (-9,223,372,036,854,775,808), and all integers between them including zero.

Operations on integers usually result in other integers within this range. Integer computations that produce values too large or too small to be represented in the desired KIND result in the loss of precision. One arithmetic rule to remember is that integer division results in truncation (for example, 8/3 evaluates to 2).

Integer data lengths can be 1, 2, 4, or 8 bytes in length.

The default data size used for an INTEGER data declaration is INTEGER(4) (same as INTEGER(KIND=4)), unless the integer-size 16 option is used to specify INTEGER(2) or the integer-size 64 option is used to specify INTEGER(8).

Integer data is signed with the sign bit being 0 (zero) for positive numbers and 1 for negative numbers.

**INTEGER(KIND=1) Representation**

INTEGER(1) values range from -128 to 127 and are stored in 1 byte, as shown below.

**INTEGER(1) Data Representation**
Integers are stored in a two's complement representation. For example:

\[ +22 = 16 \text{ (hex)} \]
\[ -7 = F9 \text{ (hex)} \]

**INTEGER(KIND=2) Representation**

INTEGER(2) values range from -32,768 to 32,767 and are stored in 2 contiguous bytes, as shown below:

**INTEGER(2) Data Representation**

Integers are stored in a two's complement representation. For example:

\[ +22 = 0016 \text{ (hex)} \]
\[ -7 = FFF9 \text{ (hex)} \]

**INTEGER(KIND=4) Representation**

INTEGER(4) values range from -2,147,483,648 to 2,147,483,647 and are stored in 4 contiguous bytes, as shown below.

**INTEGER(4) Data Representation**

Integers are stored in a two's complement representation.

**INTEGER(KIND=8) Representation**

INTEGER(8) values range from -9,223,372,036,854,775,808 to 9,223,372,036,854,775,807 and are stored in 8 contiguous bytes, as shown below.

**INTEGER(8) Data Representation**

Integers are stored in a two's complement representation.

**Logical Data Representations**

Logical data lengths can be 1, 2, 4, or 8 bytes in length.
The default data size used for a LOGICAL data declaration is LOGICAL(4) (same as LOGICAL(KIND=4)), unless the integer-size 16 compiler option is used to specify LOGICAL(2) or the integer-size 64 compiler option is used to specify LOGICAL(8).

To improve performance on systems using Intel® 64 architecture, use LOGICAL(4) (or LOGICAL(8)) rather than LOGICAL(2) or LOGICAL(1). On systems using IA-32 architecture, use LOGICAL(4) rather than LOGICAL(8), LOGICAL(2), or LOGICAL(1).

LOGICAL(KIND=1) values are stored in 1 byte. In addition to having logical values .TRUE. and .FALSE., LOGICAL(1) data can also have values in the range -128 to 127. Logical variables can also be interpreted as integer data.

In addition to LOGICAL(1), logical values can also be stored in 2 (LOGICAL(2)), 4 (LOGICAL(4)), or 8 (LOGICAL(8)) contiguous bytes, starting on an arbitrary byte boundary.

If the fpscomp nological compiler option is set (the default), the low-order bit determines whether the logical value is true or false. Specify fpscomp logical instead of fpscomp nological to interoperate with procedures written in C for Microsoft® Fortran PowerStation logical values, where 0 (zero) is false and non-zero values are true.

LOGICAL(1), LOGICAL(2), LOGICAL(4), and LOGICAL(8) data representations (when fpscomp nological is specified) appear below.

**LOGICAL(1), LOGICAL(2), LOGICAL(4), and LOGICAL(8) Data Representations**

**Character Representation**
A character string is a contiguous sequence of bytes in memory, as shown below.

**CHARACTER Data Representation**
A character string is specified by two attributes: the address $A$ of the first byte of the string, and the length $L$ of the string in bytes. For Windows* OS, the length $L$ of a string is in the range 1 through $2,147,483,647$ ($2^{31}-1$). For Linux* OS, the length $L$ of a string is in the range 1 through $2,147,483,647$ ($2^{31}-1$) for systems based on IA-32 architecture and in the range 1 through $9,223,720,368,547,758,077$ ($2^{63}-1$) for systems based on Intel® 64 architecture.

**Hollerith Representation**
Hollerith constants are stored internally, one character per byte, as shown below.

**Hollerith Data Representation**

---

**Fortran I/O**
Devices and Files Overview

In Fortran's I/O system, data is stored and transferred among files. All I/O data sources and destinations are considered files.

Devices such as the screen, keyboard, and printer are external files, as are data files stored on a device such as a disk.

Variables in memory can also act as a file on a disk and are typically used to convert ASCII representations of numbers to binary form. When variables are used in this way, they are called internal files.

For more information, see the individual topics in this section.

Logical Devices

Every file, internal or external, is associated with a logical device. You identify the logical device associated with a file by using Unit Specifier (UNIT=). The unit specifier for an internal file is the name of the character variable associated with it. The unit specifier for an external file is one of the following:

- A number you assign with the OPEN statement
- A number assigned by the Intel® Fortran run-time library with the OPEN specifier NEWUNIT=
- A number preconnected as a unit specifier to a device
- An asterisk (*)

The OPEN statement connects a unit number with an external file and allows you to explicitly specify file attributes and run-time options using OPEN statement specifiers. External unit specifiers that are preconnected to certain devices do not have to be opened. External units that you connect are disconnected when program execution terminates or when the unit is closed by a CLOSE statement.

A unit must not be connected to more than one file at a time, and a file must not be connected to more than one unit at a time. You can OPEN an already opened file but only to change some of the I/O options for the connection, not to connect an already opened file or unit to a different unit or file.

You must use a unit specifier for all I/O statements except in the following cases:

- ACCEPT, which always reads from standard input unless the FOR_ACCEPT environment variable is defined.
- INQUIRE by file, which specifies the filename rather than the unit with which the file is associated.
- PRINT, which always writes to standard output unless the FOR_PRINT environment variable is defined.
- READ statements that contain only an I/O list and format specifier, which read from standard input (UNIT=5) unless the FOR_READ environment variable is defined.
- WRITE statements that contain only an I/O list and format specifier, which write to standard output unless the FOR_WRITE environment variable is defined.
- TYPE, which always writes to standard output unless the FOR_TYPE environment variable is defined.

External Files

A unit specifier associated with an external file must be either an integer expression or an asterisk (*). The integer expression must be in the range 0 (zero) to a maximum value of 2,147,483,640. (The predefined parameters FOR_K_PRINT_UNITNO, FOR_K_TYPE_UNITNO, FOR_K_ACCEPT_UNITNO, and FOR_K_READ_UNITNO may not be in that range. For more information, see the Language Reference.)

The following example connects the external file UNDAMP.DAT to unit 10 and writes to it:

```fortran
OPEN (UNIT = 10, FILE = 'UNDAMP.DAT')
WRITE (10, '(A18,\') ' Undamped Motion:'
```

The asterisk (*) unit specifier specifies the keyboard when reading and the screen when writing. The following example uses the asterisk specifier to write to the screen:

```fortran
WRITE (*, '(1X, A30,\') ' Write this to the screen.'
```

Intel Fortran has four units preconnected to external files (devices), as shown in the following table.
Asterisk (*)
None
Always represents the keyboard and screen (unless the appropriate environment variable is defined, such as FOR_READ).

0
FORT0
Initially represents the screen (unless FORT0 is explicitly defined)

5
FORT5
Initially represents the keyboard (unless FORT5 is explicitly defined)

6
FORT6
Initially represents the screen (unless FORT6 is explicitly defined)

The asterisk (*) specifier is the only unit specifier that cannot be reconnected to another file; attempting to close such a unit causes a compile-time error. Units 0, 5, and 6 can be connected to any file with the OPEN statement; if you close one of those units, the file is automatically reconnected to its preconnected device the next time an I/O statement attempts to use that unit.

Intel® Fortran does not support buffering to stdin, and does not buffer to stdout by default unless the assume buffered_stdout option is specified. All I/O to units * and 6 use line buffering by default. Therefore, C and Fortran output to stdout should work well as long as the C code is not performing buffering. If the C code is performing buffering, the C code will have to flush the buffers after each write. For more information on stdout and stdin, see Assigning Files to Logical Units.

You can change these preconnected files by doing one of the following:

- Using an OPEN statement to open unit 5, 6, or 0. When you explicitly OPEN a file for unit 5, 6, or 0, the OPEN statement keywords specify the file-related information to be used instead of the preconnected standard I/O file.
- Setting the appropriate environment variable (FORTn) to redirect I/O to an external file.

To redirect input or output from the standard preconnected files at run time, you can set the appropriate environment variable or use the appropriate shell redirection character in a pipe (such as > or <).

When you omit the file name in the OPEN statement or use an implicit OPEN, you can define the environment variable FORTn to specify the file name for a particular unit number n. An exception to this is when the fpscomp filesfromcmd compiler option is specified.

For example, if you want unit 6 to write to a file instead of standard output, set the environment variable FORT6 to the path and filename to be used before you run the program. If the appropriate environment variable is not defined, a default filename is used, in the form fort.n where n is the logical unit number.

The following example writes to the preconnected unit 6 (the screen), then reconnects unit 6 to an external file and writes to it, and finally reconnects unit 6 to the screen and writes to it:

```fortran
REAL a, b
! Write to the screen (preconnected unit 6).
WRITE(6, '('''This is unit 6'''')')
! Use the OPEN statement to connect unit 6
! to an external file named 'COSINES'.
OPEN (UNIT = 6, FILE = 'COSINES', STATUS = 'NEW')
DO k = 1, 63, 1
  a = k/10
  b = COS (a)
! Write to the file 'COSINES'.
  WRITE (6, 100) a, b
100        FORMAT (F3.1, F5.2)
END DO
! Close it.
```
![Reconnect unit 6 to the screen, by writing to it.](6)

```fortran
WRITE(6, ' ("Cosines completed")')
END
```

### Internal Files

The unit specifier associated with an internal file is a scalar or array character variable:

- If the internal file is a scalar character variable, the file has only one record; its length is equal to that of the variable.
- If the internal file is an array character variable, the file has a record for each element in the array; each record's length is equal to one array element.

Follow these rules when using internal files:

- Use only formatted I/O, including I/O formatted with a format specification, namelist, and list-directed I/O. (List-directed and namelist I/O are treated as sequential formatted I/O.)
- If the character variable is an allocatable array or array part of an allocatable array, the array must be allocated before use as an internal file. If the character variable is a pointer, it must be associated with a target.
- Use only **READ** and **WRITE** statements. You cannot use file connection (OPEN, CLOSE), file positioning (REWIND, BACKSPACE), or file inquiry (INQUIRE) statements with internal files.

You can read and write internal files with FORMAT I/O statements, namelist I/O statements, or list-directed I/O statements exactly as you can external files. Before an I/O statement is executed, internal files are positioned at the beginning of the variable, before the first record.

With internal files, you can use the formatting capabilities of the I/O system to convert values between external character representations and Fortran internal memory representations. Reading from an internal file converts the ASCII representations into numeric, logical, or character representations, and writing to an internal file converts these representations into their ASCII representations.

This feature makes it possible to read a string of characters without knowing its exact format, examine the string, and interpret its contents. It also makes it possible, as in dialog boxes, for the user to enter a string and for your application to interpret it as a number.

If less than an entire record is written to an internal file, the rest of the record is filled with blanks.

In the following example, `str` and `fname` specify internal files:

```fortran
CHARACTER(10) str
INTEGER n1, n2, n3
CHARACTER(14) fname
INTEGER i
str = ' 1   2   3'
! List-directed READ sets n1 = 1, n2 = 2, n3 = 3.
READ(str, *) n1, n2, n3
i = 4
! Formatted WRITE sets fname = 'FM004.DAT'.
WRITE (fname, 200) i
200 FORMAT ('FM', I3.3, '.DAT')
```

### Physical Devices (Windows*)

This topic only applies to Windows* operating systems.
I/O statements that do not refer to a specific file or I/O device read from standard input and write to standard output. Standard input is the keyboard, and standard output is the screen (console). To perform input and output on a physical device other than the keyboard or screen, you specify the device name as the filename to be read from or written to.

Some physical device names are determined by the host operating system; others are recognized by Intel Fortran. Extensions on most device names are ignored.

Filenames for Device I/O

<table>
<thead>
<tr>
<th>Device</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CON</td>
<td>Console (standard output)</td>
</tr>
<tr>
<td>PRN</td>
<td>Printer</td>
</tr>
<tr>
<td>COM1</td>
<td>Serial port #1</td>
</tr>
<tr>
<td>COM2</td>
<td>Serial port #2</td>
</tr>
<tr>
<td>COM3</td>
<td>Serial port #3</td>
</tr>
<tr>
<td>COM4</td>
<td>Serial port #4</td>
</tr>
<tr>
<td>LPT1</td>
<td>Parallel Port #1</td>
</tr>
<tr>
<td>LPT2</td>
<td>Parallel Port #2</td>
</tr>
<tr>
<td>LPT3</td>
<td>Parallel Port #3</td>
</tr>
<tr>
<td>LPT4</td>
<td>Parallel Port #4</td>
</tr>
<tr>
<td>NUL</td>
<td>NULL device. Discards all output; contains no input</td>
</tr>
<tr>
<td>AUX</td>
<td>Serial port #1</td>
</tr>
<tr>
<td>LINE</td>
<td>Serial port #1</td>
</tr>
<tr>
<td>USER</td>
<td>Standard output</td>
</tr>
<tr>
<td>ERR</td>
<td>Standard error</td>
</tr>
<tr>
<td>CONOU</td>
<td>Standard output</td>
</tr>
<tr>
<td>T$</td>
<td>Standard input</td>
</tr>
</tbody>
</table>

**NOTE**

If you use the LINE, USER, or ERR name with an extension, for example, LINE.TXT, Fortran will write to a file rather than to the device.

Examples of opening physical devices as units are:

```
OPEN (UNIT = 4, FILE = 'PRN')
OPEN (UNIT = 7, FILE = 'LPT2', ERR = 100)
```

Types of I/O Statements

The table below lists the Intel Fortran I/O statements:

<table>
<thead>
<tr>
<th>Category and statement name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>File connection</td>
<td></td>
</tr>
<tr>
<td>Category and statement name</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>OPEN</td>
<td>Connects a unit number with an external file and specifies file connection characteristics.</td>
</tr>
<tr>
<td>CLOSE</td>
<td>Disconnects a unit number from an external file.</td>
</tr>
<tr>
<td><strong>File inquiry</strong></td>
<td></td>
</tr>
<tr>
<td>DEFINE FILE</td>
<td>Specifies file characteristics for a direct access relative file and connects the unit number to the file, similar to an OPEN statement. Provided for compatibility with compilers older than FORTRAN-77.</td>
</tr>
<tr>
<td>INQUIRE</td>
<td>Returns information about a named file, a connection to a unit, or the length of an output item list.</td>
</tr>
<tr>
<td><strong>Record position</strong></td>
<td></td>
</tr>
<tr>
<td>BACKSPACE</td>
<td>Moves the record position to the beginning of the previous record (sequential access only).</td>
</tr>
<tr>
<td>DELETE</td>
<td>Marks the record at the current record position in a relative file as deleted (direct access only).</td>
</tr>
<tr>
<td>ENDFILE</td>
<td>Writes an end-of-file marker after the current record (sequential access only).</td>
</tr>
<tr>
<td>FIND</td>
<td>Changes the record position in a direct access file. Provided for compatibility with compilers older than FORTRAN-77.</td>
</tr>
<tr>
<td>REWIND</td>
<td>Sets the record position to the beginning of the file (sequential access only).</td>
</tr>
<tr>
<td><strong>Record input</strong></td>
<td></td>
</tr>
<tr>
<td>READ</td>
<td>Transfers data from an external file record or an internal file to internal storage.</td>
</tr>
<tr>
<td>ACCEPT</td>
<td>Reads input from stdin. Unlike READ, ACCEPT only provides formatted sequential input and does not specify a unit number.</td>
</tr>
<tr>
<td><strong>Record output</strong></td>
<td></td>
</tr>
<tr>
<td>WRITE</td>
<td>Transfers data from internal storage to an external file record or to an internal file.</td>
</tr>
<tr>
<td>REWRITE</td>
<td>Transfers data from internal storage to an external file record at the current record position (direct access relative files only).</td>
</tr>
<tr>
<td>TYPE</td>
<td>Writes record output to stdout.</td>
</tr>
<tr>
<td>PRINT</td>
<td>Transfers data from internal storage to stdout. Unlike WRITE, PRINT only provides formatted sequential output and does not specify a unit number.</td>
</tr>
<tr>
<td>FLUSH</td>
<td>Flushes the contents of an external unit's buffer to its associated file.</td>
</tr>
</tbody>
</table>

In addition to the READ, WRITE, REWRITE, TYPE, and PRINT statements, other I/O record-related statements are limited to a specific file organization. For instance:

- The DELETE statement only applies to relative files. (Detecting deleted records is only available if the `vms` option was specified when the program was compiled.)
- The BACKSPACE statement only applies to sequential files open for sequential access.
- The REWIND statement only applies to sequential files open for sequential access and to direct access files.
- The ENDFILE statement only applies to certain types of sequential files open for sequential access and to direct access files.

The file-related statements (OPEN, INQUIRE, and CLOSE) apply to any relative or sequential file.
Forms of I/O Statements

Each type of record I/O statement can be coded in a variety of forms. The form you select depends on the nature of your data and how you want it treated. When opening a file, specify the form using the FORM specifier.

The following are the forms of I/O statements:

- **Formatted I/O statements** contain explicit format specifiers that are used to control the translation of data from internal (binary) form within a program to external (readable character) form in the records, or vice versa.
- **List-directed and namelist I/O statements** are similar to formatted statements in function. However, they use different mechanisms to control the translation of data: formatted I/O statements use explicit format specifiers, and list-directed and namelist I/O statements use data types.
- **Unformatted I/O statements** do not contain format specifiers and therefore do not translate the data being transferred (important when writing data that will be read later).

Formatted, list-directed, and namelist I/O forms require translation of data from internal (binary) form within a program to external (readable character) form in the records. Consider using unformatted I/O for the following reasons:

- Unformatted data avoids the translation process, so I/O tends to be faster.
- Unformatted data avoids the loss of precision in floating-point numbers when the output data will subsequently be used as input data.
- Unformatted data conserves file storage space (stored in binary form).

To write data to a file using formatted, list-directed, or namelist I/O statements, specify FORM= ’FORMATTED’ when opening the file. To write data to a file using unformatted I/O statements, specify FORM= ’UNFORMATTED’ when opening the file.

Data written using formatted, list-directed, or namelist I/O statements is referred to as **formatted data**. Data written using unformatted I/O statements is referred to as **unformatted data**.

When reading data from a file, you should use the same I/O statement form that was used to write the data to the file. For instance, if data was written to a file with a formatted I/O statement, you should read data from that file with a formatted I/O statement.

Although I/O statement form is usually the same for reading and writing data in a file, a program can read a file containing unformatted data (using unformatted input) and write it to a separate file containing formatted data (using formatted output). Similarly, a program can read a file containing formatted data and write it to a different file containing unformatted data.

You can access records in any sequential or relative file using sequential access. For relative files and certain (fixed-length) sequential files, you can also access records using direct access.

The table below shows categories for the main record I/O statements that can be used in Intel® Fortran programs.

<table>
<thead>
<tr>
<th>File Type, Access, and I/O Form</th>
<th>Available Statements</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>External file, sequential access</strong></td>

</tr>
<tr>
<td>Formatted</td>
<td>READ, WRITE</td>
</tr>
<tr>
<td>List-directed</td>
<td>READ, WRITE</td>
</tr>
<tr>
<td>Unformatted</td>
<td>None</td>
</tr>
</tbody>
</table>

**NOTE**
You can use the REWRITE statement only for relative files, using direct access.

### Assigning Files to Logical Units
Most I/O operations involve a disk file, keyboard, or screen display. Other devices can also be used:
- Sockets can be read from or written to if a USEROPEN routine (usually written in C) is used to open the socket.
- Pipes opened for read and write access block (wait until data is available) if you issue a READ to an empty pipe.
- Pipes opened for read-only access return EOF if you issue a READ to an empty pipe.

You can access the terminal screen or keyboard by using preconnected files listed in **Logical Devices**.

You can choose to assign files to logical units by using one of the following methods:
- Using default values, such as a preconnected unit
- Supplying a file name (and possibly a directory) in an OPEN statement
- Using environment variables

### Using Default Values
In the following example, the PRINT statement is associated with a preconnected unit (stdout) by default.

```plaintext
PRINT *,100
```

The READ statement associates the logical unit 7 with the file *fort.7* (because the FILE specifier was omitted) by default:

```plaintext
OPEN (UNIT=7,STATUS='NEW')
READ (7,100)
```

### Supplying a File Name in an OPEN Statement
The FILE specifier in an OPEN statement typically specifies only a file name (such as *filnam*) or contains both a directory and file name (such as */usr/proj/filnam*).

For example:

```plaintext
OPEN (UNIT=7, FILE='FILNAM.DAT', STATUS='OLD')
```

The DEFAULTFILE specifier in an OPEN statement typically specifies a pathname that contains only a directory (such as */usr/proj/*) or both a directory and file name (such as */usr/proj/testdata*).

Implied OPEN
Performing an implied OPEN means that the FILE and DEFAULTFILE specifier values are not specified and an environment variable is used, if present. Thus, if you used an implied OPEN, or if the FILE specifier in an OPEN statement did not specify a file name, you can use an environment variable to specify a file name or a pathname that contains both a directory and file name.

Using Environment Variables

You can use shell commands to set the appropriate environment variable to a value that indicates a directory (if needed) and a file name to associate a unit with an external file.

Intel Fortran recognizes environment variables for each logical I/O unit number in the form of FORT_n, where  \( n \) is the logical I/O unit number. If a file name is not specified in the OPEN statement and the corresponding FORT_n environment variable is not set for that unit number, Intel Fortran generates a file name in the form fort.n, where \( n \) is the logical unit number.

Implied Intel Fortran Logical Unit Numbers

The ACCEPT, PRINT, and TYPE statements, and the use of an asterisk (*) in place of a unit number in READ and WRITE statements, do not include an explicit logical unit number.

Each of these Fortran statements uses an implicit internal logical unit number and environment variable. Each environment variable is in turn associated by default with one of the Fortran file names that are associated with standard I/O files. The table below shows these relationships:

<table>
<thead>
<tr>
<th>Intel Fortran statement</th>
<th>Environment variable</th>
<th>Standard I/O file name</th>
</tr>
</thead>
<tbody>
<tr>
<td>READ (*,f) iolist</td>
<td>FOR_READ</td>
<td>stdin</td>
</tr>
<tr>
<td>READ f,iolist</td>
<td>FOR_READ</td>
<td>stdin</td>
</tr>
<tr>
<td>ACCEPT f,iolist</td>
<td>FOR_ACCEPT</td>
<td>stdin</td>
</tr>
<tr>
<td>WRITE (*,f) iolist</td>
<td>FOR_PRINT</td>
<td>stdout</td>
</tr>
<tr>
<td>PRINT f,iolist</td>
<td>FOR_PRINT</td>
<td>stdout</td>
</tr>
<tr>
<td>TYPE f,iolist</td>
<td>FOR_TYPE</td>
<td>stdout</td>
</tr>
<tr>
<td>WRITE(0,f) iolist</td>
<td>FORT0</td>
<td>stderr</td>
</tr>
<tr>
<td>READ(5,f) iolist</td>
<td>FORT5</td>
<td>stdin</td>
</tr>
<tr>
<td>WRITE(6,f) iolist</td>
<td>FORT6</td>
<td>stdout</td>
</tr>
</tbody>
</table>

You can change the file associated with these Intel Fortran environment variables, as you would any other environment variable, by means of the environment variable assignment command. For example:

```
setenv FOR_READ /usr/users/smith/test.dat
```

After executing the preceding command, the environment variable for the READ statement using an asterisk refers to file test.dat in the specified directory.

**NOTE**

The association between the logical unit number and the physical file can occur at run-time. Instead of changing the logical unit numbers specified in the source program, you can change this association at run time to match the needs of the program and the available resources. For example, before running the program, a script file can set the appropriate environment variable or allow the terminal user to type a directory path, file name, or both.
File Organization

File organization refers to the way records are physically arranged on a storage device. This topic describes the two main types of file organization.

Related topics describe the following:

- **Record type** refers to whether records in a file are all the same length, are of varying length, or use other conventions to define where one record ends and another begins. For more information on record types, see Record Types.

- **Record access** refers to the method used to read records from or write records to a file, regardless of its organization. The way a file is organized does not necessarily imply the way in which the records within that file will be accessed. For more information on record access, see File Access and File Structure and Record Access.

Types of File Organization

Fortran supports two types of file organizations:

- Sequential
- Relative

The organization of a file is specified by means of the ORGANIZATION keyword in the OPEN statement. The default file organization is always ORGANIZATION= 'SEQUENTIAL' for an OPEN statement.

You can store sequential files on magnetic tape or disk devices, and can use other peripheral devices, such as terminals, pipes, and line printers as sequential files.

You must store relative files on a disk device.

Sequential File Organization

A sequentially organized file consists of records arranged in the sequence in which they are written to the file (the first record written is the first record in the file, the second record written is the second record in the file, and so on). As a result, records can be added only at the end of the file. Attempting to add records at some place other than the end of the file will result in the file begin truncated at the end of the record just written.

Sequential files are usually read sequentially, starting with the first record in the file. Sequential files with a fixed-length record type that are stored on disk can also be accessed by relative record number (direct access).

Relative File Organization

Within a relative file are numbered positions, called *cells*. These cells are of fixed equal length and are consecutively numbered from 1 to *n*, where 1 is the first cell, and *n* is the last available cell in the file. Each cell either contains a single record or is empty. Records in a relative file are accessed according to cell number. A cell number is a record's relative record number; its location relative to the beginning of the file.

By specifying relative record numbers, you can directly retrieve, add, or delete records regardless of their locations. You can only detect deleted records if you specify option VMS when the program is compiled.

When creating a relative file, use the RECL value to determine the size of the fixed-length cells. Within the cells, you can store records of varying length, as long as their size does not exceed the cell size.

Internal Files and Scratch Files

Intel Fortran also supports internal files and scratch files.
Internal Files
When you use sequential access, you can use an internal file to reference character data in a buffer. The transfer occurs between internal storage spaces (unlike external files), such as between user variables and a character array.

An internal file consists of any of the following:
- Character variable
- Character-array element
- Character array
- Character substring
- Character array section without a vector subscript

Instead of specifying a unit number for the READ or WRITE statement, use an internal file specifier in the form of a character scalar memory reference or a character-array name reference.

An internal file is a designated internal storage space (variable buffer) of characters that is treated as a sequential file of fixed-length records. To perform internal I/O, use formatted and list-directed sequential READ and WRITE statements. You cannot use file-related statements such as OPEN and INQUIRE on an internal file (no unit number is used).

If an internal file is made up of a single character variable, array element, or substring, that file comprises a single record whose length is the same as the length of the character variable, array element, or substring it contains. If an internal file is made up of a character array, that file comprises a sequence of records, with each record consisting of a single array element. The sequence of records in an internal file is determined by the order of subscript progression.

A record in an internal file can be read only if the character variable, array element, or substring comprising the record has been defined (a value has been assigned to the record).

Prior to each READ and WRITE statement, an internal file is always positioned at the beginning of the first record.

Scratch Files
Scratch files are created by specifying STATUS= 'SCRATCH' in an OPEN statement. By default, these temporary files are created by an OPEN statement and are deleted when closed.

File Access and File Structure
Fortran supports three methods of file access:
- Sequential
- Direct
- Stream

Fortran supports three kinds of file structure:
- Formatted
- Unformatted
- Binary

Sequential-access and direct-access files can have any of the three file structures. Stream-access files can have a file structure of formatted or unformatted.

Choosing a File Access and File Structure
Each kind of file has advantages and the best choice depends on the application you are developing:
- Formatted Files
You create a formatted file by opening it with the FORM='FORMATTED' option, or by omitting the FORM parameter when creating a sequential file. The records of a formatted file are stored as ASCII characters. Numbers that would otherwise be stored in binary form are converted to ASCII format. Each record ends with the ASCII carriage return (CR) and/or line feed (LF) characters.

If you need to view a data file's contents, use a formatted file. You can load a formatted file into a text editor and read its contents directly. The numbers will look like numbers and the strings will look like character strings (an unformatted or binary file looks like a set of hexadecimal characters).

- **Unformatted Files**

You create an unformatted file by opening it with the FORM='UNFORMATTED' option, or by omitting the FORM parameter when creating a direct-access file. An unformatted file is a series of records composed of physical blocks. Each record contains a sequence of values stored in a representation that is close to that used in program memory. Little conversion is required during input/output.

The lack of formatting makes these files quicker to access and more compact than files that store the same information in a formatted form. However, if the files contain numbers, you will not be able to read them with a text editor.

- **Binary Files**

You create a binary file by specifying FORM='BINARY'. Binary files are similar to unformatted files, except binary files have no internal record format associated with them.

- **Sequential-Access Files**

Data in sequential files must be accessed in order, one record after the other (unless you change your position in the file with the REWIND or BACKSPACE statements). Some methods of I/O are possible only with sequential files, including nonadvancing I/O, list-directed I/O, and namelist I/O. Internal files also must be sequential files. You must use sequential access for files associated with sequential devices.

A sequential device is a physical storage device that does not allow explicit motion (other than reading or writing). The keyboard, screen, and printer are all sequential devices.

- **Direct-Access Files**

Data in direct-access files can be read or written to in any order. Records are numbered sequentially, starting with record number 1. All records have the length specified by the RECL option in the OPEN statement. Data in direct-access files is accessed by specifying the record you want within the file. If you need random access I/O, use direct-access files. A common example of a random-access application is a database.

- **Stream-Access Files**

Stream-access I/O is a method of accessing a file without reference to a record structure. With stream access, a file is seen as a continuous sequence of bytes and is addressed by a positive integer starting from 1.

To enable stream access, specify ACCESS='STREAM' in the OPEN statement for the file. You can use the STREAM= specifier in the INQUIRE statement to determine if STREAM is listed in the set of possible access methods for the file. A value of YES, NO, or UNKNOWN is returned.

A file enabled for stream access is positioned by file storage units (normally bytes) starting at position 1. To determine the current position, use the POS= specifier in an INQUIRE statement for the unit. You can indicate a required position in a read or write statement with a POS= specifier.

Stream access can be either formatted or unformatted.

When connected for formatted stream access, an external file has the following characteristics:

- The first file storage unit in the file is at position 1. The relationship between positions of successive file storage units is processor dependent; not all positive integers need to correspond to valid positions.
- Some file storage units may contain record markers; this imposes a record structure on the file in addition to its stream structure. If there is no record marker at the end of the file, the final record is incomplete. Writing an empty record with no record marker has no effect.

When connected for unformatted stream access, an external file has the following characteristics:
The first file storage unit in the file is at position 1. The position of each subsequent file storage unit is one greater than that of the preceding file storage unit.

If it is possible to position the file, the file storage units do not need to be read or written in order of their position. For example, you may be able to write the file storage unit at position 2, even though the file storage unit at position 1 has not been written.

Any file storage unit may be read from the file while it is connected to a unit, provided that the file storage unit has been written since the file was created, and a READ statement for this connection is allowed.

You cannot use BACKSPACE in an unformatted stream.

File Records

Files may be composed of records. Each record is one entry in the file. A record can be a line from a terminal or a logical record on a magnetic tape or disk file. All records within one file are of the same type.

In Fortran, the number of bytes transferred to a record must be less than or equal to the record length. One record is transferred for each unformatted READ or WRITE statement. A formatted READ or WRITE statement can transfer more than one record using the slash (/) edit descriptor.

For binary files, a single READ or WRITE statement reads or writes as many records as needed to accommodate the number of bytes being transferred. On output, incomplete formatted records are padded with spaces. Incomplete unformatted and binary records are padded with undefined bytes (zeros).

Record Types

An I/O record is a collection of data items, called fields, which are logically related and are processed as a unit. The record type refers to the convention for storing fields in records.

The record type of the data within a file is not maintained as an attribute of the file. The results of using a record type other than the one used to create the file are indeterminate.

A number of record types are available, as shown in the following table. The table also lists the record overhead. This refers to bytes associated with each record that are used internally by the file system and are not available when a record is read or written. Knowing the record overhead helps when estimating the storage requirements for an application. Although the overhead bytes exist on the storage media, do not include them when specifying the record length with the RECL specifier in an OPEN statement.

<table>
<thead>
<tr>
<th>Record Type</th>
<th>Available File Organizations and Portability Considerations</th>
<th>Record Overhead</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fixed-length</td>
<td>Relative or sequential file organizations.</td>
<td>None for sequential or for relative if the <strong>vms</strong> option was omitted. One byte for relative if the <strong>vms</strong> option was specified.</td>
</tr>
<tr>
<td>Variable-length</td>
<td>Sequential file organization only. The variable-length record type is generally the most portable record type across multi-vendor platforms.</td>
<td>Eight bytes per record.</td>
</tr>
<tr>
<td>Segmented</td>
<td>Sequential file organization only and only for unformatted sequential access. The segmented record type is unique to Intel Fortran and should not be used for portability with programs written in languages other than Fortran or for places where Intel Fortran is not used. However, because the segmented record type is unique to Intel Fortran products, formatted data in segmented files can be ported across Intel Fortran platforms.</td>
<td>Four bytes per record. One additional padding byte (space) is added if the specified record size is an odd number.</td>
</tr>
<tr>
<td>Stream</td>
<td>Sequential file organization only.</td>
<td>None required.</td>
</tr>
</tbody>
</table>
### Fixed-Length Records

When you specify fixed-length records, you are specifying that all records in the file contain the same number of bytes. When you open a file that is to contain fixed-length records, you must specify the record size using the RECL keyword. A sequentially organized opened file for direct access must contain fixed-length records, to allow the record position in the file to be computed correctly.

For relative files, the layout and overhead of fixed-length records depends upon whether the program accessing the file was compiled using the \texttt{vms} option:

- For relative files where the \texttt{vms} option was omitted (the default), each record has no control information.
- For relative files where the \texttt{vms} option was specified, each record has one byte of control information at the beginning of the record.

The following figures show the record layout of fixed-length records. The first is for all sequential and relative files where the \texttt{vms} option was omitted. The second is for relative files where the \texttt{vms} option was specified.
Variable-Length Records

Variable-length records can contain any number of bytes up to a specified maximum record length, and apply only to sequential files.

Variable-length records are prefixed and suffixed by 4 bytes of control information containing length fields. The trailing length field allows a BACKSPACE request to skip back over records efficiently. The 4-byte integer value stored in each length field indicates the number of data bytes (excluding overhead bytes) in that particular variable-length record.

The character count field of a variable-length record is available when you read the record by issuing a READ statement with a Q format descriptor. You can then use the count field information to determine how many bytes should be in an I/O list.

The following shows the record layout of variable-length records that are less than 2 gigabytes:

```
<table>
<thead>
<tr>
<th>Leading Length Field</th>
<th>User Data</th>
<th>Trailing Length Field</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>Record length (RECL=value)</td>
<td>4</td>
</tr>
</tbody>
</table>
```

For a record length greater than 2,147,483,639 bytes, the record is divided into subrecords. The subrecord can be of any length from 1 to 2,147,483,639, inclusive.

The sign bit of the leading length field indicates whether the record is continued or not. The sign bit of the trailing length field indicates the presence of a preceding subrecord. The position of the sign bit is determined by the endian format of the file.

The following rules describe sign bit values:

- A subrecord that is continued has a leading length field with a sign bit value of 1.
- The last subrecord that makes up a record has a leading length field with a sign bit value of 0.
- A subrecord that has a preceding subrecord has a trailing length field with a sign bit value of 1.
- The first subrecord that makes up a record has a trailing length field with a sign bit value of 0.
- If the value of the sign bit is 1, the length of the record is stored in twos-complement notation.

The following shows the record layout of variable-length records that are greater than 2 gigabytes:
Files written with variable-length records by Intel Fortran programs usually cannot be accessed as text files. Instead, use the Stream_LF record format for text files with records of varying length.

**Segmented Records**

A segmented record is a single logical record consisting of one or more variable-length, unformatted records in a sequentially organized disk file. Unformatted data written to sequentially organized files using sequential access is stored as segmented records by default.

Segmented records are useful when you want to write exceptionally long records but cannot or do not wish to define one long variable-length record, perhaps because virtual memory limitations can prevent program execution. By using smaller, segmented records, you reduce the chance of problems caused by virtual memory limitations on systems on which the program may execute.

For disk files, the segmented record is a single logical record that consists of one or more segments. Each segment is a physical record. A segmented (logical) record can exceed the absolute maximum record length (2.14 billion bytes), but each segment (physical record) individually cannot exceed the maximum record length.

To access an unformatted sequential file that contains segmented records, specify `FORM='UNFORMATTED'` and `RECORDTYPE='SEGMENTED'` when you open the file.

The following shows that the layout of segmented records consists of 4 bytes of control information followed by the user data:
The control information consists of a 2-byte integer record length count (includes the 2 bytes used by the segment identifier), followed by a 2-byte integer segment identifier that identifies this segment as one of the following:

<table>
<thead>
<tr>
<th>Identifier Value</th>
<th>Segment Identified</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>One of the segments between the first and last segments</td>
</tr>
<tr>
<td>1</td>
<td>First segment</td>
</tr>
<tr>
<td>2</td>
<td>Last segment</td>
</tr>
<tr>
<td>3</td>
<td>Only segment</td>
</tr>
</tbody>
</table>

If the specified record length is an odd number, the user data will be padded with a single blank (one byte), but this extra byte is not added to the 2-byte integer record size count.

Avoid the segmented record type when the application requires that the same file be used for programs written in languages other than Intel Fortran and for non-Intel platforms.

Stream File Data

A stream file is not grouped into records and contains no control information. Stream files are used with CARRIAGECONTROL='NONE' and contain character or binary data that is read or written only to the extent of the variables specified on the input or output statement.

The following shows the layout of a stream file:

Stream CR, Stream LF and Stream CRLF Records

Stream_CR, Stream_LF, and Stream_CRLF records are variable-length records whose length is indicated by explicit record terminators embedded in the data, not by a count. These terminators are automatically added when you write records to a stream-type file and are removed when you read records.

Each variety uses either a different 1-byte or 2-byte record terminator:

- Stream_CR files must not contain embedded carriage-return characters because Stream_CR files use only a carriage-return as the terminator.
- Stream_LF files must not contain embedded line-feed (new line) characters because Stream_LF files use only a line-feed (new line) as the terminator. This is the usual operating system text file record type on Linux* OS and OS X* systems.
- Stream_CRLF files must not contain embedded carriage returns or line-feed (new line) characters because Stream_CRLF files use a carriage return/line-feed (new line) pair as the terminator. This is the usual operating system text file record type on Windows* systems.

Guidelines for Choosing a Record Type

Before you choose a record type, consider whether your application will use formatted or unformatted data. If you are using formatted data, you can choose any record type except segmented. If you are using unformatted data, avoid the Stream, Stream_CR, Stream_LF and Stream_CRLF record types.

The segmented record type can only be used for unformatted sequential access with sequential files. You should not use segmented records for files that are read by programs written in languages other than Intel Fortran.
The Stream, Stream_CR, Stream_LF, Stream_CRLF and segmented record types can be used only with sequential files.

The default record type (RECORDTYPE) depends on the values for the ACCESS and FORM specifiers for the OPEN statement. (The RECORDTYPE= specifier is ignored for stream access.)

The record type of the file is not maintained as an attribute of the file. The results of using a record type other than the one used to create the file are indeterminate.

An I/O record is a collection of fields (data items) that are logically related and are usually processed as a unit.

Unless you specify nonadvancing I/O (ADVANCE specifier), each Intel Fortran I/O statement transfers at least one record.

### Specifying the Line Terminator for Formatted Files

Use the FOR_FMT_TERMINATOR environment variable to specify the line terminator value used for Fortran formatted files with no explicit RECORDTYPE= specifier.

The FOR_FMT_TERMINATOR environment variable is processed once at the beginning of program execution. Whatever it specifies for specific units continues for the rest of the execution.

You can specify the numbers of the units to have a specific record terminator. The READ/WRITE statements that use these unit numbers will now use the specified record terminators. Other READ/WRITE statements will work in the usual way.

A RECORDTYPE=specifier on an OPEN statement overrides the value set by FOR_FMT_TERMINATOR. The FOR_FMT_TERMINATOR value is ignored for ACCESS='STREAM' files.

### General Syntax for FOR_FMT_TERMINATOR

The syntax for this environment variable is as follows:

```
FOR_FMT_TERMINATOR=MODE[:ULIST][;MODE[:ULIST]]
```

where:

- **MODE**=CR | LF | CRLF
- **ULIST** = U | ULIST,U
- **U** = decimal | decimal - decimal

- MODE specifies the record terminator to be used. The keyword CR means to terminate records with a carriage return. The keyword LF means to terminate records with a line feed; this is the default on Linux* OS and OS X* systems. The keyword CRLF means to terminate records with a carriage return/line feed pair; this is the default on Windows systems.
- Each list member "U" is a simple unit number or a number of units as a range. The number of list members is limited to 64.
- "decimal" is a non-negative decimal number less than 232.

No spaces are allowed inside the FOR_FMT_TERMINATOR value.

On Linux* systems, the command line for the variable setting in the shell is:

```
Sh: export FOR_FMT_TERMINATOR=MODE:ULIST
```

**NOTE**

The environment variable value should be enclosed in quotes if the semicolon is present.

Example:

The following specifies that all input/output operations on unit numbers 10, 11, and 12 have records terminated with a carriage return/line feed pair:

```
FOR_FMT_TERMINATOR=CRLF:10-12
```
Record Length

Use the RECL specifier to specify the record length.

The units used for specifying record length depend on the form of the data:

- Formatted files (FORM= 'FORMATTED'): Specify the record length in bytes.
- Unformatted files (FORM= 'UNFORMATTED'): Specify the record length in 4-byte units, unless you specify the assume byterecl compiler option to request 1-byte units.

For all but variable-length sequential records on 64-bit addressable systems, the maximum record length is 2.147 billion bytes (2,147,483,647 minus the bytes for record overhead). For variable-length sequential records on 64-bit addressable systems, the theoretical maximum record length is about 17,000 gigabytes. When considering very large record sizes, also consider limiting factors such as system virtual memory.

**NOTE**
The RECL specifier is ignored for stream access.

Record Access

Record access refers to how records will be read from or written to a file, regardless of the file's organization. Record access is specified each time you open a file; it can be different each time. The type of record access permitted is determined by the combination of file organization and record type.

For example, you can do the following:

- Add records to a sequential file with ORGANIZATION= 'SEQUENTIAL' and POSITION= 'APPEND' (or use ACCESS= 'APPEND').
- Add records sequentially by using multiple WRITE statements, close the file, and then open it again with ORGANIZATION= 'SEQUENTIAL' and ACCESS= 'SEQUENTIAL' (or ACCESS= 'DIRECT' if the sequential file has fixed-length records).

Sequential Access

Sequential access transfers records sequentially to or from files or I/O devices such as terminals. You can use sequential I/O with any type of supported file organization and record type.

If you select sequential access mode for files with sequential or relative organization, records are written to or read from the file starting at the beginning of the file and continuing through it, one record after another. A particular record can be retrieved only after all of the records preceding it have been read; new records can be written only at the end of the file.

Direct Access

Direct access transfers records selected by record number to and from either sequential files stored on disk with a fixed-length record type or relative organization files.

If you select direct access mode, you can determine the order in which records are read or written. Each READ or WRITE statement must include the relative record number, indicating the record to be read or written.

You can directly access a sequential disk file only if it contains fixed-length records. Because direct access uses cell numbers to find records, you can enter successive READ or WRITE statements requesting records that either precede or follow previously requested records. For example, the first of the following statements reads record 24; the second reads record 10:

```
READ (12,REC=24) I
READ (12,REC=10) J
```
Stream Access
Stream access transfers bytes from records sequentially until a record terminator is found or a specified number of bytes have been read or written. Formatted stream records are terminated with a new line character; unformatted stream data contains no record terminators. Bytes can be read from or written to a file by byte position, where the first byte of the file is position 1. For example:

| OPEN (UNIT=12, ACCESS='STREAM')
| READ (12) I, J, K  ! start at the first byte of the file
| READ (12, POS=200) X, Y  ! then read staring at byte 200
| READ (12) A, B  ! then read starting where the previous READ stopped

The POS= specifier on INQUIRE can be used to determine the current byte position in the file.

NOTE
The RECORDTYPE= specifier is ignored for stream access.

Limitations of Record Access by File Organization and Record Type
You can use sequential and direct access modes on sequential and relative files. However, direct access to a sequential organization file can only be done if the file resides on disk and contains fixed-length records.

The table below summarizes the types of access permitted for the various combinations of file organizations and record types.

<table>
<thead>
<tr>
<th>Record Type</th>
<th>Sequential Access?</th>
<th>Direct Access?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sequential file organization</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Fixed</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Variable</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Segmented</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Stream</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Stream_CR</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Stream_LF</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Stream_CRLF</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Relative file organization</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Fixed</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

NOTE
Direct access and relative files require that the file resides on a disk device.

Record Transfer
I/O statements transfer all data as records. The amount of data that a record can contain depends on the following circumstances:

- With formatted I/O (except for fixed-length records), the number of items in the I/O statement and its associated format specifier jointly determine the amount of data to be transferred.
- With namelist and list-directed output, the items listed in the NAMELIST statement or I/O statement list (in conjunction with the NAMELIST or list-directed formatting rules) determine the amount of data to be transferred.
With unformatted I/O (except for fixed-length records), the I/O statement alone specifies the amount of data to be transferred.

When you specify fixed-length records (RECORDTYPE= 'FIXED'), all records are the same size. If the size of an I/O record being written is less than the record length (RECL), extra bytes are added (padding).

Typically, the data transferred by an I/O statement is read from or written to a single record. It is possible, however, for a single I/O statement to transfer data from or to more than one record, depending on the form of I/O used.

**Input Record Transfer**

When using advancing I/O, if an input statement specifies fewer data fields (less data) than the record contains, the remaining fields are ignored.

If an input statement specifies more data fields than the record contains, one of the following occurs:

- For formatted input using advancing I/O, if the file was opened with PAD='YES', additional fields are read as spaces. If the file is opened with PAD='NO', an error occurs (the input statement should not specify more data fields than the record contains).
- For formatted input using nonadvancing I/O (ADVANCE='NO'), an end-of-record (EOR) condition is returned. If the file was opened with PAD='YES', additional fields are read as spaces.
- For list-directed input, another record is read.
- For NAMELIST input, another record is read.
- For unformatted input, an error occurs.

**Output Record Transfer**

If an output statement specifies fewer data fields than the record contains (less data than required to fill a record), the following occurs:

- With fixed-length records (RECORDTYPE= 'FIXED'), all records are the same size. If the size of an I/O record being written is less than the record length (RECL), extra bytes are added (padding) in the form of spaces (for a formatted record) or zeros (for an unformatted record).
- With other record types, the fields present are written and those omitted are not written (might result in a short record).

If the output statement specifies more data than the record can contain, an error occurs, as follows:

- With formatted or unformatted output using fixed-length records, if the items in the output statement and its associated format specifier result in a number of bytes that exceeds the maximum record length (RECL), an error occurs.
- With formatted or unformatted output not using fixed-length records, if the items in the output statement and its associated format specifier result in a number of bytes that exceeds the maximum record length (RECL), the Intel Fortran RTL attempts to increase the RECL value and write the longer record. To obtain the RECL value, use an INQUIRE statement.
- For list-directed output and namelist output, if the data specified exceeds the maximum record length (RECL), another record is written.

**Specifying Default Pathnames and File Names**

Intel® Fortran provides a number of ways of specifying all or part of a file specification (directory and file name). The following list uses the Linux® pathname /usr/proj/testdata as an example:

- The FILE specifier in an OPEN statement typically specifies only a file name (such as testdata) or contains both a directory and file name (such as /usr/proj/testdata).
- The DEFAULTFILE specifier in an OPEN statement typically specifies a pathname that contains only a directory (such as /usr/proj/) or both a directory and file name (such as /usr/proj/testdata).
- If you used an implied OPEN (described in Assigning Files to Logical Units) or if the FILE specifier in an OPEN statement did not specify a file name, you can use an environment variable to specify a file name or a pathname that contains both a directory and file name.
Examples of Applying Default Pathnames and File Names

For example, for an implied OPEN of unit number 3, Intel Fortran will check the environment variable FORT3. If the environment variable FORT3 is set, its value is used. If it is not set, the system supplies the file name fort.3.

In the following table, assume the current directory is /usr/smith and the I/O uses unit 1, as in the statement READ (1,100).

<table>
<thead>
<tr>
<th>OPEN FILE value</th>
<th>OPEN DEFAULTFILE value</th>
<th>FORT1 environment variable value</th>
<th>Resulting pathname</th>
</tr>
</thead>
<tbody>
<tr>
<td>not specified</td>
<td>not specified</td>
<td>not specified</td>
<td>/usr/smith/fort.1</td>
</tr>
<tr>
<td>not specified</td>
<td>not specified</td>
<td>test.dat</td>
<td>/usr/smith/test.dat</td>
</tr>
<tr>
<td>not specified</td>
<td>not checked</td>
<td>/usr/tmp/t.dat</td>
<td>/usr/tmp/t.dat</td>
</tr>
<tr>
<td>not specified</td>
<td>/tmp</td>
<td>not specified</td>
<td>/tmp/fort.1</td>
</tr>
<tr>
<td>not specified</td>
<td>/tmp</td>
<td>testdata</td>
<td>/tmp/testdata</td>
</tr>
<tr>
<td>not specified</td>
<td>/usr</td>
<td>lib/testdata</td>
<td>/usr/lib/testdata</td>
</tr>
<tr>
<td>file.dat</td>
<td>/usr/group</td>
<td>not checked</td>
<td>/usr/group/file.dat</td>
</tr>
<tr>
<td>/tmp/file.dat</td>
<td>not checked</td>
<td>not checked</td>
<td>/tmp/file.dat</td>
</tr>
<tr>
<td>file.dat</td>
<td>not specified</td>
<td>not checked</td>
<td>/usr/smith/file.dat</td>
</tr>
</tbody>
</table>

When the resulting file pathname begins with a tilde character (~), C-shell-style pathname substitution is used (regardless of what shell is being used), such as a top-level directory (below the root). For additional information on tilde pathname substitution, see csh(1).

Rules for Applying Default Pathnames and File Names

Intel Fortran determines the file name and the directory path based on certain rules. It determines a file name string as follows:

- If the FILE specifier is present, its value is used.
- If the FILE specifier is not present, Intel Fortran examines the corresponding environment variable. If the corresponding environment variable is set, that value is used. If the corresponding environment variable is not set, a file name in the form fort.n is used.

Once Intel Fortran determines the resulting file name string, it determines the directory (which optionally precedes the file name) as follows:

- If the resulting file name string contains an absolute pathname, it is used and the DEFAULTFILE specifier, environment variable, and current directory values are ignored.
- If the resulting file name string does not contain an absolute pathname, Intel Fortran examines the DEFAULTFILE specifier and current directory value: If the corresponding environment variable is set and specifies an absolute pathname, that value is used. Otherwise, the DEFAULTFILE specifier value, if present, is used. If the DEFAULTFILE specifier is not present, Intel Fortran uses the current directory as an absolute pathname.

Opening Files: OPEN Statement

To open a file, you can use a preconnected file (as described in Logical Devices) or can open a file with an OPEN statement. The OPEN statement lets you specify the file connection characteristics and other information.
OPEN Statement Specifiers

The OPEN statement connects a unit number with an external file and allows you to explicitly specify file attributes and run-time options using OPEN statement specifiers. Once you open a file, you should close it before opening it again unless it is a preconnected file.

If you open a unit number that was opened previously (without being closed), one of the following occurs:

- If you specify a file specification that does not match the one specified for the original open, the Intel Fortran run-time system closes the original file and then opens the second file. This resets the current record position for the second file.
- If you specify a file specification that matches the one specified for the original open, the file is reconnected without the internal equivalent of the CLOSE and OPEN. This lets you change one or more OPEN statement run-time specifiers while maintaining the record position context.

You can use the INQUIRE Statement to obtain information about whether or not a file is opened by your program.

Especially when creating a new file using the OPEN statement, examine the defaults (see the description of the OPEN statement in the Intel Fortran Language Reference Manual) or explicitly specify file attributes with the appropriate OPEN statement specifiers.

Specifiers for File and Unit Information

These specifiers identify file and unit information:

- UNIT specifies the logical unit number.
- NEWUNIT specifies that the Intel Fortran run-time library should select an unused logical unit number.
- FILE (or NAME) and DEFAULTFILE specify the directory and/or file name of an external file.
- STATUS or TYPE indicates whether to create a new file, overwrite an existing file, open an existing file, or use a scratch file.
- STATUS or DISPOSE specifies the file existence status after CLOSE.

Specifiers for File and Record Characteristics

These specifiers identify file and record characteristics:

- ORGANIZATION indicates the file organization (sequential or relative).
- RECORDTYPE indicates which record type to use.
- FORM indicates whether records are formatted or unformatted.
- CARRIAGECONTROL indicates the terminal control type.
- RECL or RECORDSIZE specifies the record size.

Specifier for Special File Open Routine

USEROPEN names the routine that will open the file to establish special context that changes the effect of subsequent Intel Fortran I/O statements.

Specifiers for File Access, Processing, and Position

These specifiers identify file access, processing, and position:

- ACCESS indicates the access mode (direct, sequential, or stream).
- SHARED sets file locking for shared access. Indicates that other users can access the same file.
- NOSHARED sets file locking for exclusive access. Indicates that other users who use file locking mechanisms cannot access the same file.
- SHARE specifies shared or exclusive access; for example, SHARE='DENYNONE' or SHARE='DENYRW'.
- POSITION indicates whether to position the file at the beginning of file, before the end-of-file record, or leave it as is (unchanged).
- ACTION or READONLY indicates whether statements will be used to only read records, only write records, or both read and write records.
• MAXREC specifies the maximum record number for direct access.
• ASSOCIATEVARIABLE specifies the variable containing the next record number for direct access.
• ASYNCHRONOUS specifies whether input/output should be performed asynchronously.

**Specifiers for Record Transfer Characteristics**

These specifiers identify record transfer characteristics:

• BLANK indicates whether to ignore blanks in numeric fields.
• DELIM specifies the delimiter character for character constants in list-directed or namelist output.
• PAD, when reading formatted records, indicates whether padding characters should be added if the item list and format specification require more data than the record contains.
• BUFFERED indicates whether buffered or non-buffered I/O should be used.
• BLOCKSIZE specifies the physical I/O buffer or transfer size.
• BUFFERCOUNT specifies the number of physical I/O buffers.
• CONVERT specifies the format of unformatted numeric data.

**Specifiers for Error-Handling Capabilities**

These specifiers are used for error handling:

• ERR specifies a label to branch to if an error occurs.
• IOSTAT specifies the integer variable to receive the error (IOSTAT) number if an error occurs.

**Specifier for File Close Action**

DISPOSE identifies the action to take when the file is closed.

**Specifying File Locations in an OPEN Statement**

You can use the FILE and DEFAULTFILE specifiers of the OPEN statement to specify the complete definition of a particular file to be opened on a logical unit. (The Language Reference Manual describes the OPEN statement in greater detail.)

For example:

```plaintext
OPEN (UNIT=4, FILE='/usr/users/smith/test.dat', STATUS='OLD')
```

The file `test.dat` in directory `/usr/users/smith` is opened on logical unit 4. No defaults are applied, because both the directory and file name were specified. The value of the FILE specifier can be a character constant, variable, or expression.

In the following interactive example, the user supplies the file name and the DEFAULTFILE specifier supplies the default values for the full pathname string. The file to be opened is located in `/usr/users/smith` and is concatenated with the file name typed by the user into the variable DOC:

```plaintext
CHARACTER(LEN=9) DOC
WRITE (6,*) 'Type file name '
READ (5,*) DOC
OPEN (UNIT=2, FILE=DOC, DEFAULTFILE='/usr/users/smith', STATUS='OLD')
```

A slash (backslash on Windows systems) is appended to the end of the default file string if it does not have one.

**Obtaining File Information: INQUIRE Statement**

The INQUIRE statement returns information about a file and has the following forms:

• Inquiry by unit
• Inquiry by file name
• Inquiry by output item list
Inquiry by directory

Inquiry by Unit

An inquiry by unit is usually done for an opened (connected) file. An inquiry by unit causes the Intel® Fortran RTL to check whether the specified unit is connected or not. One of the following occurs, depending on whether the unit is connected or not:

If the unit is connected:

- The EXIST and OPENED specifier variables indicate a true value.
- The pathname and file name are returned in the NAME specifier variable (if the file is named).
- Other information requested on the previously connected file is returned.
- Default values are usually returned for the INQUIRE specifiers also associated with the OPEN statement.
- The RECL value unit for connected formatted files is always 1-byte units. For unformatted files, the RECL unit is 4-byte units, unless you specify the `-assume byterecl` option to request 1-byte units.

If the unit is not connected:

- The OPENED specifier indicates a false value.
- The unit NUMBER specifier variable is returned as a value of -1.
- Any other information returned will be undefined or default values for the various specifiers.

For example, the following INQUIRE statement shows whether unit 3 has a file connected (OPENED specifier) in logical variable I_OPENED, the name (case-sensitive) in character variable I_NAME, and whether the file is opened for READ, WRITE, or READWRITE access in character variable I_ACTION:

```
INQUIRE (3, OPENED=I_OPENED, NAME=I_NAME, ACTION=I_ACTION)
```

Inquiry by File Name

An inquiry by name causes the Intel Fortran RTL to scan its list of open files for a matching file name. One of the following occurs, depending on whether a match occurs or not:

If a match occurs:

- The EXIST and OPENED specifier variables indicate a true value.
- The pathname and file name are returned in the NAME specifier variable.
- The UNIT number is returned in the NUMBER specifier variable.
- Other information requested on the previously connected file is returned.
- Default values are usually returned for the INQUIRE specifiers also associated with the OPEN statement.
- The RECL value unit for connected formatted files is always 1-byte units. For unformatted files, the RECL unit is 4-byte units, unless you specify the `-assume byterecl` option to request 1-byte units.

If no match occurs:

- The OPENED specifier variable indicates a false value.
- The unit NUMBER specifier variable is returned as a value of -1.
- The EXIST specifier variable indicates (true or false) whether the named file exists on the device or not.
- If the file does exist, the NAME specifier variable contains the pathname and file name.
- Any other information returned will be default values for the various specifiers, based on any information specified when calling INQUIRE.

The following INQUIRE statement returns whether the file named log_file is connected in logical variable I_OPEN, whether the file exists in logical variable I_EXIST, and the unit number in integer variable I_NUMBER:

```
INQUIRE (FILE='log_file', OPENED=I_OPEN, EXIST=I_EXIST, NUMBER=I_NUMBER)
```
Inquiry by Output Item List

Unlike inquiry by unit or inquiry by name, inquiry by output item list does not attempt to access any external file. It returns the length of a record for a list of variables that would be used for unformatted WRITE, READ, and REWRITE statements. The following INQUIRE statement returns the maximum record length of the variable list in variable I_RECLENGTH. This variable is then used to specify the RECL value in the OPEN statement:

\[
\text{INQUIRE (IOLENGTH=I_RECLENGTH) A, B, H} \\
\text{OPEN (FILE='test.dat', FORM='UNFORMATTED', RECL=I_RECLENGTH, UNIT=9)}
\]

For an unformatted file, the IOLENGTH value is returned using 4-byte units, unless you specify the -assume byterecl option to request 1-byte units.

Inquiry by Directory

An inquiry by directory verifies that a directory exists.

If the directory exists:
- The EXIST specifier variable indicates a true value.
- The full directory pathname is returned in the DIRSPEC specifier variable.

If the directory does not exist:
- The EXIST specified variable indicates a false value.
- The value of the DIRSPEC specifier variable is unchanged.

For example, the following INQUIRE statement returns the full directory pathname:

\[
\text{LOGICAL ::L_EXISTS} \\
\text{CHARACTER (255)::C_DIRSPEC} \\
\text{INQUIRE (DIRECTORY=".", DIRSPEC=C_DIRSPEC, EXIST=L_EXISTS)}
\]

The following INQUIRE statement verifies that a directory does not exist:

\[
\text{INQUIRE (DIRECTORY="I-DO-NOT-EXIST", EXIST=L_EXISTS)}
\]

Closing Files: CLOSE Statement

Usually, any external file opened should be closed by the same program before it completes. The CLOSE statement flushes any output buffers and disconnects the unit and its external file. You must specify the unit number (UNIT specifier) to be closed.

You can also specify:
- Whether the file should be deleted or kept (STATUS specifier)
- Error handling information (ERR and IOSTAT specifiers)

To delete a file when closing it:
- In the OPEN statement, specify the ACTION keyword (such as ACTION='READ'). Avoid using the READONLY keyword, because a file opened using the READONLY keyword cannot be deleted when it is closed.
- In the CLOSE statement, specify the keyword STATUS='DELETE'.

If you opened an external file and did an inquire by unit, but do not like the default value for the ACCESS specifier, you can close the file and then reopen it, explicitly specifying the ACCESS desired.

Typically, it is not necessary to close preconnected units. Internal files are neither opened nor closed.

Record I/O Statement Specifiers

After you open a file or use a preconnected file, you can use the following statements:
- READ, WRITE, ACCEPT, and PRINT to perform record I/O.
BACKSPACE, ENDFILE, and REWIND to set record position within the file.
DELETE, REWRITE, TYPE, and FIND to perform various operations.

The record I/O statement must use the appropriate record I/O form (formatted, list-directed, namelist, or unformatted).

You can use the following specifiers with the READ and WRITE record I/O statements:
- UNIT specifies the unit number to or from which input or output will occur.
- END specifies a label to branch to if end-of-file occurs; only applies to input statements on sequential files.
- ERR specifies a label to branch to if an error occurs.
- IOSTAT specifies an integer variable to contain the error number if an error occurs.
- FMT specifies a label of a FORMAT statement or character data specifying a FORMAT.
- NML specifies the name of a NAMELIST.
- REC specifies a record number for direct access.

When using nonadvancing I/O, use the ADVANCE, EOR, and SIZE specifiers.

When using the REWRITE statement, you can use the UNIT, FMT, ERR, and IOSTAT specifiers.

File Sharing (Linux* and OS X*)
This topic only applies to Linux* and OS X* operating systems.
Depending on the value specified by the ACTION (or READONLY) specifier in the OPEN statement, the file will be opened by your program for reading, writing, or both reading and writing records. This simply checks that the program itself executes the type of statements intended.

File locking mechanisms allow users to enable or restrict access to a particular file when that file is being accessed by another process.

Intel® Fortran file locking features provide three file access modes:
- Implicit Shared mode, which occurs when no mode is specified. This is also called No Locking.
- Explicit Shared mode, when all cooperating processes have access to a file. This mode is set in the OPEN statement by the SHARED specifier or the SHARE='DENYNONE' specifier.
- Exclusive mode, when only one process has access to a file. This mode is set in the OPEN statement by the NOSHARED specifier or the SHARE='DENYRW' specifier.

The file locking mechanism looks for explicit setting of the corresponding specifier in the OPEN statement. Otherwise, the Fortran run time does not perform any setting or checking for file locking and the process can access the file regardless of the fact that other processes have already opened or locked the file.

Example 1: Implicit Shared Mode (No Locking)
Process 1 opens the file without a specifier, resulting in no locking.
Process 2 now tries to open the file:
- It gains access regardless of the mode it is using.

Example 2: Explicit Shared Mode
Process 1 opens the file with Explicit Shared mode.
Process 2 now tries to open the file:
- If process 2 opens the file with Explicit Shared mode or Implicit Shared (No Locking) mode, it gets access to the file.
- If process 2 opens the file with Exclusive mode, it receives an error.

Example 3: Exclusive Mode
Process 1 opens the file with Exclusive mode.
Process 2 now tries to open the file:

- If process 2 opens the file with Implicit Shared (No Locking) mode, it gets access to the file.
- If process 2 opens the file with Explicit Shared or Exclusive mode, it receives an error.

The Fortran runtime does not coordinate file entry updates during cooperative access. The user needs to coordinate access times among cooperating processes to handle the possibility of simultaneous WRITE and REWRITE statements on the same record positions.

### Specifying the Initial Record Position

When you open a disk file, you can use the OPEN statement POSITION specifier to request one of the following initial record positions within the file:

- The initial position before the first record (POSITION='REWIND')
  
  A sequential access READ or WRITE statement will read or write the first record in the file.

- A point beyond the last record in the file (POSITION='APPEND'), just before the end-of-file record, if one exists
  
  For a new file, this is the initial position before the first record (same as 'REWIND'). You might specify 'APPEND' before you write records to an existing sequential file using sequential access.

- The current position (POSITION='ASIS')
  
  This is usually used only to maintain the current record position when reconnecting a file. The second OPEN specifies the same unit number and specifies the same file name (or omits it), which leaves the file open, retaining the current record position. However, if the second OPEN specifies a different file name for the same unit number, the current file will be closed and the different file will be opened.

The following I/O statements allow you to change the current record position:

- REWIND sets the record position to the initial position before the first record. A sequential access READ or WRITE statement would read or write the first record in the file.

- BACKSPACE sets the record position to the previous record in a file. Using sequential access, if you wrote record 5, issued a BACKSPACE to that unit, and then read from that unit, you would read record 5.

- ENDFILE writes an end-of-file marker. This is typically done after writing records using sequential access just before you close the file.

Unless you use nonadvancing I/O, reading and writing records usually advances the current record position by one record. More than one record might be transferred using a single record I/O statement.

### Advancing and Nonadvancing Record I/O

After you open a file, if you omit the ADVANCE specifier (or specify ADVANCE= 'YES') in READ and WRITE statements, advancing I/O (normal Fortran I/O) will be used for record access. When using advancing I/O:

- Record I/O statements transfer one entire record (or multiple records).
- Record I/O statements advance the current record position to a position before the next record.

You can request nonadvancing I/O for the file by specifying the ADVANCE= 'NO' specifier in a READ and WRITE statement. You can use nonadvancing I/O only for sequential access to external files using formatted I/O (not list-directed or namelist).

When you use nonadvancing I/O, the current record position does not change, and part of the record might be transferred, unlike advancing I/O where one or more entire records are always transferred.

You can alternate between advancing and nonadvancing I/O by specifying different values for the ADVANCE specifier ('YES' and 'NO') in the READ and WRITE record I/O statements.

When reading records with either advancing or nonadvancing I/O, you can use the END specifier to branch to a specified label when the end of the file is read.

Because nonadvancing I/O might not read an entire record, it also supports an EOR specifier to branch to a specified label when the end of the record is read. If you omit the EOR and the IOSTAT specifiers when using nonadvancing I/O, an error results when the end-of-record is read.
When using nonadvancing input, you can use the SIZE specifier to return the number of characters read. For example, in the following READ statement, SIZE=X (where variable X is an integer) returns the number of characters read in X and an end-of-record condition causes a branch to label 700:

```
150 FORMAT (F10.2, F10.2, I6)
READ (UNIT=20, FMT=150, SIZE=X, ADVANCE='NO', EOR=700) A, F, I
```

**User-Supplied OPEN Procedures: USEROPEN Specifier**

You can use the USEROPEN specifier in an OPEN statement to pass control to a routine that directly opens a file. The called routine can use system calls or library routines to open the file and may establish special context that changes the effect of subsequent I/O statements.

The Intel® Fortran Run-Time Library (RTL) I/O support routines call the USEROPEN function in place of the system calls usually used when the file is first opened for I/O. The USEROPEN specifier in an OPEN statement specifies the name of a function to receive control.

The called function must open a file (or pipe) and return the file descriptor of the file (or pipe) it has opened when control is returned to the RTL. The called function may specify different options when it opens the file than a normal OPEN statement would. It may specify a different file.

You can obtain the file descriptor from the Intel® Fortran RTL for a specific unit number by using the PXFFILENO routine.

Although the called function can be written in other languages (such as Fortran), C is usually the best choice for making system calls, such as open or create.

**NOTE**

If your application requires that you use C to perform the file open and close, as well as all record operations, call the appropriate C procedure from the Intel® Fortran program without using the Fortran OPEN statement.

**NOTE**

If a filename has been specified in the OPEN statement that included the USEROPEN specifier, any subsequent CLOSE statement specifying STATUS=DELETE (or DISPOSE=DELETE) only acts on the filename specified in the OPEN statement. If you specified a different filename in the function named in USEROPEN, the CLOSE statement will have no effect on that filename.

**Syntax and Behavior of the USEROPEN Specifier**

The USEROPEN specifier for the OPEN statement has the form:

```
USEROPEN = function-name
```

The function-name represents the name of an external function. In the calling program, the function must be declared in an EXTERNAL statement. For example, the following Intel® Fortran code might be used to call the USEROPEN procedure UOPEN (known to the linker as uopen_

```
EXTERNAL  UOPEN
INTEGER   UOPEN
.
.
.
OPEN (UNIT=10, FILE='/usr/test/data', STATUS='NEW', USEROPEN=UOPEN)
```

During the execution of the OPEN statement, the external procedure called uopen_ receives control. The function opens the file, may perform other operations, and subsequently returns control (with the file descriptor) to the RTL. You can use other system calls or library routines within the USEROPEN function.

In most cases, the USEROPEN function modifies the open flags argument passed by the Intel® Fortran RTL or uses a new value before the open (or create) system call. After the function opens the file, it must return control to the RTL.
If the USEROPEN function is written in C, declare it as a C function that returns a 4-byte integer (int) result to contain the file descriptor.

If the USEROPEN function is written in Fortran, declare it as a FUNCTION with an INTEGER (KIND=4) result, perhaps with an interface block. In any case, the called function must return the file descriptor as a 4-byte integer to the RTL.

The following shows the available arguments and definitions for Linux* OS and OS X*, and then for Windows* OS:

**Linux* OS and OS X* Arguments and Definitions:**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>int uopen_</td>
<td>(1)</td>
</tr>
<tr>
<td>char *file_name,</td>
<td>(2)</td>
</tr>
<tr>
<td>int *open_flags,</td>
<td>(3)</td>
</tr>
<tr>
<td>int *create_mode,</td>
<td>(4)</td>
</tr>
<tr>
<td>int *lun,</td>
<td>(5)</td>
</tr>
<tr>
<td>int file_length);</td>
<td>(6)</td>
</tr>
</tbody>
</table>

On Linux* OS and OS X*, the function definition and the arguments passed from the Intel® Fortran RTL are as follows:

1. The function must be declared as a 4-byte integer (int).
2. Indicates the pathname to be opened; the pathname includes the file name.
3. Indicates the open flags. The open flags are described in the header file /usr/include/sys/file.h or open(2).
4. Indicates the create mode, which is the protection needed when creating a Linux* OS-style file. The create modes are described in open(2).
5. Indicates the logical unit number.
6. Indicates the pathname length (hidden character length argument of the pathname).

**Argument Notes for Linux* OS and OS X*:**
The open system call (see open(2)) requires the passed pathname, the open flags (which define the type access needed, whether the file exists, and so on), and the create mode. The logical unit number specified in the OPEN statement is passed in case the USEROPEN function needs it. The hidden character length of the pathname is also passed.

**Windows* OS Arguments and Definitions:**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>int uopen_</td>
<td>(1)</td>
</tr>
<tr>
<td>char *filename,</td>
<td>(2)</td>
</tr>
<tr>
<td>int *desired_access,</td>
<td>(3)</td>
</tr>
<tr>
<td>int *share_mode,</td>
<td>(4)</td>
</tr>
<tr>
<td>int a_null, /* always 0 */ (5)</td>
<td></td>
</tr>
<tr>
<td>int *flags_attr,</td>
<td>(6)</td>
</tr>
<tr>
<td>int b_null, /* always 0 */ (7)</td>
<td></td>
</tr>
<tr>
<td>int *unit,</td>
<td>(8)</td>
</tr>
<tr>
<td>int *flen);</td>
<td>(9)</td>
</tr>
</tbody>
</table>

On Windows*OS, the function definition and the arguments passed from the Intel® Fortran RTL are as follows:

1. The function must be declared as a 4-byte integer (int).
2. Indicates the pathname to be opened; the pathname includes the file name.
3. Indicates the mode of access. It can be set to read, write, or read/write.
4. Indicates the file protection mode.
5. This is a NULL that is passed as a literal zero by value.
6. This sets flags that specify file modes and several kinds of file features (such as whether to use sequential access or random access, whether to delete on close, etc.)
7. This is a NULL that is passed as a literal zero by value.
8. Indicates the logical unit number.
9. Indicates the pathname length (the hidden character length argument of the pathname).

**Argument Notes for Windows**:  
The argument list for a USEROPEN routine on Windows is very similar to the argument list for the Microsoft Windows function CreateFile. This lets you easily write a USEROPEN routine and pass the input arguments to a call to CreateFile. The CreateFile system call requires the filename, the desired_access, the shared_mode, and the flags_attr. These arguments have been set to reflect the file semantics requested in the OPEN statement. The logical unit number specified in the OPEN statement is passed in case the USEROPEN function needs it. The hidden character length of the pathname is also passed.

On 32-bit Windows, a Fortran USEROPEN function must use the default "C, Reference" calling convention. If you have used the iface compiler option to change the default calling convention to "stdcall" or "cvf", you will need to add a !DIR$ ATTRIBUTES DEFAULT directive in the function source to have it use the correct calling convention.

**Restrictions of Called USEROPEN Functions**  
The Intel® Fortran RTL uses exactly one file descriptor per logical unit, which must be returned by the called function. Because of this, only certain system calls or library routines can be used to open the file.

On Linux* systems, system calls and library routines that do not return a file descriptor include mknod (see mknod(2)) and fopen (see fopen(3)). For example, the fopen routine returns a file pointer instead of a file descriptor.

**Example USEROPEN Program and Function**  
The following Intel® Fortran code calls the USEROPEN function named UOPEN:

```
EXTERNAL UOPEN
INTEGER UOPEN
.
.
OPEN (UNIT=1,FILE='ex1.dat',STATUS='NEW',USEROPEN=UOPEN, ERR=9,IOSTAT=errnum)
```

If UOPEN is a Fortran function, its name is decorated appropriately for Fortran.

Likewise, if UOPEN is a C function, its name is decorated appropriately for C, as long as the following line is included in the above code:

```
!DIR$ ATTRIBUTES C::UOPEN
```

**Compiling and Linking the C and Intel® Fortran Programs**  
Use the icc or icl command to compile the called uopen C function uopen.c, and the ifort command to compile the Intel® Fortran calling program ex1.f. The same ifort command also links both object files by using the appropriate libraries:

```
icc -c uopen.c (Linux* OS)
icl -c uopen.c (Windows* OS)
ifort ex1.f uopen.o
```

**Example Source Code**  
```
program UserOpenSample
IMPLICIT NONE
EXTERNAL UOPEN
INTEGER (4) UOPEN
CHARACTER*10 :: FileName="UOPEN.DAT"
INTEGER*4 :: IOS
Character*255 :: InqFullName
Character*100 :: InqFileName
```
Program the USEROPEN Facility of Open

When the OPEN statement is executed, the USEROPEN function receives control. The function opens the file by calling CreateFile(), performs whatever operations were specified, and subsequently returns control (with the handle returned by CreateFile()) to the calling Fortran program.

```
OPEN(UNIT=10,FILE='UOPEN.DAT',STATUS='REPLACE',USEROPEN=UOPEN, &
IOSTAT=ios, ACTION='READWRITE')
```

The function UKOPEN returns control to the calling Fortran program.

```
IF (ios .EQ. 0)  THEN
   WRITE(*,110) TRIM(FileName), ios
   INQUIRE(10, NAME=InqFullName)
   CALL ParseForFileName(InqFullName,InqFileName)
   IF (InqFileName .NE. FileName) THEN
      WRITE(*,120) TRIM(FileName)
   END IF
ELSE
   WRITE(*,115) TRIM(FileName), ios
   GOTO 9999
END IF
```

```
WRITE(10,*) WriteOutBuffer
REWIND(10)
READ(10,*)  ReadInBuffer
IF (ReadInBuffer .NE. WriteOutBuffer) THEN
   WRITE(*,130) TRIM(FileName)
END IF
CLOSE(10, DISPOSE='DELETE')
WRITE(*,190) TRIM(FileName)
WRITE(*,'(X,"Test of USEROPEN Completed")')
```

```
9999  CONTINUE
END
```

NOTE: The UOPEN function uses the default calling convention, so it matches the Fortran RTL declaration of USEROPEN.

```
! The following function definition and arguments are passed from the Intel Fortran(R) Run-time Library to the function named in USEROPEN:
! The first 7 arguments correspond to the CreateFile() API arguments. The value of these arguments is set according to the caller's OPEN() arguments:
! FILENAME
! Is the address of a null-terminated character string that is the name of the file.
! DESIRED_ACCESS
! Is the desired access (read-write) mode passed by reference.
! SHARE_MODE
```
Is the file sharing mode passed by reference.
A_NULL
Is always null. The Fortran runtime library always passes a NULL
for the pointer to a SECURITY_ATTRIBUTES structure in its
CreateFile() call.
CREATE_DISP
Is the creation disposition specifying what action to take on files
that exist, and what action to take on files that do not exist.
It is passed by reference.
FLAGS_ATTR
Specifies the file attributes and flags for the file. It is passed
by reference.
B_NULL
Is always null. The Fortran runtime library always passes a NULL
for the handle to a template file in its CreateFile() call.

The last 2 arguments are the Fortran unit number and length of the
file name:
UNIT
Is the Fortran unit number on which this OPEN is being done. It is
passed by reference.
FLEN
Is the length of the file name, not counting the terminating null.
It is passed by value.

Microsoft Fortran PowerStation Compatible Files (Windows* OS)
This topic only applies to Windows* OS.
When using the fpscomp option for Microsoft* Fortran PowerStation compatibility, the following types of files are possible:

- Formatted Sequential
- Formatted Direct
- Unformatted Sequential
- Unformatted Direct
- Binary Sequential
- Binary Direct

Formatted Sequential Files
A formatted sequential file is a series of formatted records written sequentially and read in the order in which they appear in the file. Records can vary in length and can be empty. They are separated by carriage return (0D) and line feed (0A) characters as shown in the following figure.

Formatted Records in a Formatted Sequential File

An example of a program writing three records to a formatted sequential file is given below. The resulting file is shown in the following figure.

OPEN (3, FILE='FSEQ')
! FSEQ is a formatted sequential file by default.
WRITE (3, '(A, I3)') 'RECORD', 1
WRITE (3, '()')
Formatted Sequential File

In a formatted direct file, all of the records are the same length and can be written or read in any order. The record size is specified with the RECL option in an OPEN statement and should be equal to or greater than the number of bytes in the longest record.

The carriage return (CR) and line feed (LF) characters are record separators and are not included in the RECL value. Once a direct-access record has been written, you cannot delete it, but you can rewrite it.

During output to a formatted direct file, if data does not completely fill a record, the compiler pads the remaining portion of the record with blank spaces. The blanks ensure that the file contains only completely filled records, all of the same length. During input, the compiler by default also adds filler bytes (blanks) to the input record if the input list and format require more data than the record contains.

You can override the default blank padding on input by setting PAD='NO' in the OPEN statement for the file. If PAD='NO', the input record must contain the amount of data indicated by the input list and format specification. Otherwise, an error occurs. PAD='NO' has no effect on output.

An example of a program writing two records, record one and record three, to a formatted direct file is given below. The result is shown in the following figure.

Formatted Direct File

In a formatted direct file, all of the records are the same length and can be written or read in any order. The record size is specified with the RECL option in an OPEN statement and should be equal to or greater than the number of bytes in the longest record.

The carriage return (CR) and line feed (LF) characters are record separators and are not included in the RECL value. Once a direct-access record has been written, you cannot delete it, but you can rewrite it.

During output to a formatted direct file, if data does not completely fill a record, the compiler pads the remaining portion of the record with blank spaces. The blanks ensure that the file contains only completely filled records, all of the same length. During input, the compiler by default also adds filler bytes (blanks) to the input record if the input list and format require more data than the record contains.

You can override the default blank padding on input by setting PAD='NO' in the OPEN statement for the file. If PAD='NO', the input record must contain the amount of data indicated by the input list and format specification. Otherwise, an error occurs. PAD='NO' has no effect on output.

An example of a program writing two records, record one and record three, to a formatted direct file is given below. The result is shown in the following figure.
Unformatted Sequential Files

Unformatted sequential files are organized slightly differently on different platforms. This section describes unformatted sequential files created by Intel® Fortran when the *fpscomp* option is specified.

The records in an unformatted sequential file can vary in length. Unformatted sequential files are organized in chunks of 130 bytes or less called *physical blocks*. Each physical block consists of the data you send to the file (up to 128 bytes) plus two 1-byte "length bytes" inserted by the compiler. The length bytes indicate where each record begins and ends.

A *logical record* refers to an unformatted record that contains one or more physical blocks. (See the following figure.) Logical records can be as big as you want; the compiler will use as many physical blocks as necessary.

When you create a logical record consisting of more than one physical block, the compiler sets the length byte to 129 to indicate that the data in the current physical block continues on into the next physical block. For example, if you write 140 bytes of data, the logical record has the structure shown in the following figure.

**Logical Record in Unformatted Sequential File**

![Logical Record in Unformatted Sequential File](image)

The first and last bytes in an unformatted sequential file are reserved; the first contains a value of 75, and the last holds a value of 130. Fortran uses these bytes for error checking and end-of-file references.

The following program creates the unformatted sequential file shown in the following figure:

```fortran
! Note: The file is sequential by default
! -1 is FF FF FF FF hexadecimal.
!
CHARACTER xyz(3)
INTEGER(4) idata(35)
DATA      idata /35 * -1/, xyz /'x', 'y', 'z'/
!
! Open the file and write out a 140-byte record:
! 128 bytes (block) + 12 bytes = 140 for IDATA, then 3 bytes for XYZ.
OPEN (3, FILE='UFSEQ',FORM='UNFORMATTED')
WRITE (3) idata
WRITE (3) xyz
CLOSE (3)
END
```

Unformatted Sequential File

![Unformatted Sequential File](image)

- **BOF**: Beginning-of-file byte (75 decimal)
- **EOF**: End-of-file byte (130 decimal)
- **Physical-block-length byte** (0 <= L <= 129)

The first and last bytes in an unformatted sequential file are reserved; the first contains a value of 75, and the last holds a value of 130. Fortran uses these bytes for error checking and end-of-file references.
**Unformatted Direct Files**

An unformatted direct file is a series of unformatted records. You can write or read the records in any order you choose. All records have the same length, given by the RECL specifier in an OPEN statement. No delimiting bytes separate records or otherwise indicate record structure.

You can write a partial record to an unformatted direct file. Intel Fortran pads these records to the fixed record length with ASCII NULL characters. Unwritten records in the file contain undefined data.

The following program creates the sample unformatted direct file shown in the following figure:

```fortran
OPEN (3, FILE='UFDIR', RECL=10, &
 & FORM = 'UNFORMATTED', ACCESS = 'DIRECT')
WRITE (3, REC=3) .TRUE., 'abcdef'
WRITE (3, REC=1) 2049
CLOSE (3)
END
```

**Binary Sequential Files**

A binary sequential file is a series of values written and read in the same order and stored as binary numbers. No record boundaries exist, and no special bytes indicate file structure. Data is read and written without changes in form or length. For any I/O data item, the sequence of bytes in memory is the sequence of bytes in the file.

The next program creates the binary sequential file shown in the following figure:

```fortran
! NOTE: 07 is the bell character
! Sequential is assumed by default.
!
INTEGER(1) bells(4)
CHARACTER(4) wys(3)
CHARACTER(4) cvar
DATA bells /4*7/
DATA cvar /' is '/,wys /'What',' you',' see'/
OPEN (3, FILE='BSEQ',FORM='BINARY')
WRITE (3) wys, cvar
WRITE (3) 'what ', 'you get!'
WRITE (3) bells
CLOSE (3)
END
```

---

**Unformatted Direct File**

<table>
<thead>
<tr>
<th>Record 1</th>
<th>Record 2</th>
<th>Record 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>01 00 00 00</td>
<td>01 00 00 00</td>
<td>(ASCII) abcde'</td>
</tr>
<tr>
<td>(Hex)</td>
<td>(Hex)</td>
<td>(ASCII)</td>
</tr>
<tr>
<td>01 00 00 00</td>
<td>01 00 00 00</td>
<td>07 07 07 07</td>
</tr>
</tbody>
</table>

**Binary Sequential File**

```
First write: 16 bytes
Second write: 13 bytes
Third write: 4 bytes (bell characters)

1 12 13 16 17 21 22 29 30 33
(ASCII) (ASCII) (ASCII) (ASCII) (Hex)
What you see 07 07 07 07
```
Binary Direct Files

A binary direct file stores records as a series of binary numbers, accessible in any order. Each record in the file has the same length, as specified by the RECL argument to the OPEN statement. You can write partial records to binary direct files; any unused portion of the record will contain undefined data.

A single read or write operation can transfer more data than a record contains by continuing the operation into the next records of the file. Performing such an operation on an unformatted direct file would cause an error. Valid I/O operations for unformatted direct files produce identical results when they are performed on binary direct files, provided the operations do not depend on zero padding in partial records.

The following program creates the binary direct file shown in the following figure:

```fortran
OPEN (3, FILE='BDIR',RECL=10,FORM='BINARY',ACCESS='DIRECT')
WRITE (3, REC=1) 'abcdefghijklmno'
WRITE (3) 4,5
WRITE (3, REC=4) 'pq'
CLOSE (3) END
```

Using Asynchronous I/O

For external files, you can specify that I/O should be asynchronous. By doing this, you allow other statements to execute while an I/O statement is executing.

**NOTE**

In order to execute a program that uses asynchronous I/O on Linux* or OS X* systems, you must explicitly include one of the following compiler command line options when you compile and link your program:

- `-threads`
- `-reentrancy threaded`
- `-openmp`

On Windows* systems, no extra options are needed to execute a program that uses asynchronous I/O.

Using the ASYNCHRONOUS Specifier

Asynchronous I/O is supported for all READ and WRITE operations to external files. However, if you specify asynchronous I/O, you cannot use variable format expressions in formatted I/O operations.

To allow asynchronous I/O for a file, first specify `ASYNCHRONOUS='YES'` in its OPEN statement, then do the same for each READ or WRITE statement that you want to execute in this manner.
Execution of an asynchronous I/O statement initiates a "pending" I/O operation, which can be terminated in the following ways:

- by an explicit WAIT (initno) statement, which performs a wait operation for the specified pending asynchronous data transfer operation
- by a CLOSE statement for the file
- by a file-positioning statement such as REWIND or BACKSPACE
- by an INQUIRE statement for the file

Use the WAIT statement to ensure that the objects used in the asynchronous data transfer statements are not prematurely deallocated. (This is especially important for local stack objects and allocatable objects which may be deallocated before completion of the pending operation.) If you do not specify the wait operation, the program may terminate with an Access violation error. The following example shows use of the WAIT statement:

```plaintext
module mod
   real, allocatable :: X(:)
end module mod

subroutine sbr()
use mod
integer :: Y(500)
!X and Y initialization
allocate (X(500))
call foo1(X, Y)
!asynchronous writing
open(1, asynchronous='yes')
write(1, asynchronous='yes') X, Y
!some computation
call foo2()
!wait operation
wait(1)
!X deallocation
deallocate(X)
!stack allocated object Y will be deallocated when the routine returns
end subroutine sbr
```

You can use the INQUIRE statement with the keyword of ASYNCHRONOUS (ASYNCHRONOUS=specifier) to determine whether asynchronous I/O is allowed. If it is allowed, a value of YES is returned.

Additionally, you can use the INQUIRE statement with the keyword of PENDING (PENDING= specifier) to determine whether previously pending asynchronous data transfers are complete.

If an ID= specifier appears and the specified data transfer operation is complete, the variable specified by PENDING is assigned the value False and the INQUIRE statement performs a wait operation for the specified data transfer.

If the ID= specifier is omitted and all previously pending data transfer operations for the specified unit are complete, the variable specified by PENDING is assigned the value False and the INQUIRE statement performs wait operations for all previously pending data transfers for the specified unit.

Otherwise, the variable specified by PENDING is assigned the value True and no wait operations are performed. Previously pending data transfers remain pending.

**Using the ASYNCHRONOUS Attribute**

A data attribute called ASYNCHRONOUS specifies that a variable may be subject to asynchronous input/output. Assigning this attribute to a variable allows certain optimizations to occur.

Programming with Mixed Languages Overview

Mixed-language programming is the process of building programs in which the source code is written in two or more languages. It allows you to:

- Call existing code that is written in another language
- Use procedures that may be difficult to implement in a particular language

In mixed-language programming, a routine written in one language calls a function, procedure, or subroutine written in another language. For example, a Fortran program may need to call an existing shared library or system procedure written in another language.

Although mixed language programming is possible between Intel® Fortran and other languages, the primary focus of this section is programming using Intel® Fortran and C. Mixed language programming between these languages is relatively straightforward for these reasons:

- Fortran implements functions, subroutines, and procedures in approximately the same way as C.
- Fortran provides many standard features to improve interoperability with C. An entity is considered to be interoperable if equivalent declarations are possible in both languages. Interoperability is provided for variables, derived types, and procedures. For more information, see Standard Fortran and C Interoperability.

The following applies to Windows* OS: The Intel® Fortran samples area, created during product installation, contains a number of sample mixed language programs that you can compile and run. For more information, see Using the Intel® Visual Fortran Samples.

Standard Fortran and C Interoperability

The Intel® Fortran Compiler supports the Fortran standardized mechanism for allowing Fortran code to reliably communicate (or interoperate) with C code.

This mechanism includes a group of features for C interoperability, enabling mixed-language programming in a more portable manner.

The Fortran standard discusses interoperability in terms of a "companion C processor." Each Fortran implementation is free to choose which C is its companion. Although the standard explicitly specifies a companion C (not C++) processor, you can use C++, as long as you use features that are compatible with C when interoperating with Fortran.

For Intel® Fortran, the supported C companion is the Intel® C++ Compiler or the Microsoft* Visual C++ Compiler on Windows*, and the Intel® C++ Compiler or gcc* on Linux* and OS X*.

The core principle of interoperability is that something should work the same way in Fortran as it does in C. In terms of interoperability, the following applies:

- Fortran provides a way to reference procedures that are defined by the C programming language or procedures that are described by C prototypes, even if they are not actually defined by means of C.
- Conversely, a procedure defined by a Fortran subprogram can be referenced by a function defined by means of C.
- In addition, you can define global variables that are associated with C variables whose names have external linkage.
- You can also declare Fortran variables, data structures and enumerations that correspond to similar declarations in C.

The following sections describe interoperability requirements for types, variables, procedures, and global data.
Example of Fortran Calling C

The following example calls a C function.

### C Function Prototype Example

```fortran
int C_Library_Function(void* sendbuf, int sendcount, int *recvcounts);
```

### Fortran Module Example

```fortran
module ftn_C_2
    interface
        integer (C_INT) function C_Library_Function &
        (sendbuf, sendcount, recvcounts) &
        BIND(C, name='C_Library_Function')
        use, intrinsic :: ISO_C_BINDING
        implicit none
        type (C_PTR), value :: sendbuf
        integer (C_INT), value :: sendcount
        type (C_PTR), value :: recvcounts
    end function C_Library_Function
end interface
end module ftn_C_2
```

### Fortran Calling Sequence Example

```fortran
use, intrinsic :: ISO_C_BINDING, only: C_INT, C_FLOAT, C_LOC
use ftn_C_2
...
real (C_FLOAT), target :: send(100)
integer (C_INT) :: sendcount
integer (C_INT), ALLOCATABLE, target :: recvcounts(100)
...
ALLOCATE( recvcounts(100) )
...
call C_Library_Function(C_LOC(send), sendcount, &
C_LOC(recvcounts))
...
```

Example of C Calling Fortran

The following example calls a Fortran subroutine called Simulation. This subroutine corresponds to the C void function simulation.

### Fortran Code Example

```fortran
subroutine Simulation(alpha, beta, gamma, delta, arrays) BIND(C)
    use, intrinsic :: ISO_C_BINDING
    implicit none
    integer (C_LONG), value :: alpha
    real (C_DOUBLE), intent(inout) :: beta
    integer (C_LONG), intent(out) :: gamma
    real (C_DOUBLE),dimension(*) ,intent(in) :: delta
    type, BIND(C) :: pass
    integer (C_INT) :: lenc, lenf
    type (C_PTR) :: c, f
    end type pass
    type (pass), intent(inout) :: arrays
    real (C_FLOAT), ALLOCATABLE, target, save :: eta(:)
```
**Fortran Code Example**

```fortran
real (C_FLOAT), pointer :: c_array(:)
...
! Associate c_array with an array allocated in C
call C_F_POINTER (arrays%c, c_array, (/arrays%lenc/) )
...
! Allocate an array and make it available in C
arrays%lenf = 100
ALLOCATE (eta(arrays%lenf))
arrays%f = c_loc(eta)
...
end subroutine Simulation
```

**C Struct declaration Example**

```c
struct pass {int lenc, lenf; float *c, *f;};
```

**C Function Prototype Example**

```c
void simulation(long alpha, double *beta, long *gamma, double delta[], struct pass *arrays);
```

**C Calling sequence Example**

```c
simulation(alpha, &beta, &gamma, delta, &arrays);
```

**Using Standard Fortran Interoperability Syntax for Existing Fortran Extensions**

Before the introduction of the Standard Fortran interoperability features, extensions provided by Intel® Fortran were used to facilitate programming using code written in Fortran and C. The Fortran 2003 standard defined new language features for C interoperability; in many cases, these features can be used instead of existing Intel® Fortran extensions. The following table lists the legacy Intel® Fortran extensions and shows their Standard Fortran equivalents.

**NOTE**

Existing code using legacy extensions will continue to work; however, if you are writing new code, you should use the standard syntax.

<table>
<thead>
<tr>
<th>Legacy Extension</th>
<th>Standard Fortran Interoperability Equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>ATTRIBUTES ALIAS</td>
<td>Use BIND(C,NAME=&quot;alias-name&quot;).</td>
</tr>
<tr>
<td></td>
<td>The BIND(C) syntax also implies ATTRIBUTES DECORATE; the compiler applies whatever name decoration (leading or trailing underscores) that C would use for the name. If the NAME= keyword is omitted, Intel® Fortran will use the Fortran name converted to lowercase on all platforms.</td>
</tr>
<tr>
<td></td>
<td>If the procedure has no arguments, you must indicate that with () when adding BIND.</td>
</tr>
<tr>
<td></td>
<td>All arguments to a routine specified as &quot;interoperable&quot; (with BIND(C)) must themselves be interoperable.</td>
</tr>
<tr>
<td>Legacy Extension</td>
<td>Standard Fortran Interoperability Equivalent</td>
</tr>
<tr>
<td>------------------</td>
<td>---------------------------------------------</td>
</tr>
<tr>
<td>ATTRIBUTES C</td>
<td>You can also specify BIND(C) on module variables and COMMON blocks. Use BIND(C) (see ALIAS above), which has a similar effect to ATTRIBUTES C except that it does not change the argument passing mechanism to be by-value. Use the Fortran standard VALUE attribute if you need to pass by value. BIND(C) also specifies that small records are passed and returned as function value results the same way C would, which may be different from the Intel® Fortran default. Like ATTRIBUTES C, BIND(C) lowercases the external name and adds any necessary name decoration.</td>
</tr>
<tr>
<td>ATTRIBUTES DECORATE</td>
<td>Typically used with ATTRIBUTES ALIAS. See ATTRIBUTES ALIAS above.</td>
</tr>
<tr>
<td>ATTRIBUTES DEFAULT</td>
<td>Not needed when using BIND(C); the compiler always uses the semantics of the C compiler regardless of the setting of command-line options such as iface.</td>
</tr>
<tr>
<td>ATTRIBUTES EXTERN</td>
<td>Use BIND(C) with a module variable.</td>
</tr>
<tr>
<td>ATTRIBUTES REFERENCE</td>
<td>Not needed when using BIND(C). Typically used with character arguments, or to override the implicit pass-by-value of ATTRIBUTES C.</td>
</tr>
<tr>
<td>ATTRIBUTES STDCALL</td>
<td>No equivalent. The use of STDCALL with BIND(C) is supported in Intel® Fortran and, for Windows* on IA-32 architecture only, it changes the external procedure name and stack conventions. For more information, see ATTRIBUTES C and STDCALL.</td>
</tr>
<tr>
<td>ATTRIBUTES VALUE</td>
<td>Use the Fortran-standard VALUE attribute. This has an additional effect when used with a Fortran procedure; the dummy argument is received by value and then copied to a temporary variable that can be modified within the procedure. Once the procedure exits, the temporary value is discarded.</td>
</tr>
<tr>
<td>ATTRIBUTES VARYING</td>
<td>No equivalent.</td>
</tr>
<tr>
<td>%LOC function</td>
<td>Use the C_LOC function from intrinsic module ISO_C_BINDING, which may be an appropriate substitute for variables. C_FUNLOC is the corresponding function for procedures.</td>
</tr>
<tr>
<td>%VAL function</td>
<td>Declare the argument with the VALUE attribute.</td>
</tr>
<tr>
<td>Legacy Extension</td>
<td>Standard Fortran Interoperability Equivalent</td>
</tr>
<tr>
<td>------------------</td>
<td>---------------------------------------------</td>
</tr>
<tr>
<td>%REF function</td>
<td>No equivalent; this is the default when BIND(C) is used.</td>
</tr>
</tbody>
</table>

### Standard Tools for Interoperability

**ISO_C_BINDING**

The intrinsic module provides a set of named constants and procedures that can assist you in programming with mixed languages.

#### Using Intrinsic Module Example

```
USE, INTRINSIC::ISO_C_BINDING
```

There are two groups of named constants included in this intrinsic module -- those that hold kind type parameter values for intrinsic types and those that provide a Fortran equivalent to some of the C special characters, including:

<table>
<thead>
<tr>
<th>Named constant</th>
<th>C definition</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>C_NULL_CHAR</td>
<td>null character</td>
<td>'\0'</td>
</tr>
<tr>
<td>C_ALERT</td>
<td>alert</td>
<td>'\a'</td>
</tr>
<tr>
<td>C_BACKSPACE</td>
<td>backspace</td>
<td>'\b'</td>
</tr>
<tr>
<td>C_FORMFEED</td>
<td>form feed</td>
<td>'\f'</td>
</tr>
<tr>
<td>C_NEW_LINE</td>
<td>new line</td>
<td>'\n'</td>
</tr>
<tr>
<td>C_CARRIAGE_RETURN</td>
<td>carriage return</td>
<td>'\r'</td>
</tr>
<tr>
<td>C_HORIZONTAL_TAB</td>
<td>horizontal tab</td>
<td>'\t'</td>
</tr>
<tr>
<td>C_VERTICAL_TAB</td>
<td>vertical tab</td>
<td>'\v'</td>
</tr>
</tbody>
</table>

The procedures included in ISO_C_BINDING are all generic, not specific. They include:

- C_ASSOCIATED
- C_F_POINTER
- C_F_PROCPOINTER
- C_FUNLOC
- C_LOC
- C_SIZEOF

Additionally, ISO_C_BINDING includes the following derived types to interoperate with C pointers:

- C_PTR
- C_FUNPTR
- C_NULL_PTR
- C_NULL_FUNPTR

**BIND(C)**

Fortran 2003 introduced the `language-binding-spec` attribute, using the keyword BIND. The syntax is:

```
BIND(C [, NAME=scalar-default-char-constant-expr])
```
C is the only language name you can specify. Generally, an entity with the BIND(C) attribute behaves as if it were the corresponding entity in the companion C processor.

The optional NAME= specifier allows you to use a different external name than the one the standard prescribes, which is what the companion C processor would do with the Fortran name forced to lowercase. If the C name was mixed-case, specify the mixed-case name here without any name decoration, such as leading underscores. The compiler applies whatever decoration the C processor would with the same name. So NAME= is not a strict replacement for the ALIAS attribute extension, it is more like ALIAS combined with DECORATE.

BIND(C) is not equivalent to ATTRIBUTES C. Although these both downcase the external name, BIND(C) does not imply pass-by-value and has other effects that are different from ATTRIBUTES C.

You can specify ATTRIBUTES STDCALL for an interoperable procedure (a procedure whose declaration includes the BIND(C) language binding attribute). This combination has the following effects for Windows* applications targeting IA-32 architecture:

- The calling mechanism is changed to STDCALL, which affects how the stack is cleaned up on procedure exit.
- The external name from the BIND attribute is suffixed with @n, where n is the number of bytes to be removed from the stack on return.

No other effects from STDCALL, such as pass-by-value, are provided. The Fortran standard VALUE attribute (not ATTRIBUTES VALUE) may be used if desired. For all other platforms, specifying STDCALL with BIND(C) has no effect. For more information, see ATTRIBUTES C and STDCALL.

**BIND(C) on procedures**

BIND(C) is often used on procedures. It can be specified in INTERFACE blocks to specify the interface of an external interoperable procedure, and on any Fortran procedures that you want to make interoperable. For SUBROUTINES and FUNCTIONs, you need to specify BIND(C) after the argument list. For functions, you can specify BIND(C) before or after the RESULT clause. For example:

```fortran
SUBROUTINE INTEROP_SUB (ARG) BIND(C,NAME="InteropSub")
FUNCTION INTEROP_FUN (ARG) BIND(C,NAME="InteropFun") RESULT (IAMFUN)
```

The above includes an external name, which is not required. You can also specify BIND(C) in a PROCEDURE declaration, in which case it appears in the normal list of attributes before the :: separator.

Specifying BIND(C) for procedures results in the following:

- The external name is what the C compiler would use, with the Fortran name lowercased (unless NAME= is specified).
- Arguments are passed and received by reference (unless the VALUE attribute is specified for the argument).
- Only interoperable arguments are allowed.
- No hidden arguments are allowed.
- Function type must be interoperable and function values are returned exactly as the C compiler would (this mainly affects small derived types).

The standard allows for passing character strings to interoperable procedures. You can pass a character argument of default kind (kind C_CHAR is the default in Intel® Fortran); the corresponding dummy argument is an explicit-shape array of single characters. Because no length is passed, you will need to provide the length another way (usually by appending a NUL character on the end.)

The standard does not provide an easy way to write a Fortran interoperable routine that accepts a string from C. You must declare the dummy argument as an array of single characters. You can use the combination of the C_LOC and C_F_POINTER procedures, both defined in intrinsic module ISO_C_BINDING, to "cast" a character array argument to a Fortran pointer to a character string. An example follows:

```fortran
subroutine Interop_sub(arg) BIND(C)
USE, INTRINSIC :: ISO_C_BINDING
CHARACTER, DIMENSION(*) :: ARG
CALL C_F_POINTER(C_LOC(ARG), LCL_ARG) ! Local pointer to argument
CALL C_F_POINTER(C_LOC(ARG), LCL_ARG)
```
In the above, ARG comes in as an assumed-size array of single characters, with no length. The C_F_POINTER subroutine converts a C pointer to a Fortran pointer. C_LOC is used to get a C pointer (of type C_PTR) of the argument and convert it to the Fortran pointer LCL_ARG. The result is that you can use LCL_ARG as a character string.

In the example, LCL_ARG has an explicit length. There is no way to make this pointer the correct length of the incoming string. Use INDEX to find the location of the NUL character, or some other method, to obtain the length and then use that in subsequent references.

BIND

Interoperating with arguments using C descriptors

These are facilities for interoperable procedure interfaces that specify dummy arguments that are assumed-shape arrays, have assumed character length, or have the ALLOCATABLE, POINTER, or OPTIONAL attributes.

Assumed-rank

An assumed-rank object is a dummy variable whose rank is assumed from its actual argument. This facilitates interoperability with C functions that can accept arguments of arbitrary rank. The intrinsic function, RANK, can be used to obtain the rank of an assumed-rank variable.

A procedure must have an explicit interface if it has a dummy argument that is assumed-rank.

The SHAPE, SIZE, and UBOUND intrinsic functions are defined for an assumed-rank array that is associated with an assumed-size array.

An assumed-rank dummy argument may correspond to an actual argument of any rank. If the actual argument has rank zero, the dummy argument has rank zero; the shape is a zero-sized array and the LBOUND and UBOUND intrinsic functions, with no DIM argument, return zero-sized arrays. If the actual argument has rank greater than zero, the rank and extents of the dummy argument are assumed from the actual argument, including no final extent for an assumed-size array. If the actual argument is an array and the dummy argument has the ALLOCATABLE or POINTER attribute, the bounds of the dummy argument are assumed from the actual argument.

Assumed-type

An assumed-type object is a dummy variable declared as TYPE(*). This simplifies interoperability with C formal parameters of type (void *).

An explicit interface is required for a procedure that has a dummy argument that is assumed-type because an assumed-type dummy argument is polymorphic.

An assumed-type dummy argument must not correspond to an actual argument that is of derived type with type parameters, type-bound procedures, or final subroutines.

CFI_cdesc

A C descriptor is a C structure of type CFI_cdesc that is defined in the file ISO_Fortran_binding.h.

Restrictions for BIND(C)

If BIND(C) is specified for a procedure, each dummy argument must be an interoperable procedure or a variable that is interoperable, assumed shape, assumed rank, assumed type, of assumed character length, or has the ALLOCATABLE or POINTER attribute. If BIND(C) is specified for a function, the function result must be an interoperable scalar variable.

A dummy argument of a procedure that is BIND(C) must not have both the OPTIONAL and VALUE attributes.

A variable that is a dummy argument of a procedure that is BIND(C) must be of interoperable type or assumed type.

A coarray shall not be a dummy argument of a BIND(C) procedure.
The ALLOCATABLE or POINTER attribute must not be specified for a default-initialized dummy argument of a BIND(C) procedure.

**Further Requirements**

Variables with the ASYNCHRONOUS attribute can be used for asynchronous communications between Fortran and C procedures.

When a Fortran procedure that has an INTENT (OUT) allocatable dummy argument is invoked by a C function, and the actual argument in the C function is the address of a C descriptor that describes an allocated allocatable variable, the variable is deallocated on entry to the Fortran procedure. When a C function is invoked from a Fortran procedure via an interface with an INTENT (OUT) allocatable dummy argument, and the actual argument in the reference to the C function is an allocated allocatable variable, the variable is deallocated on invocation (before execution of the C function begins).

**ISO_Fortran_binding.h**

The types, macros, and functions declared in ISO_Fortran_binding.h can be used by a C function to interpret C descriptors and allocate and deallocate objects represented by C descriptors. These provide a means to specify a C prototype that interoperates with a Fortran interface that has an allocatable, assumed character length, assumed-rank, assumed-shape, or data pointer dummy argument.

The ISO_Fortran_binding.h is a C header file that contains these definitions:

- The C structures CFI_cdesc_t and CFI_dim_t
- The typedef definitions for CFI_attribute_t, CFI_index_t, CFI_rank_t, and CFI_type_t
- The macro CFI_CDESC_T and macro definitions that expand to integer constants with various useful values
- The C function prototypes or macro definitions for CFI_address, CFI_allocate, CFI_deallocate, CFI_establish, CFI_is_contiguous, CFI_section, CFI_select_part, and CFI_setpointer. Some of these functions return an error indicator; this is an integer value that indicates whether an error condition was detected. The value zero CFI_SUCCESS indicates that no error condition was detected, and a nonzero value indicates which error condition was detected. The "Macros and typedefs in ISO_Fortran_binding.h" section lists the standard error conditions and the macro names for their corresponding error codes.

In function arguments representing subscripts, bounds, extents, or strides, the ordering of the elements is the same as the ordering of the elements of the dim member of a C descriptor.

**Restrictions on C functions interoperating with Fortran procedures**

Any C function inter-operating with Fortran procedures must meet these restrictions:

- A C descriptor shall not be initialized, updated, or copied other than by calling the functions in ISO_Fortran_binding.h.
- If the address of a C descriptor is a formal parameter that corresponds to a Fortran actual argument or is a C actual argument that corresponds to a Fortran dummy argument,
  - the C descriptor shall not be modified if either the corresponding dummy argument in the Fortran interface has the INTENT(IN) attribute or the C descriptor is for a nonallocatable nonpointer object, and
  - the base_addr member of the C descriptor shall not be accessed before it is given a value if the corresponding dummy argument in the Fortran interface has the POINTER and INTENT(OUT) attributes.

In this context, modification refers to any change to the location or contents of the C descriptor, including establishing and updating. The intent of these restrictions is that the C descriptors will remain intact at all times that they are accessible to an active Fortran procedure, so that the Fortran code is not required to copy them.
Within a C function, an allocatable object shall be allocated or deallocated only by execution of the `CFI_allocate` and `CFI_deallocate` functions. A Fortran pointer can become associated with a target by execution of the CFI allocate function.

Calling `CFI_allocate` or `CFI_deallocate` for a C descriptor changes the allocation status of the Fortran variable it describes and causes the allocation status of any associated allocatable variable to change accordingly.

If the address of an object is the value of a formal parameter that corresponds to a nonpointer dummy argument in a BIND(C) interface, then

- if the dummy argument has the INTENT (IN) attribute, the object must not be defined or become undefined, and
- if the dummy argument has the INTENT (OUT) attribute, the object must not be referenced before it is defined.

When a Fortran object is deallocated, or execution of its host function is completed, or its association status becomes undefined, all C descriptors and C pointers to any part of it become undefined, and any further use of them is undefined behavior.

A C descriptor whose address is a formal parameter that corresponds to a Fortran dummy argument becomes undefined on return from a call to the function from Fortran. If the dummy argument does not have either the TARGET or ASYNCHRONOUS attribute, all C pointers to any part of the object described by the C descriptor become undefined on return from the call, and any further use of them is undefined behavior.

When a Fortran object is deallocated, or execution of its host function is completed, or its association status becomes undefined, all C descriptors and C pointers to any part of it become undefined, and any further use of them is undefined behavior.

If the address of a C descriptor is passed as an actual argument to a Fortran procedure, the C lifetime of the C descriptor shall not end before the return from the procedure call.

If an object is passed to a Fortran procedure as a nonallocatable, nonpointer dummy argument, its lifetime shall not end before the return from the procedure call.

If the lifetime of a C descriptor for an allocatable object that was established by C ends before the program exits, the object shall be unallocated at that time.

If a Fortran pointer becomes associated with a C object, the association status of the Fortran pointer becomes undefined when the lifetime of the C object ends.

C Structures, Typedefs, and Macros for Interoperability

C Structures, Typedefs, and Macros for Interoperability

The C structures `CFI_dim_t` and `CFI_cdesc_t`

`CFI_dim_t` is a typedef name for a C structure. It is used to represent lower bound, extent, and memory stride information for one dimension of an array. `CFI_dim_t` contains at least the following members in any order:

- `CFI_index_t lower_bound` - The value of the lower bound for the dimension being described.
- `CFI_index_t extent` - The value is the number of elements in the dimension being described or -1 for the last dimension of an assumed-size array.
- `CFI_index_t sm` - The value is the memory stride for a dimension; this is the difference in bytes between the addresses of successive elements in the dimension being described.

`CFI_cdesc_t` is a typedef name for a C structure, which contains a flexible array member. The first three members of the structure are `base_addr`, `elem_len`, and `version` in that order. The final member is `dim`. All other members must be between `version` and `dim`, in any order.
void * base_addr – If the object Interoperating with arguments using C descriptors is an unallocated allocatable variable or a pointer that is disassociated, the value is a null pointer. If the object has zero size, the value is not a null pointer but is processor-11 dependent. Otherwise, the value is the base address of the object being described. The base address of a scalar is its C address. The base address of an array is the C address of the first element in Fortran array element order.

size_t elem_len – If the object is a scalar, the value is the storage size in bytes of the object; otherwise, the value is the storage size in bytes of an element of the object.

int version – The value is the value of CFI_VERSION in the source file ISO_Fortran_binding.h that defined the format and meaning of this C descriptor when the descriptor was established.

CFI_rank_t rank – The value is the number of dimensions of the Fortran object being described; if the object is a scalar, the value is zero.

CFI_type_t type – The value is the specifier for the type of the object. Each interoperable intrinsic C type has a specifier. Specifiers are also provided to indicate that the type of the object is an interoperable structure, or is unknown. The macros listed in the table below provide values that correspond to each type code specifier.

<td>void *</td>
</tr>
<tr>
<td>CFI_type_struct</td>
<td>interoperable C structure</td>
</tr>
<tr>
<td>CFI_type_other</td>
<td>not otherwise specified</td>
</tr>
</tbody>
</table>
• The value for CFI_type_other is negative and distinct from all other type specifiers.
• CFI_type_struct specifies a C structure that is interoperable with a Fortran derived type; its value is positive and distinct from all other type specifiers.
• If a C type is not interoperable with a Fortran type and kind supported by the Fortran processor, its macro evaluates to a negative value.
• Otherwise, the value for an intrinsic type is positive.
• CFI_attribute_t attribute - The value is the value of an attribute code that indicates whether the object described is allocatable, a data pointer, or a nonallocatable, nonpointer data object. The values are nonnegative and distinct.

The macros listed in the table below provide values that correspond to each attribute code.

**Macros for Attribute Codes**

<table>
<thead>
<tr>
<th>Macro</th>
<th>Attribute code indicated</th>
</tr>
</thead>
<tbody>
<tr>
<td>CFI_attribute_pointer</td>
<td>data pointer object</td>
</tr>
<tr>
<td>CFI_attribute_allocatable</td>
<td>allocatable object</td>
</tr>
<tr>
<td>CFI_attribute_other</td>
<td>nonallocatable, nonpointer object</td>
</tr>
</tbody>
</table>

• CFI_attribute_pointer specifies a data object with the Fortran POINTER attribute.
• CFI_attribute_allocatable specifies an object with the Fortran ALLOCATABLE attribute.
• CFI_attribute_other specifies a nonallocatable nonpointer object.
• CFI_dim_t dim - The number of elements in the dim array is equal to the rank of the object. Each element of the array contains the lower bound, extent, and memory stride information for the corresponding dimension of the Fortran object.

For a C descriptor of an array pointer or allocatable array, the value of the lower_bound member of each element of the dim member of the descriptor is determined by argument association, allocation, or pointer association. For a C descriptor of a nonallocatable nonpointer object, the value of the lower_bound member of each element of the dim member of the descriptor is zero.

In a C descriptor of an assumed-size array, the extent member of the last element of the dim member has the value -1. The value of elem_len for a Fortran CHARACTER object is equal to the character length times the number of bytes of a single character of that kind. If the kind is C_CHAR, this value will be equal to the character length.

**Macros and typedefs in ISO_Fortran_binding.h**

Except for CFI_CDESC_T, each macro defined in ISO_Fortran_binding.h expands to an integer constant expression that is either a single token or a parenthesized expression that is suitable for use in #if preprocessing directives.

CFI_CDESC_T is a function-like macro that takes one argument, which is the rank of the C descriptor to create, and evaluates to an unqualified type of suitable size and alignment for defining a variable to use as a C descriptor of that rank. The argument shall be an integer constant expression with a value that is greater than or equal to zero and less than or equal to CFI_MAX_RANK. A pointer to a variable declared using CFI_CDESC_T can be cast to CFI_cdesc_t *. A variable declared using CFI_CDESC_T must not have an initializer.

The CFI_CDESC_T macro provides the memory for a C descriptor. The address of an entity declared using the macro is not usable as an actual argument corresponding to a formal parameter of type CFI_cdesc_t * without an explicit cast.

CFI_index_t is a typedef name for a standard signed integer type capable of representing the result of subtracting two pointers.

The CFI_MAX_RANK macro has a value equal to the largest rank supported, i.e., 31. CFI_rank_t is a typedef name for a standard integer type capable of representing the largest supported rank.
The CFI_VERSION macro has a processor-dependent value that encodes the version of the ISO_Fortran_binding.h source file containing this macro. This value is increased if a new version of the source file is incompatible with the previous version.

CFI_attribute_t is a typedef name for a standard integer type capable of representing the values of the attribute codes.

CFI_type_t is a typedef name for a standard integer type capable of representing the values for the supported type specifiers.

The macros in the table below are for use as error codes. The macro CFI_SUCCESS is the integer constant 0. The value of each macro other than CFI_SUCCESS is nonzero and is different from the values of the other error code macros.

Interoperating with arguments using C descriptors

**Data Types**

### Data Types Overview

While Fortran and C each support many of the same basic data types, there are no direct correlations. One difference is that Fortran has the concept of "kinds;" C treats these distinct types. For example, consider the Fortran INTEGER type. C has numerous integer types, from short int to long long int, and some specialty types such as intptr_t. These may or may not have corresponding kinds in Fortran. For each of the C integer types that might be interoperable, ISO_C_BINDING declares a named constant (PARAMETER) giving the kind number for the implementation's equivalent INTEGER kind.

Consider the simple C int type. This corresponds to INTEGER(C_INT), where C_INT is defined in ISO_C_BINDING. In Intel® Fortran, the value is always four (4), as a C int corresponds with Fortran INTEGER(4). However, other Fortran implementations may use different kind numbers; using the named constant ensures portability.
Now consider the `intptr_t` type. This is an integer that is large enough to hold a pointer (address). In Intel® Fortran, this is `INTEGER(4)` when building a 32-bit application and `INTEGER(8)` when building a 64-bit application. Intel® Fortran provides different copies of ISO_C_BINDING for various platforms.

Fortran has no unsigned integer types, so there are no constants for C unsigned types. Such types are not interoperable.

If there is a "kind" of C type not supported by the Fortran implementation, the named constant for that type is defined as -1, which will generate a compile-time error if you try to use it.

Similarly, there are constants defined for REAL, COMPLEX, LOGICAL and CHARACTER. For REAL, the standard offers the possibility of a C `long double` type. This is implemented in different ways by various C compilers on various platforms supported by Intel® Fortran.

- **gcc* on 32-bit Linux**: `long double` is an 80-bit floating type, as supported by the X87 instruction set. Intel® Fortran does not support this, so `C_LONG_DOUBLE` is -1.
- **gcc on OS X**: `C_LONG_DOUBLE` is defined as a 128-bit type that is the same as the Intel® Fortran data type `REAL(16)`.
- **64-bit Linux* and Windows***: `long double` is treated the same as `double`, so `C_LONG_DOUBLE` is 8.

To ensure matching, make sure you use the constants for kind values and the corresponding types in C.

LOGICAL and CHARACTER need special treatment for interoperability. The Fortran standard states that LOGICAL corresponds to the (ISO_C_BINDING) C `_Bool` type, and defines a single kind value `C_BOOL`, which is 1 in Intel® Fortran. By default, Intel® Fortran, tests LOGICALs for true/false differently than C does. Where C uses zero for false and not-zero for true, Intel® Fortran defaults to using -1 (all bits set) as true and zero as false. If you are going to use LOGICAL types to interoperate with C, be sure to specify the option `fpscomp[:logicals]`, which changes the interpretation to be C-like. This is included if you use the option `standard-semantics`, which is recommended any time you use Fortran 2003 (or later) features.

In terms of CHARACTER, C does not have character strings. It has arrays of single characters, so this is how you must represent strings in Fortran. There is a kind value defined, `C_CHAR`, corresponding to the C `char` type. Only character variables with length of one (1) are interoperable. For further discussion, see Procedures.

Derived types can also be interoperable. For additional information and restrictions, see Derived Types.

Derived Types
Scalar Types

The commonly used types are included in the following table. The following applies:

- Integer types in Fortran are always signed. In C, integer types may be specified as signed or unsigned, but are signed by default.
- The values of `C_LONG`, `C_SIZE_T`, `C_LONG_DOUBLE`, and `C_LONG_DOUBLE_COMPLEX` are different on different platforms.

<tr>
<td>char</td>
<td>CHARACTER(LEN=1)</td>
</tr>
</tbody>
</table>

While there are named constants for all possible C types, every type is not necessarily supported on every processor. Lack of support is indicated by a negative value for the constant in the module.

For a character type to be interoperable, you must either omit the length type parameter or specify it using an initialization expression whose value is one.

Characters

The C language does not have character strings. Instead, it has arrays of single characters, so this is how you must represent a character string in Fortran.

There is a kind value defined, C_CHAR, corresponding to the C char type. However, only character variables with a length of one (1) are interoperable.

The following shows a Fortran program passing a string to a C routine and the C routine calling a Fortran routine with a new string.

Fortran Program Example

```fortran
program demo_character_interop
  use, intrinsic :: iso_c_binding
  implicit none

  interface
  subroutine c_append (string) bind(C)
    character(len=1), dimension(*), intent(in) :: string
  end subroutine c_append
  end interface

  ! Call C routine passing an ordinary character value
  ! The language allows this to match an array of
```
Fortran Program Example

```fortran
! single characters of default kind
call c_append('Intel Fortran'//C_NULL_CHAR)
end program demo_character_interop

subroutine fort_print (string) bind(C)
  use, intrinsic :: iso_c_binding
  implicit none
  ! Must declare argument as an array of single characters
  ! in order to be "interoperable"
  character(len=1), dimension(100), intent(in) :: string
  integer s_len ! Length of string
  character(100), pointer :: string1
  character(100) :: string2
  ! One way to convert the array to a character variable
  call C_F_POINTER(C_LOC(string),string1)
  s_len = INDEX(string1,C_NULL_CHAR) - 1
  print *, string1(1:s_len)
  ! Another way to convert
  string2 = TRANSFER(string,string2) ! May move garbage if source length < 100
  s_len = INDEX(string2,C_NULL_CHAR) - 1
  print *, string2(1:s_len)
end subroutine fort_print
```

C Routine Example

```c
C module (c_append.c):
#include <string.h>
extern void fort_print(char * string); /* Fortran routine */
void c_append (char * string) {
  char mystring[100];
  strcpy(mystring, string);
  strcat(mystring, " interoperates with C");
  /* Call Fortran routine passing new string */
  fort_print (mystring);
  return;
}
```

Pointers

For interoperating with C pointers, the module ISO_C_BINDING contains the derived types C_PTR and C_FUNPTR, which are interoperable with C object and function type pointers, respectively.

These types, as well as certain procedures in the module, provide the mechanism for passing dynamic arrays between the two languages. Because its elements do not need to be contiguous in memory, a Fortran pointer target or assumed-shape array cannot be passed to C. However, you can pass an allocated allocatable array to C, and you can associate an array allocated in C with a Fortran pointer. Additionally, as shown in the following, you can convert a pointer in C format to one in Fortran format.

Fortran Program Example

```fortran
program demo_c_f_pointer
  use, intrinsic :: iso_c_binding
  implicit none
end program demo_c_f_pointer
```
### Fortran Program Example

```fortran
interface
    function make_array(n_elements) bind(C)
        import ! Make iso_c_binding visible here
        type(C_PTR) :: make_array
        integer(C_INT), value, intent(IN) :: n_elements
    end function make_array
end interface

type(C_PTR) :: cptr_to_array
integer(C_INT), pointer :: array(:) => NULL()
n_elements = 3 ! Number of elements

! Call C function to create and populate an array
cptr_to_array = make_array(n_elements)
! Convert to Fortran pointer to array of n_elements elements
call C_F_POINTER (cptr_to_array, array, [n_elements])
! Print value
print *, array

end program demo_c_f_pointer
```

### C Module Example

```c
#include <stdlib.h>
int *make_array(int n_elements) {
    int *parray;
    int i;
    parray = (int*) malloc(n_elements * sizeof(int));
    for (i = 0; i < n_elements; i++) {
        parray[i] = i+1;
    }
    return parray;
}
```

### Derived Types

For a derived type to be interoperable with C, you must specify the BIND attribute, as shown in the following:

#### Specifying BIND Example

```fortran
type, BIND(C) :: MyType
```

Additionally, as shown in the examples that follow, each component must have an interoperable type and interoperable type parameters, must not be a pointer, and must not be allocatable. This allows Fortran and C types to correspond.

#### Interoperable Type and Type Parameter Example

```c
typedef struct {
    int m, n;
    float r;
} MyCtype
```

The above is interoperable with the following:
### Interoperable Type and Type Parameter Example

```fortran
use, intrinsic :: ISO_C_BINDING
type, BIND(C) :: MyFtype
integer(C_INT) :: i, j
real(C_FLOAT) :: s
end type MyFtype
```

The following restrictions apply to a derived type specified with the BIND attribute:

- It cannot have the SEQUENCE attribute
- It cannot be an extended type
- It cannot have type-bound procedures

### Variables

A scalar Fortran variable is interoperable if its type and type parameters are interoperable and it is not a pointer.

An array Fortran variable is interoperable if its type and type parameters are interoperable and it has an explicit shape or assumed size. It interoperates with a C array of the same type, type parameters, and shape, but with subscripts reversed.

For example, a Fortran array declared as `integer :: a(18, 3:7, *)` is interoperable with a C array declared as `int b[][5][18]`.

Scalar variables are interoperable only if their type parameters (kind and length) are interoperable (see above), they are not a coarray, do not have the POINTER or ALLOCATABLE attribute, and if character length is not assumed nor defined by a non-constant expression.

Arrays are interoperable if the base type meets the scalar variable requirements above, if they are explicit shape or assumed-size, and are not zero-sized. Furthermore, assumed-size arrays are interoperable only with C arrays that have no size specified. An allocatable array, coarray, or array pointer is not interoperable.

### Global Data

**Global Data Overview**

A module variable or a common block can interoperate with a C global variable if the Fortran entity uses the BIND attribute and the members of that entity are also interoperable. For example, consider the entities `c_extern, c2, com` and `single` in the following module:

```fortran
module LINK_TO_C_VARS
  use, intrinsic :: ISO_C_BINDING
  integer(C_INT), BIND(C) :: c_extern
  integer(C_LONG) :: c2
  BIND(C, name='myVariable') :: c2
  common /com/ r,s
  real(C_FLOAT) :: r,s,t
  BIND(C) :: /com/, /single/
  common /single/ t
end module LINK_TO_C_VARS
```
These can interoperate with the following C external variables

```c
int cExtern;
long myVariable;
struct {float r, s;} com;
float single;
```

### Accessing Global Parameters Example

```fortran
MODULE Examp
  integer, BIND(C)::idata(20)
  real::rdata(10)
END MODULE
```

In Fortran, a variable can access a global parameter by using the standard **BIND C** attribute.

In the above, two external variables are created (the latter with proper case and decoration): `idata` and `foo_mp_rdata`.

Use the `BIND` attribute to resolve name discrepancies with C.

### Global Variable Statement Example

```fortran
int idata[20]; // declared as global (outside of any function)
```

**Fortran can declare the variable global (COMMON) and other languages can reference it as external**

```fortran
! Fortran declaring PI global
real pi_r
COMMON /pi/ pi_r ! Common Block and variable names
BIND(C)::/pi/
```

Use of `BIND(C)` above means that the name will be appropriately decorated for the target and made lowercase.

**In C, the variable is referenced as an external with the statement**

```c
//C code with external reference to pi
extern float pi;
```

Note that the global name C references is the name of the Fortran common block (`pi`), not the name of a variable within a common block (`pi_r`). Therefore, you cannot use blank common (unnamed) to make data accessible between C and Fortran.

**See Also**

**BIND Statement and Attribute**: Specifies that an object is interoperable with C and has external linkage.

**COMMON**

To reference C structures from Fortran common blocks and vice versa, you must take into account how common blocks and structures differ in their methods of storing member variables in memory. Fortran places common block variables into memory in order as close together as possible, with the following rules:

- A single BYTE, INTEGER(1), LOGICAL(1), or CHARACTER variable in common block list begins immediately following the previous variable or array in memory.
- All other types of single variables begin at the next even address immediately following the previous variable or array in memory.
- All arrays of variables begin on the next even address immediately following the previous variable or array in memory, except for CHARACTER arrays which always follow immediately after the previous variable or array.
All common blocks begin on a four-byte aligned address.

Because of these rules, you must consider the alignment of C structure elements with Fortran common block elements. Specifically, you should ensure interoperability either by making all variables exactly equivalent types and kinds in both languages (using only 4-byte and 8-byte data types in both languages simplifies this) or by using the C pack pragmas in the C code around the C structure. This makes C data packing compatible with Fortran data packing.

As an example, suppose your Fortran code has a common block named `Really`, as shown:

```fortran
USE, INTRINSIC::ISO_C_BINDING
REAL (C_float)::x,y,z(6)
REAL (C_double)::ydbl
COMMON, BIND(C) / Really / x, y, z(6), ydbl
```

You can access this data structure from your C code with the following external data structures.

```c
#pragma pack(2)
extern struct {
    float x, y, z[6];
    double ydbl;
} Really;
#pragma pack()
```

To restore the original packing, you must add `#pragma pack()` at the end of the C structure.

You can also access C structures from Fortran by creating common blocks that correspond to those structures. This is the reverse case from that shown above. However, the implementation is the same; after common blocks and structures have been defined and given a common address (name), and, assuming the alignment in memory has been accounted for, both languages share the same memory locations for the variables.

Once you have accounted for alignment and padding, you can give C access to an entire common block or set of common blocks. Alternatively, you can pass individual members of a Fortran common block in an argument list, just as you can any other data item.

**Procedures**

For a Fortran procedure to be interoperable with C, it must have an explicit interface and be declared with the `BIND` attribute, as shown in the following:

```fortran
function Func(i, j, k, l, m) BIND(C)
```

In the case of a function, the result must be scalar and interoperable.

A procedure has an associated binding label, which is global in scope. This label is the name recognized by the C processor and is, by default, the lower-case version of the Fortran name (plus any needed leading or trailing underscores). For example, the above function has the binding label `func`. You can specify an alternative binding label as follows:

```fortran
function Func(i, j, k, l, m) BIND(C, name='myC_Func')
```

All dummy arguments must be interoperable. Furthermore, you must ensure that either the Fortran routine uses the `VALUE` attribute for scalar dummy arguments, or that the C routine receives these scalar arguments as pointers to the scalar values. Consider the following call to this C function:
Call to C Function Example

```c
int c_func(int x, int *y);
```

As shown here, the interface for the Fortran call to `c_func` must have `x` passed with the `VALUE` attribute. `y` should not have the `VALUE` attribute, since it is received as a pointer:

### Fortran Call Example

```fortran
interface
  integer (C_INT) function C_Func(x, y) BIND(C)
  use, intrinsic :: ISO_C_BINDING
  implicit none
  integer (C_INT), value :: x
  integer (C_INT) :: y
  end function C_Func
end interface
```

Alternatively, the declaration for `y` can be specified as a `C_PTR` passed by value:

### Passing Pointer by Value Example

```fortran
type (C_PTR), value :: y
```

### Platform Specifics

**Summary of Mixed-Language Issues**

There are important differences in Fortran and C/C++ mixed-language programming; for instance, argument passing, naming conventions, and other interface issues must be thoughtfully and consistently reconciled between any two languages to prevent program failure and indeterminate results. However, the advantages of mixed-language programming often make the extra effort worthwhile.

A summary of major Fortran and C/C++ mixed-language issues follows:

- Generally, Fortran/C programs are mixed to allow one language to use existing code written in the other. Either Fortran or C can call the other, so the main routine can be in either language. On Linux* and OS X* systems, if Fortran is not the main routine, the `-nofor-main` compiler option must be specified on the `ifort` command line that links the application.

- When the main program is written in Fortran, the Fortran compiler automatically creates any code needed to initialize the Fortran Run-time Library (RTL). The RTL provides the Fortran environment for input/output and exception handling. When the main program is written in C/C++, the C main program needs to call `for_rtl_init_` to initialize the Fortran RTL and `for_rtl_finish_` at the end of the C main program to shut down the Fortran RTL gracefully. With the Fortran RTL initialized, Fortran I/O and error handling will work correctly even when C/C++ routines are called.

- For mixed-language applications, the Intel® Fortran main program can call subprograms written in C/C++ if the appropriate calling conventions are used.

  To use the same Microsoft* visual development environment for multiple languages, you must have the same version of the visual development environment for your languages.

- On Linux* and OS X* systems, Fortran adds an underscore to the end of external names; C does not.

- Fortran changes the case of external names to lowercase on Linux* and OS X* and to uppercase on Windows*; C leaves them in their original case.

- By default, Fortran passes data by reference; C by value. In both languages, the other method can be specified.
NOTE
It is possible to override some default Fortran behavior by using BIND(C) specifier. This is the preferred method. You can also override default Fortran behavior by using ATTRIBUTES and ALIAS.

- Fortran subroutines are equivalent to C void routines.
- Fortran requires that the length of strings be passed; C is able to calculate the length based on the presence of a trailing null. Therefore, if Fortran is passing a string to a C routine, that string needs to be terminated by a null; for example:
  "mystring"c or StringVar // CHAR(0)
- For COMPLEX, REAL*16, CHARACTER, derived types and ALLOCATABLE or array data types, Fortran adds a hidden first argument to contain function return values.
- On Linux®, the -fexceptions option enables C++ exception handling table generation, preventing Fortran routines in mixed-language applications from interfering with exception handling between C++ routines.
- For more information on debugging mixed language programs on Windows®, see Debugging Mixed-Language Programs.

Calling Subprograms from the Main Program (Windows*)
In mixed-language applications, an Intel® Visual Fortran main program can call subprograms written in a variety of languages. Conversely, an Intel® Visual Fortran subprogram (including those contained within a DLL or static library) can be called from a main program written in another language.

Windows® projects support a single language; therefore, code for each language must exist in its own project.

This topic summarizes mixed language compatibility with Intel® Visual Fortran for both managed code and unmanaged code. Managed code is architecture-independent code that runs under the control of the Microsoft® .NET Common Language Runtime Environment; unmanaged code is native, architecture-specific code.

Mixed-language applications can supply programs in a variety of formats:

<table>

Passing Arguments in Mixed-Language Programming
By default, Fortran programs pass arguments by reference; that is, they pass a pointer to each actual argument rather than the value of the argument. C programs typically pass arguments by value. Consider the following:
• When a Fortran program calls a C function, the C function's formal arguments must be declared as pointers to the appropriate data type.
• When a C program calls a Fortran subprogram, each actual argument must be specified explicitly as a pointer.

You can pass data between Fortran and C/C++ using argument lists just as you can within each language (for example, the argument list \( a, b \) and \( c \) in `CALL MYSUB(a,b,c)`). There are two ways to pass individual arguments:

• *By value*, which passes the argument's value.
• *By reference*, which passes the address of the arguments. On systems based on IA-32 architecture, Fortran, C, and C++ use 4-byte addresses. On systems based on Intel® 64 architecture, these languages use 8-byte addresses.

You need to make sure that for every call, the calling program and the called routine agree on how each argument is passed. Otherwise, the called routine receives bad data.

The Fortran technique for passing arguments changes depending on the calling convention specified. By default, Fortran passes all data by reference (except the hidden length argument of strings, which is passed by value).

On Windows® systems using IA-32 architecture only, you can alter the default calling convention. You can use either the `/iface:stdcall` option (stdcall) or the `/iface:cvf` option (Compaq® and Powerstation compatibility) to change the default calling convention, or the VALUE or C attributes in an explicit interface using the ATTRIBUTES directive. For more information on the ATTRIBUTES directive, see the Intel® Fortran Language Reference.

Both options cause the routine compiled and routines that it calls to have a `@<n>` appended to the external symbol name, where \( n \) is the number of bytes of all parameters. Both options assume that any routine called from a Fortran routine compiled this way will do its own stack cleanup, "callee pops." `/iface:cvf` also changes the way that CHARACTER variables are passed. With `/iface:cvf`, CHARACTER variables are passed as address/length pairs (that is, `/iface:mixed_str_len_arg`).

Handling Fortran Array Pointers and Allocatable Arrays

Stack Considerations in Calling Conventions (Windows®)

In the C calling convention, which is the default, the calling routine always adjusts the stack immediately after the called routine returns control. This produces slightly larger object code because the code that restores the stack must exist at every point a procedure is called.

**NOTE**
For 32-bit applications, use of the STDCALL calling convention means that the called procedure controls the stack. The code to restore the stack resides in the called procedure, so the code needs to appear only once. For 64-bit applications, the stack adjustment and @n name suffix features of STDCALL are not used.

The C calling convention makes calling with a variable number of arguments possible. In the C calling convention, the caller cleans up the stack, so it is possible to write a routine with a variable number of arguments. Therefore, the return point has the same address relative to the frame pointer, regardless of how many arguments are actually passed. Because of this, when the calling routine controls the stack, it knows how many arguments it passed, how big they are and where they reside in the stack. It can skip passing an argument and still keep track.

You can call routines with a variable number of arguments by including the ATTRIBUTES C option in your interface to a routine.

**Naming Conventions**
Naming conventions are as follows:
• A leading (prefix) underscore for Windows* operating systems based on IA-32 architecture; no underscores for Windows* operating systems based on other architectures.
• A trailing (postfix) underscore for all Linux* operating systems
• Leading and trailing underscores for all OS X* operating systems

C/C++ Naming Conventions

By default, the Fortran compiler converts function and subprogram names to lower case for Linux* and OS X* and upper case for Windows*. The C compiler never performs case conversion. A C procedure called from a Fortran program must, therefore, be named using the appropriate case.

C++ uses the same calling convention and argument-passing techniques as C, but naming conventions differ because of C++ decoration of external symbols. When the C++ code resides in a .cpp file, C++ name decoration semantics are applied to external names, often resulting in linker errors. The extern "C" syntax makes it possible for a C++ module to share data and routines with other languages by causing C++ to drop name decoration.

The following example declares prn as an external function using the C naming convention. This declaration appears in C++ source code:

```cpp
extern "C" { void prn(); }
```

To call functions written in Fortran, declare the function as you would in C and use a "C" linkage specification. For example, to call the Fortran function FACT from C++, declare it as follows:

```cpp
extern "C" { int fact(int* n); }
```

The extern "C" syntax can be used to adjust a call from C++ to other languages, or to change the naming convention of C++ routines called from other languages. However, extern "C" can only be used from within C++. If the C++ code does not use extern "C" and cannot be changed, you can call C++ routines only by determining the name decoration and generating it from the other language. Such an approach should only be used as a last resort, because the decoration scheme is not guaranteed to remain the same between versions.

When using extern "C" in a C++ program, keep in mind the following restrictions:

• You cannot declare a member function with extern "C".
• You can specify extern "C" for only one instance of an overloaded function; all other instances of an overloaded function have C++ linkage.

Compiling and Linking Intel® Fortran/C Programs

Your application can contain both C and Fortran source files. If your main program is a Fortran source file (myprog.for) that calls a routine written in C (cfunc.c), you can use the following sequence of commands to build your application.

Linux* and OS X*:

```bash
icc -c cfunc.c
ifort -o myprog myprog.for cfunc.o
```

Windows*:

```bash
icl /c cfunc.c
ifort myprog.for cfunc.obj
/link /out:myprog.exe
```

The `icc` or `icl` command for Intel® C++ or the `cl` command (for Microsoft Visual C++) compiles `cfunc.c`. The `-c` or `/c` option specifies that the linker is not called. This command creates `cfunc.o` (Linux* and OS X*) or `cfunc.obj` (Windows*).

The `ifort` command compiles `myprog.for` and links `cfunc.o` (Linux* and OS X*) or `cfunc.obj` (Windows*) with the object file created from `myprog.for` to create the executable.

Additionally, on Linux* and OS X* systems, you may need to specify one or more of the following options:

• Use the `-cxxlib` compiler option to tell the compiler to link using the C++ run-time libraries. By default, C++ libraries are not linked with Fortran applications.
• Use the -fexceptions compiler option to enable C++ exception handling table generation so C++ programs can handle C++ exceptions when there are calls to Fortran routines on the call stack. This option causes additional information to be added to the object file that is required during C++ exception handling. By default, mixed Fortran/C++ applications abort in the Fortran code if a C++ exception is thrown.

• Use the -nofor_main compiler option if your C/C++ program contains the main() entry point and is calling an Intel® Fortran subprogram, as shown in the following:

```bash
icc -c cmain.c
ifort -nofor_main cmain.o fsub.f90
```

For more information about compiling and linking Intel® Fortran and C++ programs on Windows* operating systems, and the libraries used, see Specifying Consistent Library Types.

**Building Intel® Fortran/C Mixed-Language Programs (Windows*)**

When you understand and reconcile the calling, naming and argument passing conventions between Fortran and C, you are ready to build an application.

If you are using Microsoft Visual C++* or Intel® C++, you can edit, compile and debug your code within the Microsoft integrated development environment. If you are using another C compiler, you can edit your code within the integrated development environment and either build the Fortran/C program on the command line or add the compiled C .OBJ file to your Fortran project in the Microsoft IDE.

As an example of building from the command line, if you have a main C program CMAIN.C that calls Fortran subroutines contained in FORSUBS.F90, you can create the CMAIN application with the following commands:

```bash
icl /c cmain.c
ifort cmain.obj forsubs.f90
```

Intel® Visual Fortran accepts an object file for the main program written in C and compiled by the C compiler. The compiler compiles the .F90 file and then has the linker create an executable file under the name CMAIN.EXE using the two object files.

Either compiler (C or Fortran) can do the linking, regardless of which language the main program is written in; however, if you use the Fortran compiler first, you must include LIBIFCORE.LIB and IFCONSOL.LIB with the C compiler, and you may experience some difficulty with the version of the runtime library used by the C compiler. For these reasons, you may prefer to use the C compiler first or specify your project settings for both Fortran and C so there is agreement on the C library to link against, making sure that your application links against only one copy of the C library.

If you are using the IDE to build your application, Fortran uses Fortran and C libraries depending on the information specified in the Fortran folder in Project > Properties (Project Settings dialog box). You can also specify linker settings with the Linker folder in the Project Settings dialog box.

In the Fortran folder, within the Libraries property page, the RunTime Library category determines the libraries selected.

<table>
<thead>
<tr>
<th>RunTime Library</th>
<th>Fortran Link Library Used</th>
<th>C Link Library Used</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug Single-Threaded</td>
<td>libifcore.lib</td>
<td>libcmtld.lib</td>
</tr>
<tr>
<td>Multithreaded</td>
<td>libifcoremt.lib</td>
<td>libcmt.lib</td>
</tr>
<tr>
<td>Debug Multithreaded</td>
<td>libifcoremt.lib</td>
<td>libcmtld.lib</td>
</tr>
<tr>
<td>Debug Single-Threaded DLL</td>
<td>libifcoretd.lib (libifcoretd.dll)</td>
<td>msvcrtd.lib (msvcrtd.dll)</td>
</tr>
<tr>
<td>Multithreaded DLL</td>
<td>libifcoremd.lib (libifcoremd.dll)</td>
<td>msvcrtd.lib (msvcrtd.dll)</td>
</tr>
<tr>
<td>Debug Multithreaded DLL</td>
<td>libifcoremd.dll (libifcoremd.dll)</td>
<td>msvcrtd.lib (msvcrtd.dll)</td>
</tr>
</tbody>
</table>

For example, select Debug Multi-threaded DLL in the Run-time Library list to specify that DLL (/libs:DLL), multi-threaded (/threads), and debug (/dbglibs) libraries should be linked against, namely Fortran import library libifcoremd.dll and its DLL library libifcoremd.dll and C/C++ import library msvcrtd.lib and its DLL library msvcrtd.dll.
A mixed language solution containing a Fortran library project should have **Disable Default Library Search Rules** set to No in the IDE. To check this setting, choose **Project > Properties** and then choose the Libraries category. If you change the **Disable Default Library Search Rules** setting to Yes, you will need to explicitly add the needed runtime libraries to the non-Fortran project. If you are adding libraries explicitly, make sure you add **IFCONSOL.LIB** to the libraries of the non-Fortran project. This library is needed to perform almost any kind of I/O with Intel® Visual Fortran.

When you have a C++ main program and a Fortran library subproject, you need to manually add the library path to the Intel® Visual Fortran LIB folder. You only need to do this once per user. To add the path, choose **Tools > Options > Projects and Solutions > VC++ Directories**. Use the **Show directories for:** dropdown item to select Library files. Add the path to the displayed list.

The way Microsoft Visual C++* chooses libraries is also based upon the **Project > Properties** item, but within the **C/C++** tab. In the **Code Generation** category, the run-time library item lists the following C libraries:

<table>
<thead>
<tr>
<th>Menu Item Selected</th>
<th>CL Option or Project Type</th>
<th>Default Library Specified in Object File</th>
</tr>
</thead>
<tbody>
<tr>
<td>Multithreaded</td>
<td>/MTd</td>
<td>libcmt.lib</td>
</tr>
<tr>
<td>Multithreaded DLL</td>
<td>/MD</td>
<td>msvcrt.lib (msvcrnn.dll)</td>
</tr>
<tr>
<td>Debug Multithreaded</td>
<td>/MTd</td>
<td>libcmtld.lib</td>
</tr>
<tr>
<td>Debug Multithreaded</td>
<td>/MDd</td>
<td>msvcrtd.lib (msvcrtd.dll)</td>
</tr>
</tbody>
</table>

You must take care to choose the same type of run-time libraries in both your Fortran and C project. For example, if you select Multithreaded DLL in your Fortran project, you must select Multithreaded DLL in your C project. Otherwise, when your build your mixed Fortran/C application, you will receive errors from the Linker regarding undefined and/or duplicate symbols.

If you are using Microsoft Visual C++* or Intel® C++ , the Microsoft integrated development environment can build mixed Fortran/C applications transparently, with no special directives or steps on your part. You can edit and browse your C and Fortran programs with appropriate syntax coloring for the language. You need to place your Fortran source files into a Fortran project and your C/C++ files into a Visual C++* project.

When you debug a mixed Visual C++/Fortran application, the debugger will adjust to the code type as it steps through: the C or Fortran expression evaluator will be selected automatically based on the code being debugged, and the stack window will show Fortran data types for Fortran procedures and C data types for C procedures.

**Implementation Specifics**

**Fortran Module Naming Conventions**

Fortran module entities (data and procedures) have external names that differ from other external entities. Module names use the convention:

```
modulename_mp_entity_(Linux* OS and OS* X)
 MODULENAME_mp_ENTITY(Windows* OS)
```

*modulename* is the name of the module. For Windows* operating systems, the name is uppercase by default. *entity* is the name of the module procedure or module data contained within *MODULENAME*. For Windows* operating systems, *ENTITY* is uppercase by default.

*mp* is the separator between the module and entity names and is always lowercase (except when the *assume std_mod_proc_name compiler option or standard-semantics compiler option is used*).

For example:

```fortran
MODULE mymod
  INTEGER a
  CONTAINS
```

621
This results in the following symbols being defined in the compiled object file on Linux* operating systems. (On OS X* operating systems, the symbols would begin with an underscore.)

mymod_mp_a_
mymod_mp_b_

The following symbols are defined in the compiled object file on Windows* operating systems based on IA-32 architecture:

_MYMOD_mp_A
_MYMOD_mp_B

On Windows* operating systems based on Intel® 64 architecture, there is no beginning underscore.

**Handling Fortran Array Pointers and Allocatable Arrays**

When a Standard Fortran array pointer or array is passed to another language, either its descriptor or its base address can be passed.

The following affects how Standard Fortran array pointers and arrays are passed:

- The ATTRIBUTES properties in effect
- The INTERFACE, if any, of the procedure they are passed to

If the INTERFACE declares the array pointer or array with deferred shape (for example, ARRAY(:)), its descriptor is passed. If the INTERFACE declares the array pointer or array with fixed shape, or if there is no interface, the array pointer or array is passed by base address as a contiguous array, which is like passing the first element of an array for contiguous array slices.

Use of the REFERENCE attribute on an array has no effect. Additionally, the VALUE attribute cannot be used with array arguments.

When you pass a Fortran array pointer or an array by descriptor to a non-Fortran routine, that routine needs to know how to interpret the descriptor. Part of the descriptor is a pointer to address space, such as a C pointer, and part of it is a description of the pointer or array properties, such as its rank, stride, and bounds.

For information about the Intel Fortran array descriptor format, see Handling Fortran Array Descriptors.

Standard Fortran array pointers and assumed-shape arrays are passed by passing the address of the array descriptor.

Standard Fortran pointers that point to scalar data contain the address of the data and are not passed by descriptor.

**Handling Fortran Array Descriptors**

For cases where Standard Fortran needs to keep track of more than a pointer memory address, the Intel® Fortran Compiler uses an array descriptor, which stores the details of how an array is organized.

When using an explicit interface (by association or procedure interface block), the compiler generates a descriptor for the following types of array arguments:

- Fortran array pointers
- Assumed-shape arrays
- Allocatable arrays
- Coarrays
- Class objects

Certain types of arguments do not use a descriptor, even when an appropriate explicit interface is provided. For example, explicit-shape and assumed-size arrays do not use a descriptor. In contrast, array pointers and allocatable arrays use descriptors regardless of whether they are used as arguments.
When calling between Intel® Fortran and C/C++, use an \textit{implicit} interface, which allows the array argument to be passed \textit{without} an Intel® Fortran descriptor. However, for cases where the called routine needs the information in the Intel® Fortran descriptor, declare the routine with an \textit{explicit} interface and specify the dummy array as either an assumed-shape array or with the pointer attribute.

You can associate a Fortran array pointer with any piece of memory, organized in any way desired (as long as it is "rectangular" in terms of array bounds). You can also pass Fortran array pointers to the C language, and have it correctly interpret the descriptor to obtain the information it needs.

The downside to using array descriptors is that it can increase the opportunity for errors. Additionally, the corresponding code is not portable. Specifically:

- If the descriptor is not defined correctly, the program may access the wrong memory address, possibly causing a General Protection Fault.
- Array descriptor formats are specific to each Fortran compiler. Code that uses array descriptors is not portable to other compilers or platforms.
- The array descriptor format may change in the future.
- If the descriptor was built by the compiler, it cannot be modified by the user. Changing fields of existing descriptors is illegal.

The components of the current Intel® Fortran array descriptor on systems using IA-32 architecture are as follows:

- Bytes 0 to 3 contain the base address.
- Bytes 4 to 7 contain the size of a single element of the array.
- Bytes 8 to 11 are reserved and should not be explicitly set.
- Bytes 12 to 15 contain a set of flags used to store information about the array. This includes:
  - bit 1 (0x01): array is defined -- set if the array has been defined (storage allocated).
  - bit 2 (0x02): no deallocation allowed -- set if the array pointed to cannot be deallocated (that is, it is an explicit array target).
  - bit 3 (0x04): array is contiguous -- set if the array pointed to is a contiguous whole array or slice.
  - bit 8 (0x80): set if the array pointed to is \texttt{ALLOCATABLE}.
  - Other bits are reserved.
- Bytes 16 to 19 contain the number of dimensions (rank) of the array.
- Bytes 20 to 23 are reserved and should not be explicitly set.
- The remaining bytes contain information about each dimension (up to 31). Each dimension is described by a set of three 4-byte entities:
  - The number of elements (extent).
  - The distance between the starting address of two successive elements in this dimension, in bytes.
  - The lower bound.

An array of rank one requires three additional 4-byte entities for a total of nine 4-byte entities (6 + 3*1) and ends at byte 35. An array of rank seven is described in a total of twenty-seven 4-byte entities (6 + 3*7) and ends at byte 107.

Consider the Following Declaration

```fortran
 integer,target :: a(10,10)
 integer,pointer :: p(:,:,)
 p => a(9:1,-2,1:9:3)
 call f(p)
 ...```

The descriptor for actual argument \texttt{p} would contain the following values:

- Bytes 0 to 3 contain the base address (assigned at run-time).
- Bytes 4 to 7 are set to 4 (size of a single element).
- Bytes 8 to 11 are reserved.
- Bytes 12 to 15 contain 3 (array is defined and deallocation is not allowed).
- Bytes 16 to 19 contain 2 (rank).
Bytes 20 to 23 are reserved.

Bytes 24 to 35 contain information for the first dimension, as follows:
- 5 (extent).
- -8 (distance between elements).
- 9 (the lower bound).

For the second dimension, bytes 36 to 47 contain:
- 3 (extent).
- 120 (distance between elements).
- 1 (the lower bound).

Byte 47 is the last byte for this example.

**NOTE**
The format for the descriptor on systems using Intel® 64 architecture is identical to that on systems using IA-32 architecture, except that all fields are 8-bytes long, instead of 4-bytes.

**Returning Character Data Types**

A discrepancy occurs when working with C and Fortran character strings: C strings are null-terminated while Fortran strings have known lengths. A C routine that returns a character string will be returning a pointer to a null-terminated string. A Fortran routine will not have any knowledge of the string's length.

If a Fortran routine is returning a string to a C program, the Fortran program must null-terminate the string.

**Example of Returning Character Types from C to Fortran**

The following shows the Fortran code that declares interfaces to a C routine and calls the C routine. In the example, the pointer returned by the C routine can be passed along to another C routine. However, it is not usable by Fortran as-is since Fortran has no knowledge of the string's length.

```fortran
program FCallsCReturnsCptr
use, intrinsic :: iso_c_binding

! declare the interfaces to the C routines
interface
  type(C_PTR)function my_croutine1 ( input) bind(c)
    import
    integer(c_int), value :: input
  end function my_croutine1
end interface

subroutine my_cprint( string ) bind(c)
  import c_ptr
  type(C_PTR), value :: string
end subroutine my_cprint
end interface

! This program declares a C program that returns a char*
! calls it, and has to pass that return value along to
! a different c program because type(c_ptr) is limited
! in a pure Fortran program.
program FCallsCReturnsCptr
use, intrinsic :: iso_c_binding

! declare the interfaces to the C routines
interface
  type(C_PTR)function my_croutine1 ( input) bind(c)
    import
    integer(c_int), value :: input
  end function my_croutine1
end interface

subroutine my_cprint( string ) bind(c)
  import c_ptr
  type(C_PTR), value :: string
end subroutine my_cprint
end interface
```
The example above shows the C code used to call a Fortran routine. The Fortran routine returns a string that is then printed by the C program. As shown in the example, it is relatively straightforward to pass a string back to C from Fortran. Additionally, the string can be easily used by the C program because it is NULL-terminated.

In the above example, the following restrictions and behaviors apply:

- The function's length and result do not appear in the call statement; they are added by the compiler.
- The called routine must copy the result string into the location specified by `result`; it must not copy more than `length` characters.
- If fewer than `length` characters are returned, the return location should be padded on the right with blanks; Fortran does not use zeros to terminate strings.
- The called procedure is type `void`.

**Example of Returning Character Types from Fortran to C**

The following shows the C code used to call a Fortran routine; the Fortran routine returns a string that is then printed by the C program.
Called Fortran Routine Example

```fortran
function GetFortranWords bind(c, name="GetFortranWords")
use, intrinsic :: iso_c_binding
type(C_ptr) :: GetFortranWords
character*30 returnval

returnval = "I like to type words!" // char(0)

GetFortranWords = C_LOC(returnval)
return
end
```

Legacy Extensions

**ATTRIBUTES**

Standard Fortran provides a syntax for interoperating with C, including applying the appropriate naming conventions. You can use BIND(C) for interoperability with C, instead of specifying ATTRIBUTES options.

The ATTRIBUTES options (also known as properties) C, STDCALL (Windows* only), REFERENCE, VALUE affect the calling convention of routines. You can specify:

- The C, STDCALL, and REFERENCE properties for an entire routine.
- The VALUE and REFERENCE properties for individual arguments.

By default, Fortran passes all data by reference (except the hidden length argument of strings, which is passed by value). If the C (or, for Windows*, STDCALL) option is used, the default changes to passing almost all data except arrays by value. However, in addition to the calling-convention options C and STDCALL, you can specify argument options, VALUE and REFERENCE, to pass arguments by value or by reference, regardless of the calling convention option. Arrays can only be passed by reference.

Different Fortran calling conventions can be specified by declaring the Fortran procedure to have certain attributes.

The following table summarizes the effect of the most common Fortran calling convention directives.

**Calling Conventions for ATTRIBUTES Options**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Default</th>
<th>C</th>
<th>C, REFERENCE</th>
<th>STDCALL (Windows* IA-32 architecture)</th>
<th>STDCALL, REFERENCE (Windows* IA-32 architecture)</th>
</tr>

</table>

**Naming Conventions**

Prefix

- (Windows* operating systems using IA-32 architecture, OS X* operating systems)
  - none for all others

Suffix

- none (Windows*)
  - _ (Linux*, OS X*)

Case

- Upper Case (Windows*)
  - Lower Case
The terms in the above table mean the following:

<table>
<thead>
<tr>
<th>Argument</th>
<th>Default</th>
<th>C</th>
<th>C, REFERENCE</th>
<th>STDCALL (Windows* IA-32 architecture)</th>
<th>STDCALL, REFERENCE (Windows* IA-32 architecture)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lower Case (Linux*, OS X*)</td>
<td>Caller</td>
<td>Caller</td>
<td>Caller</td>
<td>Callee</td>
<td>Callee</td>
</tr>
</tbody>
</table>

Stack Cleanup

The terms in the above table mean the following:

- **[value]** Argument assigned the VALUE attribute.
- **[reference]** Argument assigned the REFERENCE attribute.
- **Value** The argument value is pushed on the stack. All values are padded to the next 4-byte boundary.
- **Reference** On systems using IA-32 architecture, the 4-byte argument address is pushed on the stack.
  - On systems using Intel® 64 architecture, the 8-byte argument address is pushed on the stack.
  - For certain string arguments:
    - **Len:End** applies when `-nomixed-str-len-arg` (Linux* and OS X*) or `/iface:nomixed_str_len_arg` (Windows*) is set. The length of the string is pushed (by value) on the stack after all of the other arguments. This is the default.
    - **Len: Mixed** applies when `-mixed-str-len-arg` (Linux* and OS X*) or `/iface:mixed_str_len_arg` (Windows*) is set. The length of the string is pushed (by value) on the stack immediately after the address of the beginning of the string.
- **No Len or Len: Mixed**
  - **No Len** applies when `-nomixed-str-len-arg` (Linux* and OS X*) or `/iface:nomixed_str_len_arg` (Windows*) is set. The length of the string is not available to the called procedure. This is the default.
  - **Len: Mixed** applies when `-mixed-str-len-arg` (Linux* and OS X*) or `/iface:mixed_str_len_arg` (Windows*) is set. The length of the string is pushed (by value) on the stack immediately after the address of the beginning of the string.
- **No Len** For string arguments, the length of the string is not available to the called procedure.
- **String(1:1)** For string arguments, the first character is converted to INTEGER(4) as in ICHAR(string(1:1)) and pushed on the stack by value.
- **Error** Produces a compiler error.
- **Descriptor** On systems using IA-32 architecture, the 4-byte address of the array descriptor.
  - On systems using Intel® 64 architecture, the 8-byte address of the array descriptor.
- **@n** On systems using IA-32 architecture, the at sign (@) followed by the number of bytes (in decimal) required for the argument list.
- **Size dependent**
  - **Size** On systems using IA-32 architecture, derived-type arguments specified by value are passed as follows:
    - **Arguments from 1 to 4 bytes are passed by value.**
• Arguments from 5 to 8 bytes are passed by value in two registers (two arguments).
• Arguments more than 8 bytes provide value semantics by passing a temporary storage address by reference.

Upper Case Procedure name in all uppercase.
Lower Case Procedure name in all lowercase.
Callee The procedure being called is responsible for removing arguments from the stack before returning to the caller.
Caller The procedure doing the call is responsible for removing arguments from the stack after the call is over.

You can use the BIND(C, name=<string>) attribute to resolve discrepancies with C. Alternatively, the ALIAS option can be used with any other Fortran calling-convention option to preserve mixed-case names. +

For Windows* operating systems, the compiler option /iface also establishes some default argument passing conventions. The /iface compiler option has the following choices:

<table>
<thead>
<tr>
<th>Option</th>
<th>How are arguments passed?</th>
<th>Append @n to names on systems using IA-32 architecture?</th>
<th>Who cleans up stack?</th>
<th>Varargs support?</th>
</tr>
</thead>
<tbody>
<tr>
<td>/iface:cr</td>
<td>By reference</td>
<td>No</td>
<td>Caller</td>
<td>Yes</td>
</tr>
<tr>
<td>/iface:st</td>
<td>By reference</td>
<td>Yes</td>
<td>Callee</td>
<td>No</td>
</tr>
<tr>
<td>/iface:de</td>
<td>By reference</td>
<td>No</td>
<td>Caller</td>
<td>Yes</td>
</tr>
<tr>
<td>/iface:c</td>
<td>By value</td>
<td>No</td>
<td>Caller</td>
<td>Yes</td>
</tr>
<tr>
<td>/iface:st</td>
<td>By value</td>
<td>Yes</td>
<td>Callee</td>
<td>No</td>
</tr>
<tr>
<td>/iface:cv</td>
<td>By reference</td>
<td>Yes</td>
<td>Callee</td>
<td>No</td>
</tr>
</tbody>
</table>

**NOTE**
The following applies to Windows*: When interfacing to the Windows* graphical user interface or making API calls, you will typically use STDCALL.

**ALIAS**
Use the ALIAS option for the ATTRIBUTES directive if the name of a routine appears as mixed-case in C and you need to preserve the case.

To use the ALIAS option, place the name in quotation marks exactly as it is to appear in the object file.
This example uses DECORATE to automatically reconcile external name declaration for the target platform. Using the DECORATE option in combination with the ALIAS option specifies that the external name specified in ALIAS should have the correct prefix and postfix decorations for the calling mechanism in effect.

**Compiler Options**

**Using the -nofor_main Compiler Option (Linux* and OS X*)**

Intel® Fortran subprograms can be called by C/C++ main programs. Use the -nofor_main compiler option if your C/C++ program contains the main() entry point and is calling an Intel® Fortran subprogram.
Error Handling

Handling Compile Time Errors

Understanding Errors During the Build Process
The Intel® Fortran Compiler identifies syntax errors and violations of language rules in the source program.

Compiler Diagnostic Messages
These messages describe diagnostics that are reported during the processing of the source file. Compiler diagnostic messages usually provide enough information for you to determine the cause of an error and correct it. These messages generally have the following format:

```
filename(linenum): severity #error number: message
```

<table>
<thead>
<tr>
<th>Diagnostic</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>filename</td>
<td>Indicates the name of the source file currently being processed.</td>
</tr>
<tr>
<td>linenum</td>
<td>Indicates the source line where the compiler detects the condition.</td>
</tr>
<tr>
<td>severity</td>
<td>Indicates the severity of the diagnostic message: Warning, Error, or Fatal error.</td>
</tr>
<tr>
<td>message</td>
<td>Describes the problem.</td>
</tr>
</tbody>
</table>

**Error Message Example**

```
echar.for(7): error #6321: An unterminated block exits.
     DO I=1,5
      ------^ |
```

The pointer (-----^) indicates the place on the source program line where the error was found, in this case where an END DO statement was omitted.

To view the passes as they execute on the command line, specify the watch option.

**NOTE**

You can perform compile-time procedure interface checking between routines with no explicit interfaces present. To do this, generate a module containing the interface for each compiled routine using the gen-interfaces option and check implicit interfaces using the warn[:]interfaces option.

Controlling Compiler Diagnostic Warning and Error Messages
You can use a number of compiler options to control the diagnostic messages issued by the compiler. For example, compiler option WB turns compile time bounds errors into warnings. To control compiler diagnostic messages (such as warning messages), use the warn option. This option controls warnings issued by the compiler and supports a wide range of keywords. Some of these are as follows:

- **[no]alignments**: Determines whether warnings occur for data that is not naturally aligned.
• [no]declarations: Determines whether warnings occur for any undeclared symbols.
• [no]errors: Determines whether warnings are changed to errors.
• [no]general: Determines whether warning messages and informational messages are issued by the compiler.
• [no]interfaces: Determines whether warnings about the interfaces for all called SUBROUTINES and invoked FUNCTIONS are issued by the compiler.
• [no]stderrors: Determines whether warnings about Fortran standard violations are changed to errors.
• [no]truncated_source: Determines whether warnings occur when source exceeds the maximum column width in fixed-format files.

For more information, see the warn compiler option.

You can also control the display of diagnostic information with variations of the [Q]diag compiler option. This compiler option accepts numerous arguments and values, allowing you wide control over displayed diagnostic messages and reports.

Some of the most common variations include the following:

<table>
<thead>
<tr>
<th>Linux* and OS X*</th>
<th>Windows*</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-diag-enable =list /Qdiag-enable:list</td>
<td>Enables a diagnostic message or a group of messages</td>
<td></td>
</tr>
<tr>
<td>-diag-disable =list /Qdiag-disable:list</td>
<td>Disables a diagnostic message or a group of messages</td>
<td></td>
</tr>
<tr>
<td>-diag-warning =list /Qdiag-warning:list</td>
<td>Tells the compiler to change diagnostics to warnings</td>
<td></td>
</tr>
<tr>
<td>-diag-error =list /Qdiag-error:list</td>
<td>Tells the compiler to change diagnostics to errors</td>
<td></td>
</tr>
<tr>
<td>-diag-remark =list /Qdiag-remark:list</td>
<td>Tells the compiler to change diagnostics to remarks (comments)</td>
<td></td>
</tr>
</tbody>
</table>

The list items can be specific diagnostic IDs, one of the keywords warn, remark, or error, or a keyword specifying a certain group (par, vec, driver, cpu-dispatch). For more information, see [Q]diag.

Additionally, you can use the following related options:

<table>
<thead>
<tr>
<th>Linux* and OS X*</th>
<th>Windows*</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-diag-dump /Qdiag-dump</td>
<td>Tells the compiler to print all enabled diagnostic messages and stop compilation.</td>
<td></td>
</tr>
<tr>
<td>-diag-file=[file] /Qdiag-file:[file]</td>
<td>Causes the results of diagnostic analysis to be output to a file.</td>
<td></td>
</tr>
<tr>
<td>-diag-error-limit=n /Qdiag-error-limit:n</td>
<td>Specifies the maximum number of errors allowed before compilation stops.</td>
<td></td>
</tr>
</tbody>
</table>

**Linker Diagnostic Errors**

If the linker detects any errors while linking object modules, it displays messages about their cause and severity. If any errors occur, the linker does not produce an executable file. Linker messages are descriptive, and you do not normally need additional information to determine the specific error.

To view the libraries being passed to the linker on the command line, specify the watch option.
Error Severity Levels

Comment Messages

These messages indicate valid but inadvisable use of the language being compiled. The compiler displays comments by default. You can suppress comment messages with the `warn[:nousage` option.

Comment messages do not terminate translation or linking, they do not interfere with any output files either. Some examples of the comment messages are:

- Null CASE construct
- The use of a non-integer DO loop variable or expression
- Terminating a DO loop with a statement other than CONTINUE or ENDDO

Warning Messages

These messages report valid but questionable use of the language being compiled. The compiler displays warnings by default. You can suppress warning messages by using the `nowarn` option. Warnings do not stop translation or linking. Warnings do not interfere with any output files. Some representative warning messages are:

- constant truncated - precision too great
- non-blank characters beyond column 72 ignored
- Hollerith size exceeds that required by the context

Error Messages

These messages report syntactic or semantic misuse of Fortran. Errors suppress object code for the file containing the error and prevent linking, but they do not stop the compiler from scanning for any other errors. Some typical examples of error messages are:

- line exceeds 132 characters
- unbalanced parenthesis
- incomplete string

Fatal Errors

Fatal messages indicate environmental problems. Fatal error conditions stop translation, assembly, and linking. If a fatal error ends compilation, the compiler displays a termination message on standard error output. Some representative fatal error messages are:

- Disk is full, no space to write object file
- Too many segments, object format cannot support this many segments

Using the Command Line

If you are using the command line, messages are written to the standard error output file. When using the command line:

- Make sure that the appropriate environment variables have been set by executing the `compilervars.sh` (Linux* and OS X*) or `compilervars.bat` (Windows*) file. For example, this `.bat` file sets the environment variables for the include and library directory paths. For Windows*, these environment variables are preset if you use the Fortran Command Prompt window in the Intel® Visual Fortran program folder. For a list of environment variables used by the `ifort` command during compilation, see Supported Environment Variables.
- Specify the libraries to be linked against using compiler options.
- You can specify libraries (include the path, if needed) as file names on the command line.

Using the Visual Studio IDE (Windows*)

If you are using the Microsoft® Visual Studio® integrated development environment (IDE), compiler and linker errors are displayed in the Build pane of the Output window. To display the Output window, choose View > Other Windows > Output. You can also use the Task List window (View > Other Windows > Task List) to view display links to problems encountered during the build process. Click these tasks to jump to code that caused build problems. You can also check the Build log for more information.
To quickly locate the source line causing the error, follow these steps:

1. Double-click the error message text in the **Build** pane of the **Output** window.
   - or -
2. Press **F8**. The editor window appears with a marker in the left margin that identifies the line causing the error. You can continue to press **F8** to scroll through additional errors.

After you have corrected any compiler errors reported during the previous build, choose **Build project name** from the **Build** menu. The build engine recompiles only those files that have changed, or which refer to changed include or module files. If all files in your project compile without errors, the build engine links the object files and libraries to create your program or library.

You can force the build engine to recompile all source files in the project by selecting **Rebuild project name** from the **Build** menu. This is useful to verify that all of your source code is clean, especially if you are using a makefile, or if you use a new set of compiler options for all of the files in your project.

When using the IDE:

- Make sure that you have specified the correct path, library, and include directories. For more information, see Specifying Path Library and Include Directories.
- If a compiler option is not available through **Project > Properties** in the Intel® Fortran Property pages, you can type the option in the Command Line category. Use the lower part of the window under **Additional Options**, just as you would using the command line. For example, you can enter the linker option `/link /DEFAULTLIB` to specify an additional library.

**Handling Run-Time Errors**

**Understanding Run-Time Errors**

During execution, your program may encounter errors or exception conditions. These conditions can result from any of the following:

- Errors that occur during I/O operations.
- Invalid input data.
- Argument errors in calls to the mathematical library.
- Arithmetic errors.
- Other system-detected errors.

The Intel® Fortran Run-Time Library (RTL) generates appropriate messages and takes action to recover from errors whenever possible.

For a description of each Intel® Fortran run-time error message, see List of Run-Time Error Messages.

There are a few tools and aids that are useful when an application fails and you need to diagnose the error. Compiler-generated machine code listings and linker-generated map files can help you understand the effects of compiler optimizations and to see how your application is laid out in memory. They may help you interpret the information provided in a stack trace at the time of the error. See Generating Listing and Map Files.
Forcing a Core Dump for Severe Errors

You can force a core dump for severe errors that do not usually cause a core file to be created. Before running the program, set the DECFORT_DUMP_FLAG environment variable to any of the common TRUE values (Y, y, Yes, yEs, True, and so forth) to cause severe errors to create a core file. For instance, the following C shell command sets the DECFORT_DUMP_FLAG environment variable:

```
setenv decfort_dump_flag y
```

The core file is written to the current directory and can be examined using a debugger.

NOTE

If you requested a core file to be created on severe errors and you do not get one when expected, the problem might be that your process limit for the allowable size of a core file is set too low (or to zero). See the man page for your shell for information on setting process limits. For example, the C shell command limit (with no arguments) will report your current settings, and `limit coredumpsize unlimited` will raise the allowable limit to your current system maximum.

Run-Time Default Error Processing

The Intel® Fortran run-time system processes a number of errors that can occur during program execution. A default action is defined for each error recognized by the Intel® Fortran run-time system. The default actions described throughout this section occur unless overridden by explicit error-processing methods.

The way in which the Intel® Fortran run-time system actually processes errors depends upon the following factors:

- The severity of the error. For instance, the program usually continues executing when an error message with a severity level of warning or info (informational) is detected.
- For certain errors associated with I/O statements, whether or not an I/O error-handling specifier was specified.
- For certain errors, whether or not the default action of an associated signal was changed.
- For certain errors related to arithmetic operations (including floating-point exceptions), compilation options can determine whether the error is reported and the severity of the reported error.

How arithmetic exception conditions are reported and handled depends on the cause of the exception and how the program was compiled. Unless the program was compiled to handle exceptions, the exception might not be reported until after the instruction that caused the exception condition.

Run-Time Message Display and Format

When errors occur during execution (run time) of a program, the Intel® Visual Fortran run-time system issues diagnostic messages.

The location where Fortran run-time messages are displayed depends on the Understanding Project Types:

<table>
<thead>
<tr>
<th>Project Type</th>
<th>Where Messages Appear</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fortran Console applications</td>
<td>Run-time error messages are displayed on the standard error device (unless redirected).</td>
</tr>
<tr>
<td>Fortran QuickWin and Fortran Standard Graphics applications</td>
<td>Run-time error messages are displayed in a separate QuickWin message box.</td>
</tr>
<tr>
<td>Fortran Windows applications</td>
<td>Run-time error messages are displayed in a separate message box.</td>
</tr>
</tbody>
</table>

Fortran run-time messages have the following format:

```
forrtl: severity (number): message-text
```

where:

- **forrtl**: Identifies the source as the Intel® Fortran run-time system (Run-Time Library or RTL).
- **severity**: The severity levels are: severe, error, warning, or info
- **number**: This is the message number; see also the Using the IOSTAT Specifier and Fortran Exit Codes for I/O statements.
- **message-text**: Explains the event that caused the message.

The following table explains the severity levels of run-time messages, in the order of greatest to least severity. The severity of the run-time error message determines whether program execution continues:

<table>
<thead>
<tr>
<th>Severity</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>severe</td>
<td>Must be corrected. The program's execution is terminated when the error is encountered unless the program's I/O statements use the END, EOR, or ERR branch specifiers to transfer control, perhaps to a routine that uses the IOSTAT specifier. (See Using the END EOR and ERR Branch Specifiers and Using the IOSTAT Specifier and Fortran Exit Codes and Methods of Handling Errors.) For severe errors, stack trace information is produced by default, unless the environment variable FOR_DISABLE_STACK_TRACE is set. If the command line option traceback is specified, the stack trace information contains program counters set to symbolic information. Otherwise, the information contains merely hexadecimal program counter information. In some cases stack trace information is also produced by the compiled code at run-time to provide details about the creation of array temporaries. <strong>If FOR_DISABLE_STACK_TRACE is set, no stack trace information is produced.</strong></td>
</tr>
<tr>
<td>error</td>
<td>Should be corrected. The program might continue execution, but the output from this execution might be incorrect.</td>
</tr>
</tbody>
</table>
For errors of severity type error, stack trace information is produced by default, unless the environment variable \texttt{FOR_DISABLE_STACK_TRACE} is set. If the command line option \texttt{traceback} is specified, the stack trace information contains program counters set to symbolic information. Otherwise, the information contains merely hexadecimal program counter information.

In some cases stack trace information is also produced by the compiled code at run-time to provide details about the creation of array temporaries.

If \texttt{FOR_DISABLE_STACK_TRACE} is set, no stack trace information is produced.

\textbf{warning} \hspace{1em} Should be investigated. The program continues execution, but output from this execution might be incorrect.

\textbf{info} \hspace{1em} For informational purposes only; the program continues.

For a description of each Intel® Fortran run-time error message, see \textit{Run-Time Default Error Processing} and related topics.

The following example applies to Linux* and to OS X*:

In some cases, stack trace information is produced by the compiled code at run time to provide details about the creation of array temporaries.

If \texttt{FOR_DISABLE_STACK_TRACE} is set, no stack trace information is produced.

The following program generates an error at line 12:

\begin{verbatim}
program ovf
real*4 x(5),y(5)
integer*4 i
  x(1) = -1e32
  x(2) = 1e38
  x(3) = 1e38
  x(4) = 1e38
  x(5) = -36.0
  do i=1,5
     y(i) = 100.0*(x(i))
  print *, 'x = ', x(i), ' x*100.0 = ',y(i)
  end do
end
\end{verbatim}

The following command line produces stack trace information for the program executable.

\begin{verbatim}
> ifort -O0 -fpe0 -traceback ovf.f90 -o ovf.exe
> ovf.exe
\end{verbatim}

\begin{verbatim}
x = -1.000000000000E+32  x*100.0
   = -1.000000000000E+34
forrtl: error (72): floating overflow
\end{verbatim}

\begin{tabular}{|c|c|c|c|c|}
\hline
Image & PC & Routine & Line & Source \\
\hline
ovf.exe & 08049E4A & MAIN__ & 14 & ovf.f90 \\
ovf.exe & 08049F08 & Unknown & Unknown & Unknown \\
ovf.exe & 400B3507 & Unknown & Unknown & Unknown \\
ovf.exe & 08049C51 & Unknown & Unknown & Unknown \\
\hline
\end{tabular}

\textit{Abort}
The following suppresses stack trace information because the \texttt{FOR\_DISABLE\_STACK\_TRACE} environment variable is set.

\begin{verbatim}
> setenv FOR\_DISABLE\_STACK\_TRACE true > ovf.exe
\end{verbatim}

\begin{verbatim}
x = -1.0000000E+32  x*100.0 = -1.0000000E+34

forrtl: error (72): floating overflow
Abort
\end{verbatim}

### Run-Time Library Message Catalog File Location

The libifcore, libirc, and libm run-time libraries ship message catalogs. When a message by one of these libraries is to be displayed, the library searches for its message catalog in a directory specified by either the \texttt{NLSPATH} (Linux* and OS X*), or \texttt{%PATH%} (Windows*) environment variable. If the message catalog cannot be found, the message is displayed in English.

The names of the three message catalogs are as follows:

| Library  | Message Catalogs and Related Text Message Files | Linux* and OS X* | Windows*
|----------|-----------------------------------------------|------------------|---------
| libifcore | ifcore_msg.cat                                | ifcore_msg.msg    | ifcore_msg.dll |
|          | related text message files                     |                   | ifcore_msg.mc  |
| libirc   | irc_msg.cat                                    | irc_msg.msg       | irc_msg.dll    |
|          | related text message files                     |                   | irc_msg.mc     |
| libm     | libm.cat                                       | libm.msg          | libmUI.dll     |
|          | related text message files                     |                   | libmUI.mc      |

### Values Returned at Program Termination

An Intel\textsuperscript{®} Fortran program can terminate in a number of ways. On Linux* and OS X*, values are returned to the shell.

- The program runs to normal completion. A value of zero is returned.
- The program stops with a \texttt{STOP} statement. If an integer stop-code is specified, a status equal to the code is returned; if no stop-code is specified, a status of zero is returned.
- The program stops because of a signal that is caught but does not allow the program to continue. A value of '1' is returned.
- The program stops because of a severe run-time error. The error number for that run-time error is returned. See Understanding Run-Time Errors and related topics.
- The program stops with a \texttt{CALL EXIT} statement. The value passed to EXIT is returned.

---

638
The program stops with a CALL ABORT statement. A value of '134' is returned.

Understanding Run-Time Errors

Methods of Handling Errors
Whenever possible, the Intel® Fortran RTL does certain error handling, such as generating appropriate messages and taking necessary action to recover from errors. You can explicitly supplement or override default actions by using the following methods:

- To transfer control to error-handling code within the program, use the END, EOR, and ERR branch specifiers in I/O statements. See Using the END EOR and ERR Branch Specifiers.
- To identify Fortran-specific I/O errors based on the value of Intel® Fortran RTL error codes, use the I/O status specifier (IOSTAT) in I/O statements (or call the ERRSNS subroutine). See Using the IOSTAT Specifier and Fortran Exit Codes.
- Obtain system-level error codes by using the appropriate library routines.
- For certain error conditions, use the signal handling facility to change the default action to be taken.

See Also
Using the IOSTAT Specifier and Fortran Exit Codes
Using the END, EOR, and ERR Branch Specifiers

Using the END, EOR, and ERR Branch Specifiers
When a severe error occurs during Intel® Fortran program execution, the default action is to display an error message and terminate the program. To override this default action, there are three branch specifiers you can use in I/O statements to transfer control to a specified point in the program:

- The END branch specifier handles an end-of-file condition.
- The EOR branch specifier handles an end-of-record condition for non-advancing reads.
- The ERR branch specifier handles all error conditions.

If you use the END, EOR, or ERR branch specifiers, no error message is displayed and execution continues at the designated statement, usually an error-handling routine.

You might encounter an unexpected error that the error-handling routine cannot handle. In this case, do one of the following:

- Modify the error-handling routine to display the error message number.
- Remove the END, EOR, or ERR branch specifiers from the I/O statement that causes the error.

After you modify the source code, compile, link, and run the program to display the error message. For example:

```fortran
READ (8,50,ERR=400)
```

If any severe error occurs during execution of this statement, the Intel® Visual Fortran RTL transfers control to the statement at label 400. Similarly, you can use the END specifier to handle an end-of-file condition that might otherwise be treated as an error. For example:

```fortran
READ (12,70,END=550)
```

When using non-advancing I/O, use the EOR specifier to handle the end-of-record condition. For example:

```fortran
150 FORMAT (F10.2, F10.2, I6)
      READ (UNIT=20, FMT=150, SIZE=X, ADVANCE='NO', EOR=700) A, F, I
```

You can also use ERR as a specifier in an OPEN, CLOSE, or INQUIRE statement. For example:

```fortran
OPEN (UNIT=10, FILE='FILENAME', STATUS='OLD', ERR=999)
```

If an error is detected during execution of this OPEN statement, control transfers to the statement at label 999.
Using the IOSTAT Specifier and Fortran Exit Codes

You can use the IOSTAT specifier to continue program execution after an I/O error and to return information about I/O operations. Certain errors are not returned in IOSTAT.

The IOSTAT specifier can supplement or replace the END, EOR, and ERR branch transfers.

Execution of an I/O statement containing the IOSTAT specifier suppresses the display of an error message and defines the specified integer variable, array element, or scalar field reference as one of the following, which is returned as an exit code if the program terminates:

- A value of `-2' if an end-of-record condition occurs with non-advancing reads.
- A value of `-1' if an end-of-file condition occurs.
- A value of '0' for normal completion (not an error condition, end-of-file, or end-of-record condition).
- A positive integer value if an error condition occurs. (This value is one of the Fortran-specific IOSTAT numbers listed in the run-time error message. See List of Run-Time Error Messages, which lists the messages.)

Following the execution of the I/O statement and assignment of an IOSTAT value, control transfers to the END, EOR, or ERR statement label, if any. If there is no control transfer, normal execution continues.

You can include the `for_iosdef.for' file in your program to obtain symbolic definitions for the values of IOSTAT.

The following example uses the IOSTAT specifier and the `for_iosdef.for' file to handle an OPEN statement error (in the FILE specifier).

```
Error Handling OPEN Statement File Name Example

CHARACTER(LEN=40) :: FILNM
INCLUDE 'for_iosdef.for'
DO I=1,4      FILNM = ''
  WRITE (6,*)  'Type file name '
  READ (5,*) FILNM
  OPEN (UNIT=1, FILE=FILNM, STATUS='OLD', IOSTAT=IERR, ERR=100)
  WRITE (6,*) 'Opening file: ', FILNM
  !       (process the input file)
  CLOSE (UNIT=1)
  STOP
100  IF (IERR .EQ. FOR$IOS_FILOMEO) THEN
    WRITE (6,*) 'File: ', FILNM, ' does not exist '
  ELSE IF (IERR .EQ. FOR$IOS_FILOMNAM) THEN
    WRITE (6,*) 'File: ', FILNM, ' was bad, enter new file name'
  ELSE
    PRINT *, 'Unrecoverable error, code =', IERR
    STOP
  END IF
END DO
!  (for loop)
END PROGRAM
```

Another way to obtain information about an error is the ERRSNS subroutine, which allows you to obtain the last I/O system error code associated with an Intel® Fortran RTL error (see the Intel® Fortran Language Reference).

List of Run-Time Error Messages

Locating Run-Time Errors

This topic provides some guidelines for locating the cause of exceptions and run-time errors. Intel® Fortran run-time error messages do not usually indicate the exact source location causing the error. The following compiler options are related to handling errors and exceptions:
The -check [keyword] (Linux* and OS X*) or /check[:keyword] (Windows*) option generates extra code to catch certain conditions at run time. For example, if you specify the keyword bounds, the debugger will catch and stop at array or character string bounds errors. You can specify the keyword bounds to generate code to perform compile-time and run-time checks on array subscript and character substring expressions. An error is reported if the expression is outside the dimension of the array or the length of the string. The keyword of uninit generates code for dynamic checks of uninitialized variables. If a variable is read before written, a run-time error routine will be called. The noformat and nooutput_conversion keywords reduce the severity level of the associated run-time error to allow program continuation. The pointers keyword generates code to test for disassociated pointers and unallocateable arrays.

The following check[:pointers] option examples result in various output messages.

### Example: Allocatable variable not allocated
```
real, allocatable:: a(:)
!
 allocate(a(4))  ! if a is unallocated, the next statement gets an error with "check
 pointers"
 a=17
 print  *,a
 end
```

Output 1:
```
Output 1:
forrtl: severe (408): fort: (8): Attempt to fetch from allocatable variable A when it is not
allocated
```

### Example: Unassociated Pointer
```
real, pointer:: a(:)
allocate(a(5))
 a=17
 print  *,a
 deallocate(a) ! once a is deallocated, the next statement gets an error with "check
 pointers"
 a=20
 print  *,a
end
```

Output 2:
```
Output 2:
 17.00000 17.00000 17.00000 17.00000 17.00000
forrtl: severe (408): fort: (7): Attempt to use pointer A when it is not associated with a target
```

### Example: Cray pointer with zero value
```
pointer(p,a)
real, target:: b
!
p=loc(b)  ! if integer pointer p has no address assigned to it,
!
  b=17.  ! the next statement gets an error with "check pointers"
!
print  *,a
end
```

Output 3:
```
Output 3:
forrtl: severe (408): fort: (9): Attempt to use pointee A when its corresponding integer pointer P
has the value zero
```

The traceback option generates extra information in the object file to provide source file traceback information when a severe error occurs at run time. This simplifies the task of locating the cause of severe run-time errors. Without the traceback option, you could try to locate the cause of the error using a map file and the hexadecimal addresses of the stack displayed when a severe error occurs. Certain traceback-related information accompanies severe run-time errors, as described in Using Traceback Information Overview.
The `fpe` option controls the handling of floating-point arithmetic exceptions (IEEE arithmetic) at run time. If you specify the `-fpe[:3]` compiler option, all floating-point exceptions are disabled, allowing IEEE exceptional values and program continuation. In contrast, specifying `-fpe[:0]` stops execution when an exceptional value (such as a NaN) is generated, when floating overflow or divide by zero occur, or when attempting to use a denormalized number, which usually allows you to localize the cause of the error. It also forces underflow to zero.

- The `warn` and `nowarn` options control compile-time warning messages, which, in some circumstances, can help determine the cause of a run-time error.

- On Linux* and on OS X*, the `-fexceptions` option enables C++ exception handling table generation, preventing Fortran routines in mixed-language applications from interfering with exception handling between C++ routines.

- On Windows*, the Compilation Diagnostics Options in the IDE control compile-time diagnostic messages, which, in some circumstances can help determine the cause of a run-time error.

Understanding Run-Time Errors

Using Traceback Information Overview

**List of Run-Time Error Messages**

This section lists the errors processed by the compiler run-time library (RTL). For each error, the table provides the error number, the severity code, error message text, condition symbol name, and a detailed description of the error.

To define the condition symbol values (PARAMETER statements) in your program, include the following file:

```
for_iosdef.for
```

As described in the table, the severity of the message determines which of the following occurs:

- with `info` and `warning`, program execution continues
- with `error`, the results may be incorrect
- with `severe`, program execution stops (unless a recovery method is specified)

In the last case, to prevent program termination, you must include either an appropriate I/O error-handling specifier and recompile or, for certain errors, change the default action of a signal before you run the program again.

In the following table, the first column lists error numbers returned to IOSTAT variables when an I/O error is detected.

The first line of the second column provides the message as it is displayed (following `fortl:`), including the severity level, message number, and the message text. The following lines of the second column contain the status condition symbol (such as `FOR$IOS_INCRECTYP`) and an explanation of the message.

<table>
<thead>
<tr>
<th>Number</th>
<th>Severity Level, Number, and Message Text; Condition Symbol and Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td><strong>severe (1): Not a Fortran-specific error</strong>&lt;br&gt;FOR$IOS_NOTFORSPE. An error in the user program or in the RTL was not an Intel® Fortran-specific error and was not reportable through any other Intel® Fortran run-time messages.</td>
</tr>
<tr>
<td>8</td>
<td><strong>severe (8): Internal consistency check failure</strong>&lt;br&gt;FOR$IOS_BUG_CHECK. Internal error. Please check that the program is correct. Recompile if an error existed in the program. If this error persists, submit a problem report.</td>
</tr>
<tr>
<td>9</td>
<td><strong>severe (9): Permission to access file denied</strong>&lt;br&gt;FOR$IOS_PERACCFIL. Check the permissions of the specified file and whether the network device is mapped and available. Make sure the correct file and device was being accessed. Change the protection, specific file, or process used before rerunning the program.</td>
</tr>
<tr>
<td>10</td>
<td><strong>severe (10): Cannot overwrite existing file</strong></td>
</tr>
</tbody>
</table>
FOR$IOS_CANOVEEX. Specified file xxx already exists when OPEN statement specified STATUS='NEW' (create new file) using I/O unit x. Make sure correct file name, directory path, unit, and so forth were specified in the source program. Decide whether to:

- Rename or remove the existing file before rerunning the program.
- Modify the source file to specify different file specification, I/O unit, or OPEN statement STATUS.

11

**info (11): Unit not connected**

FOR$IOS_UNINOTCON. The specified unit was not open at the time of the attempted I/O operation. Check if correct unit number was specified. If appropriate, use an OPEN statement to explicitly open the file (connect the file to the unit number).

17

**severe (17): Syntax error in NAMELIST input**

FOR$IOS_SYNERRNAM. The syntax of input to a namelist-directed READ statement was incorrect.

18

**severe (18): Too many values for NAMELIST variable**

FOR$IOS_TOOMANVAL. An attempt was made to assign too many values to a variable during a namelist READ statement.

19

**severe (19): Invalid reference to variable in NAMELIST input**

FOR$IOS_INVREFVAR. One of the following conditions occurred:

- The variable was not a member of the namelist group.
- An attempt was made to subscript a scalar variable.
- A subscript of the array variable was out-of-bounds.
- An array variable was specified with too many or too few subscripts for the variable.
- An attempt was made to specify a substring of a non-character variable or array name.
- A substring specifier of the character variable was out-of-bounds.
- A subscript or substring specifier of the variable was not an integer constant.
- An attempt was made to specify a substring by using an unsubscripted array variable.

20

**severe (20): REWIND error**

FOR$IOS_REWERR. One of the following conditions occurred:

- The file was not a sequential file.
- The file was not opened for sequential or append access.
- The Intel® Fortran RTL I/O system detected an error condition during execution of a REWIND statement.

21

**severe (21): Duplicate file specifications**

FOR$IOS_DUPFILSPE. Multiple attempts were made to specify file attributes without an intervening close operation. A DEFINE FILE statement was followed by another DEFINE FILE statement or an OPEN statement.

22

**severe (22): Input record too long**

FOR$IOS_INPRECTOO. A record was read that exceeded the explicit or default record length specified when the file was opened. To read the file, use an OPEN statement with a RECL=value (record length) of the appropriate size.

23

**severe (23): BACKSPACE error**

FOR$IOS_BACERR. The Intel® Fortran RTL I/O system detected an error condition during execution of a BACKSPACE statement.
Severe (24): End-of-file during read

FOR$IOS_ENDDURREA. One of the following conditions occurred:

- An Intel® Fortran RTL I/O system end-of-file condition was encountered during execution of a READ statement that did not contain an END, ERR, or IOSTAT specification.
- An end-of-file record written by the ENDFILE statement was encountered during execution of a READ statement that did not contain an END, ERR, or IOSTAT specification.
- An attempt was made to read past the end of an internal file character string or array during execution of a READ statement that did not contain an END, ERR, or IOSTAT specification.

This error is returned by END and ERRSNS.

Severe (25): Record number outside range

FOR$IOS_RECNUMOUT. A direct access READ, WRITE, or FIND statement specified a record number outside the range specified when the file was opened.

Severe (26): OPEN or DEFINE FILE required

FOR$IOS_OPEDEFFREQ. A direct access READ, WRITE, or FIND statement was attempted for a file when no prior DEFINE FILE or OPEN statement with ACCESS='DIRECT' was performed for that file.

Severe (27): Too many records in I/O statement

FOR$IOS_TOOMANREC. An attempt was made to do one of the following:

- Read or write more than one record with an ENCODE or DECODE statement.
- Write more records than existed.

Severe (28): CLOSE error

FOR$IOS_CLOERR. An error condition was detected by the Intel® Fortran RTL I/O system during execution of a CLOSE statement.

Severe (29): File not found

FOR$IOS_FILNOTFOU. A file with the specified name could not be found during an OPEN operation.

Severe (30): Open failure

FOR$IOS_OPEFAI. An error was detected by the Intel® Fortran RTL I/O system while attempting to open a file in an OPEN, INQUIRE, or other I/O statement. This message is issued when the error condition is not one of the more common conditions for which specific error messages are provided. It can occur when an OPEN operation was attempted for one of the following:

- Segmented file that was not on a disk or a raw magnetic tape
- Standard I/O file that had been closed

Severe (31): Mixed file access modes

FOR$IOS_MIXFILACC. An attempt was made to use any of the following combinations:

- Formatted and unformatted operations on the same unit
- An invalid combination of access modes on a unit, such as direct and sequential
- An Intel® Fortran RTL I/O statement on a logical unit that was opened by a program coded in another language

Severe (32): Invalid logical unit number

FOR$IOS_INVLOGUNI. A logical unit number greater than 2,147,483,647 or less than zero was used in an I/O statement.
<table>
<thead>
<tr>
<th>Number</th>
<th>Severity Level, Number, and Message Text; Condition Symbol and Explanation</th>
</tr>
</thead>
</table>
| 33     | **severe (33): ENDFILE error**  
FOR$IOS_ENDFILERR. One of the following conditions occurred:  
• The file was not a sequential organization file with variable-length records.  
• The file was not opened for sequential, append, or direct access.  
• An unformatted file did not contain segmented records.  
• The Intel® Fortran RTL I/O system detected an error during execution of an ENDFILE statement. |
| 34     | **severe (34): Unit already open**  
FOR$IOS_UNIALROPE. A DEFINE FILE statement specified a logical unit that was already opened. |
| 35     | **severe (35): Segmented record format error**  
FOR$IOS_SEGRECFOR. An invalid segmented record control data word was detected in an unformatted sequential file. The file was probably either created with RECORDTYPE='FIXED' or 'VARIABLE' in effect, or was created by a program written in a language other than Fortran or Standard Fortran. |
| 36     | **severe (36): Attempt to access non-existent record**  
FOR$IOS_ATTACCNON. A direct-access READ or FIND statement attempted to access beyond the end of a relative file (or a sequential file on disk with fixed-length records) or access a record that was previously deleted from a relative file. |
| 37     | **severe (37): Inconsistent record length**  
FOR$IOS_INCRECLEN. An attempt was made to open a direct access file without specifying a record length. |
| 38     | **severe (38): Error during write**  
FOR$IOS_ERRDURWRI. The Intel® Fortran RTL I/O system detected an error condition during execution of a WRITE statement. |
| 39     | **severe (39): Error during read**  
FOR$IOS_ERRDURREA. The Intel® Fortran RTL I/O system detected an error condition during execution of a READ statement. |
| 40     | **severe (40): Recursive I/O operation**  
FOR$IOS_RECIO_OPE. While processing an I/O statement for a logical unit, another I/O operation on the same logical unit was attempted, such as a function subprogram that performs I/O to the same logical unit that was referenced in an expression in an I/O list or variable format expression. |
| 41     | **severe (41): Insufficient virtual memory**  
FOR$IOS_INSVIRMEM. The Intel® Fortran RTL attempted to exceed its available virtual memory while dynamically allocating space. To overcome this problem, investigate increasing the data limit. Before you try to run this program again, wait until the new system resources take effect.  

**NOTE**  
This error can be returned by STAT in an ALLOCATE or a DEALLOCATE statement. |
<p>| 42     | <strong>severe (42): No such device</strong> |</p>

<tr>
<td>64</td>
<td><strong>severe (64): Input conversion error</strong>&lt;br&gt;FOR$IOS_INPCONERR. During a formatted input operation, an invalid character was detected in an input field, or the input value overflowed the range representable in the input variable. The value of the variable was set to zero.</td>
</tr>
</tbody>
</table>

**NOTE**<br>The ERR transfer is taken after completion of the I/O statement for error numbers 61, 63, 64, and 68. The resulting file status and record position are the same as if no error had occurred. However, other I/O errors take the ERR transfer as soon as the error is detected, so file status and record position are undefined.

| 65     | **error (65): Floating invalid**<br>FOR$IOS_FLTINV. During an arithmetic operation, the floating-point values used in a calculation were invalid for the type of operation requested or invalid exceptional values. For example, the error can occur if you request a log of the floating-point values 0.0 or a negative number. For certain arithmetic expressions, specifying the `check[:]:nopower` option can suppress this message. |

| 66     | **severe (66): Output statement overflows record**<br>FOR$IOS_OUTSTAOVE. An output statement attempted to transfer more data than would fit in the maximum record size. |

| 67     | **severe (67): Input statement requires too much data**<br>FOR$IOS_INPSTAREQ. Attempted to read more data than exists in a record with an unformatted `READ` statement or with a formatted sequential `READ` statement from a file opened with a `PAD='NO'` specifier. |

| 68     | **severe (68): Variable format expression value error**<br>FOR$IOS_VFEVALERR. The value of a variable format expression was not within the range acceptable for its intended use; for example, a field width was less than or equal to zero. A value of 1 was assumed, except for a P edit descriptor, for which a value of zero was assumed. |

**NOTE**<br>The ERR transfer is taken after completion of the I/O statement for error numbers 61, 63, 64, and 68. The resulting file status and record position are the same as if no error had occurred. However, other I/O errors take the ERR transfer as soon as the error is detected, so file status and record position are undefined.

| 69     | **error (69): Process interrupted (SIGINT)**<br>FOR$IOS_SIGINT. The process received the signal `SIGINT`. Determine source of this interrupt signal (described in `signal(3)`). |

| 70     | **severe (70): Integer overflow**<br>FOR$IOS_INTOVF. During an arithmetic operation, an integer value exceeded byte, word, or longword range. The result of the operation was the correct low-order part. Consider specifying a larger integer data size (modify source program or, for an `INTEGER` declaration, possibly use the `integer-size[:]:size` option). |

<p>| 71     | <strong>severe (71): Integer divide by zero</strong>&lt;br&gt;FOR$IOS_INTDIV. During an integer arithmetic operation, an attempt was made to divide by zero. The result of the operation was set to the dividend, which is equivalent to division by 1. |</p>

<td><strong>info (95): Floating-point conversion failed</strong>&lt;br&gt;FOR$IOS_FLOCONFAI. The attempted unformatted read or write of nonnative floating-point data failed because the floating-point value:&lt;br&gt;• Exceeded the allowable maximum value for the equivalent native format and was set equal to infinity (plus or minus).</td>
</tr>
</tbody>
</table>
• Was infinity (plus or minus) and was set to infinity (plus or minus).
• Was invalid and was set to not a number (NaN).

Very small numbers are set to zero (0). This error could be caused by the specified nonnative floating-point format not matching the floating-point format found in the specified file. Check the following:
• The correct file was specified.
• The record layout matches the format Intel® Fortran is expecting.
• The ranges for the data being used (see Data Representation Overview).
• The correct nonnative floating-point data format was specified (see Supported Native and Nonnative Numeric Formats).

96 info (96): F_UFMTENDIAN environment variable was ignored: erroneous syntax
FOR$IOS_UFMTENDIAN. Syntax for specifying whether little endian or big endian conversion is performed for a given Fortran unit was incorrect. Even though the program will run, the results might not be correct if you do not change the value of F_UFMTENDIAN. For correct syntax, see Environment Variable F_UFMTENDIAN Method.

98 Severe (98): cannot allocate memory for the file buffer - out of memory
FOR_S_NOMEMFORIO. This error often occurs during a file I-O operation such as OPEN, READ, or WRITE. Either increase the amount of memory available to the program, or reduce its demand.

106 Severe (106): FORT_BLOCKSIZE environment variable has erroneous syntax
FOR_S_INVBLOCKSIZE. Syntax for specifying the default block size value was incorrect. For correct syntax, see Environment Variable FORT_BLOCKSIZE.

107 Severe (107): FORT_BUFFERCOUNT environment variable has erroneous syntax
FOR_S_INVBUFRCNT. Syntax for specifying the default buffer count value was incorrect. For correct syntax, see Environment Variable FORT_BUFFERCOUNT.

108 Severe (108): Cannot stat file
FOR$IOS_CANSTAFILE. Make sure correct file and unit were specified.

109 info (109): stream data transfer statement is not allowed to an unopened unit
FOR$IOS_SIONOTOPEN. Stream data transfer statement is not allowed to an unopened unit.

118 severe (118): The 'RECL=' value in an OPEN statement exceeds the maximum allowed for the file's record type.
FOR$IOS_MAX_FXD_RECL. The 'RECL=' value in an OPEN statement is too large for the file’s record type.

119 severe (119): The FORT_BUFFERING_THRESHOLD environment variable has erroneous syntax
FOR$ IOS_INVTHRESHOLD. If specified, the FORT_BUFFERING_THRESHOLD environment variable must be an integer value greater than zero and less than 2147483647.

120 severe (120): Operation requires seek ability
FOR$IOS_OPERREQSEE. Attempted an operation on a file that requires the ability to perform seek operations on that file. Make sure the correct unit, directory path, and file were specified.

124 severe (124): Invalid command supplied to EXECUTE_COMMAND_LINE
FOR$ IOS_INVCMDECL. The command line passed to the EXECUTE_COMMAND_LINE intrinsic is invalid.
<table>

</tbody>
</table>
FOR$IOS_F6302. More than one alternate radix for numeric I/O was specified. F6302 can indicate an error in spacing or a mismatched format for data of different radices.

569 severe (569): Illegal radix specifier
FOR$IOS_F6303. A radix specifier was not between 2 and 36, inclusive. Alternate radix constants must be of the form n#ddd... where n is a radix from 2 to 36 inclusive and ddd... are digits with values less than the radix. For example, 3#12 and 34#7AX are valid constants with valid radix specifiers. 245#7A and 39#12 do not have valid radix specifiers and generate error 569 if input.

570 severe (570): Illegal STATUS value
FOR$IOS_F6304. An illegal value was used with the STATUS option.
STATUS accepts the following values:
- 'KEEP' or 'DELETE' when used with CLOSE statements
- 'OLD', 'NEW', 'SCRATCH', or 'UNKNOWN' when used with OPEN statements

571 severe (571): Illegal MODE value
FOR$IOS_F6305. An illegal value was used with the MODE option.
MODE accepts the values 'READ', 'WRITE', or 'READWRITE'.

572 severe (572): Illegal ACCESS value
FOR$IOS_F6306. An illegal value was used with the ACCESS option.
ACCESS accepts the values 'SEQUENTIAL' and 'DIRECT'.

573 severe (573): Illegal BLANK value
FOR$IOS_F6307. An illegal value was used with the BLANK option.
BLANK accepts the values 'NULL' and 'ZERO'.

574 severe (574): Illegal FORM value
FOR$IOS_F6308. An illegal value was used with the FORM option.
FORM accepts the following values: 'FORMATTED', 'UNFORMATTED', and 'BINARY'.

575 severe (575): Illegal SHARE value
FOR$IOS_F6309. An illegal value was used with the SHARE option.
SHARE accepts the values 'COMPAT', 'DENYRW', 'DENYWR', 'DENYRD', and 'DENYNONE'.

577 severe (577): Illegal record number
FOR$IOS_F6311. An invalid number was specified as the record number for a direct-access file. The first valid record number for direct-access files is 1.

578 severe (578): No unit number associated with *
FOR$IOS_F6312. In an INQUIRE statement, the NUMBER option was specified for the file associated with * (console).

580 severe (580): Illegal unit number
FOR$IOS_F6314. An illegal unit number was specified.
Legal unit numbers can range from 0 through 2**31-1, inclusive.

581 severe (581): Illegal RECL value

<tr>
<td>FOR$IOS_F6418.</td>
<td>The program exceeded the number of units that can be connected at one time. Units are connected with the OPEN statement.</td>
</tr>
<tr>
<td>FOR$IOS_F6419.</td>
<td>The file was opened with FORM='UNFORMATTED' and ACCESS='SEQUENTIAL', but its internal physical structure was incorrect or inconsistent. Possible causes: the file was created in another mode or by a non-Fortran program.</td>
</tr>
<tr>
<td>FOR$IOS_F6420.</td>
<td>A statement such as BACKSPACE or ENDFILE specified a file that had not yet been opened. (The READ and WRITE statements do not cause this problem because they prompt you for a file if the file has not been opened yet.)</td>
</tr>
</tbody>
</table>

For example, consider you have a file LONG.DAT that is one continuous record with data fields separated by commas. You then set the buffer associated with the file to 512 bytes, read more than one buffer size of data, tab left to data in the previous buffer, and attempt to read further data, as follows:

```fortran
INTEGER value(300)
OPEN (1, FILE = 'LONG.DAT', BLOCKSIZE = 512)s
READ (1, 100) (value(i), i = 1, 300)s
100 FORMAT (290I2, TL50, 10I2)
```

In this case, error 594 occurs.

**severe (599): File already connected to a different unit**

**severe (600): Access not allowed**

**severe (601): File already exists**

**severe (602): File not found**

**severe (603): Too many open files**

**severe (604): Too many units connected**

**severe (605): Illegal structure for unformatted file**

**severe (606): Unknown unit number**

**severe (607): File read-only or locked against writing**
FOR$IOS_F6421. The program tried to transfer data to a file that was opened in read-only mode or locked against writing.

The error message may indicate a **CLOSE** error when the fault is actually coming from **WRITE**. This is because the error is not discovered until the program tries to write buffered data when it closes the file.

### Severe (608): No space left on device

FOR$IOS_F6422. The program tried to transfer data to a file residing on a device (such as a hard disk) that was out of storage space.

### Severe (609): Too many threads

FOR$IOS_F6423. Too many threads were active simultaneously. At most, 32 threads can be active at one time. Close any unnecessary processes or child windows within your application.

### Severe (610): Invalid argument

FOR$IOS_F6424.

### Severe (611): BACKSPACE illegal for SEQUENTIAL write-only files

FOR$IOS_F6425. The **BACKSPACE** statement is not allowed in files opened with **MODE='WRITE'** (write-only status) because **BACKSPACE** requires reading the previous record in the file to provide positioning.

Resolve the problem by giving the file read access or by avoiding the **BACKSPACE** statement.

Note that the **REWIND** statement is valid for files opened as write-only.

### Severe (612): File not open for reading or file locked

FOR$IOS_F6500. The program tried to read from a file that was not opened for reading or was locked.

### Severe (613): End of file encountered

FOR$IOS_F6501. The program tried to read more data than the file contains.

### Severe (614): Positive integer expected in repeat field

FOR$IOS_F6502. When the **i*c** form is used in list-directed input, the **i** must be a positive integer. For example, consider the following statement:

```fortran
READ(*,*) a, b
```

Input 2*56.7 is accepted, but input 2.1*56.7 returns error 614.

### Severe (615): Multiple repeat field

FOR$IOS_F6503. In list-directed input of the form **i*c**, an extra repeat field was used. For example, consider the following:

```fortran
READ(*,*) I, J, K
```

Input of 2*1*3 returns this error. The 2*1 means send two values, each 1; the *3 is an error.

### Severe (616): Invalid number in input

FOR$IOS_F6504. Some of the values in a list-directed input record were not numeric. For example, consider the following:

```fortran
READ(*,*) I, J
```

The preceding statement would cause this error if the input were: 123 'abc'.

### Severe (617): Invalid string in input

FOR$IOS_F6505. A string item was not enclosed in single quotation marks.
618 **severe (618): Comma missing in COMPLEX input**

FOR$IOS_F6506. When using list-directed input, the real and imaginary components of a complex number were not separated by a comma.

619 **severe (619): T or F expected in LOGICAL read**

FOR$IOS_F6507. The wrong format was used for the input field for logical data.

The input field for logical data consists of optional blanks, followed by an optional decimal point, followed by a T for true or F for false. The T or F may be followed by additional characters in the field, so that .TRUE. and .FALSE. are acceptable input forms.

620 **severe (620): Too many bytes read from unformatted record**

FOR$IOS_F6508. The program tried to read more data from an unformatted file than the current record contained. If the program was reading from an unformatted direct file, it tried to read more than the fixed record length as specified by the `RECL` option. If the program was reading from an unformatted sequential file, it tried to read more data than was written to the record.

621 **severe (621): H or apostrophe edit descriptor illegal on input**

FOR$IOS_F6509. Hollerith (H) or apostrophe edit descriptors were encountered in a format used by a `READ` statement.

622 **severe (622): Illegal character in hexadecimal input**

FOR$IOS_F6510. The input field contained a character that was not hexadecimal.

Legal hexadecimal characters are 0 - 9 and A - F.

623 **severe (623): Variable name not found**

FOR$IOS_F6511. A name encountered on input from a namelist record is not declared in the corresponding `NAMELIST` statement.

624 **severe (624): Invalid NAMELIST input format**

FOR$IOS_F6512. The input record is not in the correct form for `NAMELIST` input.

625 **severe (625): Wrong number of array dimensions**

FOR$IOS_F6513. In `NAMELIST` input, an array name was qualified with a different number of subscripts than its declaration, or a non-array name was qualified.

626 **severe (626): Array subscript exceeds allocated area**

FOR$IOS_F6514. A subscript was specified in `NAMELIST` input which exceeded the declared dimensions of the array.

627 **severe (627): Invalid subrange in NAMELIST input**

FOR$IOS_F6515. A character item in namelist input was qualified with a subrange that did not meet the requirement that $1 <= e1 <= e2 <= len$ (where "len" is the length of the character item, "e1" is the leftmost position of the substring, and "e2" is the rightmost position of the substring).

628 **severe (628): Substring range specified on non-CHARACTER item**

FOR$IOS_F6516. A non-CHARACTER item in namelist input was qualified with a substring range.

629 **severe (629): Internal file overflow**

FOR$IOS_F6600. The program either overflowed an internal-file record or tried to write to a record beyond the end of an internal file.

630 **severe (630): Direct record overflow**

</tbody>
</table>
Severity Level, Number, and Message Text; Condition Symbol and Explanation

 FOR$IOS_F6985. To control interpretation of embedded and trailing blanks within numeric input fields, you must specify BN (to ignore them) or BZ (to interpret them as zeros).

643  severe (643): Format nesting limit exceeded
 FOR$IOS_F6986. More than sixteen sets of parentheses were nested inside the main level of parentheses in a format.

644  severe (644): '.' expected in format
 FOR$IOS_F6987. No period appeared between the $ and d fields of a D, E, F, or G edit descriptor.

645  severe (645): Unexpected end of format
 FOR$IOS_F6988. An incomplete format was used.
 Improperly matched parentheses, an unfinished Hollerith (H) descriptor, or another incomplete descriptor specification can cause this error.

646  severe (646): Unexpected character in format
 FOR$IOS_F6989. A character that cannot be interpreted as part of a valid edit descriptor was used in a format. For example, consider the following:

```plaintext
WRITE(*, 100) I, J
100 FORMAT (I2, TL4.5, I2)
```

The code will generate this error because TL4.5 is not a valid edit descriptor. An integer must follow TL.

647  severe (647): M field exceeds W field in I edit descriptor
 FOR$IOS_F6990. In syntax Iw.m, the value of m cannot exceed the value of w.

648  severe (648): Integer out of range in format
 FOR$IOS_F6991. An integer value specified in an edit descriptor was too large to represent as a 4-byte integer.

649  severe (649): format not set by ASSIGN
 FOR$IOS_F6992. The format specifier in a READ, WRITE, or PRINT statement was an integer variable, but an ASSIGN statement did not properly assign it the statement label of a FORMAT statement in the same program unit.

650  severe (650): Separator expected in format
 FOR$IOS_F6993. Within format specifications, edit descriptors must be separated by commas or slashes (/).

651  severe (651): %c or $: nonstandard edit descriptor in format
 FOR$IOS_F6994.

652  severe (652): Z: nonstandard edit descriptor in format
 FOR$IOS_F6995. Z is not a standard edit descriptor in format.
 If you want to transfer hexadecimal values, you must use the edit descriptor form Zw\.m], where w is the field width and m is the minimum number of digits that must be in the field (including leading zeros).

653  severe (653): DOS graphics not supported under Windows NT
 FOR$IOS_F6996.

654  severe (654): Graphics error

</table>
FOR$IOS_F6711. The subscript for a substring within a string is not a valid string position: at least 1 and no greater than the length of the string.

667 severe (667): VECTOR argument to PACK has incompatible character length
FOR$IOS_F6712. The character length of elements in the VECTOR argument to PACK is not the same as the character length of elements in the array to be packed.

668 severe (668): VECTOR argument to PACK is too small
FOR$IOS_F6713. The VECTOR argument to PACK must have at least as many elements as there are true elements in MASK (the array that controls packing).

669 severe (669): SOURCE and PAD arguments to RESHAPE have different character lengths
FOR$IOS_F6714. The character length of elements in the SOURCE and PAD arguments to PACK must be the same.

670 severe (670): Element 'n' of SHAPE argument to RESHAPE is negative
FOR$IOS_F6715. The SHAPE vector specifies the shape of the reshaped array. Since an array cannot have a negative dimension, SHAPE cannot have a negative element.

671 severe (671): SOURCE too small for specified SHAPE in RESHAPE, and no PAD
FOR$IOS_F6716. If there is no PAD array, the SOURCE argument to RESHAPE must have enough elements to make an array of the shape specified by SHAPE.

672 severe (672): Out of memory
FOR$IOS_F6717. The system ran out of memory while trying to make the array specified by RESHAPE. If possible, reset your virtual memory size through the Windows* Control Panel, or close unnecessary applications and deallocate all allocated arrays that are no longer needed.

673 severe (673): SHAPE and ORDER arguments to RESHAPE have different sizes ('size1' and 'size2')
FOR$IOS_F6718. ORDER specifies the order of the array dimensions given in SHAPE, and they must be vectors of the same size.

674 severe (674): Element 'n' of ORDER argument to RESHAPE is out of range ('range')
FOR$IOS_F6719. The ORDER argument specifies the order of the dimensions of the reshaped array, and it must be a permuted list of (1, 2, ..., n) where n is the highest dimension in the reshaped array.

675 severe (675): Value 'val' occurs twice in ORDER argument to RESHAPE
FOR$IOS_F6720. The ORDER vector specifies the order of the dimensions of the reshaped array, and it must be a permuted list of (1, 2, ..., n) where n is the highest dimension in the reshaped array. No dimension can occur twice.

676 severe (676): Impossible nextelt overflow in RESHAPE
FOR$IOS_F6721.

677 severe (677): Invalid value 'dim' for argument DIM for SPREAD of rank 'rank' source
FOR$IOS_F6722. The argument specified for DIM to SPREAD must be greater than or equal to 1, and less than or equal to one larger than the number of dimensions (rank) of SOURCE.
Consider the following statement:

```
result = SPREAD (SOURCE= array, DIM = dim, NCOPIES = k)
```

In this case, $1 <= dim <= n+1$, where $n$ is the number of dimensions in array.

The optional argument $\text{DIM}$ specifies the dimension along which to perform an end-off shift in an array, and must be greater than or equal to 1 and less than or equal to the number of dimensions in the array. That is, $1 \leq \text{DIM} \leq n$, where $n$ is the number of dimensions in array holding the elements to be shifted.

701 severe (701): Shape mismatch (dimension 'dim') between ARRAY and SHIFT in EOSHIFT

FOR$I\text{OS}_F6745$. The $\text{SHIFT}$ argument to EOSHIFT must be either scalar or an array one dimension smaller than the shifted array. If an array, the shape of the $\text{SHIFT}$ must conform to the shape of the array being shifted in every dimension except the one being shifted along.

702 severe (702): BOUNDARY argument to EOSHIFT has wrong LEN ('len1 instead of len2')

FOR$I\text{OS}_F6746$. The character length of elements in the BOUNDARY argument and in the array being end-off shifted must be the same.

703 severe (703): BOUNDARY has LEN 'len' instead of 'len' to EOSHIFT

FOR$I\text{OS}_F6747$. 

704 severe (704): Internal error - bad arguments to EOSHIFT

FOR$I\text{OS}_F6748$. 

705 severe (705): GETARG: value of argument 'num' is out of range

FOR$I\text{OS}_F6750$. The value used for the number of the command-line argument to retrieve with GETARG must be 0 or a positive integer. If the number of the argument to be retrieved is greater than the actual number of arguments, blanks are returned, but no error occurs.

706 severe (706): FLUSH: value of LUNIT 'num' is out of range

FOR$I\text{OS}_F6751$. The unit number specifying which I/O unit to flush to its associated file must be an integer between 0 and $2^{31}-1$, inclusive. If the unit number is valid, but the unit is not opened, error F6752 is generated.

707 severe (707): FLUSH: Unit 'n' is not connected

FOR$I\text{OS}_F6752$. The I/O unit specified to be flushed to its associated file is not connected to a file.

708 severe (708): Invalid string length ('len') to ICHAR

FOR$I\text{OS}_F6753$. The character argument to ICHAR must have length of one.

709 severe (709): Invalid string length ('len') to IACHAR

FOR$I\text{OS}_F6754$. The character argument to IACHAR must have length of one.

710 severe (710): Integer zero raised to negative power

FOR$I\text{OS}_F6755$. Zero of any type (integer, real, or complex) cannot be raised to a negative power. Raising to a negative power inverts the operand.

711 severe (711): INTEGER zero raised to zero power

FOR$I\text{OS}_F6756$. Zero of any type (integer, real, or complex) cannot be raised to zero power.

712 severe (712): SIZE argument ('size') to ISHFTC intrinsic out of range

FOR$I\text{OS}_F6757$. The argument $\text{SIZE}$ must be positive and must not exceed the bit size of the integer being shifted. The bit size of this integer can be determined with the function $\text{BIT\_SIZE}$. 

713 severe (713): SHIFT argument ('shift') to ISHFTC intrinsic out of range
FOR$IOS_F6758. The argument \texttt{SHIFT} to \texttt{ISHFTC} must be an integer whose absolute value is less than or equal to the number of bits being shifted: either all bits in the number being shifted or a subset specified by the optional argument \texttt{SIZE}.

714 severe (714): Out of range: DIM argument to LBOUND has value 'dim' FOR$IOS_F6759. The optional argument \texttt{DIM} specifies the dimension whose lower bound is to be returned, and must be greater than or equal to 1 and less than or equal to the number of dimensions in the array. That is, $1 \leq \text{DIM} \leq n$, where $n$ is the number of dimensions in array.

715 severe (715): Out of range: DIM argument ('dim') to LBOUND greater than ARRAY rank 'rank' FOR$IOS_F6760. The optional argument \texttt{DIM} specifies the dimension whose lower bound is to be returned, and must be greater than or equal to 1 and less than or equal to the number of dimensions (rank) in the array. That is, $1 \leq \text{DIM} \leq n$, where $n$ is the number of dimensions in array.

716 severe (716): Out of range: DIM argument to MAXVAL has value 'dim' FOR$IOS_F6761. The optional argument \texttt{DIM} specifies the dimension along which maximum values are returned, and must be greater than or equal to 1 and less than or equal to the number of dimensions in the array. That is, $1 \leq \text{DIM} \leq n$, where $n$ is the number of dimensions in array.

717 severe (717): Out of range: DIM argument to MAXVAL has value 'dim' with ARRAY of rank 'rank' FOR$IOS_F6762. The optional argument \texttt{DIM} specifies the dimension along which maximum values are returned, and must be greater than or equal to 1 and less than or equal to the number of dimensions (rank) in the array. That is, $1 \leq \text{DIM} \leq n$, where $n$ is the number of dimensions in array.

718 severe (718): Cannot allocate temporary array -- out of memory FOR$IOS_F6763. There is not enough memory space to hold a temporary array.

Dynamic memory allocation is limited by several factors, including swap file size and memory requirements of other applications that are running. If you encounter an unexpectedly low limit, you might need to reset your virtual memory size through the Windows Control Panel or redefine the swap file size. Allocated arrays that are no longer needed should be deallocated.

719 severe (719): Attempt to DEALLOCATE part of a larger object FOR$IOS_F6764. An attempt was made to \texttt{DEALLOCATE} a pointer to an array subsection or an element within a derived type. The whole data object must be deallocated; parts cannot be deallocated.

720 severe (720): Pointer in DEALLOCATE is ASSOCIATED with an ALLOCATABLE array FOR$IOS_F6765. Deallocating a pointer associated with an allocatable target is illegal. Instead, deallocate the target the pointer points to, which frees memory and disassociates the pointer.

721 severe (721): Attempt to DEALLOCATE an object which was not allocated FOR$IOS_F6766. You cannot deallocate an array unless it has been previously allocated. You cannot deallocate a pointer whose target was not created by allocation. The intrinsic function \texttt{ALLOCATED} can be used to determine whether an allocatable array is currently allocated.

722 severe (722): Cannot ALLOCATE scalar POINTER -- out of memory FOR$IOS_F6767. There is not enough memory space to allocate the pointer.
<table>
<thead>
<tr>
<th>Number</th>
<th>Severity Level, Number, and Message Text; Condition Symbol and Explanation</th>
</tr>
</thead>
</table>

Dynamic memory allocation is limited by several factors, including swap file size and memory requirements of other applications that are running. If you encounter an unexpectedly low limit, you might need to reset your virtual memory size through the Windows Control Panel or redefine the swap file size. Allocated arrays that are no longer needed should be deallocated.

723 **severe (723): DEALLOCATE: object not allocated/associated**

FOR$IOS_F6768. You cannot deallocate an array unless it has been previously allocated. You cannot deallocate a pointer whose target was not created by allocation, or a pointer that has undefined association status.

The intrinsic function `ALLOCATED` can be used to determine whether an allocatable array is currently allocated.

724 **severe (724): Cannot ALLOCATE POINTER array -- out of memory**

FOR$IOS_F6769. There is not enough memory space to allocate the `POINTER` array.

Dynamic memory allocation is limited by several factors, including swap file size and memory requirements of other applications that are running. If you encounter an unexpectedly low limit, you might need to reset your virtual memory size through the Windows Control Panel or redefine the swap file size. Allocated arrays that are no longer needed should be deallocated.

725 **severe (725): DEALLOCATE: Array not allocated**

FOR$IOS_F6770. It is illegal to `DEALLOCATE` an array that is not allocated. You can check the allocation status of an array before deallocating with the `ALLOCATED` function.

726 **severe (726): DEALLOCATE: Character array not allocated**

FOR$IOS_F6771. It is illegal to `DEALLOCATE` an array that is not allocated. You can check the allocation status of an array before deallocating with the `ALLOCATED` function.

727 **severe (727): Cannot ALLOCATE allocatable array -- out of memory**

FOR$IOS_F6772. There is not enough memory space to hold the array.

Dynamic memory allocation is limited by several factors, including swap file size and memory requirements of other applications that are running. If you encounter an unexpectedly low limit, you might need to reset your virtual memory size through the Windows Control Panel or redefine the swap file size. Allocated arrays that are no longer needed should be deallocated.

An automatic data object is an object that is declared in a procedure subprogram or interface, is not a dummy argument, and depends on a nonconstant expression. For example:

```
SUBROUTINE  EXAMPLE (N)
  DIMENSION A (N, 5), B(10*N)
```

The arrays A and B in the example are automatic data objects.

728 **severe (728): Cannot allocate automatic object -- out of memory**

FOR$IOS_F6773. There is not enough memory space to hold the automatic data object.

Dynamic memory allocation is limited by several factors, including swap file size and memory requirements of other applications that are running. If you encounter an unexpectedly low limit, you might need to reset your virtual memory size through the Windows Control Panel or redefine the swap file size. Allocated arrays that are no longer needed should be deallocated.

729 **severe (729): DEALLOCATE failure: ALLOCATABLE array is not ALLOCATED**

FOR$IOS_F6774. It is illegal to `DEALLOCATE` an array that is not allocated. You can check the allocation status of an array before deallocating with the `ALLOCATED` function.

730 **severe (730): Out of range: DIM argument to MINVAL has value 'dim'**
FOR$IOS_F6775. The optional argument DIM specifies the dimension along which minimum values are returned, and must be greater than or equal to 1 and less than or equal to the number of dimensions in the array. That is, 1 <= DIM <= n, where n is the number of dimensions in array.

731 severe (731): Out of range: DIM argument to MINVAL has value 'dim' with ARRAY of rank 'rank'

FOR$IOS_F6776. The optional argument DIM specifies the dimension along which minimum values are returned, and must be greater than or equal to 1 and less than or equal to the number of dimensions (rank) in the array. That is, 1 <= DIM <= n, where n is the number of dimensions in array.

732 severe (732): P argument to MOD is double precision zero

FOR$IOS_F6777. MOD(A, P) is computed as A - INT(A, P) * P. P cannot be zero.

733 severe (733): P argument to MOD is integer zero

FOR$IOS_F6778. MOD(A, P) is computed as A - INT(A, P) * P. P cannot be zero.

734 severe (734): P argument to MOD is real zero

FOR$IOS_F6779. MOD(A, P) is computed as A - INT(A, P) * P. P cannot be zero.

735 severe (735): P argument to MODULO is real zero

FOR$IOS_F6780. MODULO(A, P) for real numbers is computed as A - FLOOR(A, P) * P. So, P cannot be zero.

736 severe (736): P argument to MODULO is zero

FOR$IOS_F6781. In the function, MODULO(A, P), P cannot be zero.

737 severe (737): Argument S to NEAREST is zero

FOR$IOS_F6782. The sign of the S argument to NEAREST(X, S) determines the direction of the search for the nearest number to X, and cannot be zero.

738 severe (738): Heap storage exhausted

FOR$IOS_F6783.

739 severe (739): PUT argument to RANDOM_SEED is too small

FOR$IOS_F6784. The integer array PUT must be greater than or equal to the number of integers the processor uses to set the seed value. This number can be determined by calling RANDOM_SEED with the SIZE argument. For example:

```
INTEGER, ALLOCATABLE SEED
CALL RANDOM_SEED( )        ! initialize processor
CALL RANDOM_SEED(SIZE = K) ! get size of seed
ALLOCATE SEED(K)            ! allocate array
CALL RANDOM_SEED(PUT = SEED) ! set the seed
```

NOTE
RANDOM_SEED can be called with at most one argument at a time.

740 severe (740): GET argument to RANDOM_SEED is too small
FOR$IOS_F6785. The integer array GET must be greater than or equal to the number of integers the processor uses to set the seed value. This number can be determined by calling RANDOM_SEED with the SIZE argument. For example:

```fortran
INTEGER, ALLOCATABLE SEED
CALL RANDOM_SEED( )           ! initialize processor
CALL RANDOM_SEED(SIZE = K)    ! get size of seed
ALLOCATE SEED(K)              ! allocate array
CALL RANDOM_SEED(GET = SEED)  ! get the seed
```

**NOTE**

RANDOM_SEED can be called with at most one argument at a time.

<td>FOR$IOS_F6789. The optional argument DIM specifies the dimension whose upper bound is to be returned, and must be greater than or equal to 1 and less than or equal to the number of dimensions (rank) in the array. That is, 1 &lt;= DIM &lt;= n, where n is the number of dimensions in array.</td>
</tr>
<tr>
<td><strong>745</strong> severe (745): Out of range: UBOUND of assumed-size array with DIM==rank ('rank')</td>
</tr>
<tr>
<td>FOR$IOS_F6790. The optional argument DIM specifies the dimension whose upper bound is to be returned.</td>
</tr>
<tr>
<td>An assumed-size array is a dummy argument in a subroutine or function, and the upper bound of its last dimension is determined by the size of actual array passed to it. Assumed-size arrays have no determined shape, and you cannot use UBOUND to determine the extent of the last dimension. You can use UBOUND to determine the upper bound of one of the fixed dimensions, in which case you must pass the dimension number along with the array name.</td>
</tr>
<tr>
<td><strong>746</strong> severe (746): Out of range: DIM argument ('dim') to UBOUND greater than ARRAY rank</td>
</tr>
<tr>
<td>FOR$IOS_F6791. The optional argument DIM specifies the dimension whose upper bound is to be returned, and must be greater than or equal to 1 and less than or equal to the number of dimensions (rank) in the array. That is, 1 &lt;= DIM &lt;= n, where n is the number of dimensions in array.</td>
</tr>
<tr>
<td><strong>747</strong> severe (747): Shape mismatch: Dimension 'shape' extents are 'ext1' and 'ext2'</td>
</tr>
<tr>
<td>FOR$IOS_F6792.</td>
</tr>
<tr>
<td><strong>748</strong> severe (748): Illegal POSITION value</td>
</tr>
<tr>
<td>FOR$IOS_F6793. An illegal value was used with the POSITION specifier.</td>
</tr>
</tbody>
</table>

POSITION accepts the following values:
• 'ASIS' (the default)
• 'REWRIND' - on Fortran I/O systems, this is the same as 'ASIS'
• 'APPEND'

749 severe (749): Illegal ACTION value
FOR$IOS_F6794. An illegal value was used with the ACTION specifier.
ACTION accepts the following values:
• 'READ'
• 'WRITE'
• 'READWRITE' - the default

750 severe (750): DELIM= specifier not allowed for an UNFORMATTED file
FOR$IOS_F6795. The DELIM specifier is only allowed for files connected for formatted data transfer. It is used to delimit character constants in list-directed an namelist output.

751 severe (751): Illegal DELIM value
FOR$IOS_F6796. An illegal value was used with the DELIM specifier.
DELIM accepts the following values:
• 'APOSTROPHE'
• 'QUOTE'
• 'NONE' - the default

752 severe (752): PAD= specifier not allowed for an UNFORMATTED file
FOR$IOS_F6797. The PAD specifier is only allowed for formatted input records. It indicates whether the formatted input record is padded with blanks when an input list and format specification requires more data than the record contains.

753 severe (753): Illegal PAD= value
FOR$IOS_F6798. An illegal value was used with the PAD specifier.
PAD accepts the following values:
• 'NO'
• 'YES' - the default

754 severe (754): Illegal CARRIAGECONTROL=value
FOR$IOS_F6799. An illegal value was used with the CARRIAGECONTROL specifier.
CARRIAGECONTROL accepts the following values:
• 'FORTRAN' - default if the unit is connected to a terminal or console
• 'LIST' - default for formatted files
• 'NONE' - default for unformatted files

755 severe (755): SIZE= specifier only allowed with ADVANCE='NO'
FOR$IOS_F6800. The SIZE specifier can only appear in a formatted, sequential READ statement that has the specifier ADVANCE='NO' (indicating non-advancing input).

756 severe (756): Illegal character in binary input
FOR$IOS_F6801.
### Signal Handling (Linux® and OS X® only)

A **signal** is an abnormal event generated by one of various sources, such as:

- A user of a terminal.
- Program or hardware error.
- Request of another program.
- When a process is stopped to allow access to the control terminal.

You can optionally set certain events to issue signals, for example:

- When a process resumes after being stopped
- When the status of a child process changes
- When input is ready at the terminal

Some signals terminate the receiving process if no action is taken (optionally creating a **core** file), while others are simply ignored unless the process has requested otherwise.

Except for certain signals, calling the **signal** or **sigaction** routine allows specified signals to be ignored or causes an interrupt (transfer of control) to the location of a user-written signal handler.

You can establish one of the following actions for a signal with a call to **signal**:

- Ignore the specified signal (identified by number).
- Use the default action for the specified signal, which can reset a previously established action.
- Transfer control from the specified signal to a procedure to receive the signal, specified by name.

Calling the **signal** routine lets you change the action for a signal, such as intercepting an operating system signal and preventing the process from being stopped.

The table below shows the signals that the Intel® Fortran RTL arranges to catch when a program is started:

<table>
<thead>
<tr>
<th>Number</th>
<th>Severity Level, Number, and Message Text; Condition Symbol and Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>757</td>
<td><strong>severe</strong> (757): Illegal character in octal input FOR$IOS_F6802.</td>
</tr>
<tr>
<td>758</td>
<td><strong>severe</strong> (758): End of record encountered FOR$IOS_F6803.</td>
</tr>
<tr>
<td>759</td>
<td><strong>severe</strong> (759): Illegal subscript in namelist input record FOR$IOS_F6804.</td>
</tr>
</tbody>
</table>

**Footnotes:**

1 Identifies errors not returned by IOSTAT.
Calling the `signal` routine (specifying the numbers for these signals) results in overwriting the signal-handling facility set up by the Intel® Fortran RTL. The only way to restore the default action is to save the returned value from the first call to `signal`.

When using a debugger, it may be necessary to enter a command to allow the Intel® Fortran RTL to receive and handle the appropriate signals.

**Overriding the Default Run-Time Library Exception Handler**

To override the default run-time library exception handler on Linux* and OS* X, your application must call `signal` to change the action for the signal of interest.

For example, assume that you want to change the signal action to cause your application to call `abort()` and generate a core file.

The following example adds a function named `clear_signal_` to call `signal()` and change the action for the `SIGABRT` signal:

```c
#include <signal.h>

void clear_signal_() { signal (SIGABRT, SIG_DFL); }

int myabort_() {
    abort();
    return 0;
}
```

A call to the `clear_signal_` local routine must be added to main. Make sure that the call appears before any call to the local `myabort_` routine:

```fortran
program aborts
  integer i

  call clear_signal()

  i = 3
  if (i < 5) then
    call myabort()
  end if
end
```

**Advanced Exception and Termination Handling**

**Advanced Exception and Termination Handling Overview**

This section provides information about exception and termination handling issues.

To employ some of the exception handling techniques presented, you will need a C language compiler, which has support for `try-except` constructs or some other form of support for structured exception handling.

**See Also**

- General Default Exception Handling
- Default Console Event Handling
- General Default Termination Handling
- Handlers for the Application (Project) Types
- Providing Your Own Exception/Termination Handler

**General Default Exception Handling**

The Intel® Visual Fortran run-time system provides minimal default support for exception handling, console event handling, and application termination rundown.
The default exception handling support provided depends on the type of application (project type) being developed:

- A default exception handler is included with Fortran Console, Fortran QuickWin, and Fortran Standard Graphics applications.
- No default exception handler is included with Fortran Windows or Fortran DLL applications or with C Console applications that contain Fortran procedures.

When you use the default exception handler, all events are enabled. You cannot connect or disconnect individual events from the default Fortran exception handler. However, you can disable the Fortran exception handler, and enable your own. To disable the exception handler, set the `FOR_IGNORE_EXCEPTIONS` environment variable to TRUE.

Most exceptions captured by the Intel® Visual Fortran default handler are dealt with as severe errors. When an exception occurs, the Fortran run-time system will display an error message and traceback output as described in Understanding Run-Time Errors. A run-time error with a severe error (as described in Run-Time Message Display and Format) causes the Intel® Visual Fortran run-time system to terminate the application. Most I/O programming errors are also severe and will terminate an application.

I/O programming errors are not exceptions and cannot be caught by an exception handler. An unhandled I/O programming error is reported through a different mechanism in the Intel® Visual Fortran run-time system. Regardless of the application (project) type, unhandled I/O programming error will generate an error message and traceback output.

Understanding Run-Time Errors
Understanding Project Types

**Default Console Event Handling**

When the Fortran run-time system is initialized, it establishes a default console event handler through the `SetConsoleCtrlHandler` Windows API routine. The default handler will respond to the following event types:

- `CTRL_C_EVENT`
- `CTRL_BREAK_EVENT`
- `CTRL_CLOSE_EVENT`

These event types will result in an orderly program abort with an appropriate diagnostic message. To disable this default call to `SetConsoleCtrlHandler`, set an environment variable named `FOR_DISABLE_CONSOLE_CTRL_HANDLER` to the value YES (Y or y), or TRUE (T or t), or a number greater than zero.

Other console events such as a `CTRL_LOGOFF_EVENT` or `CTRL_SHUTDOWN_EVENT` are not handled by the default handler. The handler is notified of these events but returns FALSE to the operating system. This allows an Intel® Visual Fortran application activated as a Windows® service to continue execution when a user logs off.

**See Also**

Establishing Console Event Handlers

**General Default Termination Handling**

When a Fortran Console, Fortran QuickWin, or Fortran Standard Graphics application terminates execution, either by normal termination or due to a severe error or exception, the following actions are taken by the Fortran run-time system:

- Any Open files are closed and the requested `DISPOSITION` operations are performed.
- With a QuickWin application, any open QuickWin windows are closed.
- The C run-time `exit()` routine is called with the status code to return to the operating system. The C run-time `exit()` routine will call the Windows API routine `ExitProcess` to terminate the process. (See `crt0dat.c` in the C run-time sources).
In a Fortran DLL or Fortran Windows* application, any unhandled I/O programming errors will cause the following actions:

- Any Open files are closed and the requested DISPOSITION operations are performed.
- The C run-time exit() routine is called with the status code to return to the operating system. The C run-time exit() routine will call the Windows API routine ExitProcess to terminate the process. (See _crt0dat.c in the C run-time sources.)

Any unhandled exceptions that occur in a Fortran DLL or Fortran Windows application will have application dependent behavior. Since there is no Fortran default handler present, the behavior depends on what you provide for a handler. If you do not explicitly provide a handler, the default mechanisms provided in your main program will determine the behavior. In a Fortran Windows* application, the C run-time system will terminate the application.

Handlers for the Application (Project) Types

To understand how Intel® Fortran handlers are incorporated into your application, and how you might incorporate your own handlers, you should understand how each application type is constructed. This section describes handlers for the various application (project) types.

Fortran Console Applications

Fortran Console applications resemble C applications, with the Intel® Fortran run-time system providing the C main() function.

The entry point for a console application is specified as the C library’s mainCRTStartup() routine (see module _crt0.c in the C run-time sources). This initializes the C run-time system, wraps the Fortran run-time system main() in a try-except construct using the C run-time’s exception filter (_XcptFilter()), and calls the Fortran run-time system main() routine in run-time module _for_main.c. In simplified form, it looks like this:

```c
mainCRTStartup() {
    C initialization code here
    _try {
        more initialization code here
        mainret = main();    /* calls Fortran run-time main() */
        exit(mainret)
    } _except ( _XcptFilter() )
        { _exit ( GetExceptionCode() ) }
}
```

In the Fortran run-time system, main() initializes the Fortran run-time system (if not already initialized), wraps a try-except construct around MAIN__ (the entry point to the Fortran code) with a filter expression that invokes the Fortran run-time system default handler on exceptions, and calls MAIN__. It also wraps a try-finally construct around all of this so run-time system clean up gets done (with for_rtl_finish_) when the program exits. In simplified form, it looks like this:

```c
main() {
    _try {
        _try {
            for_rtl_init()
            MAIN__
        } _except ( expression-invoking-fortran-default-handler )
            { }
    } _finally { for_rtl_finish() }
}
```

In the Fortran code, symbol MAIN__ is the entry point called by the run-time system’s main() routine. MAIN__ has the code to do any further run-time initialization or checks. For example, if the user compiled with the non-default fpe[:]0 option, there would be a call to FOR_SET_FPE to tell the run-time system how to setup/react to floating-point exceptions.
Fortran QuickWin and Standard Graphics Applications

A Fortran QuickWin (including Fortran Standard Graphics) application is a specialized windows application where Intel® Visual Fortran provides the WinMain() function.

The entry point for a QuickWin application is specified as the C library WinMainCRTStartup() routine (see module crt0.c in the C run-time sources). This gets the C run-time initialized, wraps the Intel® Visual Fortran defined WinMain() in a try-except construct using the C run-time exception filter (_XcptFilter()) and calls the Intel® Visual Fortran defined WinMain() routine. In simplified form, it looks like this:

```c
WinMainCRTStartup() {
    C initialization code here
    __try {
        more initialization code here
        mainret = WinMain()      /* calls qwin library WinMain() */
        exit(mainret)
    } __except ( _XcptFilter() )
            { _exit ( GetExceptionCode() ) }
}
```

In the QuickWin library, WinMain() performs some initialization specific to QuickWin, creates a new thread which begins execution at QWINForkMain, and then sits in a message loop directing the action. The message loop is wrapped in a try-except-finally construct which invokes the Fortran run-time system default handler if an exception occurs, and calls for_rtl_finish_ at exit. QWINForkMain() running in the other thread calls the Fortran run-time system main(), which in turn calls MAIN__. In simplified form, it looks like this:

```c
WinMain() {
    Initialization code here
    BeginThreadEx (... , QWINForkMain, ...) 
    __try {
        __try {
            the message loop...
            for_rtl_finish()
            return (msg.wParam)    
        } __except ( expression-invoking-default-fortran-handler )
            { }
        } __finally {
            for_rtl_finish()
            return (msg.wParam)
        }
    }
}
```

QWINForkMain resembles the following:

```c
QWINForkMain() {
    main()      /* calls the CVF rtl main() which calls MAIN__ */
    cleanup and exit...
}
```

The routines main() and MAIN__ are the same as previously described for a Fortran Console application.

Fortran DLL Applications

A Fortran DLL is a collection of one or more routines that you generally call from some other main program. As such, the routines execute in the structure and environment created by the code which calls into the DLL. You can provide DLL initialization through a DllMain() function, but you probably would control general application initialization from the main program.

There are no automatic provisions for any exception handler in a DLL. There is no environment initialization except what you provide. Of course, if your main application is also written in Fortran, you will get the default Fortran handlers provided by that application type.
Fortran Windows* Applications

A Fortran Windows* application has as its entry point WinMainCRTStartup() and each user writes the code for the WinMain function declaration and interface. Examples are provided to show how to do this in Fortran code. The compiler still generates symbol MAIN__ with the initialization code in place, but nothing calls MAIN__. Also, nothing connects up to the run-time system’s main() so there’s no try-except construct to hook in the default Intel® Fortran handler, and no run-time system initialization or cleanup. In simplified form, it looks like this:

```fortran
WinMainCRTStartup() {
  C initialization code
  __try {
    more initialization code
    mainret = WinMain()   /* calls the user's WinMain() */
    exit(mainret)
  } __except (_XcptFilter()) {
    _exit (GetExceptionCode())
  }
}
```

The Fortran code contains:

```fortran
integer(4) function WinMain( HANDLE, HANDLE, LPSTR, int )
  ...
  ! whatever Fortran the user codes here...
  ...
end
```

Providing Your Own Exception/Termination Handler

For Fortran Console, Fortran QuickWin, and Fortran Standard Graphics applications, the default exception and termination handlers are probably sufficient to meet most needs. As described in Handlers for the Application (Project) Types, Fortran DLL and Fortran Windows* applications do not have default handlers. Whenever the default exception and termination handlers do not meet all your needs, consider providing your own handler. This is really a question you need to answer for each specific application. Some examples:

- Suppose your application creates some files during the course of its execution and you do not want to leave them on the disk if an unexpected error or exception occurs. The default termination actions only cause the files to be closed if you specifically opened them with DISPOSE='DELETE'. But suppose you do not want them deleted under normal termination. If an unexpected event occurs, you need to get control so you can clean up these files as needed.
- Perhaps your application can recover from a particular situation, for example, an integer divide-by-zero operation. You want to gain control if that exception occurs and deal with it.
- Perhaps you just want to output an application-specific error message when an exception occurs.
- You are building a Fortran DLL to run under a Visual Basic* GUI and you do not want the DLL to crash the application if an exception occurs in the DLL.
- Your code takes a lock on a global resource and you want to be sure and release the resource if an unexpected event occurs.

The list of possibilities is endless and only the application developer can anticipate particular needs.

The most general way to establish your own handler is to use Windows* structured exception handling capabilities (SEH). For lighter-weight exception handling requirements, you can use SIGNALQQ.

Using Windows* Structured Exception Handling (SEH)

Using Windows* Structured Exception Handling (SEH) Overview

Windows* provides a robust exception and termination handling mechanism called Structured Exception Handling (SEH). Structured exception handling requires support in both the operating system and compilers. Unfortunately, Intel® Fortran does not include extensions for SEH support, but you can still take advantage of this powerful tool. By introducing a bit of C code in your application, you can use SEH to meet your exception handling needs.

A good reference on this subject is Chapter 16 in the book Advanced Windows (Third Edition) by Jeffrey Richter.

Custom Handlers for Fortran Console, Fortran QuickWin, and Fortran Standard Graphics Applications

Fortran Console and Fortran QuickWin (and Fortran Standard Graphics) applications have the full benefit of the Fortran default exception and error handling processing facilities. You may, however, want to supplement or replace the default facilities.

Custom Handlers for Fortran DLL Applications

There are two aspects to creating custom handlers for Fortran DLL applications:

- Containing errors and exceptions
- Enabling floating-point traps

Containing Errors and Exceptions in Fortran DLLs

If you are building a Fortran DLL and intend to call it from a main program written in some other language, you want to be careful that errors and exceptions in the DLL do not crash your main application.

Here are a few basic principles to keep in mind if you are building a Fortran DLL:

- Construct your library routines so that they return a status to the caller and let the caller decide what to do.
- To return an expected status to the caller, you need to be defensive in your library code, so consider these other principles:
- Where it makes sense, have the library code check input arguments passed in from the caller to make sure they are valid for whatever the library routine is going to do with them. For example, suppose the routine implements some numerical algorithm that has a valid domain of inputs it can act on and still produce well defined behavior. You can check the input arguments before you execute the algorithm and avoid unexpected behavior that might otherwise result (like unexpected floating-point exceptions). You might use Fortran intrinsic procedures like ISNAN and FP_CLASS to detect exceptional IEEE numbers. Your DLL code needs to return a status to the caller indicating the problem and let the caller take the appropriate action (gracefully shut down the application, try again with different input, etc.).
- In your library code, always check the success or failure of calls to I/O routines and dynamic memory allocation/deallocation. In Fortran, the I/O statements have optional ERR, END, EOR, and IOSTAT arguments that you can use to determine if the I/O requested was successful. Dynamic memory ALLOCATE and DEALLOCATE statements have an optional STAT specifier that allows you to obtain the status of the dynamic memory allocation/deallocation and prevent program termination.
- If you do not specify an action to take on an error, the Fortran run-time system has no choice but to deal with the error as an unhandled severe error and terminate the program. For a specific example of using IOSTAT and ERR to deal gracefully with an OPEN statement that gets a file-not-found error, see Using the IOSTAT Specifier and Fortran Exit Codes. You can do the same sort of thing in your code, but just return the status back to your Visual Basic* or other non-Fortran main program and let it decide what to do.
- Try to write your DLL code so unexpected program exceptions cannot occur, but devise a strategy for
dealing with unexpected exceptions if they do happen. The most effective alternative for dealing with an
exception is to use Windows Structured Exception Handling support to gain control when an exception
happens. Wrap all your DLL routine calls in C try/except constructs and have the except() filter
expression call a routine you define which determines how to respond.

**Enabling Floating-Point Traps in Fortran DLLs**

Before you can worry about how you will handle a floating-point trap condition occurring in a DLL, you have
to consider the problem of unmasking those traps so they can occur. If you are compiling with fpe[:3] and
polling the floating-point status word to check for exceptions, you do not have to worry about the problem of
unmasking traps. You do not want traps unmasked in that case.

If your strategy is to compile with fpe[:0] and allow traps on floating-point exceptions, you need to take
action to unmask the traps in the floating-point control word because most other languages mask traps by
default.

Recall that a Fortran Console or Fortran QuickWin (or Standard Graphics) application would have unmasked
traps for you automatically because the Fortran run-time system provides the main program and calls your
MAIN__ which executes some prolog code before the actual application code starts. You do not have that in a
Fortran DLL called by some other language. Different languages establish different initial environments. You
must provide the desired initial environment yourself.

ISNAN
FP_CLASS
ALLOCATE
DEALLOCATE

*Custom Handlers for Fortran Windows* Applications

Fortran Windows* applications are not hooked up to the Fortran default exception handling processing
facilities. Fortran Windows* applications are considered to be an area devoted to full customization, and the
Fortran run-time system tries to "stay out of the way," so you can do whatever you want in your code.

**Establishing Console Event Handlers**

Control-C event handling is basically not reliable due to the threaded nature of processes executing on the
Windows operating systems. Depending on what is happening at the instant a user types the Control-C, an
event handler may or may not get the opportunity to execute. In any case, there are two ways to establish a
handler if you want to do so. You can use the Windows* API routine SetConsoleCtrlHandler directly or
you can use SIGNALQQ to establish a handler for the C SIGINT or SIGBREAK signals.

The Fortran run-time system establishes a console event handler through a call to SetConsoleCtrlHandler as part of its run-time initialization processing. See Default Console Event Handling for a description of this
handler's behavior.

If you call SetConsoleCtrlHandler to establish your own event handler, your handler will be called first on
console events.

If you establish a handler through SIGNALQQ with SIGINT or SIGBREAK, the C run-time system will establish
its own internal handler for console events through a call to SetConsoleCtrlHandler, and it will record
your routine as the desired action to take upon occurrence of an event. When an event is delivered to the C
run-time handler, it will reset the action for the signal to SIG_DFL and then call your handler routine.

You must call SIGNALQQ again to reset the action to your routine if you want to continue from the control
event. Your handler is called with the signal code (either SIGINT or SIGBREAK) as the argument. After your
routine returns to the C run-time event handler, the C handler will return the value TRUE to the operating
system indicating the event has been handled.

**See Also**

SIGNALQQ
Default Console Event Handling

Using SIGNALQQ

For lightweight exception handling requirements, a handler established with SIGNALQQ may meet your needs. This section describes how signal handling with SIGNALQQ works in detail and also how the Fortran run-time routine GETEXCEPTIONPTRSQQ works.

Reference is made to C run-time sources provided with Microsoft* Visual C++. The discussion is worth reviewing even if you do not have Visual C++ available.

C-Style Signal Handling Overview

Many Fortran applications were developed on UNIX* systems where C-style signal handling was the usual way of dealing with exceptions. When ported to Windows*, these applications can continue to use the C signal interface. SIGNALQQ will work with any application type using pure Fortran or mixed Fortran and C code.

SIGNALQQ is just a Fortran jacket to the C run-time signal() function. When you call SIGNALQQ, you are actually registering your signal handler (or action) for a particular signal with the C run-time system. The C run-time system simply stores your handler (or action) in an internal exception action table or variable where it associates your handler with the desired signal. The operating system has no knowledge of this association.

If you have Visual C++ available, you can look at the code for the C run-time signal routine in ...

MICROSOFT VISUAL STUDIO .NET\VC7\CRT\SRC\WINSIG.C and see how the table is managed. The table itself is defined and initialized in source file WINXFLTR.C, available in the same folder. When a signal occurs, the C run-time system checks its internal table to see if you have registered a handler for the particular signal. It calls your routine if you have assigned a handler.

Signal is Really SEH Again

Notice that it is the C run-time system that calls your handler when a signal occurs, not the operating system. So how did the C run-time get the exception delivered to it? Recall that the entry point of your image is either mainCRTStartup or WinMainCRTStartup, depending on the application type. Refer to Handlers for the Application (Project) Types and look at these entry points (or look at source file Crt0.c in the C run-time sources). Notice that they wrap a try-except construct around a call to either main() or WinMain() and that the filter expression associated with the __except construct calls a function _XcptFilter. _XcptFilter is passed two arguments which are the operating system supplied exception information.

When an exception occurs, the operating system looks at the list of exception filters and, starting with the inner most nested try-except construct, evaluates except filter expressions until it finds one which does not return EXCEPTION_CONTINUE_SEARCH. If your application type includes main from the Fortran run-time system and thus the except construct associated with main, the Fortran run-time filter will be evaluated before the C run-time filter. The Fortran filter expression will check to see if you have established your own handler with SIGNALQQ. If it finds there is such a handler, or if you have set the environment variable FOR_IGNORE_EXCEPTIONS, it will return EXCEPTION_CONTINUE_SEARCH to allow the C run-time exception filter the opportunity to deal with the exception and find your handler. If you have not established your own handler or set the environment variable, the Fortran run-time will perform its default exception handling processing.

The C filter function, _XcptFilter, compares the exception code from the operating system with its mapping of operating system exceptions to C signal codes. If it finds a match in the table, it uses the exception action entry in the table corresponding to the signal code. This is the same table where your SIGNALQQ handler is recorded as the action for the requested signal code. If you have established a handler, it will be called from _XcptFilter. Before your handler is called, _XcptFilter resets the specified action for the signal to SIG_DFL in the exception action table. If you try to continue from the exception and you want your handler invoked on the next occurrence of the signal, you must call SIGNALQQ again to reestablish your handler as the action for that signal. When your handler routine is finished executing and returns to
_XcptFilter, the value EXCEPTION_CONTINUE_EXECUTION is returned to the operating system by _XcptFilter. The operating system will then resume execution at the point of the exception. If you do not want to continue execution, your handler should take appropriate action to shut down the application.

Not every operating system exception code maps to a C signal code. You can see the mapping in source WINXFLTR.C if you have it. Here is the list if you do not have WINXFLTR.C:

How GETEXCEPTIONPTRSQQ Works

When the C run-time exception filter function _XcptFilter calls your handler that you established with SIGNALQQ, the only argument passed to your handler is the C signal number. The C run-time system also saves a pointer to the exception information supplied by the operating system. This pointer is named _pxcptinfoptrs and you can retrieve it through the Fortran run-time routine GETEXCEPTIONPTRSQQ (W*32). See C header file signal.h for the public definition of _pxcptinfoptrs.

The value returned by GETEXCEPTIONPTRSQQ can be used in your handler routine to generate a traceback with TRACEBACKQQ. GETEXCEPTIONPTRSQQ just returns _pxcptinfoptrs. This pointer is only valid while you are executing within the evaluation of the C run-time filter function _XcptFilter because the exception information is on the program stack, so do not use GETEXCEPTIONPTRSQQ in any other context.

The Using the Intel® Visual Fortran Samples folder, created during product installation, contains a sample program called GETEPPTRS, which demonstrates use of GETEXCEPTIONPTRSQQ.

• Summary of Language Extensions
• A to Z Reference
• Glossary
This document contains the complete description of the Intel® Fortran programming language, which includes Fortran 2003, Fortran 95, Fortran 90, and some Fortran 2008 language features. It contains information on language syntax and semantics, on adherence to various Fortran standards, and on extensions to those standards.

This manual is intended for experienced applications programmers who have a basic understanding of Fortran concepts and the Fortran 2003 and Standard Fortran language.

Some familiarity with your operating system is helpful. This manual is not a Fortran or programming tutorial.

This document covers the following topics:

- Program Elements and Source Forms
  This topic describes program elements, the Fortran standard character set, and source forms.
- Data Types, Constants, and Variables
  This topic describes intrinsic and derived data types, constants, variables (scalars and arrays), and substrings.
- Expressions and Assignment Statements
  This topic summarizes Fortran expressions and assignment statements, which are used to define or redefine variables.
- Specification Statements
  This topic summarizes specification statements, which are used to declare the attributes of data objects.
- Dynamic Allocation
  This topic summarizes statements used in dynamic allocation: ALLOCATE, DEALLOCATE, and NULLIFY. It also describes the effects of allocation and deallocation.
- Execution Control
  This topic summarizes constructs and statements that can transfer control within a program.
- Program Units and Procedures
  This topic describes program units (including modules), subroutines and functions, and procedure interfaces.
- Intrinsic Procedures
  This topic describes argument keywords used in intrinsic procedures and provides an overview of intrinsic procedures.
- Data Transfer I/O Statements
  This topic summarizes data transfer input/output (I/O) statements.
- I/O Formatting
  This topic describes the rules for I/O formatting.
- File Operation I/O Statements
  This topic summarizes auxiliary I/O statements you can use to perform file operations.
- Compilation Control Statements
  This topic summarizes compilation control statements INCLUDE and OPTIONS.
- Directive Enhanced Compilation
  This topic describes general directives and OpenMP® Fortran compiler directives.
- Scope and Association
This topic describes scope, which refers to the area in which a name is recognized, and association, which is the language concept that allows different names to refer to the same entity in a particular region of a program.

- Deleted and Obsolescent Language Features
  This topic describes deleted features in Fortran 2003 and obsolescent language features in Fortran 2003.

- Additional Language Features
  This topic describes some statements and language features supported for programs written in older versions of Fortran.

- Additional Character Sets
  This topic describes the additional character sets available on Windows*, Linux*, and OS X* systems.

- Data Representation Models
  This topic describes data representation models for numeric intrinsic functions.

- Run-Time Library Routines
  This topic summarizes the many run-time library routines.

- Summary of Language Extensions
  This topic summarizes Intel Fortran extensions to the Fortran 2003 Standard.

- A to Z Reference
  This topic contains language summary tables and descriptions of all Intel® Fortran statements, intrinsics, directives, and module library routines, which are listed in alphabetical order.

- Glossary
  This topic contains abbreviated definitions of some commonly used terms in this manual.

Other books in this documentation set provide details about the features of the compilers, how to improve the run-time performance of Fortran programs, floating-point support, and compiler options.

For information on conventions used in this document, see Conventions.

For a summary of the latest Fortran 2003 features in this release, see Fortran 2003 Features.

For a summary of Fortran 2008 features in this release, see Fortran 2008 Features.
New Language Features

The major new features for this release are as follows:

- **BLOCK_LOOP and NOBLOCK_LOOP directives**
  Enable or disable loop blocking for the immediately following nested DO loops. For more information, see BLOCK_LOOP and NOBLOCK_LOOP.

- **ATTRIBUTES FASTMEM directive**
  Enables High Band Width (HBW) memory allocation for an allocated object. This directive option only applies to Intel® MIC Architecture and it is only available for Linux* OS. For more information, see ATTRIBUTES FASTMEM.

- **FOR__SET_FTN_ALLOC routine**
  Lets you specify your own routine to dynamically allocate common blocks. For more information, see FOR__SET_FTN_ALLOC.

- **TARGET ENTER DATA directive (OpenMP* API)**
  Specifies that variables are mapped to a device data environment. This directive only applies to Intel® MIC Architecture. For more information, see TARGET ENTER DATA.

- **TARGET EXIT DATA directive (OpenMP* API)**
  Specifies that variables are unmapped from a device data environment. This directive only applies to Intel® MIC Architecture. For more information, see TARGET EXIT DATA.

For a summary of Fortran 2003 features, see Fortran 2003 Features.

For a summary of new Fortran 2008 features, see Fortran 2008 Features.

For a summary of new draft Fortran 2015 features, see Draft Fortran 2015 Features.

For information on new compiler options in this release, see New Options in the Compiler Options reference.
Program Units

A Fortran program consists of one or more program units. A program unit is usually a sequence of statements that define the data environment and the steps necessary to perform calculations; it is terminated by an END statement.

A program unit can be either a main program, an external subprogram, a module, a submodule, or a block data program unit. An executable program contains one main program, and, optionally, any number of the other kinds of program units. Program units can be separately compiled.

An external subprogram is a function or subroutine that is not contained within a main program, a module, a submodule, or another subprogram. It defines a procedure to be performed and can be invoked from other program units of the Fortran program. Modules, submodules, and block data program units are not executable, so they are not considered to be procedures. (Modules and submodules can contain module procedures, though, which are executable.)

Modules contain definitions that can be made accessible to other program units: data and type definitions, definitions of procedures (called module subprograms), and procedure interfaces. Module subprograms can be either functions or subroutines. They can be invoked by other module subprograms in the module, or by other program units that access the module.

A submodule extends a module or another submodule. It can contain the definitions of procedures declared in a module or submodule.

A block data program unit specifies initial values for data objects in named common blocks. In Standard Fortran, this type of program unit can be replaced by a module program unit.

Main programs, external subprograms, and module subprograms can contain internal subprograms. The entity that contains the internal subprogram is its host. Internal subprograms can be invoked only by their host or by other internal subprograms in the same host. Internal subprograms must not contain internal subprograms.

The following sections discuss Statements, Names, and Keywords.

See Also
Program Units and Procedures Overview

Statements

Program statements are grouped into two general classes: executable and nonexecutable. An executable statement specifies an action to be performed. A nonexecutable statement describes program attributes, such as the arrangement and characteristics of data, as well as editing and data-conversion information.

Order of Statements in a Program Unit

The following figure shows the required order of statements in a Fortran program unit. In this figure, vertical lines separate statement types that can be interspersed. For example, you can intersperse DATA statements with executable constructs.

Horizontal lines indicate statement types that cannot be interspersed. For example, you cannot intersperse DATA statements with CONTAINS statements.
PUBLIC and PRIVATE statements are only allowed in the scoping units of modules. In Standard Fortran, NAMELIST statements can appear only among specification statements. However, Intel® Fortran allows them to also appear among executable statements.

The following table shows other statements restricted from different types of scoping units.

**Statements Restricted in Scoping Units**

<table>
<thead>
<tr>
<th>Scoping Unit</th>
<th>Restricted Statements</th>
</tr>
</thead>
<tbody>
<tr>
<td>Main program</td>
<td>ENTRY, IMPORT, and RETURN statements</td>
</tr>
<tr>
<td>Module&lt;sup&gt;1&lt;/sup&gt;</td>
<td>ENTRY, FORMAT, IMPORT, OPTIONAL, and INTENT statements, statement functions, and executable statements</td>
</tr>
</tbody>
</table>
### Scoping Unit

<table>
<thead>
<tr>
<th>Scoping Unit</th>
<th>Restricted Statements</th>
</tr>
</thead>
<tbody>
<tr>
<td>Submodule(^1)</td>
<td>ENTRY, FORMAT, IMPORT, OPTIONAL, and INTENT statements, statement functions, and executable statements</td>
</tr>
<tr>
<td>Block data program unit</td>
<td>CONTAINS, ENTRY, IMPORT, and FORMAT statements, interface blocks, statement functions, and executable statements</td>
</tr>
<tr>
<td>Internal subprogram</td>
<td>CONTAINS, IMPORT, and ENTRY statements</td>
</tr>
<tr>
<td>Interface body</td>
<td>CONTAINS, DATA, ENTRY, IMPORT(^2), SAVE, and FORMAT statements, statement functions, and executable statements</td>
</tr>
<tr>
<td>BLOCK construct</td>
<td>CONTAINS, DATA, ENTRY, and IMPORT statements, statement functions, and these specification statements: COMMON, EQUIVALENCE, IMPLICIT, INTENT (or its equivalent attribute), NAMELIST, OPTIONAL (or its equivalent attribute), and VALUE (or its equivalent attribute)</td>
</tr>
</tbody>
</table>

\(^1\) The scoping unit of a module does not include any module subprograms that the module contains.

\(^2\) An IMPORT statement can appear only in an interface body that is not a separate module procedure interface body.

### Keywords

A keyword can either be a part of the syntax of a statement (statement keyword), or it can be the name of a dummy argument (argument keyword). Examples of statement keywords are WRITE, INTEGER, DO, and OPEN. Examples of argument keywords are arguments to the intrinsic functions.

In the intrinsic function UNPACK \((\text{vector}, \text{mask}, \text{field})\), for example, \(\text{vector}, \text{mask},\) and \(\text{field}\) are argument keywords. They are dummy argument names, and any variable may be substituted in their place. Dummy argument names and real argument names are discussed in topic Program Units and Procedures.

Keywords are not reserved. The compiler recognizes keywords by their context. For example, a program can have an array named IF, read, or Goto, even though this is not good programming practice. The only exception is the keyword PARAMETER. If you plan to use variable names beginning with PARAMETER in an assignment statement, you need to use compiler option altparam.

Using keyword names for variables makes programs harder to read and understand. For readability, and to reduce the possibility of hard-to-find bugs, avoid using names that look like parts of Fortran statements. Rules that describe the context in which a keyword is recognized are discussed in topic Program Units and Procedures.

Argument keywords are a feature of Standard Fortran that let you specify dummy argument names when calling intrinsic procedures, or anywhere an interface (either implicit or explicit) is defined. Using argument keywords can make a program more readable and easy to follow. This is described more fully in topic Program Units and Procedures. The syntax statements in the A-Z Reference show the dummy keywords you can use for each Fortran procedure.

Program Units and Procedures Overview
Names

Names identify entities within a Fortran program unit (such as variables, function results, common blocks, named constants, procedures, program units, namelist groups, and dummy arguments). In FORTRAN 77, names were called "symbolic names".

A name can contain letters, digits, underscores ( _ ), and the dollar sign ($) special character. The first character must be a letter or a dollar sign.

In Fortran 2003, a name can contain up to 63 characters.

The length of a module name (in MODULE and USE statements) may be restricted by your file system.

NOTE
Be careful when defining names that contain dollar signs. A dollar sign can be a symbol for command or symbol substitution in various shell and utility commands.

In an executable program, the names of the following entities are global and must be unique in the entire program:

- Program units
- External procedures
- Common blocks
- Modules

Examples

The following examples demonstrate valid and invalid names

Valid Names

NUMBER
FIND_IT
X

Invalid Names

5Q Begins with a numeral.
B.4 Contains a special character other than _ or $.
_EXPRESSION Begins with an underscore.

The following are all valid examples of using names:

 INTEGER (SHORT) K !K names an integer variable
 SUBROUTINE EXAMPLE !EXAMPLE names the subroutine
 LABEL: DO I = 1,N !LABEL names the DO block

Character Sets

Intel® Fortran supports the following characters:

- The Fortran 2003 character set which consists of the following:
  - All uppercase and lowercase letters (A through Z and a through z)
  - The numerals 0 through 9
  - The underscore ( _ )
- The following special characters:
<table>
<thead>
<tr>
<th>Character</th>
<th>Name</th>
<th>Character</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>blank or &lt;Tab&gt;</td>
<td>Blank (space) or tab</td>

<td>Commercial at</td>
</tr>
</tbody>
</table>

### Other printable characters

Printable characters include the tab character (09 hex), ASCII characters with codes in the range 20(hex) through 7E(hex), and characters in certain special character sets.

Printable characters that are not in the Standard Fortran character set can only appear in comments, character constants, Hollerith constants, character string edit descriptors, and input/output records.

Uppercase and lowercase letters are treated as equivalent when used to specify program behavior (except in character constants and Hollerith constants).

ASCII Character Set for Linux* and OS X*

### Source Forms

Within a program, source code can be in free, fixed, or tab form. Fixed or tab forms must not be mixed with free form in the same source program, but different source forms can be used in different source programs.

All source forms allow lowercase characters to be used as an alternative to uppercase characters.

Several characters are indicators in source code (unless they appear within a comment or a Hollerith or character constant). The following are rules for indicators in all source forms:

- **Comment indicator**

  A comment indicator can precede the first statement of a program unit and appear anywhere within a program unit. If the comment indicator appears within a source line, the comment extends to the end of the line.
An all blank line is also a comment line.
Comments have no effect on the interpretation of the program unit.
For more information, see comment indicators in free source form, or fixed and tab source forms.

- **Statement separator**

  More than one statement (or partial statement) can appear on a single source line if a statement separator is placed between the statements. The statement separator is a semicolon character (;).

  Consecutive semicolons (with or without intervening blanks) are considered to be one semicolon.

  If a semicolon is the first character on a line, the last character on a line, or the last character before a comment, it is ignored.

- **Continuation indicator**

  A statement can be continued for more than one line by placing a continuation indicator on the line. Intel Fortran allows at least 511 continuation lines for a fixed or tab source program and at least 255 continuation lines for a free form source program.

  Comments can occur within a continued statement, but comment lines cannot be continued.

  For more information, see continuation indicators in free source form, or fixed and tab source forms.

The following table summarizes characters used as indicators in source forms.

### Indicators in Source Forms

<table>
<thead>
<tr>
<th>Source Item</th>
<th>Indicator</th>
<th>Source Form</th>
<th>Position</th>
</tr>
</thead>
<tbody>
<tr>
<td>Comment</td>
<td>!</td>
<td>All forms</td>
<td>Anywhere in source code</td>
</tr>
<tr>
<td>Comment line</td>
<td>!</td>
<td>Free</td>
<td>At the beginning of the source line</td>
</tr>
<tr>
<td></td>
<td>!, C, or *</td>
<td>Fixed</td>
<td>In column 1</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Tab</td>
<td>In column 1</td>
</tr>
<tr>
<td>Continuation line</td>
<td>&amp;</td>
<td>Free</td>
<td>At the end of the source line</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Fixed</td>
<td>In column 6</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Tab</td>
<td>After the first tab</td>
</tr>
<tr>
<td>Statement separator</td>
<td>;</td>
<td>All forms</td>
<td>Between statements on the same line</td>
</tr>
<tr>
<td>Statement label</td>
<td>1 to 5 decimal digits</td>
<td>Free</td>
<td>Before a statement</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Fixed</td>
<td>In columns 1 through 5</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Tab</td>
<td>Before the first tab</td>
</tr>
<tr>
<td>A debugging statement</td>
<td>D</td>
<td>Fixed</td>
<td>In column 1</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Tab</td>
<td>In column 1</td>
</tr>
</tbody>
</table>

1. If the character appears in a Hollerith or character constant, it is not an indicator and is ignored.
2. For fixed or tab source form, at least 511 continuation lines are allowed. For free source form, at least 255 continuation lines are allowed.
3. Fixed and tab forms only.
Source form and line length can be changed at any time by using the FREEFORM, NOFREEFORM, or FIXEDFORMLINESIZE directives. The change remains in effect until the end of the file, or until changed again.

You can also select free source form by using compiler option free.

Source code can be written so that it is useable for all source forms.

**Statement Labels**

A statement label (or statement number) identifies a statement so that other statements can refer to it, either to get information or to transfer control. A label can precede any statement that is not part of another statement.

A statement label must be one to five decimal digits long; blanks and leading zeros are ignored. An all-zero statement label is invalid, and a blank statement cannot be labeled.

Labeled FORMAT and labeled executable statements are the only statements that can be referred to by other statement. FORMAT statements are referred to only in the format specifier of an I/O statement or in an ASSIGN statement. Two statements within a scoping unit cannot have the same label.

**See Also**

free

**Free Source Form**

In free source form, statements are not limited to specific positions on a source line. In Standard Fortran, a free form source line can contain from 0 to 132 characters. Intel® Fortran allows the line to be of any length.

Blank characters are significant in free source form. The following are rules for blank characters:

- Blank characters must not appear in lexical tokens, except within a character context. For example, there can be no blanks between the exponentiation operator **. Blank characters can be used freely between lexical tokens to improve legibility.
- Blank characters must be used to separate names, constants, or labels from adjacent keywords, names, constants, or labels. For example, consider the following statements:

  ```fortran
  INTEGER NUM
  GO TO 40
  20 DO K=1,8
  ```

  The blanks are required after INTEGER, TO, 20, and DO.
- Some adjacent keywords must have one or more blank characters between them. Others do not require any; for example, BLOCK DATA can also be spelled BLOCKDATA. The following list shows which keywords have optional or required blanks:

<table>
<thead>
<tr>
<th>Optional Blanks</th>
<th>Required Blanks</th>
</tr>
</thead>
<tbody>
<tr>
<td>BLOCK DATA</td>
<td>CASE DEFAULT</td>
</tr>
<tr>
<td>DOUBLE COMPLEX</td>
<td>DO WHILE</td>
</tr>
<tr>
<td>DOUBLE PRECISION</td>
<td>IMPLICIT type-specifier</td>
</tr>
<tr>
<td>ELSE IF</td>
<td>IMPLICIT NONE</td>
</tr>
<tr>
<td>ELSE WHERE</td>
<td>INTERFACE ASSIGNMENT</td>
</tr>
<tr>
<td>END ASSOCIATE</td>
<td>INTERFACE OPERATOR</td>
</tr>
<tr>
<td>END BLOCK</td>
<td>MODULE PROCEDURE</td>
</tr>
<tr>
<td>END BLOCK DATA</td>
<td>RECURSIVE FUNCTION</td>
</tr>
<tr>
<td>END DO</td>
<td>RECURSIVE SUBROUTINE</td>
</tr>
<tr>
<td>END ENUM</td>
<td>RECURSIVE type-specifier FUNCTION</td>
</tr>
<tr>
<td>Optional Blanks</td>
<td>Required Blanks</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>--------------------------------------</td>
</tr>
<tr>
<td>END FILE</td>
<td>type-specifier FUNCTION</td>
</tr>
<tr>
<td>END FOR ALL</td>
<td>type-specifier RECURSIVE FUNCTION</td>
</tr>
<tr>
<td>END FUNCTION</td>
<td></td>
</tr>
<tr>
<td>END IF</td>
<td></td>
</tr>
<tr>
<td>END INTERFACE</td>
<td></td>
</tr>
<tr>
<td>END MODULE</td>
<td></td>
</tr>
<tr>
<td>END PROGRAM</td>
<td></td>
</tr>
<tr>
<td>END SELECT</td>
<td></td>
</tr>
<tr>
<td>END SUBMODULE</td>
<td></td>
</tr>
<tr>
<td>END SUBROUTINE</td>
<td></td>
</tr>
<tr>
<td>END TYPE</td>
<td></td>
</tr>
<tr>
<td>END WHERE</td>
<td></td>
</tr>
<tr>
<td>GO TO</td>
<td></td>
</tr>
<tr>
<td>IN OUT</td>
<td></td>
</tr>
<tr>
<td>SELECT CASE</td>
<td></td>
</tr>
<tr>
<td>SELECT TYPE</td>
<td></td>
</tr>
</tbody>
</table>

For information on statement separators (;) in all forms, see Source Forms.

**Comment Indicator**

In free source form, the exclamation point character (!) indicates a comment if it is within a source line, or a comment line if it is the first character in a source line.

**Continuation Indicator**

In free source form, the ampersand character (&) indicates a continuation line (unless it appears in a Hollerith or character constant, or within a comment). The continuation line is the first noncomment line following the ampersand. Although Standard Fortran permits up to 256 continuation lines in free-form programs, Intel® Fortran allows up to 511 continuation lines.

The following shows a continued statement:

```plaintext
TCOSH(Y) = EXP(Y) + &    ! The initial statement line
    EXP(-Y)                ! A continuation line
```

If the first nonblank character on the next noncomment line is an ampersand, the statement continues at the character following the ampersand. For example, the preceding example can be written as follows:

```plaintext
TCOSH(Y) = EXP(Y) + &
          EXP(-Y)
```

If a lexical token must be continued, the first nonblank character on the next noncomment line must be an ampersand followed immediately by the rest of the token. For example:

```plaintext
TCOSH(Y) = EXP(Y) + EXP(-Y)
          &P(-Y)
```
If you continue a character constant, an ampersand must be the first non-blank character of the continued line; the statement continues with the next character following the ampersand. For example:

```
ADVERTISER = "Davis, O'Brien, Chalmers & Peter & son"
ARCHITECT = "O'Connor, Emerson, and Davis & Associates"
```

If the ampersand is omitted on the continued line, the statement continues with the first non-blank character in the continued line. So, in the preceding example, the whitespace before "Associates" would be ignored.

The ampersand cannot be the only nonblank character in a line, or the only nonblank character before a comment; an ampersand in a comment is ignored.

**See Also**

*Source Forms* for details on the general rules for all source forms

**Fixed and Tab Source Forms**

In the Fortran standard, fixed source form is identified as obsolescent.

In fixed and tab source forms, there are restrictions on where a statement can appear within a line.

By default, a statement can extend to character position 72. In this case, any text following position 72 is ignored and no warning message is printed. You can specify compiler option extend-source to extend source lines to character position 132.

Except in a character context, blanks are not significant and can be used freely throughout the program for maximum legibility.

Some Fortran compilers use blanks to pad short source lines out to 72 characters. By default, Intel® Fortran does not. If portability is a concern, you can use the concatenation operator to prevent source lines from being padded by other Fortran compilers (see the example in "Continuation Indicator" below) or you can force short source lines to be padded by using compiler option pad-source.

**Comment Indicator**

In fixed and tab source forms, the exclamation point character (!) indicates a comment if it is within a source line. (It must not appear in column 6 of a fixed form line; that column is reserved for a continuation indicator.)

The letter C (or c), an asterisk (*), or an exclamation point (!) indicates a comment line when it appears in column 1 of a source line.

**Continuation Indicator**

In fixed and tab source forms, a continuation line is indicated by one of the following:

- For fixed form: Any character (except a zero or blank) in column 6 of a source line
- For tab form: Any digit (except zero) after the first tab

The compiler considers the characters following the continuation indicator to be part of the previous line.

Although Standard Fortran permits up to 19 continuation lines in a fixed-form program, Intel® Fortran allows up to 511 continuation lines.

If a zero or blank is used as a continuation indicator, the compiler considers the line to be an initial line of a Fortran statement.

The statement label field of a continuation line must be blank (except in the case of a debugging statement).

When long character or Hollerith constants are continued across lines, portability problems can occur. Use the concatenation operator to avoid such problems. For example:

```
PRINT *, 'This is a very long character constant '/
   + 'which is safely continued across lines'
```
Use this same method when initializing data with long character or Hollerith constants. For example:

```
CHARACTER(*) LONG_CONST
PARAMETER (LONG_CONST = 'This is a very long '//' + 'character constant which is safely continued '//' + 'across lines')
CHARACTER*100 LONG_VAL
DATA LONG_VAL /LONG_CONST/
```

Hollerith constants must be converted to character constants before using the concatenation method of line continuation.

The Fortran Standard requires that, within a program unit, the END statement cannot be continued, and no other statement in the program unit can have an initial line that appears to be the program unit END statement. In these instances, Intel Fortran produces warnings when standards checking is requested.

**Debugging Statement Indicator**

In fixed and tab source forms, the statement label field can contain a statement label, a comment indicator, or a debugging statement indicator.

The letter D indicates a debugging statement when it appears in column 1 of a source line. The initial line of the debugging statement can contain a statement label in the remaining columns of the statement label field.

If a debugging statement is continued onto more than one line, every continuation line must begin with a D and a continuation indicator.

By default, the compiler treats debugging statements as comments. However, you can specify compiler option d-lines to force the compiler to treat debugging statements as source text to be compiled.

**See Also**

Fixed-Format Lines
Tab-Format Lines
Source Forms for details on the general rules for all source forms
d-lines, Qd-lines
extend-source
pad-source, Qpad-source

**Fixed-Format Lines**

In fixed source form, a source line has columns divided into fields for statement labels, continuation indicators, statement text, and sequence numbers. Each column represents a single character.

The column positions for each field follow:

<table>
<thead>
<tr>
<th>Field</th>
<th>Column</th>
</tr>
</thead>
<tbody>
<tr>
<td>Statement label</td>
<td>1 through 5</td>
</tr>
<tr>
<td>Continuation indicator</td>
<td>6</td>
</tr>
<tr>
<td>Statement</td>
<td>7 through 72 (or 132 with compiler option extend-source)</td>
</tr>
<tr>
<td>Sequence number</td>
<td>73 through 80</td>
</tr>
</tbody>
</table>

By default, a sequence number or other identifying information can appear in columns 73 through 80 of any fixed-format line in an Intel® Fortran program. The compiler ignores the characters in this field.

If you extend the statement field to position 132, the sequence number field does not exist.
NOTE
If you use the sequence number field, do not use tabs anywhere in the source line, or the compiler may interpret the sequence numbers as part of the statement field in your program.

Source Forms
Fixed and Tab Source Forms
extend-source

Tab-Format Lines
In tab source form, you can specify a statement label field, a continuation indicator field, and a statement field, but not a sequence number field.
The following figure shows equivalent source lines coded with tab and fixed source form.

Line Formatting Example

The statement label field precedes the first tab character. The continuation indicator field and statement field follow the first tab character.
The continuation indicator is any nonzero digit. The statement field can contain any Fortran statement. A Fortran statement cannot start with a digit.
If a statement is continued, a continuation indicator must be the first character (following the first tab) on the continuation line.
Many text editors and terminals advance the terminal print carriage to a predefined print position when you press the <Tab> key. However, the Intel® Fortran compiler does not interpret the tab character in this way. It treats the tab character in a statement field the same way it treats a blank character. In the source listing that the compiler produces, the tab causes the character that follows to be printed at the next tab stop (usually located at columns 9, 17, 25, 33, and so on).
NOTE
If you use the sequence number field, do not use tabs anywhere in the source line, or the compiler may interpret the sequence numbers as part of the statement field in your program.

See Also
Source Forms for details on the general rules for all source forms
Fixed and Tab Source Forms for details on the general rules for fixed and tab source forms

Source Code Useable for All Source Forms
To write source code that is useable for all source forms (free, fixed, or tab), follow these rules:

<table>
<thead>
<tr>
<th>Blanks</th>
<th>Treat as significant (see Free Source Form).</th>
</tr>
</thead>
<tbody>
<tr>
<td>Statement labels</td>
<td>Place in column positions 1 through 5 (or before the first tab character).</td>
</tr>
<tr>
<td>Statements</td>
<td>Start in column position 7 (or after the first tab character).</td>
</tr>
<tr>
<td>Comment indicator</td>
<td>Use only !. Place anywhere except in column position 6 (or immediately after the first tab character).</td>
</tr>
<tr>
<td>Continuation indicator</td>
<td>Use only &amp;. Place in column position 73 of the initial line and each continuation line, and in column 6 of each continuation line (no tab character can precede the ampersand in column 6).</td>
</tr>
</tbody>
</table>

The following example is valid for all source forms:

```
Column:
12345678... 73

! Define the user function MY_SIN
DOUBLE PRECISION FUNCTION MY_SIN(X)
  MY_SIN = X - X**3/FACTOR(3) + X**5/FACTOR(5) &
  - X**7/FACTOR(7)
CONTAINS
  INTEGER FUNCTION FACTOR(N)
  FACTOR = 1
  DO 10 I = N, 1, -1
       10 FACTOR = FACTOR * I
END FUNCTION FACTOR
END FUNCTION MY_SIN
```
Data Types, Constants, and Variables

Data Types, Constants, and Variables Overview

Each constant, variable, array, expression, or function reference in a Fortran statement has a data type. The data type of these items can be inherent in their construction, implied by convention, or explicitly declared. Each data type has the following properties:

• A name
  The names of the intrinsic data types are predefined, while the names of derived types are defined in derived-type definitions. Data objects (constants, variables, or parts of constants or variables) are declared using the name of the data type.

• A set of associated values
  Each data type has a set of valid values. Integer and real data types have a range of valid values. Complex and derived types have sets of values that are combinations of the values of their individual components.

• A way to represent constant values for the data type
  A constant is a data object with a fixed value that cannot be changed during program execution. The value of a constant can be a numeric value, a logical value, or a character string.

A constant that does not have a name is a literal constant. A literal constant must be of intrinsic type and it cannot be array-valued.

A constant that has a name is a named constant. A named constant can be of any type, including derived type, and it can be array-valued. A named constant has the PARAMETER attribute and is specified in a type declaration statement or PARAMETER statement.

• A set of operations to manipulate and interpret these values
  The data type of a variable determines the operations that can be used to manipulate it. Besides intrinsic operators and operations, you can also define operators and operations.

Type Declarations
Defined Operations
PARAMETER
Expressions for details on valid operations for data types

Intrinsic Data Types

Intel® Fortran provides the following intrinsic data types:

• INTEGER
  The following kind parameters are available for data of type integer:

  • INTEGER([KIND=]1) or INTEGER*1
  • INTEGER([KIND=]2) or INTEGER*2
  • INTEGER([KIND=]4) or INTEGER*4
  • INTEGER([KIND=]8) or INTEGER*8

• REAL
  The following kind parameters are available for data of type real:

  • REAL([KIND=]4) or REAL*4
• REAL([KIND=]8) or REAL*8
• REAL([KIND=]16) or REAL*16
• DOUBLE PRECISION
  No kind parameter is permitted for data declared with type DOUBLE PRECISION. This data type is the same as REAL([KIND=]8).
• COMPLEX
  The following kind parameters are available for data of type complex:
  • COMPLEX([KIND=]4) or COMPLEX*8
  • COMPLEX([KIND=]8) or COMPLEX*16
  • COMPLEX([KIND=]16) or COMPLEX*32
• DOUBLE COMPLEX
  No kind parameter is permitted for data declared with type DOUBLE COMPLEX. This data type is the same as COMPLEX([KIND=]8).
• LOGICAL
  The following kind parameters are available for data of type logical:
  • LOGICAL([KIND=]1) or LOGICAL*1
  • LOGICAL([KIND=]2) or LOGICAL*2
  • LOGICAL([KIND=]4) or LOGICAL*4
  • LOGICAL([KIND=]8) or LOGICAL*8
• CHARACTER
  There is one kind parameter available for data of type character: CHARACTER([KIND=]1).
• BYTE
  This is a 1-byte value; the data type is equivalent to INTEGER([KIND=]1).

The intrinsic function KIND can be used to determine the kind type parameter of a representation method. For more portable programs, you should not use the forms INTEGER([KIND=]n) or REAL([KIND=]n). You should instead define a PARAMETER constant using the SELECTED_INT_KIND or SELECTED_REAL_KIND function, whichever is appropriate. For example, the following statements define a PARAMETER constant for an INTEGER kind that has 9 digits:

```fortran
INTEGER, PARAMETER :: MY_INT_KIND = SELECTED_INT_KIND(9)
...
INTEGER(MY_INT_KIND) :: J
...
```

Note that the syntax :: is used in type declaration statements.

The following sections describe the intrinsic data types and forms for literal constants for each type.

See Also
KIND intrinsic function
Declarations for Noncharacter Types for details on declaration statements for intrinsic data types
Declarations for Character Types for details on declaration statements for intrinsic data types
Expressions for details on operations for intrinsic data types
Storage Units and Storage Sequence for details on storage requirements for intrinsic data types

Integer Data Types
Integer data types can be specified as follows:

```fortran
INTEGER
INTEGER([KIND=]n)
INTEGER*n
```

\[ n \] is an initialization expression that evaluates to kind 1, 2, 4, or 8.
If a kind parameter is specified, the integer has the kind specified. If a kind parameter is not specified, integer constants are interpreted as follows:

- If the integer constant is within the default integer kind range, the kind is default integer.
- If the integer constant is outside the default integer kind range, the kind of the integer constant is the smallest integer kind that holds the constant.

Default integer is affected by compiler option integer-size, the INTEGER compiler directive, and the OPTIONS statement.

The intrinsic inquiry function KIND returns the kind type parameter, if you do not know it. You can use the intrinsic function SELECTED_INT_KIND to find the kind values that provide a given range of integer values. The decimal exponent range is returned by the intrinsic function RANGE.

**Examples**

The following examples show ways an integer variable can be declared.

An entity-oriented example is:

```
INTEGER, DIMENSION(:), POINTER :: days, hours
INTEGER(2), POINTER :: k, limit
INTEGER(1), DIMENSION(10) :: min
```

An attribute-oriented example is:

```
INTEGER days, hours
INTEGER(2) k, limit
INTEGER(1) min
DIMENSION days(:), hours(:), min (10)
POINTER days, hours, k, limit
```

An integer can be used in certain cases when a logical value is expected, such as in a logical expression evaluating a condition, as in the following:

```
INTEGER I, X
READ (*,*) I
IF (I) THEN
  X = 1
END IF
```

**See Also**

Integer Constants
integer-size

**Integer Constants**

An integer constant is a whole number with no decimal point. It can have a leading sign and is interpreted as a decimal number.

Integer constants take the following form:

```
[s]n[n...][ _k]
```

- \(s\) Is a sign; required if negative (-), optional if positive (+).
- \(n\) Is a decimal digit (0 through 9). Any leading zeros are ignored.
- \(k\) Is the optional kind parameter: 1 for INTEGER(1), 2 for INTEGER(2), 4 for INTEGER(4), or 8 for INTEGER(8). It must be preceded by an underscore ( _ ).

An unsigned constant is assumed to be nonnegative.

Integer constants are interpreted as decimal values (base 10) by default. To specify a constant that is not in base 10, use the following extension syntax:

```
[s] [[base] #] nnn...
```
\[ s \]

Is an optional plus (+) or minus (-) sign.

\[ base \]

Is any constant from 2 through 36.

If \( base \) is omitted but \# is specified, the integer is interpreted in base 16. If both \( base \) and \# are omitted, the integer is interpreted in base 10.

For bases 11 through 36, the letters A through Z represent numbers greater than 9. For example, for base 36, A represents 10, B represents 11, C represents 12, and so on, through Z, which represents 35. The case of the letters is not significant.

The value of \( nnn \) cannot be bigger than \( 2^{**31}-1 \). The value is extended with zeroes on the left or truncated on the left to make it the correct size. A minus sign for \( s \) negates the value.

Note that compiler option integer-size can affect the KIND type parameter of INTEGER data and integer constants.

**Examples**

**Valid Integer (base 10) Constants**

0

-127

+32123

47_2

**Invalid Integer (base 10) Constants**

9999999999999999999 Number too large.

3.14 Decimal point not allowed; this is a valid REAL constant.

32,767 Comma not allowed.

33_3 3 is not a valid kind type for integers.

The following seven integers are all assigned a value equal to 3,994,575 decimal:

\[
\begin{align*}
I &= 2\#1111001111001111001111 \\
m &= 7\#45644664 \\
J &= +8\#17171717 \\
K &= #3CF3CF \\
n &= +17\#2DE110 \\
L &= 3994575 \\
index &= 36\#2DM8F
\end{align*}
\]

The following seven integers are all assigned a value equal to -3,994,575 decimal:

\[
\begin{align*}
I &= -2\#1111001111001111001111 \\
m &= -7\#45644664 \\
J &= -8\#17171717 \\
K &= -#3CF3CF \\
n &= -17\#2DE110 \\
L &= -3994575 \\
index &= -36\#2DM8F
\end{align*}
\]
You can use integer constants to assign values to data. The following table shows assignments to different data and lists the integer and hexadecimal values in the data:

<table>
<thead>
<tr>
<th>Fortran Assignment</th>
<th>Integer Value in Data</th>
<th>Hexadecimal Value in Data</th>
</tr>
</thead>
<tbody>
<tr>
<td>LOGICAL(1)X</td>
<td>X = -128</td>
<td>-128</td>
</tr>
<tr>
<td>INTEGER(1)X</td>
<td>X = 127</td>
<td>127</td>
</tr>
<tr>
<td></td>
<td>X = 255</td>
<td>-1</td>
</tr>
<tr>
<td>LOGICAL(2)X</td>
<td>X = 255</td>
<td>255</td>
</tr>
<tr>
<td>INTEGER(2)X</td>
<td>X = -32768</td>
<td>-32768</td>
</tr>
<tr>
<td></td>
<td>X = 32767</td>
<td>32767</td>
</tr>
<tr>
<td></td>
<td>X = 65535</td>
<td>-1</td>
</tr>
</tbody>
</table>

Numeric Expressions
integer-size

Real Data Types

Real data types can be specified as follows:

REAL

REAL([KIND=]n)

REAL* n

DOUBLE PRECISION

n

Is an initialization expression that evaluates to kind 4, 8, or 16.

If a kind parameter is specified, the real constant has the kind specified. If a kind parameter is not specified, the kind is default real.

Default real is affected by compiler options specifying real size and by the REAL directive.

The default KIND for DOUBLE PRECISION is affected by compiler option double-size. If this compiler option is not specified, default DOUBLE PRECISION is REAL(8).

No kind parameter is permitted for data declared with type DOUBLE PRECISION.

The intrinsic inquiry function KIND returns the kind type parameter. The intrinsic inquiry function RANGE returns the decimal exponent range, and the intrinsic function PRECISION returns the decimal precision. You can use the intrinsic function SELECTED_REAL_KIND to find the kind values that provide a given precision and exponent range.

Examples

The following examples show how real variables can be declared.

An entity-oriented example is:

```
REAL (KIND = high), OPTIONAL :: testval
REAL, SAVE :: a(10), b(20,30)
```

An attribute-oriented example is:

```
REAL (KIND = high) testval
REAL a(10), b(20,30)
OPTIONAL testval
SAVE a, b
```

REAL(16) Constants
real-size

General Rules for Real Constants

A real constant approximates the value of a mathematical real number. The value of the constant can be positive, zero, or negative.

The following is the general form of a real constant with no exponent part:

\[ s[n...] \] \_k

A real constant with an exponent part has one of the following forms:

\[ s[n...]E[s]nn... \] \_k
\[ s[n...]D[s]nn... \]
\[ s[n...]Q[s]nn... \]

- \( s \) is a sign; required if negative (-), optional if positive (+).
- \( n \) is a decimal digit (0 through 9). A decimal point must appear if the real constant has no exponent part.
- \( k \) is the optional kind parameter: 4 for REAL(4), 8 for REAL(8), or 16 for REAL(16). It must be preceded by an underscore ( _ ).

Description

Leading zeros (zeros to the left of the first nonzero digit) are ignored in counting significant digits. For example, in the constant 0.00001234567, all of the nonzero digits, and none of the zeros, are significant. (See the following sections for the number of significant digits each kind type parameter typically has).

The exponent represents a power of 10 by which the preceding real or integer constant is to be multiplied (for example, 1.0E6 represents the value 1.0 * 10**6).

A real constant with no exponent part and no kind type parameter is (by default) a single-precision (REAL(4)) constant. You can change the default behavior by specifying compiler option fpconstant.

If the real constant has no exponent part, a decimal point must appear in the string (anywhere before the optional kind parameter). If there is an exponent part, a decimal point is optional in the string preceding the exponent part; the exponent part must not contain a decimal point.

The exponent letter E denotes a single-precision real (REAL(4)) constant, unless the optional kind parameter specifies otherwise. For example, -9.E2_8 is a double-precision constant (which can also be written as -9.D2).

The exponent letter D denotes a double-precision real (REAL(8)) constant.

The exponent letter Q denotes a quad-precision real (REAL(16)) constant.

A minus sign must appear before a negative real constant; a plus sign is optional before a positive constant. Similarly, a minus sign must appear between the exponent letter (E, D, or Q) and a negative exponent, whereas a plus sign is optional between the exponent letter and a positive exponent.

If the real constant includes an exponent letter, the exponent field cannot be omitted, but it can be zero.

To specify a real constant using both an exponent letter and a kind parameter, the exponent letter must be E, and the kind parameter must follow the exponent part.
See Also
fpconstant

REAL(4) Constants
A single-precision REAL constant occupies four bytes of memory. The number of digits is unlimited, but typically only the leftmost seven digits are significant.
IEEE* S_floating format is used.
Note that compiler option real-size can affect REAL data.

Examples
Valid REAL(4) Constants
3.14159
3.14159_4
621712._4
-.00127
+5.0E3
2E-3_4

Invalid REAL(4) Constants
1,234,567.  Commas not allowed.
325E-47    Too small for REAL; this is a valid DOUBLE PRECISION constant.
-47.E47    Too large for REAL; this is a valid DOUBLE PRECISION constant.
625._6     6 is not a valid kind for reals.
100        Decimal point missing; this is a valid integer constant.
$25.00     Special character not allowed.

REAL(8) or DOUBLE PRECISION Constants
A REAL(8) or DOUBLE PRECISION constant has more than twice the accuracy of a REAL(4) number, and greater range.
A REAL(8) or DOUBLE PRECISION constant occupies eight bytes of memory. The number of digits that precede the exponent is unlimited, but typically only the leftmost 15 digits are significant.
IEEE T_floating format is used.
Note that compiler option double-size can affect DOUBLE PRECISION data.
The default KIND for DOUBLE PRECISION is affected by compiler option double-size.
Examples
Valid REAL(8) or DOUBLE PRECISION Constants
123456789D+5
123456789E+5_8
+2.7843D00
-.522D-12
2E200_8
2.3_8
3.4E7_8

Invalid REAL(8) or DOUBLE PRECISION Constants
-.25D0_2
2 is not a valid kind for reals.
+2.7182812846182
No D exponent designator is present; this is a valid single-precision constant.
123456789.D400
Too large for any double-precision format.
123456789.D-400
Too small for any double-precision format.

General Rules for Real Constants
Compiler Reference ... Data and I/O section: Data Representation
Complex Data Types

Complex data types can be specified as follows:

```
COMPLEX
COMPLEX([KIND=]n)
COMPLEX*s
DOUBLE COMPLEX
```

- \( n \) is an initialization expression that evaluates to kind 4, 8, or 16.
- \( s \) is 8, 16, or 32. COMPLEX(4) is specified as COMPLEX*8; COMPLEX(8) is specified as COMPLEX*16; COMPLEX(16) is specified as COMPLEX*32.

If a kind parameter is specified, the complex constant has the kind specified. If no kind parameter is specified, the kind of both parts is default real, and the constant is of type default complex.

Default real is affected by compiler option real-size and by the REAL directive.

The default KIND for DOUBLE COMPLEX is affected by compiler option double-size. If the compiler option is not specified, default DOUBLE COMPLEX is COMPLEX(8).

No kind parameter is permitted for data declared with type DOUBLE COMPLEX.

Examples

The following examples show how complex variables can be declared.

An entity-oriented example is:

```
COMPLEX (4), DIMENSION (8) :: cz, cq
```

An attribute-oriented example is:

```
COMPLEX(4) cz, cq
DIMENSION(8) cz, cq
```

General Rules for Complex Constants
COMPLEX(4) Constants
COMPLEX(8) or DOUBLE COMPLEX Constants

General Rules for Complex Constants

A complex constant approximates the value of a mathematical complex number. The constant is a pair of real or integer values, separated by a comma, and enclosed in parentheses. The first constant represents the real part of that number; the second constant represents the imaginary part.

The following is the general form of a complex constant:

\((c, c)\)

- \( c \) is as follows:
  - For COMPLEX(4) constants, \( c \) is an integer or REAL(4) constant.
  - For COMPLEX(8) constants, \( c \) is an integer, REAL(4) constant, or DOUBLE PRECISION (REAL(8)) constant. At least one of the pair must be DOUBLE PRECISION.
  - For COMPLEX(16) constants, \( c \) is an integer, REAL(4) constant, REAL(8) constant, or REAL(16) constant. At least one of the pair must be a REAL(16) constant.

Note that the comma and parentheses are required.
**COMPLEX(4) Constants**

A COMPLEX(4) constant is a pair of integer or single-precision real constants that represent a complex number.

A COMPLEX(4) constant occupies eight bytes of memory and is interpreted as a complex number.

If the real and imaginary part of a complex literal constant are both real, the kind parameter value is that of the part with the greater decimal precision.

The rules for REAL(4) constants apply to REAL(4) constants used in COMPLEX constants. (See General Rules for Complex Constants and REAL(4) Constants for the rules on forming REAL(4) constants.)

The REAL(4) constants in a COMPLEX constant have IEEE S_floating format.

Note that compiler option real-size can affect REAL data.

**Examples**

**Valid COMPLEX(4) Constants**

- (1.7039, -1.70391)
- (44.36_4, -12.2E16_4)
- (+12739E3, 0.)
- (1, 2)

**Invalid COMPLEX(4) Constants**

- (1.23, )
  - Missing second integer or single-precision real constant.
- (1.0, 2H12)
  - Hollerith constant not allowed.

**See Also**

General Rules for Complex Constants
real-size

**COMPLEX(8) or DOUBLE COMPLEX Constants**

A COMPLEX(8) or DOUBLE COMPLEX constant is a pair of constants that represents a complex number. One of the pair must be a double-precision real constant, the other can be an integer, single-precision real, or double-precision real constant.

A COMPLEX(8) or DOUBLE COMPLEX constant occupies 16 bytes of memory and is interpreted as a complex number.

The rules for DOUBLE PRECISION (REAL(8)) constants also apply to the double precision portion of COMPLEX(8) or DOUBLE COMPLEX constants. (See General Rules for Complex Constants and REAL(8) or DOUBLE PRECISION Constants for the rules on forming DOUBLE PRECISION constants.)

The DOUBLE PRECISION constants in a COMPLEX(8) or DOUBLE COMPLEX constant have IEEE T_floating format.

The default KIND for DOUBLE COMPLEX is affected by compiler option double-size.

**Examples**

**Valid COMPLEX(8) or DOUBLE COMPLEX Constants**

- (1.7039, -1.7039D0)
- (547.3E0_8, -1.44_8)
- (1.7039E0, -1.7039D0)
Invalid COMPLEX(8) or DOUBLE COMPLEX Constants

(1.23D0,)
Second constant missing.

(1D1,2H12)
Hollerith constants not allowed.

(1,1.2)
Neither constant is DOUBLE PRECISION; this is a valid single-precision constant.

See Also
General Rules for Complex Constants
double-size

COMPLEX(16) Constants
A COMPLEX(16) constant is a pair of constants that represents a complex number. One of the pair must be a REAL(16) constant, the other can be an integer, single-precision real, double-precision real, or REAL(16) constant.

A COMPLEX(16) constant occupies 32 bytes of memory and is interpreted as a complex number.

The rules for REAL(16) constants apply to REAL(16) constants used in COMPLEX constants. (See General Rules for Complex Constants and REAL(16) Constants for the rules on forming REAL(16) constants.)

The REAL(16) constants in a COMPLEX constant have IEEE X_floating format.

Note that compiler option real-size can affect REAL data.

Examples

Valid COMPLEX(16) Constants

(1.7039,-1.7039Q2)

(547.3E0_16,-1.44)

(+12739D3,0.Q0)

Invalid COMPLEX(16) Constants

(1.23Q0,)
Second constant missing.

(1D1,2H12)
Hollerith constants not allowed.

(1.7039E0,-1.7039D0)
Neither constant is REAL(16); this is a valid double-precision constant.

See Also
General Rules for Complex Constants
real-size

Logical Data Types
Logical data types can be specified as follows:

LOGICAL
LOGICAL([KIND=]n)
LOGICAL*

n Is an initialization expression that evaluates to kind 1, 2, 4, or 8.
If a kind parameter is specified, the logical constant has the kind specified. If no kind parameter is specified, the kind of the constant is default logical.

**Examples**

The following examples show how logical variables can be declared.

An entity-oriented example is:

```fortran
LOGICAL, ALLOCATABLE :: flag1, flag2
LOGICAL (KIND = byte), SAVE :: doit, dont
```

An attribute-oriented example is:

```fortran
LOGICAL flag1, flag2
LOGICAL (KIND = byte) doit, dont
ALLOCATABLE flag1, flag2
SAVE doit, dont
```

**See Also**

Logical Constants

### Logical Constants

A logical constant represents only the logical values true or false, and takes one of the following forms:

- `.TRUE.[_k]`
- `.FALSE.[_k]`

`k` is the optional kind parameter: 1 for LOGICAL(1), 2 for LOGICAL(2), 4 for LOGICAL(4), or 8 for LOGICAL(8). It must be preceded by an underscore ( `_ `).

The numeric value of `.TRUE. and `.FALSE. can be -1 and 0 or 1 and 0 depending on compiler option fpscomp [no]logicals. Logical data can take on integer data values. Logical data type ranges correspond to their comparable integer data type ranges. For example, the LOGICAL(2) range is the same as the INTEGER(2) range.

### Character Data Type

The character data type can be specified as follows:

```fortran
CHARACTER
CHARACTER([LEN=] len)
CHARACTER(LEN= len, KIND= n)
CHARACTER(len, [KIND=] n)
CHARACTER(KIND= n [, LEN= len])
CHARACTER* len [,]
```

`n` is an initialization expression that evaluates to kind 1.

`len` is a string length (not a kind). For more information, see Declaration Statements for Character Types.

If no kind type parameter is specified, the kind of the constant is default character.

On Windows systems, several Multi-Byte Character Set (MBCS) functions are available to manipulate special non-English characters.

**See Also**

Character Constants

C Strings in Character Constants
Character Substrings
Character Data Type

Character Constants

A character constant is a character string enclosed in delimiters (apostrophes or quotation marks). It takes one of the following forms:

\[[k_]\[ch...]' [C]
\[[k_][ch...]' [C]

- \(k\) is the optional kind parameter: 1 (the default). It must be followed by an underscore (\(_\)). Note that in character constants, the kind must precede the constant.

- \(ch\) is an ASCII character.

- \(C\) is a C string specifier. C strings can be used to define strings with nonprintable characters. For more information, see C Strings in Character Constants.

Description

The value of a character constant is the string of characters between the delimiters. The value does not include the delimiters, but does include all blanks or tabs within the delimiters.

If a character constant is delimited by apostrophes, use two consecutive apostrophes (\(''\)) to place an apostrophe character in the character constant.

Similarly, if a character constant is delimited by quotation marks, use two consecutive quotation marks (\(""\)) to place a quotation mark character in the character constant.

The length of the character constant is the number of characters between the delimiters, but two consecutive delimiters are counted as one character.

The length of a character constant must be in the range of 0 to 7188. Each character occupies one byte of memory.

If a character constant appears in a numeric context (such as an expression on the right side of an arithmetic assignment statement), it is considered a Hollerith constant.

A zero-length character constant is represented by two consecutive apostrophes or quotation marks.

Examples

**Valid Character Constants**

"WHAT KIND TYPE?"
'TODAY'S DATE IS: '
"The average is:"

Invalid Character Constants

'HEADINGS
'Map Number:'

No trailing apostrophe.
Beginning delimiter does not match ending delimiter.

Declarations for Character Types
C Strings in Character Constants

String values in the C language are terminated with null characters (CHAR(0)) and can contain nonprintable characters (such as backspace).

Nonprintable characters are specified by escape sequences. An escape sequence is denoted by using the backslash (\) as an escape character, followed by a single character indicating the nonprintable character desired.

This type of string is specified by using a standard string constant followed by the character C. The standard string constant is then interpreted as a C-language constant. Backslashes are treated as escapes, and a null character is automatically appended to the end of the string (even if the string already ends in a null character).

The following table shows the escape sequences that are allowed in character constants:

### C-Style Escape Sequences

<table>
<thead>
<tr>
<th>Escape Sequence</th>

<td>A formfeed</td>
</tr>
<tr>
<td>\n or \N</td>
<td>A new line</td>
</tr>
<tr>
<td>\r or \R</td>
<td>A carriage return</td>
</tr>
<tr>
<td>\t or \T</td>
<td>A horizontal tab</td>
</tr>
<tr>
<td>\v or \V</td>
<td>A vertical tab</td>
</tr>
<tr>
<td>\xhh or \Xhh</td>
<td>A hexadecimal bit pattern</td>
</tr>
<tr>
<td>\ooo</td>
<td>An octal bit pattern</td>
</tr>
<tr>
<td>\0</td>
<td>A null character</td>
</tr>
<tr>
<td>\</td>
<td>A backslash</td>
</tr>
</tbody>
</table>

If a string contains an escape sequence that isn’t in this table, the backslash is ignored.

A C string must also be a valid Fortran string. If the string is delimited by apostrophes, apostrophes in the string itself must be represented by two consecutive apostrophes (’’).

For example, the escape sequence \’string causes a compiler error because Fortran interprets the apostrophe as the end of the string. The correct form is \’’string.

If the string is delimited by quotation marks, quotation marks in the string itself must be represented by two consecutive quotation marks (“”).

The sequences \ooo and \xhh allow any ASCII character to be given as a one- to three-digit octal or a one- to two-digit hexadecimal character code. Each octal digit must be in the range 0 to 7, and each hexadecimal digit must be in the range 0 to F. For example, the C strings ‘\010’C and ‘\x08’C both represent a backspace character followed by a null character.

The C string ‘\abcd’C is equivalent to the string ‘\abcd’ with a null character appended. The string ‘’C represents the ASCII null character.

Character Substrings

A character substring is a contiguous segment of a character string. It takes one of the following forms:

v ([e1]:[e2])

a (s [, s] . . . ) ([e1]:[e2])
\( v \) is a character scalar constant, or the name of a character scalar variable or character structure component.

\( e_1 \) is a scalar integer (or other numeric) expression specifying the leftmost character position of the substring; the starting point.

\( e_2 \) is a scalar integer (or other numeric) expression specifying the rightmost character position of the substring; the ending point.

\( a \) is the name of a character array.

\( s \) is a subscript expression.

Both \( e_1 \) and \( e_2 \) must be within the range 1,2, ..., \( len \), where \( len \) is the length of the parent character string. If \( e_1 \) exceeds \( e_2 \), the substring has length zero.

Description

Character positions within the parent character string are numbered from left to right, beginning at 1.

If the value of the numeric expression \( e_1 \) or \( e_2 \) is not of type integer, it is converted to integer before use (any fractional parts are truncated).

If \( e_1 \) is omitted, the default is 1. If \( e_2 \) is omitted, the default is \( len \). For example, \( \text{NAMES}(1,3)(:7) \) specifies the substring starting with the first character position and ending with the seventh character position of the character array element \( \text{NAMES}(1,3) \).

Examples

Consider the following example:

```
CHARACTER*8 C, LABEL
LABEL = 'XVERSUSY'
C = LABEL(2:7)
```

\( \text{LABEL}(2:7) \) specifies the substring starting with the second character position and ending with the seventh character position of the character variable assigned to \( \text{LABEL} \), so \( C \) has the value 'VERSUS'.

Consider the following example:

```
TYPE ORGANIZATION
  INTEGER ID
  CHARACTER*35 NAME
END TYPE ORGANIZATION
TYPE(ORGANIZATION) DIRECTOR
CHARACTER*25 BRANCH, STATE(50)
```

The following are valid substrings based on this example:

```
BRANCH(3:15) ! parent string is a scalar variable
STATE(20) (1:3) ! parent string is an array element
DIRECTOR\NAME(:) ! parent string is a structure component
```

Consider the following example:

```
CHARACTER(*), PARAMETER :: MY_BRANCH = "CHAPTER 204"
CHARACTER(3) BRANCH_CHAP
BRANCH_CHAP = MY_BRANCH(9:11) ! parent string is a character constant
```

\( \text{BRANCH} \text{\_CHAP} \) is a character string of length 3 that has the value '204'.

Structure Components
Derived Data Types
You can create derived data types from intrinsic data types or previously defined derived types.
A derived type is resolved into "ultimate" components that are either of intrinsic type or are pointers.
The set of values for a specific derived type consists of all possible sequences of component values permitted
by the definition of that derived type. Structure constructors are used to specify values of derived types.
Nonintrinsic assignment for derived-type entities must be defined by a subroutine with an ASSIGNMENT
interface. Any operation on derived-type entities must be defined by a function with an OPERATOR interface.
Arguments and function values can be of any intrinsic or derived type.
A derived type can be parameterized by type parameters. Each type parameter is defined to be either a kind
or a length type parameter, and can have a default value.

TYPE Statement (Derived Types)
Parameterized Derived-Type Declarations
Record Structures for details on record structures

Derived-Type Definition Overview
A derived-type definition specifies the name of a user-defined type and the types of its components. For
more information on the syntax of a derived-type definition, see TYPE. For more information on derived-type
definitions for polymorphic objects, see CLASS.

Default Initialization
Default initialization occurs if initialization appears in a derived-type component definition.
The specified initialization of the component will apply even if the definition is PRIVATE.
Default initialization applies to dummy arguments with INTENT(OUT). It does not imply the derived-type
component has the SAVE attribute.
Explicit initialization in a type declaration statement overrides default initialization.
To specify default initialization of an array component, use a constant expression that includes one of the
following:
• An array constructor
• A single scalar that becomes the value of each array element
Pointers can have an association status of associated, disassociated, or undefined. If no default initialization
status is specified, the status of the pointer is undefined. To specify disassociated status for a pointer
component, use =>NULL( ).

Examples
You do not have to specify initialization for each component of a derived type. For example:

```
TYPE REPORT
   CHARACTER (LEN=20) REPORT_NAME
   INTEGER DAY
   CHARACTER (LEN=3) MONTH
   INTEGER :: YEAR = 1995 ! Only component with default initialization
END TYPE REPORT
```

Consider the following:

```
TYPE (REPORT), PARAMETER :: NOV_REPORT = REPORT ("Sales", 15, "NOV", 1996)
```
In this case, the explicit initialization in the type declaration statement overrides the YEAR component of NOV_REPORT.

The default initial value of a component can also be overridden by default initialization specified in the type definition. For example:

```plaintext
TYPE MGR_REPORT
  TYPE (REPORT) :: STATUS = NOV_REPORT
  INTEGER NUM
END TYPE MGR_REPORT

TYPE (MGR_REPORT) STARTUP
```

In this case, the STATUS component of STARTUP gets its initial value from NOV_REPORT, overriding the initialization for the YEAR component.

### Procedure Pointers as Derived-Type Components

A component of derived type can be a procedure pointer. A procedure pointer component definition takes the following form:

```plaintext
PROCEDURE ([ proc-interface ], proc-attr [, proc-attr]... :: proc-decl-list
```

- **proc-interface** (Optional) Is the name of an interface or a type specifier.
- **proc-attr** Is one of the following attributes:
  - PUBLIC
  - PRIVATE
  - POINTER (required)
  - NOPASS or PASS [ (arg-name) ]
    where arg-name is the name of a dummy argument.
    PASS and NOPASS refer to passed-object dummy arguments. They are mutually exclusive. You can only specify one or the other in a proc-attr list, not both.
    If you specify NOPASS, procedures will not have have passed-object dummy arguments. NOPASS is required if the interface is implicit.
    The PASS attribute can be used to confirm the default (as the first argument), The NOPASS attribute prevents passing the object as an argument.
- **proc-decl-list** Is one or more of the following:
  - procedure-name [= null-init]
    where null-init is a reference to intrinsic function NULL with no arguments.
    If => null-init appears, the procedure must have the POINTER attribute.

### Examples

The following example defines a type that represents a list of procedures with the same interface, which can be called at some future time:

```plaintext
TYPE PROCEDURE_LIST
  PROCEDURE (PROC_INTERFACE), POINTER :: PROC
  TYPE (PROCEDURE_LIST), POINTER :: NEXT => NULL()
END TYPE PROCEDURE_LIST

ABSTRACT INTERFACE
  SUBROUTINE PROC_INTERFACE
    ...
  END SUBROUTINE PROC_INTERFACE
END INTERFACE
```
A procedure pointer can be pointer-assigned to a procedure pointer variable, invoked directly, or passed as an actual argument. For example:

```fortran
TYPE (PROCEDURE_LIST) :: a, b(6)
PROCEDURE (PROC_INTERFACE), POINTER :: R
...
R => a%PROC
CALL SUBROUTINE_NEXT(a%PROC)
CALL b(i)%PROC
```

**Type-Bound Procedures**

In a derived-type definition, you can optionally specify a type-bound-procedure-part, which consists of a CONTAINS statement, optionally followed by a PRIVATE statement, and one or more procedure binding statements. Specific, GENERIC, and FINAL procedure bindings are defined below.

A *type-bound-procedure-part* in a derived-type definition takes the following form:

```fortran
CONTAINS
[PRIVATE]
proc-binding-stmt
[ proc-binding-stmt]...
```

*proc-binding-stmt* is one of the following:

- *specific-binding*
- *generic-binding*
- *final-binding*

The default accessibility of type-bound procedures is public even if the components are private. You can change this by including the PRIVATE statement following the CONTAINS statement.

**specific-binding**

A specific type-bound procedure binds a procedure to a type or it specifies a deferred binding to an abstract type. It takes the following form:

```fortran
PROCEDURE [ (interface-name) ] [ [ , binding-attr-list ] :: ] binding-name [ => procedure-name ]
```

*interface-name* (Optional) Is the interface for the procedure. It must be the name of an abstract interface or a procedure that has an explicit interface. *interface-name* can only be specified if the binding has the DEFERRED attribute.

*binding-attr-list* (Optional) Is one or more of the following. The same attribute can only appear once for the same binding:

- **PASS**
  
  Defines the "passed-object dummy argument" of the procedure.

- **NOPASS**
  
  Indicates that the procedure has no passed-object dummy argument. Use this keyword if the procedure pointer component has an implicit interface or has no arguments. PASS and NOPASS can not both be specified for the same binding.

- **access-spec**
  
  Is the PUBLIC or PRIVATE attribute.

- **NON_OVERRIDABLE**
  
  Determines whether a binding can be overridden in an extended type. You must not specify NON_OVERRIDABLE for a binding with the DEFERRED attribute.

- **DEFERRED**
  
  Indicates the binding is deferred.
Indicates that the procedure is deferred. Deferred bindings must only be specified for derived-type definitions with the ABSTRACT attribute. A procedure with the DEFERRED binding attribute must specify an interface_name. An overriding binding can have the DEFERRED attribute only if the binding it overrides is deferred. The NON_OVERRIDABLE and DEFERRED binding attributes must not both be specified for the same procedure.

**binding-name**

Is the name of the type-bound procedure. It is referred to in the same way as a component of a type.

**procedure-name**

(Optional) Is the name of the actual procedure which implements binding-name. It is the name of an accessible module procedure or an external procedure that has an explicit interface. It defines the interface for the procedure, and the procedure to be executed when the procedure is referenced.

If neither =>procedure-name nor interface-name appears, the procedure-name is the same as the binding-name. If =>procedure-name appears, you must specify the double-colon separator and you must not specify an interface-name.

In general, the invoking variable, the passed-object dummy argument, is passed as an additional argument. By default, this is the first dummy argument of the actual procedure. So, the first argument in the argument list becomes the second argument, etc.

A passed-object dummy argument can be changed by declaring the type-bound procedure with the PASS(arg-name) attribute. In this case, the variable is passed as the named argument. The PASS attribute can also be used to confirm the default as the first argument. The NOPASS attribute prevents passing the object as an argument.

Consider the following:

```fortran
TYPE MY_TYPE
  ...  ! Component declarations
CONTAINS
  PROCEDURE :: PROC1 => MY_PROC
  PROCEDURE :: PROC2
END TYPE MY_TYPE
```

This binds MY_PROC with the PROC1.

If B is a scalar variable of type MY_TYPE, an example of a type-bound call is:

```fortran
CALL B%PROC1(C, D)
```

When PASS is in effect, the call passes B to the first argument of the procedure, C to the second argument, and D to the third argument.

### generic-binding

A generic type-bound procedure defines a generic interface that is bound to the type. It takes the following form:

```fortran
GENERIC [ , access-spec ] :: generic-spec => binding-name1 [ , binding-name2]...
```

- **access-spec**
  
  Is the PUBLIC or PRIVATE attribute. Only one can be specified.

- **generic-spec**
  
  Is an explicit INTERFACE statement using one of the following:
  
  - **generic-name**
    
    The generic-name cannot be the name of a nongeneric binding of the type. For more information, see Defining Generic Names for Procedures.
  
  - **OPERATOR (op)**
    
    Type-bound generic operators cannot have the NOPASS attribute. The dynamic type of the passed-object dummy argument determines which actual procedure is called. For more information, see Defining Generic Operators.
  
  - **ASSIGNMENT (=)**
    
    See Defining Generic Assignment.
The same \textit{generic-spec} can be used in several generic bindings within a single derived-type definition. In this case, every occurrence of the same \textit{generic-spec} must have the same accessibility.

\textit{binding-name1, binding-name2, ...} Is the name of the type-bound procedure. Each specific binding-name must have the passed-object dummy argument.

Consider the following:

```fortran
TYPE MY_TYPE2
...
CONTAINS
  PROCEDURE :: MYPROC => MYPROC1
  PROCEDURE, PASS(C) :: UPROC => UPROC1
  GENERIC :: OPERATOR(+) => MYPROC, UPROC
END TYPE MY_TYPE2
...
TYPE, EXTENDS(MY_TYPE2) :: MY_TYPE3
...
CONTAINS
  PROCEDURE :: MYPROC => MYPROC2
  PROCEDURE, PASS(C) :: UPROC => UPROC2
END TYPE MY_TYPE3
```

The type MY_TYPE3 inherits the generic operator `+`. Invoking the generic (`+`) invokes the specific type-bound procedure. For entities of type MY_TYPE3, that invokes the overriding actual procedure (MYPROC2 or UPROC2).

\textit{final-binding}

An extensible derived type can have one or more "final subroutines" associated with it. A final subroutine can be executed to perform clean-up operations after a data entity of that type is finalized (ceases to exist).

A finalization procedure defines one or more final subroutines that are bound to the type. It takes the following form:

```fortran
FINAL [ :: ] sub1 [, sub2]...
```

\textit{sub1, sub2, ...} Is a final subroutine, which is a module procedure with exactly one dummy argument of the derived type. The dummy argument cannot be INTENT(OUT), it cannot be optional, and it cannot be a pointer or allocatable. All array shape and length type parameters are assumed.

A final subroutine must not have a dummy argument with the same kind type parameters and rank as the dummy argument of another final subroutine of the type.

You cannot specify a subroutine that was previously specified as a final subroutine for the derived type.

The following example declares two module subroutines to be final:

```fortran
TYPE MY_TYPE
...
! Component declarations
CONTAINS
  FINAL :: CLEAN1, CLEAN2
END TYPE MY_TYPE
```

\textbf{See Also}

TYPE Statement (Derived Types)
Passed-Object Dummy Arguments

\textbf{Type Extension}

Type extension lets you create new derived types by extending pre-existing derived types.

Any derived type can be extended using the \texttt{EXTENDS} keyword, except for types with the \texttt{SEQUENCE} or \texttt{BIND(C)} attributes. \texttt{SEQUENCE} types and \texttt{BIND(C)} types (as well as intrinsic types) are non-extensible.
The extended type either inherits or overrides each type-bound procedure of the parent type. An overriding procedure must be compatible with the parent procedure; in particular, each dummy argument must have the same type except for the passed-object dummy argument which must have the new type. A type-bound procedure that is declared to be NON_OVERRIDABLE cannot be overridden during type extension.

The extended type inherits all the components and parameters of the parent type and they are known by the same name. The extended type can also specify additional components.

For example, consider the following derived-type definition:

```fortran
TYPE PERSON_INFO
    INTEGER :: AGE
    CHARACTER (LEN = 60) :: NAME
END TYPE PERSON_INFO
```

Derived type PERSON_INFO (the parent type) can be extended to create a new type as follows:

```fortran
TYPE, EXTENDS (PERSON_INFO) :: EMPLOYEE_DATA
    INTEGER :: ID
    REAL :: SALARY
END TYPE EMPLOYEE_DATA
```

Extended type EMPLOYEE_DATA inherits all the components in type PERSON_INFO, as well as additional components ID and SALARY.

TYPE Statement (Derived Types)
Passed-Object Dummy Arguments

Parameterized Derived-Type Declarations

A derived type is parameterized if the derived TYPE statement has type parameter names or it inherits any type parameters.

The type parameters must be listed in the type definition. You must specify a type and you must specify whether they are KIND or LEN parameters. A type parameter definition takes the following form:

```fortran
INTEGER [kind-selector], type-param-attr-spec :: type-param-decl-list
```

- kind-selector (Optional) Is one of the kind type parameter numbers allowed for integer data types. For more information, see Integer Data Types.
- type-param-attr-spec Is KIND or LEN.
- type-param-decl-list Is one or more of the following separated by commas:
  - type-param-name [= init-spec]
  - type-param-name

- type-param-name Is the name of the type parameter. Each type-param-name must match one of the type-param-name parameters listed in the derived TYPE statement.
- init-spec (Optional) Must be a scalar integer initialization expression.

If init-spec is specified, the type parameter has a default value that is specified by the expression init-spec. If necessary, the value of init-spec is converted to an integer value of the same kind as the type parameter in accordance with the rules of intrinsic assignment.

Explicit values for the type parameters are normally specified when an object of the parameter type is declared.

Within the type definition, kind type parameters may be used in constant expressions and specification expressions. Length type parameters may be used in specification expressions but not in constant expressions. The type parameters need not be used anywhere in the derived type.

Kind type parameters also participate in generic resolution Unambiguous Generic Procedure References. A single generic can include two specific procedures that have interfaces distinguished only by the value of a kind type parameter of a dummy argument.
An explicit interface is required if a parameterized derived type is used as a dummy argument. In a SELECT TYPE construct, the kind type parameter values of a type guard statement must be the same as those of the dynamic type of the selector. A BIND(C) type and a SEQUENCE type must not have type parameters.

Advantages to Using This Feature

Adding type parameters to a derived type allows you to declare objects of similar types that differ depending on the kind and length parameters used in the object declaration. For example, the type definition `matrix` below has two type parameters, a kind parameter \( k \) and a length parameter \( b \).

```fortran
TYPE matrix ( k, b )
  INTEGER, KIND :: k = 4
  INTEGER (8), LEN :: b
  REAL (k) :: element (b,b)
END TYPE matrix
```

The user can declare a matrix named `square` of 10 by 10 elements of REAL(8) with the following declaration:

```fortran
TYPE (matrix (8, 10)) :: square
```

The user can declare another matrix named `big_square` of 100 by 100 elements of REAL(4) with the following declaration:

```fortran
TYPE (matrix (10)) :: square    ! k defaults to 4
```

Parameterized TYPE Statements

SELECT TYPE

SEQUENCE

Parameterized TYPE Statements

A derived type-spec (see Type Declarations) in a parameterized type declaration has the general form:

```
type-name [ ( type-param-spec-list ) ]
```

- `type-name` is an accessible derived type.
- `type-param-spec-list` is one or more of the following separate by commas:
  - `[ keyword = ] type-param-value`
  - `keyword` is the name of a type parameter for the type `type-name`.
  - `type-param-value` is a scalar integer expression or an asterisk "*" or a colon ".:"

A `type-param-spec-list` must appear only if the type is parameterized. There must be at most one `type-param-spec` corresponding to each parameter of the type. If a type parameter does not have a default value, there must be a `type-param-spec` corresponding to that type parameter.

The following topics in this section include cumulative examples demonstrating various kinds of parameterized TYPE statements.

Examples

Consider the following:

```fortran
TYPE matrix (k, d1, d2)
  INTEGER, KIND :: k = kind (0.0)                  ! k has a default value
  INTEGER (selected_int_kind (12)), LEN :: d1, d2  ! Non-default kind for d1
  REAL (k) :: element (d1 ,d2)                     ! Non-default kind for d1
END TYPE
```

```fortran
! dim is an integer variable
TYPE(matrix(k = KIND(0d0), d1=200+5, d2=dim)) :: my_matrix1
! k has a default value and so the type-param-spec can be omitted
```
Each keyword must be the name of one of the parameters of the type. Similar to keyword arguments in procedure calls, "keyword=" can be omitted only if "keyword=" has been omitted for each preceding type parameter. If a keyword appears, the value corresponds to the type parameter named by the keyword. If keywords do not appear, the value corresponds to type parameters in type parameter order. If necessary, the value is converted according to the rules of intrinsic assignment to a value of the same kind as the type parameter.

**See Also**

Parameterized Derived-Type Declarations

Structure Constructors for Parameterized Derived Types

A type-param-spec-list must be given when constructing a parameterized derived type. See Parameterized TYPE Statements.

The syntax takes the following form:

```
derived-type-spec ([ comp-spec-list ])
```

*derived-type-spec* is a derived type-spec. See Type Declarations for details on type specifications.

*comp-spec-list* is a list of one or more component specifications.

**Example**

```
Matrix (kind (0.0),1,3) :: my_matrix
my_matrix = matrix (kind (0.0),1,3) ((1.0,2.0,3.0))
```

**See Also**

Parameterized Derived-Type Declarations

Parameterized TYPE Statements

Structure Constructors

**Type Parameter Order for Parameterized Derived Types**

The type parameter order of a non-extended type is the order of the type parameter list in the derived type definition. The type parameter order of an extended type consists of the order of its parent type followed by the order of the type parameter list in the derived type definition.

A type parameter declared in an extended type must not have the same name as any accessible component or type parameter of its parent type.

**Examples**

Consider the following:

```
Type :: t1 (k1,k2)
   Integer, kind :: k1,k2
   Real(k1) :: a(k2)
End type

Type, extends (t1) :: t2(k3)
   Integer, kind :: k3
   Logical(k3) flag
End type
```

The type parameter order for type *t1* is *k1*, then *k2*.

The type parameter order for type *t2* is *k1*, then *k2*, then *k3*. 
Deferred-Length Type Parameters for Parameterized Derived Types

Similar to deferred character lengths and deferred array bounds, the length type parameters of a derived type can be deferred. A deferred-length type parameter is specified when type-param-value in the type-param-spec is a colon (":").

A derived type object with a deferred-length type parameter must have an ALLOCATABLE or POINTER attribute. The value of a deferred type parameter is deferred until allocation or association.

When the dummy argument is allocatable or a pointer, the actual argument must have deferred the same type parameters as the dummy argument.

```
TYPE(matrix(k=KIND(0.0), d1= :, d2= :)), pointer :: my_mtrx_ptr, my_mtrx_alloc
TYPE(matrix(KIND(0.0), 100, 200)), target :: my_mtrx_tgt
TYPE(matrix(KIND(0.0), 1, 2)) :: my_mtrx_src

my_mtrx_ptr => my_mtrx_tgt  ! Gets values from target
! my_mtrx_ptr has d1= 100 and d2 = 200.

ALLOCATE(matrix(KIND(0.0), 10, 20) :: my_mtrx_alloc)  ! Gets values from allocation
! my_mtrx_alloc has d1=10 and d2=20
DEALLOCATE(my_mtrx_alloc)

ALLOCATE(my_mtrx_alloc, source=my_mtrx_src)  ! Gets values from allocation
! my_mtrx_alloc has d1=1 and d2=2
```

All non-deferred type parameter values of the declared type of the pointer object that correspond to non-deferred type parameters of the pointer target must agree. If a pointer object has non-deferred type parameters that correspond to deferred type parameters of a pointer target, the pointer target must not have undefined association status.

Deferred type parameters of functions, including function procedure pointers, have no values. Instead, they indicate that those type parameters of the function result will be determined by execution of the function, if it returns an allocated allocatable result or an associated pointer result.

If an ALLOCATE statement specifies a derived type object with deferred type parameters, it must either have the derived-type specification or a source-expr (a scalar expression). The kind type parameter values and the non-deferred length type parameter values in the derived-type specification or source-expr must be the same as the corresponding values of the derived type object.

```
TYPE(matrix(k=KIND(0.0), d1= 100, d2= :)), pointer :: my_mtrx_alloc
TYPE(matrix(KIND(0.0), 1, 2)) :: my_mtrx_src

ALLOCATE(my_mtrx_alloc, source=my_mtrx_src)  ! Illegal - d1 is not deferred
! my_mtrx_src must have the same value for d1
```

See Also
Parameterized Derived-Type Declarations
Parameterized TYPE Statements
ALLOCATE
ALLOCATABLE
POINTER - Fortran
Assumed-Length Type Parameters for Parameterized Derived Types

The length type parameter is assumed when an asterisk is used as a type-param-value in a type-param-spec. An asterisk may be used only in the declaration of a dummy argument, in the associate name in a SELECT TYPE statement, or in the allocation of a dummy argument. The value is taken from that of the actual argument.

```
Type(matrix(KIND(0d0), 10, :)), pointer :: y(:)
Call print_matrix(y)
...
Subroutine print_matrix(x)
   ! d1 here is assumed and its value '10' is obtained from the actual argument
   Type(matrix(k=KIND(0d0), d1=*, d2=:), pointer :: x(:)
   ALLOCATE(matrix(KIND(0.0), *, 10) :: x(10))
...
End Subroutine
```

All length type parameters of the dummy argument must be assumed for a final subroutine. All length type parameters of the first dummy argument to a user-defined I/O subroutine must be assumed. All of the length type parameters of a passed-object dummy argument must be assumed. In a SELECT TYPE construct, each length type parameter in a type-guard-stmt must be assumed.

Array Constructors

If type-spec in an array constructor specifies a parameterized derived type, all ac-value expressions in the array constructor must be of that derived type and must have the same kind type parameter values as specified by type-spec. Also, type-spec specifies the declared type and type parameters of the array constructor.

Each ac-value expression in the array constructor must be compatible with intrinsic assignment to a variable of this type and type parameter. Each value is converted to the type parameters of the array constructor in accordance with the rules of intrinsic assignment.

If type-spec is omitted, each ac-value expression in the array constructor must have the same length type parameters; in which case, the declared type and type parameters of the array constructor are those of the ac-value expressions.

Type Parameter Inquiry

The value of a derived-type parameter can be accessed from outside the type definition, using the same notation as component access.

```
print *, 'No: of Rows =', my_matrix%d1
print *, 'No: of Columns =', my_matrix%d2
```

Unlike components, a type parameter inquiry cannot be used on the left-hand side of an assignment, and type parameters are effectively always public. The value of a deferred type parameter of an unallocated allocatable, or of a pointer that is not associated with a target, is undefined and must not be inquired about. The length type parameters of an optional dummy argument that is not present must not be the subject of an inquiry.

The type parameters of intrinsic types can also be inquired using this syntax. The result is always scalar, even if the object is an array.

```
REAL(selected_real_kind(10,20)) :: z(100)
.. PRINT *, z%kind ! A single value is printed
```

This is same as calling KIND(z). However, the type parameter inquiry can be used even when the intrinsic function is not available.
Do i=1, (len - ch%len)/2
...
! The inquiry ch%len cannot be replaced with len(ch) since len is the
! name of a dummy argument

SELECT TYPE

Structure Components
A reference to a component of a derived-type structure takes the following form:
parent [%component [(s-list)]] ... %component [(s-list)]

parent
Is the name of a scalar or array of derived type. The percent sign (%) is called a component selector.

component
Is the name of a component of the immediately preceding parent or component.

s-list
Is a list of one or more subscripts. If the list contains subscript triplets or vector subscripts, the reference is to an array section.

Each subscript must be a scalar integer (or other numeric) expression with a value that is within the bounds of its dimension.
The number of subscripts in any s-list must equal the rank of the immediately preceding parent or component.

Description
Each parent or component (except the rightmost) must be of derived type.

The parent or one of the components can have nonzero rank (be an array). Any component to the right of a parent or component of nonzero rank must not have the POINTER attribute.

The rank of the structure component is the rank of the part (parent or component) with nonzero rank (if any); otherwise, the rank is zero. The type and type parameters (if any) of a structure component are those of the rightmost part name.

The structure component must not be referenced or defined before the declaration of the parent object.

If the parent object has the INTENT, TARGET, or PARAMETER attribute, the structure component also has the attribute.

Examples
The following example shows a derived-type definition with two components:

```fortran
TYPE EMPLOYEE
  INTEGER ID
  CHARACTER(LEN=40) NAME
END TYPE EMPLOYEE
```

The following shows how to declare CONTRACT to be of type EMPLOYEE:

```fortran
TYPE(EMPLOYEE) :: CONTRACT
```

Note that both examples started with the keyword TYPE. The first (initial) statement of a derived-type definition is called a derived-type statement, while the statement that declares a derived-type object is called a TYPE statement.

The following example shows how to reference component ID of parent structure CONTRACT:

```fortran
CONTRACT%ID
```
The following example shows a derived type with a component that is a previously defined type:

```fortran
TYPE DOT
    REAL X, Y
END TYPE DOT

TYPE SCREEN
    TYPE(DOT) C, D
END TYPE SCREEN
```

The following declares a variable of type SCREEN:

```fortran
TYPE(SCREEN) M
```

Variable M has components M%C and M%D (both of type DOT); M%C has components M%C%X and M%C %Y of type REAL.

The following example shows a derived type with a component that is an array:

```fortran
TYPE CAR_INFO
    INTEGER YEAR
    CHARACTER(LEN=15), DIMENSION(10) :: MAKER
    CHARACTER(LEN=10) MODEL, BODY_TYPE*8
    REAL PRICE
END TYPE

TYPE(CAR_INFO) MY_CAR
```

Note that MODEL has a character length of 10, but BODY_TYPE has a character length of 8. You can assign a value to a component of a structure; for example:

```fortran
MY_CAR%YEAR = 1985
```

The following shows an array structure component:

```fortran
MY_CAR%MAKER
```

In the preceding example, if a subscript list (or substring) was appended to MAKER, the reference would not be to an array structure component, but to an array element or section.

Consider the following:

```fortran
MY_CAR%MAKER(2) (4:10)
```

In this case, the component is substring 4 to 10 of the second element of array MAKER.

Consider the following:

```fortran
TYPE CHARGE
    INTEGER PARTS(40)
    REAL LABOR
    REAL MILEAGE
END TYPE CHARGE

TYPE(CHARGE) MONTH
TYPE(CHARGE) YEAR(12)
```

Some valid array references for this type follow:

```fortran
MONTH%PARTS(I) ! An array element
MONTH%PARTS(I:K) ! An array section
YEAR(I)%PARTS ! An array structure component (a whole array)
YEAR(J)%PARTS(I) ! An array element
YEAR(J)%PARTS(I:K) ! An array section
YEAR(J:K)%PARTS(I) ! An array section
YEAR%PARTS(I) ! An array section
```
The following example shows a derived type with a pointer component that is of the type being defined:

```
TYPE NUMBER
  INTEGER NUM
END TYPE
```

```
TYPE(NUMBER), POINTER :: START_NUM => NULL( )
TYPE(NUMBER), POINTER :: NEXT_NUM => NULL( )
END TYPE
```

A type such as this can be used to construct linked lists of objects of type NUMBER. Note that the pointers are given the default initialization status of disassociated.

The following example shows a private type:

```
TYPE, PRIVATE :: SYMBOL
  LOGICAL TEST
  CHARACTER(LEN=50) EXPLANATION
END TYPE SYMBOL
```

This type is private to the module. The module can be used by another scoping unit, but type SYMBOL is not available.

**Structure Constructors**

A structure constructor lets you specify scalar values of a derived type. It takes the following form:

```
d-name (comp-spec)
```

- **d-name**
  - Is the name of the derived type. It cannot be an abstract type.

- **comp-spec**
  - Is a component specification. Only one `comp-spec` can be specified for a component. However, you can specify more than one `comp-spec` in a constructor. A component specification takes the following form:
    
    `[keyword=] comp-data-source`

- **keyword**
  - Is the name of a component of the derived type `d-name`.

- **comp-data-source**
  - Is one of the following:
    
    - `expr`
    - `data-target`
    - `proc-target`

  - **expr**
    - Is an expression specifying component values. The values must agree in number and order with the components of the derived type. If necessary, values are converted (according to the rules of assignment), to agree with their corresponding components in type and kind parameters.

  - **data-target**
    - Is a data pointer component. It must have the same rank as its corresponding component.

  - **proc-target**
    - Is a procedure pointer component.

**Description**

A structure constructor must not appear before its derived type is defined.
If `keyword= appears, any `expr` is assigned to the component named by the keyword. If `keyword= is omitted, each `comp-data-source` is assigned to the corresponding component in component order. The `keyword= can be omitted from a `comp-spec` only if the `keyword=` has been omitted from each preceding `comp-spec` in the constructor, if any.

If a component of the derived type is an array, the shape in the expression list must conform to the shape of the component array.

If a component of the derived type is a pointer, the value in the expression list must evaluate to an object that would be a valid target in a pointer assignment statement. (A constant is not a valid target in a pointer assignment statement.)

If all the values in a structure constructor are constant expressions, the constructor is a derived-type constant expression.

The type name and all components of the type for which a `comp-spec` appears must be accessible in the scoping unit containing the structure constructor.

For a pointer component, the corresponding `comp-data-source` must be an allowable `data-target` or `proc-target` for such a pointer in a pointer assignment statement. If the `comp-data-source` is a pointer, the association of the component is that of the pointer; otherwise, the component is pointer-associated with the `comp-data-source`.

If a component with default initialization has no corresponding `comp-data-source`, then the default initialization is applied to that component.

If a component of a derived type is allocatable, the corresponding constructor expression must either be a reference to the intrinsic function NULL with no arguments or an allocatable entity of the same rank, or it must evaluate to an entity of the same rank.

If the expression is a reference to the intrinsic function NULL, the corresponding component of the constructor has a status of unallocated.

If the expression is an allocatable entity, the corresponding component of the constructor has the same allocation status as that allocatable entity. If the entity is allocated, the constructor component has the same dynamic type, bounds, and value. If a length parameter of the component is deferred, its value is the same as the corresponding parameter of the expression. Otherwise the corresponding component of the constructor has an allocation status of allocated and has the same bounds and value as the expression.

**Examples**

Consider the following derived-type definition:

```fortran
TYPE EMPLOYEE
  INTEGER ID
  CHARACTER(LEN=40) NAME
END TYPE EMPLOYEE
```

This can be used to produce the following structure constructor:

```fortran
EMPLOYEE(3472, "John Doe")
```

The following example shows a type with a component of derived type:

```fortran
TYPE ITEM
  REAL COST
  CHARACTER(LEN=30) SUPPLIER
  CHARACTER(LEN=20) ITEM_NAME
END TYPE ITEM
```

```fortran
TYPE PRODUCE
  REAL MARKUP
  TYPE(ITEM) FRUIT
END TYPE PRODUCE
```
In this case, you must use an embedded structure constructor to specify the values of that component; for example:

```
PRODUCE(.70, ITEM (.25, "Daniels", "apple"))
```

**Binary, Octal, Hexadecimal, and Hollerith Constants**

Binary, octal, hexadecimal, and Hollerith constants are nondecimal constants. They have no intrinsic data type, but assume a numeric data type depending on their use.

Standard Fortran allows unsigned binary, octal, and hexadecimal constants to be used in DATA statements; the constant must correspond to an integer scalar variable.

In Intel® Fortran, binary, octal, hexadecimal, and Hollerith constants can appear wherever numeric constants are allowed.

See Also

Determining the Data Type of Nondecimal Constants

**Binary Constants**

A binary constant is an alternative way to represent a numeric constant. A binary constant takes one of the following forms:

- `B'd[d...]'
- `B"d[d...]"

`d` is a binary (base 2) digit (0 or 1).

You can specify up to 128 binary digits in a binary constant.

**Examples**

**Valid Binary Constants**

- `B'0101110'
- `B"1"

**Invalid Binary Constants**

- `B'0112'
  The character 2 is invalid.
- `B10011'
  No apostrophe after the B.
- "1000001"
  No B before the first quotation mark.

See Also

Alternative Syntax for Binary, Octal, and Hexadecimal Constants

**Octal Constants**

An octal constant is an alternative way to represent numeric constants. An octal constant takes one of the following forms:

- `O'd[d...]'
- `O"d[d...]"

Is an octal (base 8) digit (0 through 7).

You can specify up to 128 bits (43 octal digits) in octal constants.

**Examples**

**Valid Octal Constants**

O'07737'

O"1"

**Invalid Octal Constants**

O'7782'  
The character 8 is invalid.

O7772'  
No apostrophe after the O.

"0737"  
No O before the first quotation mark.

**See Also**

Alternative Syntax for Binary, Octal, and Hexadecimal Constants

**Hexadecimal Constants**

A hexadecimal constant is an alternative way to represent numeric constants. A hexadecimal constant takes one of the following forms:

Z'd[d...]'

Z"d[d...]"

\(d\)  
Is a hexadecimal (base 16) digit (0 through 9, or an uppercase or lowercase letter in the range of A to F).

You can specify up to 128 bits (32 hexadecimal digits) in hexadecimal constants.

**Examples**

**Valid Hexadecimal Constants**

Z'AF9730'

Z"FFABC"

Z'84'

**Invalid Hexadecimal Constants**

Z'999.'  
Decimal not allowed.

ZF9"  
No quotation mark after the Z.

**See Also**

Alternative Syntax for Binary, Octal, and Hexadecimal Constants

**Hollerith Constants**

A Hollerith constant is a string of printable ASCII characters preceded by the letter H. Before the H, there must be an unsigned, nonzero default integer constant stating the number of characters in the string (including blanks and tabs).

Hollerith constants are strings of 1 to 2000 characters. They are stored as byte strings, one character per byte.
Examples

Valid Hollerith Constants

16HTODAY'S DATE IS:

1HB

4H ABC

Invalid Hollerith Constants

3HABCD  Wrong number of characters.

0H  Hollerith constants must contain at least one character.

Determining the Data Type of Nondecimal Constants

Binary, octal, hexadecimal, and Hollerith constants have no intrinsic data type. In most cases, the default integer data type is assumed.

However, these constants can assume a numeric data type depending on their use. When the constant is used with a binary operator (including the assignment operator), the data type of the constant is the data type of the other operand. For example:

<table>
<thead>
<tr>
<th>Statement</th>
<th>Data Type of Constant</th>
<th>Length of Constant (in bytes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER(2) ICOUNT</td>
<td></td>
<td></td>
</tr>
<tr>
<td>INTEGER(4) JCOUNT</td>
<td></td>
<td></td>
</tr>
<tr>
<td>INTEGER(4) N</td>
<td></td>
<td></td>
</tr>
<tr>
<td>REAL(8) DOUBLE</td>
<td></td>
<td></td>
</tr>
<tr>
<td>REAL(4) RAFFIA, RALPHA</td>
<td></td>
<td></td>
</tr>
<tr>
<td>RAFFIA = B'100110011111010011'</td>
<td>REAL(4)</td>
<td>4</td>
</tr>
<tr>
<td>RAFFIA = Z'99AF2'</td>
<td>REAL(4)</td>
<td>4</td>
</tr>
<tr>
<td>RALPHA = 4HABCD</td>
<td>REAL(4)</td>
<td>4</td>
</tr>
<tr>
<td>DOUBLE = B'11111111110011001010'</td>
<td>REAL(8)</td>
<td>8</td>
</tr>
<tr>
<td>DOUBLE = Z'FFF99A'</td>
<td>REAL(8)</td>
<td>8</td>
</tr>
<tr>
<td>DOUBLE = 8HABCDEFGH</td>
<td>REAL(8)</td>
<td>8</td>
</tr>
<tr>
<td>JCOUNT = ICOUNT + B'011101101111'</td>
<td>INTEGER(2)</td>
<td>2</td>
</tr>
<tr>
<td>JCOUNT = ICOUNT + O'777'</td>
<td>INTEGER(2)</td>
<td>2</td>
</tr>
<tr>
<td>JCOUNT = ICOUNT + 2HXY</td>
<td>INTEGER(2)</td>
<td>2</td>
</tr>
<tr>
<td>IF (N .EQ. B'1010100') GO TO 10</td>
<td>INTEGER(4)</td>
<td>4</td>
</tr>
<tr>
<td>IF (N .EQ. O'123') GO TO 10</td>
<td>INTEGER(4)</td>
<td>4</td>
</tr>
<tr>
<td>IF (N. EQ. 1HZ) GO TO 10</td>
<td>INTEGER(4)</td>
<td>4</td>
</tr>
</tbody>
</table>
When a specific data type (generally integer) is required, that type is assumed for the constant. For example:

<table>
<thead>
<tr>
<th>Statement</th>
<th>Data Type of Constant</th>
<th>Length of Constant (in bytes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Y(IX) = Y(O'15') + 3.</td>
<td>INTEGER(4)</td>
<td>4</td>
</tr>
<tr>
<td>Y(IX) = Y(1HA) + 3.</td>
<td>INTEGER(4)</td>
<td>4</td>
</tr>
</tbody>
</table>

When a nondecimal constant is used as an actual argument, the following occurs:

- For binary, octal, and hexadecimal constants, if the value fits in a default integer, that integer kind is used. Otherwise, the smallest integer kind large enough to hold the value is used.
- For Hollerith constants, a numeric data type of sufficient size to hold the length of the constant is assumed.

For example:

<table>
<thead>
<tr>
<th>Statement</th>
<th>Data Type of Constant</th>
<th>Length of Constant (in bytes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>CALL APAC(Z'34BC2')</td>
<td>INTEGER(4)</td>
<td>4</td>
</tr>
<tr>
<td>CALL APAC(9HABCDEFGHI)</td>
<td>REAL(16)</td>
<td>9</td>
</tr>
</tbody>
</table>

When a binary, octal, or hexadecimal constant is used in any other context, the default integer data type is assumed. In the following examples, default integer is INTEGER(4):

<table>
<thead>
<tr>
<th>Statement</th>
<th>Data Type of Constant</th>
<th>Length of Constant (in bytes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>IF (Z'AF77') 1,2,3</td>
<td>INTEGER(4)</td>
<td>4</td>
</tr>
<tr>
<td>IF (2HAB) 1,2,3</td>
<td>INTEGER(4)</td>
<td>4</td>
</tr>
<tr>
<td>I = O'7777' - Z'A39'</td>
<td>INTEGER(4)</td>
<td>4</td>
</tr>
<tr>
<td>I = 1HC - 1HA</td>
<td>INTEGER(4)</td>
<td>4</td>
</tr>
<tr>
<td>J = NOT. O'73777'</td>
<td>INTEGER(4)</td>
<td>4</td>
</tr>
<tr>
<td>J = NOT. 1HB</td>
<td>INTEGER(4)</td>
<td>4</td>
</tr>
</tbody>
</table>

1 When two typeless constants are used in an operation, they both take default integer type.

When nondecimal constants are not the same length as the length implied by a data type, the following occurs:

- Binary, octal, and hexadecimal constants
  These constants can specify up to 16 bytes of data. When the length of the constant is less than the length implied by the data type, the leftmost digits have a value of zero.
  When the length of the constant is greater than the length implied by the data type, the constant is truncated on the left. An error results if any nonzero digits are truncated.
  The Data Type Storage Requirements table lists the number of bytes that each data type requires.
- Hollerith constants
  When the length of the constant is less than the length implied by the data type, blanks are appended to the constant on the right.
  When the length of the constant is greater than the length implied by the data type, the constant is truncated on the right. If any characters other than blank characters are truncated, a warning occurs.
  Each Hollerith character occupies one byte of memory.
Enumerations and Enumerators

An enumeration defines the name of a group of related values and the name of each value within the group. It takes the following form:

```
ENUM, BIND(C)
   ENUMERATOR [ :: ] c1 [ = expr][, c2 [ = expr]]...
   [ENUMERATOR [ :: ] c3 [ = expr][, c4 [ = expr]]...]
END ENUM
```

- `c1`, `c2`, `c3`, `c4` Is the name of the enumerator being defined.
- `expr` Is an optional scalar integer initialization expression specifying the value for the enumerator.

If `=` appears in an enumerator, a double-colon separator must appear before the enumerator or list of enumerators.

The compiler ensures that the integer kind declared for the enumerator is compatible with the integer type used by the corresponding C enumeration. The processor uses the same representation for the types declared by all C enumeration specifiers that specify the same values in the same order.

An enumerator is treated as if it were explicitly declared with the PARAMETER attribute.

The order in which the enumerators appear in an enumerator definition is significant.

If you do not explicitly assign each enumerator a value by specifying an `expr`, the compiler assigns a value according to the following rules:

- If the enumerator is the first enumerator in the enumerator definition, the enumerator has the value 0.
- If the enumerator is not the first enumerator in the enumerator definition, its value is the result of adding one to the value of the immediately preceding enumerator in the enumerator definition.

You can define the enumerators in multiple ENUMERATOR statements or in one ENUMERATOR statement. The order in which the enumerators are declared in an enumeration definition is significant, but the number of ENUMERATOR statements is not.

Examples

The following example shows an enumeration definition:

```
ENUM, BIND(C)
   ENUMERATOR ORANGE
   ENUMERATOR :: RED = 5, BLUE = 7
   ENUMERATOR GREEN
END ENUM
```

The kind type parameter for this enumeration is processor dependent, but the processor must select a kind sufficient to represent the values of the enumerators.

The order of the enumerators is significant if the values are not assigned explicitly. In the above example, the value of ORANGE becomes defined as a named constant with the value zero and the value of GREEN becomes defined as a named constant with the value 8. Note that if RED was the enumerator preceding GREEN, the value of GREEN would be 6 rather than 8.

The following declaration may be considered to be equivalent to the above enumeration definition:

```
INTEGER(SELECTED_INT_KIND(4)), PARAMETER :: ORANGE = 0, RED = 5, BLUE = 7, GREEN = 8
```

An entity of the same kind type parameter value can be declared using the intrinsic function KIND with one of the enumerators as its argument, for example:

```
INTEGER(KIND(BLUE)) :: X
```
Variables
A variable is a data object whose value can be changed (defined or redefined) at any point in a program. A variable can be any of the following:

- A scalar
  A scalar is a single object that has a single value; it can be of any intrinsic or derived (user-defined) type.

- An array
  An array is a collection of scalar elements of any intrinsic or derived type. All elements must have the same type and kind parameters.

- A subobject designator
  A subobject is part of an object. The following are subobjects:
  - An array element
  - An array section
  - A structure component
  - A character substring
  For example, B(3) is a subobject (array element) designator for array B. A subobject cannot be a variable if its parent object is a constant.

The name of a variable is associated with a single storage location. A designator is a name followed by zero or more component selectors, complex part selectors, array section selectors, array element selectors, image selectors, and substring selectors.

Variables are classified by data type, as constants are. The data type of a variable indicates the type of data it contains, including its precision, and implies its storage requirements. When data of any type is assigned to a variable, it is converted to the data type of the variable (if necessary).

A variable is defined when you give it a value. A variable can be defined before program execution by a DATA statement or a type declaration statement. During program execution, variables can be defined or redefined in assignment statements and input statements, or undefined (for example, if an I/O error occurs). When a variable is undefined, its value is unpredictable.

When a variable becomes undefined, all variables associated by storage association also become undefined. An object with subobjects, such as an array, can only be defined when all of its subobjects are defined. Conversely, when at least one of its subobjects are undefined, the object itself, such as an array or derived type, is undefined.

This section also discusses the Data Types of Scalar Variables and Arrays.

See Also
Type Declarations
DATA
Data Type of Numeric Expressions
Storage Association for details on storage association of variables

Data Types of Scalar Variables
The data type of a scalar variable can be explicitly declared in a type declaration statement. If no type is declared, the variable has an implicit data type based on predefined typing rules or definitions in an IMPLICIT statement.

An explicit declaration of data type takes precedence over any implicit type. Implicit type specified in an IMPLICIT statement takes precedence over predefined typing rules.

See Also
Specification of Data Type
Implicit Typing Rules
Specification of Data Type

Type declaration statements explicitly specify the data type of scalar variables. For example, the following statements associate VAR1 with a 16-byte complex storage location, and VAR2 with an 8-byte double-precision storage location:

```
COMPLEX(8) VAR1
REAL(8) VAR2
```

**NOTE**
If no kind parameter is specified for a data type, the default kind is used. The default kind can be affected by compiler options that affect the size of variables.

You can explicitly specify the data type of a scalar variable only once.

If no explicit data type specification appears, any variable with a name that begins with the letter in the range specified in the IMPLICIT statement becomes the data type of the variable.

Character type declaration statements specify that given variables represent character values with the length specified. For example, the following statements associate the variable names INLINE, NAME, and NUMBER with storage locations containing character data of lengths 72, 12, and 9, respectively:

```
CHARACTER*72 INLINE
CHARACTER NAME*12, NUMBER*9
```

In single subprograms, assumed-length character arguments can be used to process character strings with different lengths. The assumed-length character argument has its length specified with an asterisk, for example:

```
CHARACTER*(*) CHARDUMMY
```

The argument CHARDUMMY assumes the length of the actual argument.

See Also
Type Declarations
Assumed-Length Character Arguments
IMPLICIT
Declarations for Character Types

Implicit Typing Rules

By default, all scalar variables with names beginning with I, J, K, L, M, or N are assumed to be default integer variables. Scalar variables with names beginning with any other letter are assumed to be default real variables. For example:

<table>
<thead>
<tr>
<th>Real Variables</th>
<th>Integer Variables</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALPHA</td>
<td>JCOUNT</td>
</tr>
<tr>
<td>BETA</td>
<td>ITEM_1</td>
</tr>
<tr>
<td>TOTAL_NUM</td>
<td>NTOTAL</td>
</tr>
</tbody>
</table>

Names beginning with a dollar sign ($) are implicitly INTEGER.

You can override the default data type implied in a name by specifying data type in either an IMPLICIT statement or a type declaration statement.

See Also
Type Declarations
IMPLICIT
**Arrays**

An array is a set of scalar elements that have the same type and kind parameters. Any object that is declared with an array specification is an array. Arrays can be declared by using a type declaration statement, or by using a `DIMENSION`, `COMMON`, `ALLOCATABLE`, `POINTER`, or `TARGET` statement.

An array can be referenced by element (using subscripts), by section (using a section subscript list), or as a whole. A subscript list (appended to the array name) indicates which array element or array section is being referenced.

A section subscript list consists of subscripts, subscript triplets, or vector subscripts. At least one subscript in the list must be a subscript triplet or vector subscript.

When an array name without any subscripts appears in an intrinsic operation (for example, addition), the operation applies to the whole array (all elements in the array).

An array has the following properties:

- **Data type**
  An array can have any intrinsic or derived type. The data type of an array (like any other variable) is specified in a type declaration statement or implied by the first letter of its name. All elements of the array have the same type and kind parameters. If a value assigned to an individual array element is not the same as the type of the array, it is converted to the array's type.

- **Rank**
  The rank of an array is the number of dimensions in the array. An array can have up to 31 dimensions. A rank-one array represents a column of data (a vector), a rank-two array represents a table of data arranged in columns and rows (a matrix), a rank-three array represents a table of data on multiple pages (or planes), and so forth.

- **Bounds**
  Arrays have a lower and upper bound in each dimension. These bounds determine the range of values that can be used as subscripts for the dimension. The value of either bound can be positive, negative, or zero.

  The bounds of a dimension are defined in an array specification.

- **Size**
  The size of an array is the total number of elements in the array (the product of the array's extents).

  The extent is the total number of elements in a particular dimension. It is determined as follows: upper bound - lower bound + 1. If the value of any of an array's extents is zero, the array has a size of zero.

- **Shape**
  The shape of an array is determined by its rank and extents, and can be represented as a rank-one array (vector) where each element is the extent of the corresponding dimension.

  Two arrays with the same shape are said to be conformable. A scalar is conformable to an array of any shape.

The name and rank of an array must be specified when the array is declared. The extent of each dimension can be constant, but does not need to be. The extents can vary during program execution if the array is a dummy argument array, an automatic array, an array pointer, or an allocatable array.

A whole array is referenced by the array name. Individual elements in a named array are referenced by a scalar subscript or list of scalar subscripts (if there is more than one dimension). A section of a named array is referenced by a section subscript.

This section also discusses:

- Whole Arrays
- Array Elements
- Array Sections
- Array Constructors
Examples

The following are examples of valid array declarations:

<table>
<thead>
<tr>
<th>Array Declaration</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DIMENSION A(10, 2, 3)</td>
<td>DIMENSION statement</td>
</tr>
<tr>
<td>ALLOCATABLE B(:, :)</td>
<td>ALLOCATABLE statement</td>
</tr>
<tr>
<td>POINTER C(:, :, :)</td>
<td>POINTER statement</td>
</tr>
<tr>
<td>REAL, DIMENSION (2, 5) :: D</td>
<td>Type declaration with</td>
</tr>
<tr>
<td></td>
<td>DIMENSION attribute</td>
</tr>
</tbody>
</table>

Consider the following array declaration:

```
INTEGER L(2:11,3)
```

The properties of array L are as follows:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data type</td>
<td>INTEGER</td>
</tr>
<tr>
<td>Rank</td>
<td>2 (two dimensions)</td>
</tr>
<tr>
<td>Bounds</td>
<td>First dimension: 2 to 11</td>
</tr>
<tr>
<td></td>
<td>Second dimension: 1 to 3</td>
</tr>
<tr>
<td>Size</td>
<td>30; the product of the extents: 10 x 3</td>
</tr>
<tr>
<td>Shape</td>
<td>(/10,3/) (or 10 by 3); a vector of the extents 10 and 3</td>
</tr>
</tbody>
</table>

The following example shows other valid ways to declare this array:

```
DIMENSION L(2:11,3)
INTEGER, DIMENSION(2:11,3) :: L
COMMON L(2:11,3)
```

The following example shows references to array elements, array sections, and a whole array:

```
REAL B(10)           ! Declares a rank-one array with 10 elements

INTEGER C(5,8)       ! Declares a rank-two array with 5 elements in
                      !    dimension one and 8 elements in dimension two
...
B(3) = 5.0           ! Reference to an array element
B(2:5) = 1.0         ! Reference to an array section consisting of
                      !    elements: B(2), B(3), B(4), B(5)
...
C(4,8) = I           ! Reference to an array element
C(1:3,3:4) = J       ! Reference to an array section consisting of
                      !    elements: C(1,3) C(1,4)
                      !    C(2,3) C(2,4)
                      !    C(3,3) C(3,4)
B = 99               ! Reference to a whole array consisting of
                      !    elements: B(1), B(2), B(3), B(4), B(5),
                      !    B(6), B(7), B(8), B(9), and B(10)
```

Declarations for Arrays for details on array specifications
Categories of Intrinsic Functions for details on intrinsic functions that perform array operations
Whole Arrays

A whole array is a named array; it is either a named constant or a variable. It is referenced by using the array name (without any subscripts).

If a whole array appears in a nonexecutable statement, the statement applies to the entire array. For example:

```
INTEGER, DIMENSION(2:11,3) :: L   ! Specifies the type and
!    dimensions of array L
```

If a whole array appears in an executable statement, the statement applies to all of the elements in the array. For example:

```
L = 10       ! The value 10 is assigned to all the
!   elements in array L
WRITE *, L   ! Prints all the elements in array L
```

Array Elements

An array element is one of the scalar data items that make up an array. A subscript list (appended to the array or array component) determines which element is being referred to. A reference to an array element takes the following form:

```
array(subscript-list)
```

- **array** Is the name of the array.
- **subscript-list** Is a list of one or more subscripts separated by commas. The number of subscripts must equal the rank of the array. Each subscript must be a scalar integer (or other numeric) expression with a value that is within the bounds of its dimension.

Description

Each array element inherits the type, kind type parameter, and certain attributes (INTENT, PARAMETER, and TARGET) of the parent array. An array element cannot inherit the POINTER attribute.

If an array element is of type character, it can be followed by a substring range in parentheses; for example:

```
ARRAY_D(1,2) (1:3)    ! Elements are substrings of length 3
```

However, by convention, such an object is considered to be a substring rather than an array element.

The following are some valid array element references for an array declared as REAL B(10,20): B(1,3), B(10,10), and B(5,8).

You can use functions and array elements as subscripts. For example:

```
REAL A(3, 3)
REAL B(3, 3), C(89), R
B(2, 2) = 4.5                       ! Assigns the value 4.5 to element B(2, 2)
R = 7.0                             
C(INT*C + 1) = 2.0                   ! Element 15 of C = 2.0
A(1,2) = B(INT(C(15)), INT(SQRT))   ! Element A(1,2) = element B(2,2) = 4.5
```

For information on forms for array specifications, see Declaration Statements for Arrays.

Array Element Order

The elements of an array form a sequence known as array element order. The position of an element in this sequence is its subscript order value.

The elements of an array are stored as a linear sequence of values. A one-dimensional array is stored with its first element in the first storage location and its last element in the last storage location of the sequence. A multidimensional array is stored so that the leftmost subscripts vary most rapidly. This is called the order of subscript progression.
The following figure shows array storage in one, two, and three dimensions:

**Array Storage**

For example, in two-dimensional array BAN, element BAN(1,2) has a subscript order value of 4; in three-dimensional array BOS, element BOS(1,1,1) has a subscript order value of 1.

In an array section, the subscript order of the elements is their order within the section itself. For example, if an array is declared as B(20), the section B(4:19:4) consists of elements B(4), B(8), B(12), and B(16). The subscript order value of B(4) in the array section is 1; the subscript order value of B(12) in the section is 3.

Array Sections

An array section is a portion of an array that is an array itself. It is an array subobject. A section subscript list (appended to the array or array component) determines which portion is being referred to. A reference to an array section takes the following form:

```
array(sect-subscript-list)
```

- `array` is the name of the array.
- `sect-subscript-list` is a list of one or more section subscripts (subscripts, subscript triplets, or vector subscripts) indicating a set of elements along a particular dimension.

At least one of the items in the section subscript list must be a subscript triplet or vector subscript. A subscript triplet specifies array elements in increasing or decreasing order at a given stride. A vector subscript specifies elements in any order.

Each subscript and subscript triplet must be a scalar integer (or other numeric) expression. Each vector subscript must be a rank-one integer expression.

Description

If no section subscript list is specified, the rank and shape of the array section is the same as the parent array.

Otherwise, the rank of the array section is the number of vector subscripts and subscript triplets that appear in the list. Its shape is a rank-one array where each element is the number of integer values in the sequence indicated by the corresponding subscript triplet or vector subscript.

If any of these sequences is empty, the array section has a size of zero. The subscript order of the elements of an array section is that of the array object that the array section represents.

Each array section inherits the type, kind type parameter, and certain attributes (INTENT, PARAMETER, and TARGET) of the parent array. An array section cannot inherit the POINTER attribute.

If an array (or array component) is of type character, it can be followed by a substring range in parentheses. Consider the following declaration:

```
CHARACTER(LEN=15) C(10,10)
```

In this case, an array section referenced as C(:, :) (1:3) is an array of shape (10,10), whose elements are substrings of length 3 of the corresponding elements of C.

The following shows valid references to array sections. Note that the syntax (/.../) denotes an array constructor.

```
REAL, DIMENSION(20) :: B
...
PRINT *, B(2:20:5)  ! The section consists of elements
       !   B(2), B(7), B(12), and B(17)
K = (/3, 1, 4/)
B(K) = 0.0    ! Section B(K) is a rank-one array with shape (3) and
       !   size 3. (0.0 is assigned to B(1), B(3), and B(4).)
```

Subscript Triplets

A subscript triplet is a set of three values representing the lower bound of the array section, the upper bound of the array section, and the increment (stride) between them. It takes the following form:

[first-bound] : [last-bound] [:stride]

**first-bound**
Is a scalar integer (or other numeric) expression representing the first value in the subscript sequence. If omitted, the declared lower bound of the dimension is used.

**last-bound**
Is a scalar integer (or other numeric) expression representing the last value in the subscript sequence. If omitted, the declared upper bound of the dimension is used.

When indicating sections of an assumed-size array, this subscript must be specified.

**stride**
Is a scalar integer (or other numeric) expression representing the increment between successive subscripts in the sequence. It must have a nonzero value. If it is omitted, it is assumed to be 1.

The stride has the following effects:

- If the stride is positive, the subscript range starts with the first subscript and is incremented by the value of the stride, until the largest value less than or equal to the second subscript is attained.

  For example, if an array has been declared as B(6,3,2), the array section specified as B(2:4,1:2,2) is a rank-two array with shape (3,2) and size 6. It consists of the following six elements:

  \[
  \begin{array}{ll}
  B(2,1,2) & B(2,2,2) \\
  B(3,1,2) & B(3,2,2) \\
  B(4,1,2) & B(4,2,2) \\
  \end{array}
  \]

  If the first subscript is greater than the second subscript, the range is empty.

- If the stride is negative, the subscript range starts with the value of the first subscript and is decremented by the absolute value of the stride, until the smallest value greater than or equal to the second subscript is attained.

  For example, if an array has been declared as A(15), the array section specified as A(10:3:-2) is a rank-one array with shape (4) and size 4. It consists of the following four elements:

  \[
  \begin{array}{llll}
  A(10) & A(8) & A(6) & A(4) \\
  \end{array}
  \]

  If the second subscript is greater than the first subscript, the range is empty.

If a range specified by the stride is empty, the array section has a size of zero.

A subscript in a subscript triplet need not be within the declared bounds for that dimension if all values used to select the array elements are within the declared bounds. For example, if an array has been declared as A(15), the array section specified as A(4:16:10) is valid. The section is a rank-one array with shape (2) and size 2. It consists of elements A(4) and A(14).

If the subscript triplet does not specify bounds or stride, but only a colon (:), the entire declared range for the dimension is used.

If you leave out all subscripts, the section defaults to the entire extent in that dimension. For example:

```
REAL A(10)
A(1:5:2) = 3.0 ! Sets elements A(1), A(3), A(5) to 3.0
A(:5:2) = 3.0 ! Same as the previous statement
             ! because the lower bound defaults to 1
A(2::3) = 3.0 ! Sets elements A(2), A(5), A(8) to 3.0
             ! The upper bound defaults to 10
A(7:9) = 3.0 ! Sets elements A(7), A(8), A(9) to 3.0
```
! The stride defaults to 1
A(:, ) = 3.0       ! Same as A = 3.0; sets all elements of
    !   A to 3.0

Array Sections

Vector Subscripts

A vector subscript is a one-dimensional (rank one) array of integer values (within the declared bounds for
the dimension) that selects a section of a whole (parent) array. The elements in the section do not have to
be in order and the section can contain duplicate values.

For example, A is a rank-two array of shape (4,6). B and C are rank-one arrays of shape (2) and (3),
respectively, with the following values:

B = (/1,4/)           ! Syntax (/.../) denotes an array constructor
C = (/2,1,1/)         ! This constructor produces a many-one array section

Array section A(3,B) consists of elements A(3,1) and A(3,4). Array section A(C,1) consists of elements
A(2,1), A(1,1), and A(1,1). Array section A(B,C) consists of the following elements:

A(1,2)    A(1,1)    A(1,1)
A(4,2)    A(4,1)    A(4,1)

An array section with a vector subscript that has two or more elements with the same value is called a
many-one array section. For example:

REAL A(3, 3), B(4)
INTEGER K(4)
! Vector K has repeated values
K = (/3, 1, 1, 2/)
! Sets all elements of A to 5.0
A = 5.0
B = A(3, K)

The array section A(3,K) consists of the elements:

A(3, 3)  A(3, 1)  A(3, 1)  A(3, 2)

A many-one section must not appear on the left of the equal sign in an assignment statement, or as an input
item in a READ statement.

The following assignments to C also show examples of vector subscripts:

INTEGER A(2), B(2), C(2)
...
B    = (/1,2/)
C(B) = A(B)
C    = A(/1,2/)

An array section with a vector subscript must not be any of the following:

• An internal file
• An actual argument associated with a dummy array that is defined or redefined (if the INTENT attribute is
  specified, it must be INTENT(IN))
• The target in a pointer assignment statement

If the sequence specified by the vector subscript is empty, the array section has a size of zero.

Array Constructors

Array Constructors

An array constructor can be used to create and assign values to rank-one arrays and array constants. An
array constructor takes one of the following forms:
ac-spec

Is one of the following:

type-spec ::

or

[type-spec ::] ac-value-list

type-spec

Is a type specifier.

ac-value-list

Is a list of one or more expressions or implied-DO loops.

An implied-DO loop in an array constructor takes the following form:

(ac-value-list, do-variable = expr1, expr2 [, expr3])

do-variable

Is the name of a scalar integer variable. Its scope is that of the implied-DO loop.

expr

Is a scalar integer expression. The expr1 and expr2 specify a range of values for the loop; expr3 specifies the stride. The expr3 must be a nonzero value; if it is omitted, it is assumed to be 1.

Description

If type-spec is omitted, each ac-value-list expression must have the same type and kind type parameters, and the same length parameters. In this case, the array constructed has the same type as the ac-value-list expressions.

If type-spec appears, it specifies the type and type parameters of the array constructor. Each ac-value-list expression must be compatible with intrinsic assignment to a variable of this type and type parameters. Each value is converted to the type parameters of the array constructor in accordance with the rules of intrinsic assignment.

If type-spec specifies an intrinsic type, each ac-value-list expression must be of an intrinsic type that conforms with a variable of type-type-spec.

If type-spec specifies a derived type, all ac-value-list expressions must be of that derived type and must have the same kind type parameter values as specified by type-spec.

If the sequence of values specified by the array constructor is empty (an empty array expression or the implied-DO loop produces no values), the rank-one array has a size of zero.

An ac-value is interpreted as follows:

<table>
<thead>
<tr>
<th>Form of ac-value</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>A scalar expression</td>
<td>Its value is an element of the new array.</td>
</tr>
<tr>
<td>An array expression</td>
<td>The values of the elements in the expression (in array element order) are the corresponding sequence of elements in the new array.</td>
</tr>
<tr>
<td>An implied-DO loop</td>
<td>It is expanded to form a list of array elements under control of the DO variable (like a DO construct).</td>
</tr>
</tbody>
</table>

The following shows the three forms of an ac-value:

C1 = (/4, 8, 7, 6/) ! A scalar expression
C2 = (/B(I, 1:5), B(I:J, 7:9)/!) ! An array expression
C3 = (/(I, I=1, 4)/) ! An implied-DO loop
You can also mix these forms, for example:

\[ C_4 = (\#/4, A(1:5), (I, I=1, 4), 7/) \]

If every expression in an array constructor is a constant expression, the array constructor is a constant expression.

If \textit{type-spec} is omitted, Intel® Fortran allows the character expressions to be of different character lengths. The length of the resultant character array is the maximum of the lengths of the individual character expressions. For example:

\begin{verbatim}
print *, len ( ('/a','ab','abc','d'/) )
print *,'+'+//('/a','ab','abc','d')//!'--'
\end{verbatim}

This causes the following to be displayed:

\begin{verbatim}
3
++a --++ab --++abc--++d --
\end{verbatim}

If an implied-DO loop is contained within another implied-DO loop (nested), they cannot have the same DO variable (\textit{do-variable}).

To define arrays of more than one dimension, use the \texttt{RESHAPE} intrinsic function.

The following are alternative forms for array constructors:

- Square brackets (instead of parentheses and slashes) to enclose array constructors; for example, the following two array constructors are equivalent:

\begin{verbatim}
INTEGER C(4)
C = (/4,8,7,6/)
C = [4,8,7,6]
\end{verbatim}

- A colon-separated triplet (instead of an implied-DO loop) to specify a range of values and a stride; for example, the following two array constructors are equivalent:

\begin{verbatim}
INTEGER D(3)
D = (/1:5:2/)  ! Triplet form - also [1:5:2]
D = (/(I, I=1, 5, 2)/)  ! implied-DO loop form
\end{verbatim}

The stride is optional; it defaults to 1. For example, the following two array constructors are equivalent:

\begin{verbatim}
INTEGER E(5)
E = (/1:5/)  ! Triplet form with default stride - also [1:5]
E = (/(I, I=1, 5)/)  ! implied-DO loop form
\end{verbatim}

\textbf{Examples}

The following example shows an array constructor using an implied-DO loop:

\begin{verbatim}
INTEGER ARRAY_C(10)
ARRAY_C = (/(I, I=30, 48, 2)/)
\end{verbatim}

The values of \texttt{ARRAY_C} are the even numbers 30 through 48.

Implied-DO expressions and values can be mixed in the value list of an array constructor. For example:

\begin{verbatim}
INTEGER A(10)
A = (/1, 0, (I, I = -1, -6, -1), -7, -8 /)
! Mixed values and implied-DO in value list.
\end{verbatim}

This example sets the elements of \texttt{A} to the values, in order, 1, 0, -1, -2, -3, -4, -5, -6, -7, -8.

The following example shows an array constructor of derived type that uses a structure constructor:

\begin{verbatim}
TYPE EMPLOYEE
  INTEGER ID
  CHARACTER(LEN=30) NAME
END TYPE EMPLOYEE

TYPE(EMPLOYEE) CC_4T(4)
CC_4T = (/EMPLOYEE(2732,"JONES"), EMPLOYEE(0217,"LEE"),
          EMPLOYEE(1889,"RYAN"), EMPLOYEE(4339,"EMERSON")/)
\end{verbatim}
The following example shows how the RESHAPE intrinsic function can be used to create a multidimensional array:

```
E = (/2.3, 4.7, 6.6/)
D = RESHAPE(SOURCE = (/3.5, (/2.0, 1.0/), E/), SHAPE = (/2,3/))
```

D is a rank-two array with shape (2,3) containing the following elements:

```
  3.5  1.0  4.7
  2.0  2.3  6.6
```

The following shows another example:

```fortran
INTEGER B(2,3), C(8)
! Assign values to a (2,3) array.
B = RESHAPE((/1, 2, 3, 4, 5, 6/),(/2,3/))
! Convert B to a vector before assigning values to
! vector C.
C = (/ 0, RESHAPE(B,(/6/)), 7 /)
```

Consider the following derived-type definition:

```
TYPE EMPLOYEE
  INTEGER AGE
  CHARACTER (LEN = 60) NAME
END TYPE EMPLOYEE
```

The following equivalent lines use the above type to construct a derived-type array value:

```
(// EMPLOYEE (45, 'OLIVER'), EMPLOYEE (30, 'ONEIL') //)
```

The following example shows an array constructor that specifies a length type parameter:

```
(// CHARACTER(LEN=8) :: 'Andrews', 'Donahue', 'Dehenney', 'Washington' //)
```

In this constructor, without the type specification, Intel® Fortran makes all of the array elements length 10, that is, as long as the longest character element.

**Coarrays**

Coarrays and synchronization constructs are defined by the Fortran 2008 Standard and are implemented as Intel® Fortran extensions that support parallel programming using a Single Program Multiple Data (SPMD) model. These features are not available on OS X* systems.

You must specify compiler option `[-Q]coarray` to enable coarrays in your program.

A Fortran program containing coarrays is interpreted as if it were replicated a fixed number of times and all copies were executed asynchronously.

Each replication is called an "image", and each image has its own set of data objects. The number of images is set at run-time, but it can also be set by a compiler option or an environment variable.

The array syntax of Fortran is extended with additional trailing subscripts in square brackets to provide a clear representation of references to data that is spread across images. References without square brackets are to local data, so source code that can run independently is uncluttered. Any appearance of square brackets indicates communication between images.
Usually, each image resides on one processor. However, several images may share a processor and one image can execute on a cluster.

**Examples**

Consider the following statement:

```plaintext
real, dimension(500), codimension[*] :: a,b
```

This statement declares two objects a and b, each as a coarray. A coarray always has the same shape on each image. In this case, each image has two real coarrays of size 500.

Consider that an image executes the following statement:

```plaintext
a(:) = b(:)[q]
```

In this case, the coarray b on image q is copied into coarray a on the executing image.

**See Also**

Image Control Statements  
Coarrays  
Using Coarrays

**Image Selectors**

An image selector determines the image index for a coindexed object. It takes the following form:

```
[cosubscript-list ]
```

<table>
<thead>
<tr>
<th>cosubscript-list</th>
</tr>
</thead>
</table>

 Is a scalar integer expression; its value must be within the cobounds for its codimension. The number of cosubscripts must be equal to the corank of the object. If the lower bound is not specified, it is assumed to be 1.

Considering the cobounds and bounds, respectively, the cosubscript list in an image selector determines the image index in the same way that a subscript list in an array element determines the subscript order value.

An image selector must specify an image index value that is not greater than the number of images.

**Examples**

Assume that there are 16 images and the coarray C is declared as follows:

```plaintext
REAL :: C(15)[5,*]
```

C(:,[1,4]) is valid because it selects image 16, but C(:,[2,4]) is invalid because it selects image 17.

**See Also**

Coarrays

**Deferred-Coshape Coarrays**

A deferred-coshape(allocatable) coarray has cobounds that are determined by allocation or argument association.

An allocatable coarray has the ALLOCATABLE attribute and a deferred-coshape specification.

A deferred-coshape specification is indicated by a colon (:).

The corank of an allocatable coarray is equal to the number of colons in its deferred-coshape specification.

The cobounds of an unallocated allocatable coarray are undefined. No part of such a coarray can be referenced or defined; however, the coarray may appear as an argument to an intrinsic inquiry function.

The cobounds of an allocated allocatable coarray are those specified when the coarray is allocated.

The cobounds of an allocatable coarray are unaffected by any subsequent redefinition or undefined of the variables on which the cobounds' expressions depend.
Explicit-Coshape Coarrays

An explicit-coshape coarray is a named coarray that has its corank and cobounds declared by an explicit-coshape specification.

An explicit-coshape specification takes the following form:

\[
[[\text{lower-cobound}:] \text{upper-cobound}, \] ... [\text{lower-cobound}:] *
\]

- \(lc\) is a specification expression indicating the lower cobound of the coarray. The expression can have a positive, negative, or zero value. If necessary, the value is converted to integer type.
  
  If the lower bound is not specified, it is assumed to be 1.

- \(uc\) is a specification expression indicating the upper cobound of the coarray. The expression can have a positive, negative, or zero value. If necessary, the value is converted to integer type. The upper cobound must not be less than the lower cobound (\(lc\), if specified).

A nonallocatable coarray must have a coarray specification (coarray-spec) that is an explicit-coshape specification.

The corank is equal to one plus the number of upper cobounds.

A lower cobound or upper cobound that is not a constant expression must appear only in a subprogram or interface body.

If an explicit-coshape coarray is a local variable of a subprogram and has cobounds that are not constant expressions, the cobounds are determined on entry to a procedure defined by the subprogram, by evaluating the cobounds expressions. The cobounds of such a coarray are unaffected by the redefinition or undefinition of any variable during execution of the procedure.

The values of each lower cobound and upper cobound determine the cobounds of the coarray along a particular codimension. The cosubscript range of the coarray in that codimension is the set of integer values between and including the lower and upper cobounds.

Examples

The following are examples of variables with coarray specifications (coarray-specs):

- \(A\) \([*]\)
- \(AA\) \([2:*]\)
- \(B\) \([2, \, 3, \, *]\)
- \(C\) \([3:5, \, -2:7, \, *]\)

See Also

Coarrays

Referencing Coarray Images

Data on other images is normally referenced by cosubscripts enclosed in square brackets.

For coarray images, each set of cosubscripts maps to an image index, which is an integer between one and the number of images, in the same way as a set of array subscripts maps to a position in array element order.

To find the image index for each image, specify intrinsic function \(\text{THIS\_IMAGE}()\) with no arguments.

To find the set of subscript indices that corresponds to the current image for a coarray \(z\), specify \(\text{THIS\_IMAGE}(z)\).

To find the image index that corresponds to a set of cosubscript indices \(\text{sub}\) for a coarray \(z\), specify intrinsic function \(\text{IMAGE\_INDEX}(z, \text{sub})\).

To find the number of images, specify intrinsic function \(\text{NUM\_IMAGES}\).
Specifying Data Objects for Coarray Images

Each image has its own set of data objects, all of which can be accessed in the normal way.

The rank, bounds, extents, size, and shape of a whole coarray are provided by the data in parentheses in its declaration or allocation. Its corank, cobounds, and coextents are provided by the data in square brackets in its declaration or allocation. Any subobject of the coarray that is a coarray has the same corank, cobounds, and coextents. The cosize of a coarray is always equal to the number of images.

Objects can be declared with codimensions in square brackets immediately following dimensions in parentheses or in place of them, for example:

```fortran
real :: a[*], d[*]                   ! Scalar coarrays
real, dimension(50), codimension[50,*] :: x ! An array coarray
integer :: n(100)[*]
character :: b(40)[40,0:*]
type(para) :: w[30,*]
```

Unless the coarray is allocatable, the form for the dimensions in square brackets is the same as that for dimensions in parentheses in an assumed-size array.

The total number of subscripts plus cosubscripts is limited to 31. Note that the Fortran 2008 Standard limits the total number of subscripts plus cosubscripts to 15.

You can address a coarray on another image by using subscripts in square brackets following any subscripts in parentheses, for example:

```fortran
b(6)[4,7] = n(6)[4]
e[4] = c
b(:,[3,4]) = c[2]
```

Any object whose designator includes square brackets is called a coindexed object. Each subscript in square brackets must be a scalar integer expression.

Subscripts in parentheses must be used whenever the parent array has nonzero rank. For example, for a(:, [2,3], you cannot specify a[2,3].

NUM_IMAGES
Expressions and Assignment Statements

Expressions

An expression represents either a data reference or a computation, and is formed from operators, operands, and parentheses. The result of an expression is either a scalar value or an array of scalar values.

If the value of an expression is of intrinsic type, it has a kind type parameter. (If the value is of intrinsic type CHARACTER, it also has a length parameter.) If the value of an expression is of derived type, it has no kind type parameter.

An operand is a scalar or array. An operator can be either intrinsic or defined. An intrinsic operator is known to the compiler and is always available to any program unit. A defined operator is described explicitly by a user in a function subprogram and is available to each program unit that uses the subprogram.

The simplest form of an expression (a primary) can be any of the following:

- A constant; for example, 4.2
- A subobject of a constant; for example, 'LMNOP' (2:4)
- A variable; for example, VAR_1
- A structure constructor; for example, EMPLOYEE(3472, "JOHN DOE")
- An array constructor; for example, (/12.0,16.0/)
- A function reference; for example, COS(X)
- Another expression in parentheses; for example, (I+5)

Any variable or function reference used as an operand in an expression must be defined at the time the reference is executed. If the operand is a pointer, it must be associated with a target object that is defined. An integer operand must be defined with an integer value rather than a statement label value. All of the characters in a character data object reference must be defined.

When a reference to an array or an array section is made, all of the selected elements must be defined. When a structure is referenced, all of the components must be defined.

In an expression that has intrinsic operators with an array as an operand, the operation is performed on each element of the array. In expressions with more than one array operand, the arrays must be conformable (they must have the same shape). The operation is applied to corresponding elements of the arrays, and the result is an array of the same shape (the same rank and extents) as the operands.

In an expression that has intrinsic operators with a pointer as an operand, the operation is performed on the value of the target associated with the pointer.

For defined operators, operations on arrays and pointers are determined by the procedure defining the operation.

A scalar is conformable with any array. If one operand of an expression is an array and another operand is a scalar, it is as if the value of the scalar were replicated to form an array of the same shape as the array operand. The result is an array of the same shape as the array operand.

The following sections describe numeric, character, relational, and logical expressions; defined operations; a summary of operator precedence; and initialization and specification expressions.

Numeric Expressions

Numeric expressions express numeric computations, and are formed with numeric operands and numeric operators. The evaluation of a numeric operation yields a single numeric value.

The term numeric includes logical data, because logical data is treated as integer data when used in a numeric context. The default for .TRUE. is -1; .FALSE. is 0. Note that the default can change if compiler option fpscomp logicals is used.

Numeric operators specify computations to be performed on the values of numeric operands. The result is a scalar numeric value or an array whose elements are scalar numeric values. The following are numeric operators:

<table>
<thead>
<tr>
<th>Operator</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>**</td>
<td>Exponentiation</td>
</tr>
<tr>
<td>*</td>
<td>Multiplication</td>
</tr>
<tr>
<td>/</td>
<td>Division</td>
</tr>
<tr>
<td>+</td>
<td>Addition or unary plus (identity)</td>
</tr>
<tr>
<td>-</td>
<td>Subtraction or unary minus (negation)</td>
</tr>
</tbody>
</table>

Unary operators operate on a single operand. Binary operators operate on a pair of operands. The plus and minus operators can be unary or binary. When they are unary operators, the plus or minus operators precede a single operand and denote a positive (identity) or negative (negation) value, respectively. The exponentiation, multiplication, and division operators are binary operators.

Valid numeric operations must have results that are defined by the arithmetic used by the processor. For example, raising a negative-valued base to a real power is invalid.

Numeric expressions are evaluated in an order determined by a precedence associated with each operator, as follows (see also Summary of Operator Precedence):

<table>
<thead>
<tr>
<th>Operator</th>
<th>Precedence</th>
</tr>
</thead>
<tbody>
<tr>
<td>**</td>
<td>Highest</td>
</tr>
<tr>
<td>* and /</td>
<td></td>
</tr>
<tr>
<td>Unary + and -</td>
<td></td>
</tr>
<tr>
<td>Binary + and -</td>
<td>Lowest</td>
</tr>
</tbody>
</table>

Operators with equal precedence are evaluated in left-to-right order. However, exponentiation is evaluated from right to left. For example, A**B**C is evaluated as A**(B**C). B**C is evaluated first, then A is raised to the resulting power.

Normally, two operators cannot appear together. However, Intel® Fortran allows two consecutive operators if the second operator is a plus or minus.

Examples

In the following example, the exponentiation operator is evaluated first because it takes precedence over the multiplication operator:

A**B*C is evaluated as (A**B) *C

Ordinarily, the exponentiation operator would be evaluated first in the following example. However, because Intel Fortran allows the combination of the exponentiation and minus operators, the exponentiation operator is not evaluated until the minus operator is evaluated:

A**-B*C is evaluated as A**(- (B*C))

Note that the multiplication operator is evaluated first, since it takes precedence over the minus operator.
When consecutive operators are used with constants, the unary plus or minus before the constant is treated the same as any other operator. This can produce unexpected results. In the following example, the multiplication operator is evaluated first, since it takes precedence over the minus operator:

\[ X/-15.0*Y \] is evaluated as \[ X/-(15.0*Y) \]

fpscomp

**Using Parentheses in Numeric Expressions**

You can use parentheses to force a particular order of evaluation. When part of an expression is enclosed in parentheses, that part is evaluated first. The resulting value is used in the evaluation of the remainder of the expression.

In the following examples, the numbers below the operators indicate a possible order of evaluation. Alternative evaluation orders are possible in the first three examples because they contain operators of equal precedence that are not enclosed in parentheses. In these cases, the compiler is free to evaluate operators of equal precedence in any order, as long as the result is the same as the result gained by the algebraic left-to-right order of evaluation.

```
4 + 3 * 2 - 6/2   = 7
  ^  ^  ^  ^
  2  1  4  3
(4 + 3) * 2 - 6/2   = 11
  ^  ^  ^  ^
  1  2  4  3
(4 + 3 * 2 - 6)/2   = 2
  ^  ^  ^  ^
  2  1  3  4
((4 + 3) * 2 - 6)/2   = 4
  ^  ^  ^  ^
  1  2  3  4
```

Expressions within parentheses are evaluated according to the normal order of precedence. In expressions containing nested parentheses, the innermost parentheses are evaluated first.

Nonessential parentheses do not affect expression evaluation, as shown in the following example:

```
4 + (3 * 2) - (6/2)
  ^  ^  ^
  4  3  2
```

However, using parentheses to specify the evaluation order is often important in high-accuracy numerical computations. In such computations, evaluation orders that are algebraically equivalent may not be computationally equivalent when processed by a computer (because of the way intermediate results are rounded off).

Parentheses can be used in argument lists to force a given argument to be treated as an expression, rather than as the address of a memory item.

**Data Type of Numeric Expressions**

If every operand in a numeric expression is of the same data type, the result is also of that type.

If operands of different data types are combined in an expression, the evaluation of that expression and the data type of the resulting value depend on the ranking associated with each data type. The following table shows the ranking assigned to each data type:

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Ranking</th>
</tr>
</thead>
<tbody>
<tr>
<td>LOGICAL(1) and BYTE</td>
<td>Lowest</td>
</tr>
<tr>
<td>LOGICAL(2)</td>
<td></td>
</tr>
<tr>
<td>LOGICAL(4)</td>
<td></td>
</tr>
<tr>
<td>LOGICAL(8)</td>
<td></td>
</tr>
</tbody>
</table>
The data type of the value produced by an operation on two numeric operands of different data types is the data type of the highest-ranking operand in the operation. For example, the value resulting from an operation on an integer and a real operand is of real type. However, an operation involving a COMPLEX(4) or COMPLEX(8) data type and a DOUBLE PRECISION data type produces a COMPLEX(8) result.

The data type of an expression is the data type of the result of the last operation in that expression, and is determined according to the following conventions:

- **Integer operations**: Integer operations are performed only on integer operands. (Logical entities used in a numeric context are treated as integers.) In integer arithmetic, any fraction resulting from division is truncated, not rounded. For example, the result of 9/10 is 0, not 1.

- **Real operations**: Real operations are performed only on real operands or combinations of real, integer, and logical operands. Any integer operands present are converted to real data type by giving each a fractional part equal to zero. The expression is then evaluated using real arithmetic. However, in the statement \( Y = (I \div J) \times X \), an integer division operation is performed on \( I \) and \( J \), and a real multiplication is performed on that result and \( X \).

If one operand is a higher-precision real (REAL(8) or REAL(16)) type, the other operand is converted to that higher-precision real type before the expression is evaluated.

When a single-precision real operand is converted to a double-precision real operand, low-order binary digits are set to zero. This conversion does not increase accuracy; conversion of a decimal number does not produce a succession of decimal zeros. For example, a REAL variable having the value 0.3333333 is converted to approximately 0.3333333134651184D0. It is not converted to either 0.3333333000000000D0 or 0.3333333333333333D0.

- **Complex operations**: In operations that contain any complex operands, integer operands are converted to real type, as previously described. The resulting single-precision or double-precision operand is designated as the real part of a complex number and the imaginary part is assigned a value of zero. The expression is then evaluated using complex arithmetic and the resulting value is of complex type. Operations involving a COMPLEX(4) or COMPLEX(8) operand and a DOUBLE PRECISION operand are performed as COMPLEX(8) operations; the DOUBLE PRECISION operand is not rounded.

These rules also generally apply to numeric operations in which one of the operands is a constant. However, if a real or complex constant is used in a higher-precision expression, additional precision will be retained for the constant. The effect is as if a DOUBLE PRECISION (REAL(8)) or REAL(16) representation of the constant were given. For example, the expression 1.0D0 + 0.3333333 is treated as if it is 1.0D0 + dble(0.3333333).
**Character Expressions**

A character expression consists of a character operator (//) that concatenates two operands of type character. The evaluation of a character expression produces a single value of that type.

The result of a character expression is a character string whose value is the value of the left character operand concatenated to the value of the right operand. The length of a character expression is the sum of the lengths of the values of the operands. For example, the value of the character expression 'AB'//'CDE' is 'ABCDE', which has a length of five.

Parentheses do not affect the evaluation of a character expression; for example, the following character expressions are equivalent:

- ('ABC'//'DE')//'F'
- 'ABC'//('DE'//'F')
- 'ABC'//'DE'//'F'

Each of these expressions has the value 'ABCDEF'.

If a character operand in a character expression contains blanks, the blanks are included in the value of the character expression. For example, 'ABC '//'DE'//'F ' has a value of 'ABC D EF '.

**Relational Expressions**

A relational expression consists of two or more expressions whose values are compared to determine whether the relationship stated by the relational operator is satisfied. The following are relational operators:

<table>
<thead>
<tr>
<th>Operator</th>
<th>Relationship</th>
</tr>
</thead>
<tbody>
<tr>
<td>.LT. or &lt;</td>
<td>Less than</td>
</tr>
<tr>
<td>.LE. or &lt;=</td>
<td>Less than or equal to</td>
</tr>
<tr>
<td>.EQ. or ==</td>
<td>Equal to</td>
</tr>
<tr>
<td>.NE. or /=</td>
<td>Not equal to</td>
</tr>
<tr>
<td>.GT. or &gt;</td>
<td>Greater than</td>
</tr>
<tr>
<td>.GE. or &gt;=</td>
<td>Greater than or equal to</td>
</tr>
</tbody>
</table>

The result of the relational expression is .TRUE. if the relation specified by the operator is satisfied; the result is .FALSE. if the relation specified by the operator is not satisfied.

Relational operators are of equal precedence. Numeric operators and the character operator // have a higher precedence than relational operators.

In a numeric relational expression, the operands are numeric expressions. Consider the following example:

APPLE+PEACH > PEAR+ORANGE

This expression states that the sum of APPLE and PEACH is greater than the sum of PEAR and ORANGE. If this relationship is valid, the value of the expression is .TRUE.; if not, the value is .FALSE.

Operands of type complex can only be compared using the equal operator (== or .EQ.) or the not equal operator (/= or .NE.). Complex entities are equal if their corresponding real and imaginary parts are both equal.

In a character relational expression, the operands are character expressions. In character relational expressions, less than (< or .LT.) means the character value precedes in the ASCII collating sequence, and greater than (> or .GT.) means the character value follows in the ASCII collating sequence. For example:

- 'AB'//'ZZZ' .LT. 'CCCCC'

This expression states that 'ABZZZ' is less than 'CCCCC'. In this case, the relation specified by the operator is satisfied, so the result is .TRUE..
Character operands are compared one character at a time, in order, starting with the first character of each operand. If the two character operands are not the same length, the shorter one is padded on the right with blanks until the lengths are equal; for example:

```
'ABC' .EQ. 'ABC  
'AB' .LT. 'C'
```

The first relational expression has the value .TRUE. even though the lengths of the expressions are not equal, and the second has the value .TRUE. even though 'AB' is longer than 'C'.

A relational expression can compare two numeric expressions of different data types. In this case, the value of the expression with the lower-ranking data type is converted to the higher-ranking data type before the comparison is made.

Data Type of Numeric Expressions

Logical Expressions
A logical expression consists of one or more logical operators and logical, numeric, or relational operands. The following are logical operators:

<table>
<thead>
<tr>
<th>Operator</th>
<th>Example</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>.AND.</td>
<td>A .AND. B</td>
<td>Logical conjunction: the expression is true if both A and B are true.</td>
</tr>
<tr>
<td>.OR.</td>
<td>A .OR. B</td>
<td>Logical disjunction (inclusive OR): the expression is true if either A, B, or both, are true.</td>
</tr>
<tr>
<td>.NEQV.</td>
<td>A .NEQV. B</td>
<td>Logical inequivalence (exclusive OR): the expression is true if either A or B is true, but false if both are true.</td>
</tr>
<tr>
<td>.XOR.</td>
<td>A .XOR. B</td>
<td>Same as .NEQV.</td>
</tr>
<tr>
<td>.EQV.</td>
<td>A .EQV. B</td>
<td>Logical equivalence: the expression is true if both A and B are true, or both are false.</td>
</tr>
<tr>
<td>.NOT.</td>
<td>.NOT. A</td>
<td>Logical negation: the expression is true if A is false and false if A is true.</td>
</tr>
</tbody>
</table>

1 .NOT. is a unary operator.

Periods cannot appear consecutively except when the second operator is .NOT. For example, the following logical expression is valid:

```
A+B/(A-1) .AND. .NOT. D+B/(D-1)
```

Data Types Resulting from Logical Operations
Logical operations on logical operands produce single logical values (.TRUE. or .FALSE.) of logical type.

Logical operations on integers produce single values of integer type. The operation is carried out bit-by-bit on corresponding bits of the internal (binary) representation of the integer operands.

Logical operations on a combination of integer and logical values also produce single values of integer type. The operation first converts logical values to integers, then operates as it does with integers.

Logical operations cannot be performed on other data types.
Evaluation of Logical Expressions

Logical expressions are evaluated according to the precedence of their operators. Consider the following expression:

\[ A*B + C*ABC = X*Y + DM/ZZ \quad \text{AND} \quad \text{.NOT.} \quad K*B > TT \]

This expression is evaluated in the following sequence:

\[ ((A*B) + (C*ABC)) = ((X*Y) + (DM/ZZ)) \quad \text{AND} \quad \text{.NOT.} \quad ((K*B) > TT) \]

As with numeric expressions, you can use parentheses to alter the sequence of evaluation.

When operators have equal precedence, the compiler can evaluate them in any order, as long as the result is the same as the result gained by the algebraic left-to-right order of evaluation (except for exponentiation, which is evaluated from right to left).

You should not write logical expressions whose results might depend on the evaluation order of subexpressions. The compiler is free to evaluate subexpressions in any order. In the following example, either \((A(I)+1.0)\) or \(B(I)*2.0\) could be evaluated first:

\[ (A(I)+1.0) \quad \text{GT} \quad B(I)*2.0 \]

Some subexpressions might not be evaluated if the compiler can determine the result by testing other subexpressions in the logical expression. Consider the following expression:

\[ A \quad \text{AND} \quad (F(X,Y) \quad \text{GT} \quad 2.0) \quad \text{AND} \quad B \]

If the compiler evaluates \(A\) first, and \(A\) is false, the compiler might determine that the expression is false and might not call the subprogram \(F(X,Y)\).

Summary of Operator Precedence

Defined Operations

When operators are defined for functions, the functions can then be referenced as defined operations.

The operators are defined by using a generic interface block specifying OPERATOR, followed by the defined operator (in parentheses).

A defined operation is not an intrinsic operation. However, you can use a defined operation to extend the meaning of an intrinsic operator.

For defined unary operations, the function must contain one argument. For defined binary operations, the function must contain two arguments.

Interpretation of the operation is provided by the function that defines the operation.

A Standard Fortran defined operator can contain up to 31 letters, and is enclosed in periods (.). Its name cannot be the same name as any of the following:

- The intrinsic operators (.\text{NOT.}, .\text{AND.}, .\text{OR.}, .\text{XOR.}, .\text{EQV.}, .\text{NEQV.}, .\text{EQ.}, .\text{NE.}, .\text{GT.}, .\text{GE.}, .\text{LT.}, and .\text{LE.})
- The logical literal constants (.\text{TRUE.} or .\text{FALSE.})

An intrinsic operator can be followed by a defined unary operator.

The result of a defined operation can have any type. The type of the result (and its value) must be specified by the defining function.

Examples

The following examples show expressions containing defined operators:

\[ \text{.COMPLEMENT.} \quad A \]
\[ X \quad \text{PLUS.} \quad Y \quad \text{PLUS.} \quad Z \]
\[ M \quad \text{MINUS.} \quad N \]

Initialization and Specification Expressions

An initialization expression is an expression that is evaluated when a program is compiled. It can be used as a kind type parameter, a named constant, or to specify an initial value for an entity.

A specification expression is a scalar, integer expression that is restricted specifications such as length type parameters and array bounds.

Initialization and specification expressions can appear in specification statements, with some restrictions.

Initialization Expressions

An initialization expression is an expression that you can use as a kind type parameter, a named constant, or to specify an initial value for an entity. It is evaluated when a program is compiled.

In an initialization expression, each operation is intrinsic and each primary is one of the following:

- A constant or subobject of a constant
- An array constructor where each element and each scalar integer expression of each implied-DO is an initialization expression
- A structure constructor where each component specification corresponding to an allocatable component is a reference to the transformational intrinsic function NULL, and each other component specification is an initialization expression
- A reference to an elemental standard intrinsic function, where each argument is an initialization expression
- A reference to a transformational standard intrinsic function other than NULL, where each argument is an initialization expression
- A reference to the transformational intrinsic function NULL that does not have an argument with a type parameter that is one of the following:
  - Assumed
  - Defined by an expression that is not an initialization expression
- A specification inquiry where each designator or function argument is one of the following:
  - An initialization expression
  - A variable whose properties inquired about are not assumed, deferred, or defined by an expression that is not an initialization expression
- A kind type parameter of the derived type being defined
- A DO variable within an array constructor where each scalar integer expression of the corresponding DO loop is an initialization expression
- Another initialization expression enclosed in parentheses, where each subscript, section subscript, substring starting and ending point, and type parameter value is an initialization expression

If an initialization expression invokes an inquiry function for a type parameter or an array bound of an object, the type parameter or array bound must be specified in a prior specification statement (or to the left of the inquiry function in the same statement). The previous specification cannot be in the same entity declaration.

**Examples**

**Valid Initialization Expressions**

- `-1 + 3`
- `SIZE(B)` ! B is a named constant
- `?_2`
- `INT(J, 4)` ! J is a named constant
- `SELECTED_INT_KIND (2)`

**Invalid Initialization Expressions**

- `SUM(A)` Not an allowed function.
- `A/4.1 - K**1.2` Exponential does not have integer power (A and K are named constants).
- `HUGE(4.0)` Argument is not an integer.

Specification Expressions
Structure Constructors
Intrinsic Procedures Overview

**Specification Expressions**

A specification expression is a restricted scalar integer expression that you can use in specifications such as length type parameters and array bounds.

In a restricted expression, each operation is intrinsic and each primary is one of the following:

- A constant or subobject of a constant
- An object designator with a base object that is one of the following:
  - A dummy argument that does not have the OPTIONAL or INTENT (OUT) attribute
  - In a common block
  - Made accessible by use or host association
• A local variable of the procedure containing the BLOCK construct in which the restricted expression appears
• A local variable of an outer BLOCK construct containing the BLOCK construct in which the restricted expression appears
• An array constructor where each element and each scalar integer expression of each Do loop is a restricted expression
• A structure constructor whose components are restricted expression
• A specification inquiry where each designator or function argument is a restricted expression or a variable whose properties inquired about are not one of the following:
  • Dependent on the upper bound of the last dimension of an assumed-size array
  • Deferred
  • Defined by an expression that is not a restricted expression
• A specification inquiry that is a constant expression
• A reference to the intrinsic function PRESENT
• A reference to any other intrinsic function where each argument is a restricted expression
• A reference to a specification function where each argument is a restricted expression
• A type parameter of the derived type being defined
• A DO variable within an array constructor, where each scalar integer expression of the corresponding implied-DO is a restricted expression
• A restricted expression enclosed in parentheses, where each subscript, section subscript, substring starting and ending point, and type parameter value is a restricted expression, and where any final subroutine that is invoked is pure

A specification inquiry is a reference to one of the following:

• Array inquiry function ALLOCATED, COSHAPE, IMAGE_INDEX, IS_CONTIGUOUS, LBOUND, LCOREBOUND, PRESENT, RANK, SHAPE, SIZE, or UBOUND
• Numeric inquiry function DIGITS, EPSILON, HUGE, ILEN, MAXEXPONENT, MINEXPONENT, PRECISION, RADIX, RANGE, SIZE, SIZEOF, STORAGE_SIZE, or TINY
• Character inquiry function LEN or NEW_LINE
• Bit inquiry function BIT SIZE
• Kind inquiry function KIND
• A type parameter inquiry
• IEEE inquiry function IEEE_SUPPORT_DATATYPE, IEEE_SUPPORT_DENORMAL, IEEE_SUPPORT_DIVIDE, IEEE_SUPPORT_INF, IEEE_SUPPORT_IO, IEEE_SUPPORT_NAN, IEEE_SUPPORT_ROUNDING, IEEE_SUPPORT_SQRT, IEEE_SUPPORT_STANDARD, or IEEE_SUPPORT_UNDERFLOW_CONTROL from the intrinsic module IEEE_ARITHMETIC
• IEEE inquiry function IEEE_SUPPORT_FLAG or IEE_SUPPORT_HALTING from the intrinsic module IEEE_EXCEPTIONS
• The function IEEE_SUPPORT from the intrinsic module ISO_C_BINDING

*Specification functions* can be used in specification expressions to determine the attributes of data objects.

A function is a specification function if it is a pure function, does not have a dummy procedure argument, and is not one of the following:

• An standard intrinsic function
• An internal function
• A statement function
• Defined as RECURSIVE

**NOTE**
The requirement that specification functions be pure ensures that they cannot have side effects that could affect other objects being declared in the same specification.
The restriction that specification functions cannot be internal ensures that they cannot use host association to inquire about other objects being declared in the same specification. The restriction against recursion prevents the creation of a new instance of a procedure during construction of that procedure.

Evaluation of a specification expression must not directly or indirectly cause invocation of a procedure defined by the subprogram in which it appears.

A variable in a specification expression must have its type and type parameters (if any) specified in one of the following ways:

- By a previous declaration in the same scoping unit
- By the implicit typing rules currently in effect for the scoping unit
- By host or use association

If a variable in a specification expression is typed by the implicit typing rules, its appearance in any subsequent type declaration statement must confirm the implied type and type parameters.

If a specification expression includes a specification inquiry that depends on a type parameter or an array bound of an entity specified in the same specification statement, the type parameter or array bound must be specified in a previous specification statement (or to the left of the inquiry function in the same statement). The previous specification cannot be in the same entity declaration. If a specification expression includes a reference to the value of an element of an array specified in the same specification statement, the array must be completely specified in previous declarations.

In a specification expression, the number of arguments for a function reference is limited to 255.

**Examples**

The following shows valid specification expressions:

<table>
<thead>
<tr>
<th>Expression</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MAX(I) + J</td>
<td>I and J are scalar integer variables</td>
</tr>
<tr>
<td>UBOUND(ARRAY_B,20)</td>
<td>ARRAY_B is an assumed-shape dummy array</td>
</tr>
</tbody>
</table>

**Assignments**

An assignment causes variables to be defined or redefined.

Assignment is specified by the following:

- An **intrinsic assignment statement**
  This lets you assign a value to a nonpointer variable.
- A **defined assignment statement**
  This lets you specify an assignment operation.
- **pointer assignment**
  This lets you associate a pointer with a target.
- **masked array assignment**
  This kind of assignment is denoted by a WHERE construct or statement. It lets you perform an array operation on selected elements in an array.
- **element array assignment**
This kind of assignment is denoted by a `FORALL` construct or statement. It is a generalization of masked array assignment. It allows more general array shapes to be assigned, especially if it is used in construct form.

Note that the `ASSIGN` statement assigns a label to an integer variable. It is discussed elsewhere.

**Intrinsic Assignment Statements**

Intrinsic assignment is used to assign a value to a nonpointer variable. In the case of pointers, intrinsic assignment is used to assign a value to the target associated with the pointer variable. The value assigned to the variable (or target) is determined by evaluation of the expression to the right of the equal sign.

An intrinsic assignment statement takes the following form:

```
variable = expression
```

- `variable` is the name of a scalar or array of intrinsic or derived type (with no defined assignment). The array cannot be an assumed-size array, and neither the scalar nor the array can be declared with the `PARAMETER` or `INTENT(IN)` attribute.
- `expression` is of intrinsic type or the same derived type as `variable`. Its shape must conform with `variable`. If necessary, it is converted to the same type and kind as `variable`.

**Description**

Before a value is assigned to the variable, the expression part of the assignment statement and any expressions within the variable are evaluated. No definition of expressions in the variable can affect or be affected by the evaluation of the expression part of the assignment statement.

**NOTE**

When the run-time system assigns a value to a scalar integer or character variable and the variable is shorter than the value being assigned, the assigned value may be truncated and significant bits (or characters) lost. This truncation can occur without warning, and can cause the run-time system to pass incorrect information back to the program.

The following rules apply to intrinsic assignment statements:

- The variable and expression must be conformable unless the variable is an allocatable array that has the same rank as the expression, and is neither a coarray nor a coindexed object.
- If the expression is an array, then the variable must also be an array.
- If the variable is polymorphic, it must be allocatable. It must not be a coarray. The polymorphic variable must be type compatible with the expression. Otherwise, the declared types of the variable and expression must conform.
- If the variable is a pointer, it must be associated with a definable target. The shape of the target and expression must conform and their type and kind parameters must match.
- If the variable is of type character, the expression must have the same kind type parameter.
- If the variable is of derived type:
  - Each kind type parameter of the variable must have the same value as the corresponding kind type parameter of the expression.
  - Each length type parameter of the variable must have the same value as the corresponding type parameter of the expression unless the variable is an allocatable array and its corresponding type parameter is deferred.
  - If the variable is a coindexed object, each deferred-length type parameter must have the same value as the corresponding type parameter of the expression. Also, the variable must not be polymorphic, and it must not have an allocatable ultimate component.
The following sections discuss numeric, logical, character, derived-type, and array intrinsic assignment.

Defining Generic Assignment for details on subroutine subprograms that define assignment

Numeric Assignment Statements
For numeric assignment statements, the variable and expression must be numeric type.
The expression must yield a value that conforms to the range requirements of the variable. For example, a real expression that produces a value greater than 32767 is invalid if the entity on the left of the equal sign is an INTEGER(2) variable.

Significance can be lost if an INTEGER(4) value, which can exactly represent values of approximately the range -2*10**9 to +2*10**9, is converted to REAL(4) (including the real part of a complex constant), which is accurate to only about seven digits.

If the variable has the same data type as that of the expression on the right, the statement assigns the value directly. If the data types are different, the value of the expression is converted to the data type of the variable before it is assigned.

The following table summarizes the data conversion rules for numeric assignment statements.

<table>
<thead>
<tr>
<th>Scalar Memory Reference (V)</th>
<th>Expression (E)</th>
<th>Integer, Logical or Real</th>
<th>Complex</th>
</tr>
</thead>
<tbody>
<tr>
<td>Integer or Logical</td>
<td>V = INT(E)</td>
<td>V = INT(REAL(E))</td>
<td>Imaginary part of E is not used.</td>
</tr>
<tr>
<td>REAL (KIND=4)</td>
<td>V = REAL(E)</td>
<td>V = REAL(REAL(E))</td>
<td>Imaginary part of E is not used.</td>
</tr>
<tr>
<td>REAL (KIND=8)</td>
<td>V = DBLE(E)</td>
<td>V = DBLE(REAL(E))</td>
<td>Imaginary part of E is not used.</td>
</tr>
<tr>
<td>REAL (KIND=16)</td>
<td>V = QEXT(E)</td>
<td>V = QEXT(REAL(E))</td>
<td>Imaginary part of E is not used.</td>
</tr>
<tr>
<td>COMPLEX (KIND=4)</td>
<td>V = CMPLX(REAL(E), 0.0)</td>
<td>V = CMPLX(REAL(REAL(E)), REAL(AIMAG(E)))</td>
<td></td>
</tr>
<tr>
<td>COMPLEX (KIND=8)</td>
<td>V = CMPLX(DBLE(E), 0.0)</td>
<td>V = CMPLX(DBLE(REAL(E)), DBLE(AIMAG(E)))</td>
<td></td>
</tr>
<tr>
<td>COMPLEX (KIND=16)</td>
<td>V = CMPLX(QEXT(E), 0.0)</td>
<td>V = CMPLX(QEXT(REAL(E)), QEXT(AIMAG(E)))</td>
<td></td>
</tr>
</tbody>
</table>

Examples
Valid Numeric Assignment Statements

BETA = -1./(2.*X) + A*A/(4.*(X*X))
PI = 3.14159
SUM = SUM + 1.
ARRAY_A = ARRAY_B + ARRAY_C + SCALAR_I  ! Valid if all arrays conform in shape

Invalid Numeric Assignment Statements

3.14 = A - B  Entity on the left must be a variable.
ICOUNT = A/B(3:7)  Implicitly typed data types do not match.
SCALAR_I = ARRAY_A(:)  Shapes do not match.

See Also
INT
REAL Function
DBLE
QEXT
CMPLX
AIMAG

Logical Assignment Statements

For logical assignment statements, the variable must be of logical type and the expression can be of logical or numeric type.

If necessary, the expression is converted to the same type and kind as the variable.

Examples

The following examples demonstrate valid logical assignment statements:

PAGEND = .FALSE.
PRNTOK = LINE .LE. 132 .AND. .NOT. PAGEND
ABIG = A.GT.B .AND. A.GT.C .AND. A.GT.D
LOGICAL_VAR = 123  ! Moves binary value of 123 to LOGICAL_VAR

Character Assignment Statements

For character assignment statements, the variable and expression must be of character type and have the same kind parameter.

The variable and expression can have different lengths. If the length of the expression is greater than the length of the variable, the character expression is truncated on the right. If the length of the expression is less than the length of the variable, the character expression is filled on the right with blank characters.

If you assign a value to a character substring, you do not affect character positions in any part of the character scalar variable not included in the substring. If a character position outside of the substring has a value previously assigned, it remains unchanged. If the character position is undefined, it remains undefined.

Examples

Valid Character Assignment Statements. (All variables are of type character.)

FILE = 'PROG2'
REVOL(1) = 'MAR'//'CIA'
LOCA(3:8) = 'PLANT5'
TEXT(I,J+1)(2:N-1) = NAME//X

Invalid Character Assignment Statements

'ABC' = CHARS  Left element must be a character variable, array element, or substring reference.
Derived-Type Assignment Statements

In derived-type assignment statements, the variable and expression must be of the same derived type. There must be no accessible interface block with defined assignment for objects of this derived type.

The derived-type assignment is performed as if each component of the expression is assigned to the corresponding component of the variable. Pointer assignment is performed for pointer components, and intrinsic assignment is performed for nonpointer components.

Examples

The following example shows derived-type assignment:

```fortran
TYPE DATE
   LOGICAL(1) DAY, MONTH
   INTEGER(2) YEAR
END TYPE DATE

TYPE(DATE) TODAY, THIS_WEEK(7)
TYPE APPOINTMENT
...
   TYPE(DATE) APP_DATE
END TYPE

TYPE(APPOINTMENT) MEETING

DO I = 1,7
   CALL GET_DATE(TODAY)
   THIS_WEEK(I) = TODAY
END DO
MEETING%APP_DATE = TODAY
```

Pointer Assignments

Array Assignment Statements

Array assignment is permitted when the array expression on the right has the same shape as the array variable on the left, or the expression on the right is a scalar.

If the expression is a scalar, and the variable is an array, the scalar value is assigned to every element of the array.

If the expression is an array, the variable must also be an array. The array element values of the expression are assigned (element by element) to corresponding elements of the array variable.

A many-one array section is a vector-valued subscript that has two or more elements with the same value. In intrinsic assignment, the variable cannot be a many-one array section because the result of the assignment is undefined.

Examples

In the following example, X and Y are arrays of the same shape:

```fortran
X = Y
```
The corresponding elements of \( Y \) are assigned to those of \( X \) element by element; the first element of \( Y \) is assigned to the first element of \( X \), and so forth. The processor can perform the element-by-element assignment in any order.

The following example shows a scalar assigned to an array:

\[
B(C+1:N, C) = 0
\]

This sets the elements \( B(C+1,C), B(C+2,C), ..., B(N,C) \) to zero.

The following example causes the values of the elements of array \( A \) to be reversed:

\[
\text{REAL } A(20)
\]

\[
... \\
A(1:20) = A(20:1:-1)
\]

**Defined Assignment Statements**

Defined assignment specifies an assignment operation. It is defined by a subroutine subprogram containing a generic interface block that specifies ASSIGNMENT(=). The subroutine is specified in a SUBROUTINE or ENTRY statement that has two nonoptional dummy arguments.

Defined elemental assignment is indicated by specifying ELEMENTAL in the SUBROUTINE statement.

The dummy arguments represent the variable and expression, in that order. The rank (and shape, if either or both are arrays), type, and kind parameters of the variable and expression in the assignment statement must match those of the corresponding dummy arguments.

The dummy arguments must not both be numeric, or of type logical or character with the same kind parameter.

If the variable in an elemental assignment is an array, the defined assignment is performed element-by-element, in any order, on corresponding elements of the variable and expression. If the expression is scalar, it is treated as if it were an array of the same shape as the variable with every element of the array equal to the scalar value of the expression.

**Pointer Assignments**

In ordinary assignment involving pointers, the pointer is an alias for its target. In pointer assignment, the pointer is associated with a target. If the target is undefined or disassociated, the pointer acquires the same status as the target. Pointer assignment has the following form:

\[
\text{pointer-object}
\]

\[
[s\text{-spec}] \rightarrow \text{target}
\]

**pointer-object**

Is a variable name or structure component declared with the POINTER attribute.

**s-spec**

Is a shape specification consisting of bounds information in the form "[lower-bound]:" or "[lower-bound] : upper-bound".
**Description**

If the target is a variable, it must have the POINTER or TARGET attribute, or be a subobject whose parent object has the TARGET attribute.

If the target is an expression, the result must be a pointer.

If the target is not a pointer (it has the TARGET attribute), the pointer object is associated with the target.

If the target is a pointer (it has the POINTER attribute), its status determines the status of the pointer object, as follows:
- If the pointer is associated, the pointer object is associated with the same object as the target
- If the pointer is disassociated, the pointer object becomes disassociated
- If the pointer is undefined, the pointer object becomes undefined

A pointer must not be referenced or defined unless it is associated with a target that can be referenced or defined.

When pointer assignment occurs, any previous association between the pointer object and a target is terminated.

Pointers can also be assigned for a pointer structure component by execution of a derived-type intrinsic assignment statement or a defined assignment statement.

Pointers can also become associated by using the ALLOCATE statement to allocate the pointer.

Pointers can become disassociated by deallocation, nullification of the pointer (using the DEALLOCATE or NULLIFY statements), or by reference to the NULL intrinsic function.

Pointer assignment for arrays allows lower bounds to be specified. The specified lower bounds can be any scalar integer expressions.

Remapping of the elements of a rank-one array is permitted. The mapping is in array-element order and the target array must be large enough. The specified bounds may be any scalar integer expressions.

**Examples**

The following are examples of pointer assignments:

```fortran
HOUR => MINUTES(1:60)  ! target is an array
M_YEAR => MY_CAR%YEAR   ! target is a structure component
NEW_ROW%RIGHT => CURRENT_ROW  ! pointer object is a structure component
PTR => M              ! target is a variable
POINTER_C => NULL ()   ! reference to NULL intrinsic
```

The following example shows a target as a pointer:

```fortran
INTEGER, POINTER :: P, N
INTEGER, TARGET :: M
INTEGER S
M = 14
N => M             ! N is associated with M
P => N             ! P is associated with M through N
S = P + 5
```

The value assigned to S is 19 (14 + 5).

You can use the intrinsic function **ASSOCIATED** to find out if a pointer is associated with a target or if two pointers are associated with the same target. For example:

```fortran
REAL C (:), D(:), E(:)
POINTER C, D
TARGET E
```
LOGICAL STATUS
! Pointer assignment.
C => E
! Pointer assignment.
D => E
! Returns TRUE; C is associated.
STATUS = ASSOCIATED (C)
! Returns TRUE; C is associated with E.
STATUS = ASSOCIATED (C, E)
! Returns TRUE; C and D are associated with the
! same target.
STATUS = ASSOCIATED (C, D)

The following example shows how to specify lower bounds on a pointer:
REAL, TARGET :: A(4,4)
POINTER P
P (0:,0:) => A            ! LBOUND (P) == [0,0]
    ! UBOUND (P) == [3,3]

The following example shows pointer remapping of the elements of a rank-one array:
REAL, TARGET :: V(100)
POINTER P
INTEGER N
P(1:N,1:2*N) => V(1:2*N*N)

Specification Statements

Specification Statements Overview

A specification statement is a nonexecutable statement that declares the attributes of data objects. In Fortran 2003 and Standard Fortran, many of the attributes that can be defined in specification statements can also be optionally specified in type declaration statements.

The following are specification statements:

- **Type Declarations**
  Explicitly specify the properties (for example: data type, rank, and extent) for data objects or functions.
- **ALLOCATABLE attribute and statement**
  Specifies that an array is an allocatable array with a deferred shape. The shape of an allocatable array is determined when an ALLOCATE statement is executed, dynamically allocating space for the array.
- **ASYNCHRONOUS attribute and statement**
  Specifies that a variable can be used for asynchronous input and output.
- **AUTOMATIC and STATIC attributes and statements**
  Control the storage allocation of variables in subprograms.
- **BIND attribute and statement**
  Specifies that an object is interoperable with C and has external linkage.
- **CODIMENSION attribute and statement**
  Specifies that an entity is a coarray.
- **COMMON statement**
  Defines one or more contiguous areas, or blocks, of physical storage (called common blocks) that can be accessed by any of the scoping units in an executable program. COMMON statements also define the order in which variables and arrays are stored in each common block, which can prevent misaligned data items.
- **CONTIGUOUS attribute and statement**
  Specifies that the target of a pointer or an assumed-sized array is contiguous.
- **DATA statement**
  Assigns initial values to variables before program execution.
- **DIMENSION attribute and statement**
  Specifies that an object is an array, and defines the shape of the array.
- **EQUIVALENCE statement**
  Specifies that a storage area is shared by two or more objects in a program unit. This causes total or partial storage association of the objects that share the storage area.
- **EXTERNAL attribute and statement**
  Allows an external or dummy procedure to be used as an actual argument.
- **IMPLICIT statement**
  Overrides the default implicit typing rules for names.
- **INTENT attribute and statement**
  Specifies the intended use of one or more dummy arguments.
- **INTRINSIC attribute and statement**
  Allows the specific name of an intrinsic procedure to be used as an actual argument. Certain specific function names cannot be used. For more information, see Intrinsic Functions Not Allowed as Actual Arguments.
• **NAMELIST statement**
  Associates a name with a list of variables. This group name can be referenced in some input/output operations.

• **OPTIONAL attribute and statement**
  Allows dummy arguments to be omitted in a procedure reference.

• **PARAMETER attribute and statement**
  Defines a named constant.

• **POINTER attribute and statement**
  Specifies that an object or a procedure is a pointer (a dynamic variable).

• **PRIVATE and PUBLIC and attributes and statements**
  Specifies the accessibility of entities in a module. (These attributes are also called accessibility attributes.)

• **PROTECTED attribute and statement**
  Specifies limitations on the use of module entities.

• **SAVE attribute and statement**
  Causes the values and definition of objects to be retained after execution of a RETURN or END statement in a subprogram.

• **TARGET attribute and statement**
  Specifies that an object can become the target of a pointer.

• **VALUE attribute and statement**
  Specifies a type of argument association for a dummy argument.

• **VOLATILE attribute and statement**
  Specifies that the value of an object is entirely unpredictable, based on information local to the current program unit.

**Type Declarations**

**Declarations for Noncharacter Types**

The following table shows the data types that can appear in noncharacter type declarations.

<table>
<thead>
<tr>
<th>Noncharacter Data Types</th>
</tr>
</thead>
<tbody>
<tr>
<td>BYTE¹</td>
</tr>
<tr>
<td>LOGICAL²</td>
</tr>
<tr>
<td>LOGICAL([KIND=]1) (or LOGICAL*1)</td>
</tr>
<tr>
<td>LOGICAL([KIND=]2) (or LOGICAL*2)</td>
</tr>
<tr>
<td>LOGICAL([KIND=]4) (or LOGICAL*4)</td>
</tr>
<tr>
<td>LOGICAL([KIND=]8) (or LOGICAL*8)</td>
</tr>
</tbody>
</table>
Noncharacter Data Types

INTEGER\(^3\)
- INTEGER\([\text{KIND=}1]\) (or INTEGER*1)
- INTEGER\([\text{KIND=}2]\) (or INTEGER*2)
- INTEGER\([\text{KIND=}4]\) (or INTEGER*4)
- INTEGER\([\text{KIND=}8]\) (or INTEGER*8)

REAL\(^4\)
- REAL\([\text{KIND=}4]\) (or REAL*4)
- DOUBLE PRECISION (REAL\([\text{KIND=}8]\) or REAL*8)
- REAL\([\text{KIND=}16]\) (or REAL*16)

COMPLEX\(^5\)
- COMPLEX\([\text{KIND=}4]\) (or COMPLEX*8)
- DOUBLE COMPLEX (COMPLEX\([\text{KIND=}8]\) or COMPLEX*16)
- COMPLEX\([\text{KIND=}16]\) (or COMPLEX*32)

1. Same as INTEGER(1).
2. This is treated as default logical.
3. This is treated as default integer.
4. This is treated as default real.
5. This is treated as default complex.

In noncharacter type declarations, you can optionally specify the name of the data object or function as v*n, where n is the length (in bytes) of v. The length specified overrides the length implied by the data type. The value for n must be a valid length for the type of v. The type specifiers BYTE, DOUBLE PRECISION, and DOUBLE COMPLEX have one valid length, so the n specifier is invalid for them.

For an array specification, the n must be placed immediately following the array name; for example, in an INTEGER declaration, IVEC*2(10) is an INTEGER(2) array of 10 elements.

Note that certain compiler options can affect the defaults for numeric and logical data types.

Examples

In a noncharacter type declaration, a subsequent kind parameter overrides any initial kind parameter. For example, consider the following statements:

```fortran
INTEGER(KIND=2) I, J, K, M12*4, Q, IVEC*4(10)
REAL(KIND=8) WX1, WXZ, WX3*4, WX5, WX6*4
REAL(KIND=8) PI/3.14159E0/, E/2.72E0/, QARRAY(10)/5*0.0, 5*1.0/
```

In the first statement, M12*4 and IVEC*4 override the KIND=2 specification. In the second statement, WX3*4 and WX6*4 override the KIND=8 specification. In the third statement, QARRAY is initialized with implicit conversion of the REAL(4) constants to a REAL(8) data type.

See Also
Type Declarations for details on the general form and rules for type declarations

Declarations for Character Types

A CHARACTER type specifier can be immediately followed by the length of the character object or function. It takes one of the following forms:
**Keyword Forms**

CHARACTER ([LEN=]len])
CHARACTER ([LEN=]len [, [KIND=]n])]
CHARACTER ([KIND=n [, LEN=len])]

**Nonkeyword Form**

CHARACTER*len[,]  

*len Is a length type parameter. It can have one of the following values:
- A scalar integer expression
- *
- :

The following rules also apply:
- In keyword forms
  The *len* is a specification expression, an asterisk (*), or a colon (:). If no length is specified, the default length is 1.
  If the length evaluates to a negative value, the length of the character entity is zero.
- In nonkeyword form
  The *len* is a specification expression or an asterisk enclosed in parentheses, or a scalar integer literal constant (with no kind parameter). The comma is permitted only if no double colon (::) appears in the type declaration statement.
  This form can also (optionally) be specified following the name of the data object or function (v*len). In this case, the length specified overrides any length following the CHARACTER type specifier.

The largest valid value for *len* in both forms is 2**31-1 on IA-32 architecture; 2**63-1 on Intel® 64 architecture. Negative values are treated as zero.

*n* Is a scalar integer initialization expression specifying a valid kind parameter. Currently the only kind available is 1.

**Description**

An automatic object can appear in a character declaration. The object cannot be a dummy argument, and its length must be declared with a specification expression that is not a constant expression.

The length specified for a character-valued statement function or statement function dummy argument of type character must be an integer constant expression.

When an asterisk length specification *(*) is used for a function name or dummy argument, it assumes the length of the corresponding function reference or actual argument. Similarly, when an asterisk length specification is used for a named constant, the name assumes the length of the actual constant it represents.

For example, STRING assumes a 9-byte length in the following statements:

```
CHARACTER*(*) STRING  
PARAMETER (STRING = 'VALUE IS:')
```

A function name must not be declared with a * length unless it is of type CHARACTER and is the name of the result of an external function or the name of a dummy function.

A function name declared with a * length must not be an array, a pointer, recursive, elemental, or pure.
If the CHARACTER type declaration statement specifies a colon (:) length, the length type parameter is a deferred type parameter. An entity or component with a deferred type parameter must specify the ALLOCATABLE or POINTER attribute. A deferred type parameter is a length type parameter whose value can change during execution of the program.

The nonkeyword form is considered obsolescent in the Fortran standard.

**Examples**

In the following example, the character string last_name is given a length of 20:

```
CHARACTER (LEN=20) last_name
```

In the following example, stri is given a length of 12, while the other two variables retain a length of 8.

```
CHARACTER *8 strg, strh, stri*12
```

In the following example, a dummy argument strh will assume the length of the associated actual argument, while the other two variables retain a length of 8:

```
CHARACTER *8 strg, strh(*), stri
```

The following examples show ways to specify strings of known length:

```
CHARACTER*32 string1
CHARACTER string2*32
```

The following examples show ways to specify strings of unknown length:

```
CHARACTER string3*(*)
CHARACTER*(*) string4
```

The following example declares an array NAMES containing 100 32-character elements, an array SOCSEC containing 100 9-character elements, and a variable NAMETY that is 10 characters long and has an initial value of 'ABCDEFGHJI'.

```
CHARACTER*32 NAMES(100),SOCSEC(100)*9,NAMETY*10 /'ABCDEFGHJI'/
```

The following example includes a CHARACTER statement declaring two 8-character variables, LAST and FIRST.

```
INTEGER, PARAMETER :: LENGTH=4
CHARACTER*(4+LENGTH) LAST, FIRST
```

The following example shows a CHARACTER statement declaring an array LETTER containing 26 one-character elements. It also declares a dummy argument BUBBLE that has a passed length defined by the calling program.

```
CHARACTER LETTER(26), BUBBLE*(*)
```

In the following example, NAME2 is an automatic object:

```
SUBROUTINE AUTO_NAME(NAME1)
  CHARACTER(LEN = *) NAME1
  CHARACTER(LEN = LEN(NAME1)) NAME2
```

The following example shows the handling of a deferred-length CHARACTER variables:

```
CHARACTER(:), ALLOCATABLE :: namea
namea = 'XYZ'                   ! Allocates namea as length 3 with value 'XYZ'
DEALLOCATE (namea)
ALLOCATE (CHARACTER(10)::namea) ! Allocates namea as length 10, no value
namea = 'ABCDEF'                ! Reallocates namea to length 6 with value 'ABCDEF'
```

**Declarations for Derived Types**

A derived-type declaration specifies the properties of objects and functions of derived (user-defined) type. The derived type must be defined before you can specify objects of that type in a TYPE type declaration. An object of derived type must not have the PUBLIC attribute if its type is PRIVATE. A structure constructor specifies values for derived-type objects.

**Examples**

The following are examples of derived-type declarations:

```
TYPE(EMPLOYEE) CONTRACT
...
TYPE(SETS), DIMENSION(:,::), ALLOCATABLE :: SUBSET_1
```

The following example shows a public type with private components:

```
TYPE LIST_ITEMS
  PRIVATE
  ...
  TYPE(LIST_ITEMS), POINTER :: NEXT, PREVIOUS
END TYPE LIST_ITEMS
```

**See Also**

TYPE Statement (Derived Types)
Use and Host Association Overview
PUBLIC
PRIVATE Statement
Structure Constructors
Type Declarations for details on the general form and rules for type declarations

**Declarations for Arrays**

An array declaration (or array declarator) declares the shape of an array. It takes the following form:

```
(a-spec)
```

**a-spec**

Is one of the following array specifications:

- Explicit-shape
- Assumed-shape
- Assumed-size
- Deferred-shape
- Assumed-rank

The array specification can be appended to the name of the array when the array is declared.

**Examples**

The following examples show array declarations:

```
SUBROUTINE SUB(N, C, D, Z)
  REAL, DIMENSION(N, 15) :: IARRY       ! An explicit-shape array
  REAL C(:,), D(0:)                   ! An assumed-shape array
  REAL, POINTER :: B(:,::)            ! A deferred-shape array pointer
  REAL, ALLOCATABLE, DIMENSION(::) :: K ! A deferred-shape allocatable array
  REAL :: Z(N,*)                      ! An assumed-size array
END SUBROUTINE SUB
```

**See Also**

Type Declarations for details on the general form and rules for type declaration statements
Explicit-Shape Specifications

An explicit-shape array is declared with explicit values for the bounds in each dimension of the array. An explicit-shape specification takes the following form:

\[
([dl:] \ du[, [dl:] \ du] ...)\]

- \( dl \) is a specification expression indicating the lower bound of the dimension. The expression can have a positive, negative, or zero value. If necessary, the value is converted to integer type. If the lower bound is not specified, it is assumed to be 1.

- \( du \) is a specification expression indicating the upper bound of the dimension. The expression can have a positive, negative, or zero value. If necessary, the value is converted to integer type.

The bounds can be specified as constant or nonconstant expressions, as follows:

- If the bounds are constant expressions, the subscript range of the array in a dimension is the set of integer values between and including the lower and upper bounds. If the lower bound is greater than the upper bound, the range is empty, the extent in that dimension is zero, and the array has a size of zero.

- If the bounds are nonconstant expressions, the array must be declared in a procedure. The bounds can have different values each time the procedure is executed, since they are determined when the procedure is entered.

The bounds are not affected by any redefinition or undefinition of the variables in the specification expression that occurs while the procedure is executing.

The following explicit-shape arrays can specify nonconstant bounds:

- An automatic array (the array is a local variable)
- An adjustable array (the array is a dummy argument to a subprogram)

The following are examples of explicit-shape specifications:

```
INTEGER I(3:8, -2:5)         ! Rank-two array; range of dimension one is 3 to 8, range of dimension two is -2 to 5
...                          !
SUBROUTINE SUB(A, B, C)
  INTEGER :: B, C
  REAL, DIMENSION(B:C) :: A  ! Rank-one array; range is B to C
```

Consider the following:

```
INTEGER M(10, 10, 10)
INTEGER K(-3:6, 4:13, 0:9)
```

M and K are both explicit-shape arrays with a rank of 3, a size of 1000, and the same shape (10,10,10). Array M uses the default lower bound of 1 for each of its dimensions. So, when it is declared only the upper bound needs to be specified. Each of the dimensions of array K has a lower bound other than the default, and the lower bounds as well as the upper bounds are declared.

Automatic Arrays

An automatic array is an explicit-shape array that is a local variable. Automatic arrays are only allowed in function and subroutine subprograms, and are declared in the specification part of the subprogram. At least one bound of an automatic array must be a nonconstant specification expression. The bounds are determined when the subprogram is called.

The following example shows automatic arrays:

```
SUBROUTINE SUB1 (A, B)
  INTEGER A, B, LOWER
  COMMON /BOUND/ LOWER
  ...
  INTEGER AUTO_ARRAY1(B)
  ...
  INTEGER AUTO_ARRAY2(LOWER:B)
```
...  
  INTEGER AUTO_ARRAY3(20, B*A/2)
END SUBROUTINE

Consider the following:
SUBROUTINE EXAMPLE (N, R1, R2)
  DIMENSION A (N, 5), B(10*N)
...
  N = IFIX(R1) + IFIX(R2)

When the subroutine is called, the arrays A and B are dimensioned on entry into the subroutine with the value of the passed variable N. Later changes to the value of N have no effect on the dimensions of array A or B.

Adjustable Arrays

An adjustable array is an explicit-shape array that is a dummy argument to a subprogram. At least one bound of an adjustable array must be a nonconstant specification expression. The bounds are determined when the subprogram is called.

The array specification can contain integer variables that are either dummy arguments or variables in a common block.

When the subprogram is entered, each dummy argument specified in the bounds must be associated with an actual argument. If the specification includes a variable in a common block, the variable must have a defined value. The array specification is evaluated using the values of the actual arguments, as well as any constants or common block variables that appear in the specification.

The size of the adjustable array must be less than or equal to the size of the array that is its corresponding actual argument.

To avoid possible errors in subscript evaluation, make sure that the bounds expressions used to declare multidimensional adjustable arrays match the bounds as declared by the caller.

In the following example, the function computes the sum of the elements of a rank-two array. Notice how the dummy arguments M and N control the iteration:

FUNCTION THE_SUM(A, M, N)
  DIMENSION A(M, N)
  SUMX = 0.0
  DO J = 1, N
    DO I = 1, M
      SUMX = SUMX + A(I, J)
    END DO
  END DO
  THE_SUM = SUMX
END FUNCTION

The following are examples of calls on THE_SUM:
DIMENSION A1(10,35), A2(3,56)
SUM1 = THE_SUM(A1,10,35)
SUM2 = THE_SUM(A2,3,56)

The following example shows how the array bounds determined when the procedure is entered do not change during execution:
DIMENSION ARRAY(9,5)
L = 9
M = 5
CALL SUB(ARRAY,L,M)
END

SUBROUTINE SUB(X,I,J)
  DIMENSION X(-I/2:I/2,J)
The assignments to I and J do not affect the declaration of adjustable array X as X(-4:4,5) on entry to subroutine SUB.

Specification Expressions

**Assumed-Shape Specifications**
An assumed-shape array is a dummy argument array that assumes the shape of its associated actual argument array. An assumed-shape specification takes the following form:

\[ ([dl];[, [dl];] ...) \]

*dl* is a specification expression indicating the lower bound of the dimension. The expression can have a positive, negative, or zero value. If necessary, the value is converted to integer type. If the lower bound is not specified, it is assumed to be 1.

The rank of the array is the number of colons (:) specified.

The value of the upper bound is the extent of the corresponding dimension of the associated actual argument array + *lower-bound* - 1.

**Examples**
The following is an example of an assumed-shape specification:

```
INTERFACE
  SUBROUTINE SUB(M)
    INTEGER M(:, 1:, 5:)
  END SUBROUTINE
END INTERFACE

INTEGER L(20, 5:25, 10)
CALL SUB(L)
```

Array M has the same extents as array L, but array M has bounds (1:20, 1:21, 5:14).

Note that an explicit interface is required when calling a routine that expects an assumed-shape or pointer array.

Consider the following:

```
SUBROUTINE ASSUMED(A)
  REAL A(:, :, :)
END SUBROUTINE
```

Array A has rank 3, indicated by the three colons (:) separated by commas (,). However, the extent of each dimension is unspecified. When the subroutine is called, A takes its shape from the array passed to it. For example, consider the following:

```
REAL X (4, 7, 9)
...  
CALL ASSUMED(X)
```

This gives A the dimensions (4, 7, 9). The actual array and the assumed-shape array must have the same rank.
Consider the following:

```fortran
SUBROUTINE ASSUMED(A)
    REAL A(3:, 0:, -2:)
    ...
```

If the subroutine is called with the same actual array `X(4, 7, 9)`, as in the previous example, the lower and upper bounds of `A` would be:

```
A(3:6, 0:6, -2:6)
```

## Assumed-Size Specifications

An **assumed-size array** is a dummy argument array that assumes the size (only) of its associated actual argument array; the rank and extents can differ for the actual and dummy arrays. An assumed-size specification takes the following form:

```
([expli-shape-spec,] [expli-shape-spec,] ... [dl:] *)
```

- `expli-shape-spec` is an explicit-shape specification.
- `dl` is a specification expression indicating the lower bound of the dimension. The expression can have a positive, negative, or zero value. If necessary, the value is converted to integer type. If the lower bound is not specified, it is assumed to be 1.
- `*` is the upper bound of the last dimension.

The rank of the array is the number of explicit-shape specifications plus 1.

The size of the array is assumed from the actual argument associated with the assumed-size dummy array as follows:

- If the actual argument is an array of type other than default character, the size of the dummy array is the size of the actual array.
- If the actual argument is an array element of type other than default character, the size of the dummy array is `a + 1 - s`, where `s` is the subscript order value and `a` is the size of the actual array.
- If the actual argument is a default character array, array element, or array element substring, and it begins at character storage unit `b` of an array with `n` character storage units, the size of the dummy array is as follows:
  
  ```fortran
  MAX(INT((n + 1 - b)/y), 0)
  ```

  The `y` is the length of an element of the dummy array.

An assumed-size array can only be used as a whole array reference in the following cases:

- When it is an actual argument in a procedure reference that does not require the shape
- In the intrinsic function `LBOUND`

Because the actual size of an assumed-size array is unknown, an assumed-size array cannot be used as any of the following in an I/O statement:

- An array name in the I/O list
- A unit identifier for an internal file
- A run-time format specifier

### Examples

The following is an example of an assumed-size specification:

```fortran
SUBROUTINE SUB(A, N)
    REAL A, N
    DIMENSION A(1:N, *)
    ...
```
The following example shows that you can specify lower bounds for any of the dimensions of an assumed-size array, including the last:

```fortran
SUBROUTINE ASSUME(A)
  REAL A(-4:-2, 4:6, 3:*)
END SUBROUTINE
```

See Also
Array Elements
Assumed-Rank Specifications
An assumed-rank array is declared with array bounds.
You declare an assumed-rank object (a dummy variable) by using DIMENSION(..) or (..)array bounds in its declaration.
Its rank is assumed from its effective argument, which means it is passed by descriptor.
An assumed-rank entity must not have the CODIMENSION or VALUE attribute. It can have the CONTIGUOUS attribute.
An assumed-rank variable name must not appear in a designator or expression except as one of the following:
- An actual argument corresponding to a dummy argument that is assumed-rank
- The argument of the C_LOC function in the ISO_C_BINDING intrinsic module
- The first argument in a reference to an intrinsic inquiry function
If an assumed-size or nonallocatable, nonpointer, assumed-rank array is an actual argument corresponding to a dummy argument that is an INTENT(OUT) assumed-rank array, it must not be polymorphic, finalizable, of a type with an allocatable ultimate component, or of a type for which default initialization is specified.
You can find the rank of an assumed-rank object by using the RANK intrinsic.
If a procedure has an assumed-rank argument, the procedure must have an explicit interface.
When an assumed-rank object is passed from Fortran to a BIND(C) routine, it is passed by C descriptor. A Fortran procedure that has the BIND(C) language-binding-spec attribute will also receive an assumed-rank object by C descriptor.

Examples
The following shows an assumed-rank object:

```fortran
SUBROUTINE sub (foo, bar)
  ! As sub does not have BIND, foo and bar are passed by "normal" descriptor
  REAL, DIMENSION(..) :: foo
  INTEGER :: bar(..)

  INTERFACE
    SUBROUTINE csub (baz) BIND(C)
      REAL, DIMENSION(..) :: baz
    END SUBROUTINE
  END INTERFACE

  CALL baz(foo) ! Passed by C descriptor
END SUBROUTINE
```

RANK
Deferred-Shape Specifications
A deferred-shape array is an array pointer or an allocatable array.
The array specification contains a colon (:) for each dimension of the array. No bounds are specified. The bounds (and shape) of allocatable arrays and array pointers are determined when space is allocated for the array during program execution.
An array pointer is an array declared with the POINTER attribute. Its bounds and shape are determined when it is associated with a target by pointer assignment, or when the pointer is allocated by execution of an ALLOCATE statement.

In pointer assignment, the lower bound of each dimension of the array pointer is the result of the LBOUND intrinsic function applied to the corresponding dimension of the target. The upper bound of each dimension is the result of the UBOUND intrinsic function applied to the corresponding dimension of the target.

A pointer dummy argument can be associated only with a pointer actual argument. An actual argument that is a pointer can be associated with a nonpointer dummy argument.

A function result can be declared to have the pointer attribute.

An allocatable array is declared with the ALLOCATABLE attribute. Its bounds and shape are determined when the array is allocated by execution of an ALLOCATE statement.

Examples

The following are examples of deferred-shape specifications:

```fortran
REAL, ALLOCATABLE :: A(:, :) ! Allocatable array
REAL, POINTER :: C(:,), D (:,:, :) ! Array pointers
```

If a deferred-shape array is declared in a DIMENSION or TARGET statement, it must be given the ALLOCATABLE or POINTER attribute in another statement. For example:

```fortran
DIMENSION P(:, :, :)
POINTER P
TARGET B(:, :)
ALLOCATABLE B
```

If the deferred-shape array is an array of pointers, its size, shape, and bounds are set in an ALLOCATE statement or in the pointer assignment statement when the pointer is associated with an allocated target. A pointer and its target must have the same rank.

For example:

```fortran
REAL, POINTER :: A(:, :,), B(:,), C(:, :)
INTEGER, ALLOCATABLE :: I(:)
REAL, ALLOCATABLE, TARGET :: D(:,,:), E(:)
...
ALLOCATE (A(2, 3), I(5), D(SIZE(I), 12), E(98))
C => D ! Pointer assignment statement
B => E(25:56) ! Pointer assignment to a section of a target
```

Effects of Equivalency and Interaction with COMMON Statements

Making Arrays Equivalent

When you make an element of one array equivalent to an element of another array, the EQUIVALENCE statement also sets equivalences between the other elements of the two arrays. Thus, if the first elements of two equal-sized arrays are made equivalent, both arrays share the same storage. If the third element of a 7-element array is made equivalent to the first element of another array, the last five elements of the first array overlap the first five elements of the second array.
Two or more elements of the same array should not be associated with each other in one or more EQUIVALENCE statements. For example, you cannot use an EQUIVALENCE statement to associate the first element of one array with the first element of another array, and then attempt to associate the fourth element of the first array with the seventh element of the other array.

Consider the following example:

```fortran
DIMENSION TABLE (2,2), TRIPLE (2,2,2)
EQUIVALENCE (TABLE(2,2), TRIPLE(1,2,2))
```

These statements cause the entire array TABLE to share part of the storage allocated to TRIPLE. The following table shows how these statements align the arrays:

### Equivalence of Array Storage

<table>
<thead>
<tr>
<th>Array TRIPLE</th>
<th>Element Number</th>
<th>Array TABLE</th>
<th>Element Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>TRIPLE(1,1,1)</td>
<td>1</td>
<td>TABLE(1,1)</td>
<td>1</td>
</tr>
<tr>
<td>TRIPLE(2,1,1)</td>
<td>2</td>
<td>TABLE(2,1)</td>
<td>2</td>
</tr>
<tr>
<td>TRIPLE(1,2,1)</td>
<td>3</td>
<td>TABLE(1,2)</td>
<td>3</td>
</tr>
<tr>
<td>TRIPLE(2,2,1)</td>
<td>4</td>
<td>TABLE(2,2)</td>
<td>4</td>
</tr>
<tr>
<td>TRIPLE(1,1,2)</td>
<td>5</td>
<td></td>
<td></td>
</tr>
<tr>
<td>TRIPLE(2,1,2)</td>
<td>6</td>
<td></td>
<td></td>
</tr>
<tr>
<td>TRIPLE(1,2,2)</td>
<td>7</td>
<td></td>
<td></td>
</tr>
<tr>
<td>TRIPLE(2,2,2)</td>
<td>8</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Each of the following statements also aligns the two arrays as shown in the above table:

```fortran
EQUIVALENCE (TABLE, TRIPLE(2,2,1))
EQUIVALENCE (TRIPLE(1,1,2), TABLE(2,1))
```

You can also make arrays equivalent with nonunity lower bounds. For example, an array defined as A(2:3,4) is a sequence of eight values. A reference to A(2,2) refers to the third element in the sequence. To make array A(2:3,4) share storage with array B(2:4,4), you can use the following statement:

```fortran
EQUIVALENCE (A(3,4), B(2,4))
```

The entire array A shares part of the storage allocated to array B. The following table shows how these statements align the arrays. The arrays can also be aligned by the following statements:

```fortran
EQUIVALENCE (A, B(4,1))
EQUIVALENCE (B(3,2), A(2,2))
```

### Equivalence of Arrays with Nonunity Lower Bounds

<table>
<thead>
<tr>
<th>Array B</th>
<th>Element Number</th>
<th>Array A</th>
<th>Element Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>B(2,1)</td>
<td>1</td>
<td>A(2,1)</td>
<td>1</td>
</tr>
<tr>
<td>B(3,1)</td>
<td>2</td>
<td>A(3,1)</td>
<td>2</td>
</tr>
<tr>
<td>B(4,1)</td>
<td>3</td>
<td>A(2,2)</td>
<td>3</td>
</tr>
<tr>
<td>B(2,2)</td>
<td>4</td>
<td>A(3,2)</td>
<td>4</td>
</tr>
<tr>
<td>B(3,2)</td>
<td>5</td>
<td>A(2,3)</td>
<td>5</td>
</tr>
<tr>
<td>B(4,2)</td>
<td>6</td>
<td></td>
<td></td>
</tr>
<tr>
<td>B(2,3)</td>
<td>7</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Array B</td>
<td>Array A</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--------------</td>
<td>--------------</td>
<td>--------</td>
<td>--------</td>
</tr>
<tr>
<td>Array Element</td>
<td>Element Number</td>
<td>Array Element</td>
<td>Element Number</td>
</tr>
<tr>
<td>B(3,3)</td>
<td>8</td>
<td>A(3,3)</td>
<td>6</td>
</tr>
<tr>
<td>B(4,3)</td>
<td>9</td>
<td>A(2,4)</td>
<td>7</td>
</tr>
<tr>
<td>B(2,4)</td>
<td>10</td>
<td>A(3,4)</td>
<td>8</td>
</tr>
<tr>
<td>B(3,4)</td>
<td>11</td>
<td></td>
<td></td>
</tr>
<tr>
<td>B(4,4)</td>
<td>12</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Only in the EQUIVALENCE statement can you identify an array element with a single subscript (the linear element number), even though the array was defined as multidimensional. For example, the following statements align the two arrays as shown in the above table:

```
DIMENSION B(2:4,1:4), A(2:3,1:4)
EQUIVALENCE(B(6), A(4))
```

**Making Substrings Equivalent**

When you make one character substring equivalent to another character substring, the EQUIVALENCE statement also sets associations between the other corresponding characters in the character entities; for example:

```
CHARACTER NAME*16, ID*9
EQUIVALENCE(NAME(10:13), ID(2:5))
```
These statements cause character variables NAME and ID to share space (see the following figure). The arrays can also be aligned by the following statement:

```europeans
EQUIVALENCE(NAME(9:9), ID(1:1))
```

**Equivalence of Substrings**

<table>
<thead>
<tr>
<th>NAME</th>
<th>Character Position</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td></td>
</tr>
<tr>
<td>5</td>
<td></td>
</tr>
<tr>
<td>6</td>
<td></td>
</tr>
<tr>
<td>7</td>
<td></td>
</tr>
<tr>
<td>8</td>
<td></td>
</tr>
<tr>
<td>9</td>
<td></td>
</tr>
<tr>
<td>10</td>
<td></td>
</tr>
<tr>
<td>11</td>
<td></td>
</tr>
<tr>
<td>12</td>
<td></td>
</tr>
<tr>
<td>13</td>
<td></td>
</tr>
<tr>
<td>14</td>
<td></td>
</tr>
<tr>
<td>15</td>
<td></td>
</tr>
<tr>
<td>16</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>ID</th>
<th>Character Position</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td></td>
</tr>
<tr>
<td>5</td>
<td></td>
</tr>
<tr>
<td>6</td>
<td></td>
</tr>
<tr>
<td>7</td>
<td></td>
</tr>
<tr>
<td>8</td>
<td></td>
</tr>
<tr>
<td>9</td>
<td></td>
</tr>
</tbody>
</table>

ZK-0618-GE

If the character substring references are array elements, the EQUIVALENCE statement sets associations between the other corresponding characters in the complete arrays.
Character elements of arrays can overlap at any character position. For example, the following statements cause character arrays FIELDS and STAR to share storage (see the following figure).

```fortran
CHARACTER FIELDS(100)*4, STAR(5)*5
EQUIVALENCE(FIELDS(1)(2:4), STAR(2)(3:5))
```

**Equivalence of Character Arrays**

<table>
<thead>
<tr>
<th>Character Position</th>
<th>Subscript</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>3</td>
<td>3</td>
</tr>
<tr>
<td>4</td>
<td>4</td>
</tr>
<tr>
<td>5</td>
<td>5</td>
</tr>
<tr>
<td>6</td>
<td>1</td>
</tr>
<tr>
<td>7</td>
<td>2</td>
</tr>
<tr>
<td>8</td>
<td>3</td>
</tr>
<tr>
<td>9</td>
<td>4</td>
</tr>
<tr>
<td>10</td>
<td>5</td>
</tr>
</tbody>
</table>

**FIELDS**

<table>
<thead>
<tr>
<th>Subscript</th>

<td>3</td>
</tr>
<tr>
<td>9</td>
<td>4</td>
</tr>
<tr>
<td>10</td>
<td>5</td>
</tr>
</tbody>
</table>
The EQUIVALENCE statement cannot assign the same storage location to two or more substrings that start at different character positions in the same character variable or character array. The EQUIVALENCE statement also cannot assign memory locations in a way that is inconsistent with the normal linear storage of character variables and arrays.

**EQUIVALENCE and COMMON Interaction**

A common block can extend beyond its original boundaries if variables or arrays are associated with entities stored in the common block. However, a common block can only extend beyond its last element; the extended portion cannot precede the first element in the block.

**Examples**

The following two figures demonstrate valid and invalid extensions of the common block, respectively.

**A Valid Extension of a Common Block**

![Diagram of a valid extension of a common block](image)

**An Invalid Extension of a Common Block**

![Diagram of an invalid extension of a common block](image)

The second example is invalid because the extended portion, B(1), precedes the first element of the common block.

The following example shows a valid EQUIVALENCE statement and an invalid EQUIVALENCE statement in the context of a common block.

```language
COMMON A, B, C
DIMENSION D(3)
EQUIVALENCE(B, D(1)) ! Valid, because common block is extended ! from the end.

COMMON A, B, C
DIMENSION D(3)
EQUIVALENCE(B, D(3)) ! Invalid, because D(1) would extend common ! block to precede A's location.
```
Dynamic Allocation Overview

Data objects can be static or dynamic. If a data object is static, a fixed amount of memory storage is created for it at compile time and is not freed until the program exits. If a data object is dynamic, memory storage for the object can be created (allocated), altered, or freed (deallocated) as a program executes.

Pointers, classes, deferred length character, allocatable scalars and arrays, and automatic arrays are dynamic data objects.

No storage space is created for a pointer until it is allocated with an ALLOCATE statement or until it is assigned to a allocated target. The storage space allocated is uninitialized.

A pointer can be dynamically disassociated from a target by using a NULLIFY statement.

An ALLOCATE statement can also be used to create storage for an allocatable array. A DEALLOCATE statement can be used to free the storage space reserved in a previous ALLOCATE statement. It also causes any pointers to become disassociated.

Automatic arrays differ from allocatable arrays in that they are automatically allocated and deallocated whenever you enter or leave a procedure, respectively.

NOTE
Dynamic memory allocation is limited by several factors, including swap file size and memory requirements of other applications that are running. Dynamic allocations that are too large or otherwise attempt to use the protected memory of other applications result in General Protection Fault errors. If you encounter an unexpectedly low limit, you might need to reset your virtual memory size through the Control Panel or redefine the swap file size.

Some programming techniques can help minimize memory requirements, such as using one large array instead of two or more individual arrays. Allocated arrays that are no longer needed should be deallocated.

TARGET Statement

Effects of Allocation

Allocation of Allocatable Variables

The status of an allocatable variable becomes "allocated" under the following conditions:

- If it is allocated by an ALLOCATE statement
- If it is allocated during assignment
- If it is allocated by the intrinsic subroutine MOVE_ALLOC

An allocatable variable with allocated status can be referenced, defined, or deallocated; allocating it causes an error condition in the ALLOCATE statement. The intrinsic function ALLOCATED returns TRUE for such a variable.
The status of an allocatable variable becomes "unallocated" under the following conditions:

- If it is not allocated
- If it is deallocated
- If it is unallocated by the intrinsic subroutine MOVE_ALLOC

An allocatable variable with unallocated status must not be referenced or defined. It must not be supplied as an actual argument corresponding to a nonallocatable dummy argument, except to certain intrinsic inquiry functions. It can be allocated with the ALLOCATE statement. Deallocation it causes an error condition in the DEALLOCATE statement. The intrinsic function ALLOCATED returns FALSE for such a variable.

At the beginning of execution of a program, allocatable variables are unallocated.

When the allocation status of an allocatable variable changes, the allocation status of any associated allocatable variable also changes accordingly. Allocation of an allocatable variable establishes values for the deferred type parameters of all associated allocatable variables.

An unsaved allocatable local variable of a procedure has a status of unallocated at the beginning of each invocation of the procedure. An unsaved local variable of a construct has a status of unallocated at the beginning of each execution of the construct.

When an object of derived type is created by an ALLOCATE statement, any allocatable ultimate components have an allocation status of unallocated unless the SOURCE= specifier appears and the corresponding component of the SOURCE= expression is allocated.

The intrinsic function ALLOCATED can be used to determine whether a variable is allocated or unallocated.

**Allocation of Allocatable Arrays**

The bounds (and shape) of an allocatable array are determined when it is allocated. Subsequent redefinition or undefined of any entities in the bound expressions does not affect the array specification.

If the lower bound is greater than the upper bound, that dimension has an extent of zero, and the array has a size of zero. If the lower bound is omitted, it is assumed to be 1.

When an array is allocated, it is definable. If you try to allocate a currently allocated allocatable array, an error occurs.

If an allocatable variable is a coarray, the corank is declared, but the cobounds are determined when it is allocated.

The intrinsic function ALLOCATED can be used to determine whether an allocatable array is currently allocated; for example:

```fortran
REAL, ALLOCATABLE :: E(:, :)   
...
IF (.NOT. ALLOCATED(E)) ALLOCATE(E(2:4, 7))
```

**Allocation Status**

During program execution, the allocation status of an allocatable array is one of the following:

- Not currently allocated
  - The array was never allocated or the last operation on it was a deallocation. Such an array must not be referenced or defined.
- Currently allocated
  - The array was allocated by an ALLOCATE statement. Such an array can be referenced, defined, or deallocated.

If an allocatable array has the SAVE attribute, it has an initial status of "not currently allocated". If the array is then allocated, its status changes to "currently allocated". It keeps that status until the array is deallocated.

If an allocatable array does not have the SAVE attribute, it has the status of "not currently allocated" at the beginning of each invocation of the procedure. If the array's status changes to "currently allocated", it is deallocated if the procedure is terminated by execution of a RETURN or END statement.
Example: Allocating Virtual Memory

The following example shows a program that performs virtual memory allocation. This program uses Fortran standard-conforming statements instead of calling an operating system memory allocation routine.

```fortran
! Program accepts an integer and displays square root values

INTEGER(4) :: N
READ (5,*) N                         ! Reads an integer value
CALL MAT(N)
END

! Subroutine MAT uses the typed integer value to display the square
! root values of numbers from 1 to N (the number read)

SUBROUTINE MAT(N)
REAL(4), ALLOCATABLE :: SQR(:)       ! Declares SQR as a one-dimensional allocatable array
ALLOCATE (SQR(N))                    ! Allocates array SQR
DO J=1,N
   SQR(J) = SQRT(FLOATJ(J))          ! FLOATJ converts integer to REAL
ENDDO
WRITE (6,*) SQR                      ! Displays calculated values
DEALLOCATE (SQR)                     ! Deallocates array SQR
END SUBROUTINE MAT

See Also
ALLOCATED
ALLOCATE

Allocation of Pointer Targets

When a pointer is allocated, the pointer is associated with a target and can be used to reference or define the target. (The target can be an array or a scalar, depending on how the pointer was declared.)

Other pointers can become associated with the pointer target (or part of the pointer target) by pointer assignment.

In contrast to allocatable arrays, a pointer can be allocated a new target even if it is currently associated with a target. The previous association is broken and the pointer is then associated with the new target.

If the previous target was created by allocation, it becomes inaccessible unless it can still be referred to by other pointers that are currently associated with it.

The intrinsic function ASSOCIATED can be used to determine whether a pointer is currently associated with a target. (The association status of the pointer must be defined.) For example:

```fortran
REAL, TARGET :: TAR(0:50)
REAL, POINTER :: PTR(:)
PTR => TAR
...
IF (ASSOCIATED(PTR,TAR))...

POINTER - Fortran
Pointer Assignments
ASSOCIATED

Effects of Deallocation
Deallocation of Allocatable Variables

Deallocation of an unallocated allocatable variable causes an error condition in the DEALLOCATE statement. Deallocating an allocatable variable with the TARGET attribute causes the pointer association status of any pointer associated with it to become undefined.

When the execution of a procedure is terminated by execution of a RETURN or END statement, an unsaved allocatable local variable of the procedure retains its allocation and definition status if it is a function result variable or a subobject of one; otherwise, it is deallocated.

If an executable construct references a function whose result is either allocatable or a structure with a subobject that is allocatable, and the function reference is executed, an allocatable result and any subobject that is an allocated allocatable entity in the result returned by the function is deallocated after execution of the innermost executable construct containing the reference.

If a function whose result is either allocatable or a structure with an allocatable subobject is referenced in the specification part of a scoping unit, and the function reference is executed, an allocatable result and any subobject that is an allocated allocatable entity in the result returned by the function is deallocated before execution of the executable constructs of the scoping unit.

When a procedure is invoked, any allocated allocatable object that is an actual argument corresponding to an INTENT (OUT) allocatable dummy argument is deallocated. Any allocated allocatable object that is a subobject of an actual argument corresponding to an INTENT (OUT) dummy argument is deallocated.

When an intrinsic assignment statement is executed, any noncoarray allocated allocatable subobject of the variable is deallocated before the assignment takes place.

When a variable of derived type is deallocated, any allocated allocatable subobject is deallocated.

If an allocatable component is a subobject of a finalizable object, that object is finalized before the component is automatically deallocated.

The effect of automatic deallocation is the same as that of a DEALLOCATE statement without a dealloc-opt argument.

When a DEALLOCATE statement is executed for which an object is a coarray, there is an implicit synchronization of all images. On each image, execution of the segment following the statement is delayed until all other images have executed the same statement the same number of times. If the coarray is a dummy argument, its ultimate argument must be the same coarray on every image.

There is also an implicit synchronization of all images in association with the deallocation of a coarray or coarray subcomponent caused by the execution of a RETURN or END statement.

The intrinsic function ALLOCATED can be used to determine whether a variable is allocated or unallocated.

Consider the following example:

```fortran
SUBROUTINE PROCESS
    REAL, ALLOCATABLE :: TEMP(:)
    REAL, ALLOCATABLE, SAVE :: X(:)
    ...
END SUBROUTINE PROCESS
```

Upon return from subroutine PROCESS, the allocation status of X is preserved because X has the SAVE attribute. TEMP does not have the SAVE attribute, so it will be deallocated if it was allocated. On the next invocation of PROCESS, TEMP will have an allocation status of unallocated.

Deallocation of Allocatable Arrays

If the DEALLOCATE statement specifies an array that is not currently allocated, an error occurs.

If an allocatable array with the TARGET attribute is deallocated, the association status of any pointer associated with it becomes undefined.

If a RETURN or END statement terminates a procedure, an allocatable array has one of the following allocation statuses:

- It keeps its previous allocation and association status if the following is true:
• It has the SAVE attribute.
• It is in the scoping unit of a module that is accessed by another scoping unit which is currently executing.
• It is accessible by host association.
• It remains allocated if it is accessed by use association.
• Otherwise, its allocation status is deallocated.

The intrinsic function ALLOCATED can be used to determine whether an allocatable array is currently allocated; for example:

```fortran
SUBROUTINE TEST
  REAL, ALLOCATABLE, SAVE :: F(:,:)
  REAL, ALLOCATABLE :: E(:,,:,:)
  ...
  IF (.NOT. ALLOCATED(E)) ALLOCATE(E(2:4,7,14))
END SUBROUTINE TEST
```

Note that when subroutine TEST is exited, the allocation status of F is maintained because F has the SAVE attribute. Since E does not have the SAVE attribute, it is deallocated. On the next invocation of TEST, E will have the status of "not currently allocated".

RETURN
END
SAVE

Deallocation of Pointer Targets

A pointer must not be deallocated unless it has a defined association status. If the DEALLOCATE statement specifies a pointer that has undefined association status, or a pointer whose target was not created by allocation, an error occurs.

A pointer must not be deallocated if it is associated with an allocatable array, or it is associated with a portion of an object (such as an array element or an array section).

If a pointer is deallocated, the association status of any other pointer associated with the target (or portion of the target) becomes undefined.

Execution of a RETURN or END statement in a subprogram causes the pointer association status of any pointer declared (or accessed) in the procedure to become undefined, unless any of the following applies to the pointer:

• It has the SAVE attribute.
• It is in the scoping unit of a module that is accessed by another scoping unit which is currently executing.
• It is accessible by host association.
• It is in blank common.
• It is in a named common block that appears in another scoping unit that is currently executing.
• It is the return value of a function declared with the POINTER attribute.

If the association status of a pointer becomes undefined, it cannot subsequently be referenced or defined.

Examples

The following example shows deallocation of a pointer:

```fortran
INTEGER ERR
REAL, POINTER :: PTR_A(:)
...
ALLOCATE (PTR_A(10), STAT=ERR)
...
DEALLOCATE(PTR_A)
```

SAVE
Execution Control Overview

Execution of a program consists of the asynchronous execution of the program in a fixed number of one or more of its images. Each image has its own execution environment, including floating-point status, a set of data objects, input/output units, and procedure pointers.

A program normally executes statements in the order in which they are written. Executable control constructs and statements, and procedure invocations, modify this normal execution by transferring control to another statement in the program, or by selecting blocks (groups) of constructs and statements for execution or repetition.

Procedures may be invoked by the CALL statement (subroutine), during expression evaluation (function), or as part of data definition and handling (user-defined operators and FINAL procedures). There are many ways to define a procedure: for example, external, internal, contained, type-bound, defined operator or assignment, and module. All procedures have one entry point; procedures usually return to their caller.

The control constructs ASSOCIATE, CASE, DO, IF, and SELECT TYPE contain blocks and can be named. The name must be a unique identifier in the scoping unit, and must appear on the initial line and terminal line of the construct. On the initial line, the name is separated from the statement keyword by a colon (:).

A block can contain any executable Fortran statement except an END statement. You can transfer control out of a block, but you cannot transfer control into another block.

DO loops cannot partially overlap blocks. The DO statement and its terminal statement must appear together in a statement block.

The following are execution control statements or constructs:

- **ASSOCIATE construct**
  Creates a temporary association between a named entity and a variable or the value of an expression. The association lasts for the duration of the block.

- **BLOCK construct**
  Executes a block of statements or constructs that can contain declarations.

- **CALL statement**
  Transfers control to a subroutine subprogram.

- **CASE construct**
  Conditionally executes one block of constructs or statements depending on the value of a scalar expression in a SELECT CASE statement.

- **CONTINUE statement**
  Primarily used to terminate a labeled DO construct when the construct would otherwise end improperly with either a GO TO, arithmetic IF, or other prohibited control statement.

- **CRITICAL construct**
  Limits execution of a block to one image at a time.

- **DO construct**
  Controls the repeated execution of a block of statements or constructs. The following statements are used in DO constructs:
    - **DO CONCURRENT statement**
      Specifies that there are no data dependencies between the iterations of a DO loop.
    - **DO WHILE statement**
      Executes the range of a DO construct while a specified condition remains true.
• CYCLE statement
  Interrupts the current execution cycle of the innermost (or named) DO construct.

• EXIT statement
  Terminates execution of a DO construct

• END statement
  Marks the end of a program unit.

• IF construct and IF statement
  The IF construct conditionally executes one block of statements or constructs. The IF statement conditionally executes one statement. The decision to transfer control or to execute the statement or block is based on the evaluation of a logical expression within the IF statement or construct.

• PAUSE statement
  Temporarily suspends program execution until the user or system resumes execution.

These statements are deleted features in the Fortran Standard. Intel® Fortran fully supports features deleted in the Fortran Standard.

• RETURN statement
  Transfers control from a subprogram to the calling program unit.

• SELECT TYPE construct
  Selects for execution at most one of its constituent blocks based on the dynamic type of an expression specified.

• STOP and ERROR STOP statement
  The STOP statement terminates program execution before the end of the program unit. The ERROR STOP statement initiates error termination of execution.

Branch Statements Overview

Branching affects the normal execution sequence by transferring control to a labeled statement in the same scoping unit. The transfer statement is called the branch statement, while the statement to which the transfer is made is called the branch target statement.

Any executable statement can be a branch target statement, except for the following:

• CASE statement
• ELSE statement
• ELSE IF statement

Certain restrictions apply to the following statements:

<table>
<thead>
<tr>
<th>Statement</th>
<th>Restriction</th>
</tr>
</thead>
<tbody>
<tr>
<td>DO terminal statement</td>
<td>The branch must be taken from within its nonblock DO construct(^1).</td>
</tr>
<tr>
<td>END DO</td>
<td>The branch must be taken from within its block DO construct.</td>
</tr>
<tr>
<td>END IF</td>
<td>The branch should be taken from within its IF construct(^2).</td>
</tr>
<tr>
<td>END SELECT</td>
<td>The branch must be taken from within its SELECT CASE construct or within its SELECT TYPE construct.</td>
</tr>
</tbody>
</table>

\(^1\) If the terminal statement is shared by more than one nonblock DO construct, the branch can only be taken from within the innermost DO construct

\(^2\) You can branch to an END IF statement from outside the IF construct; this is a deleted feature in the Fortran Standard. Intel® Fortran fully supports features deleted in the Fortran Standard.

The following are branch statements:
- **GOTO - Unconditional** statement  
  Transfers control to the same branch target statement every time it executes.

- **GOTO - COMPUTED** statement  
  Transfers control to one of a set of labeled branch target statements based on the value of an expression.

- **ASSIGN and assigned GO TO statements**  
  Assigns a label to an integer variable. Subsequently, this variable can be used as a branch target statement by an assigned GO TO statement or as a format specifier in a formatted input/output statement.

  These statements are deleted features in Fortran 95. Intel® Fortran fully supports features deleted in Fortran 95.

- **IF - Arithmetic** statement  
  Conditionally transfers control to one of three statements, based on the value of an arithmetic expression.

Execution Control Overview

### Effects of DO Constructs

#### Iteration Loop Control

DO iteration loop control takes the following form:

```fortran
do-var = expr1, expr2 [, expr3]
```

**do-var**  
Is the name of a scalar variable of type integer or real. It cannot be the name of an array element or structure component.

**expr**  
Is a scalar numeric expression of type integer, logical, or real. If it is not the same type as *do-var*, it is converted to that type.

**Description**

A DO variable or expression of type real is a deleted feature in the Fortran Standard. Intel® Fortran fully supports features deleted in the Fortran Standard.

The following steps are performed in iteration loop control:

1. The expressions *expr1*, *expr2*, and *expr3* are evaluated to respectively determine the initial, terminal, and increment parameters.  
   The increment parameter (*expr3*) is optional and must not be zero. If an increment parameter is not specified, it is assumed to be of type default integer with a value of 1.

2. The DO variable (*do-var*) becomes defined with the value of the initial parameter (*expr1*).

3. The iteration count is determined as follows:

   ```fortran
   MAX(INT({expr2 - expr1 + expr3}/expr3), 0)
   ```

   The iteration count is zero if either of the following is true:

   ```fortran
   expr1 > expr2 and expr3 > 0  
   expr1 < expr2 and expr3 < 0
   ```

4. The iteration count is tested. If the iteration count is zero, the loop terminates and the DO construct becomes inactive. (Compiler option f66 can affect this.) If the iteration count is nonzero, the range of the loop is executed.

5. The iteration count is decremented by one, and the DO variable is incremented by the value of the increment parameter, if any.
After termination, the DO variable retains its last value (the one it had when the iteration count was tested and found to be zero).

The DO variable must not be redefined or become undefined during execution of the DO range.

If you change variables in the initial, terminal, or increment expressions during execution of the DO construct, it does not affect the iteration count. The iteration count is fixed each time the DO construct is entered.

**Examples**

The following example specifies 25 iterations:

```fortran
DO 100 K=1,50,2
```

K=49 during the final iteration, K=51 after the loop.

The following example specifies 27 iterations:

```fortran
DO 350 J=50,-2,-2
```

J=-2 during the final iteration, J=-4 after the loop.

The following example specifies 9 iterations:

```fortran
DO NUMBER=5,40,4
```

NUMBER=37 during the final iteration, NUMBER=41 after the loop. The terminating statement of this DO loop must be END DO.

**See Also**

Deleted and Obsolescent Language Features for details on obsolescent features in Standard Fortran, as well as features deleted in Standard Fortran f66.

**Nested DO Constructs**

A DO construct can contain one or more complete DO constructs (loops). The range of an inner nested DO construct must lie completely within the range of the next outer DO construct. Nested nonblock DO constructs can share a labeled terminal statement.

The following figure shows correctly and incorrectly nested DO constructs:

In a nested DO construct, you can transfer control from an inner construct to an outer construct. However, you cannot transfer control from an outer construct to an inner construct.

If two or more nested DO constructs share the same terminal statement, you can transfer control to that statement only from within the range of the innermost construct. Any other transfer to that statement constitutes a transfer from an outer construct to an inner construct, because the shared statement is part of the range of the innermost construct.

When the nested DO constructs contain no statements between the DO statements in the nest of DO constructs, the nest is called "perfectly nested". When perfectly nested DO constructs are modified by a COLLAPSE clause in any of these OpenMP* directives:

- !$OMP DISTRIBUTE
- !$OMP DO
- !$OMP SIMD

There are restrictions on which general compiler directives (see General Compiler Directives) and OpenMP Fortran compiler directives (see OpenMP Fortran Compiler Directives) can appear before the DO statements in the nested DO construct:

- Any OpenMP or general directives that are allowed to affect DO loops are allowed prior to the first DO loop of the "perfectly nested" DO construct.
• It is an error if any of these directives are between any of the perfectly nested DO loop statements for the loops affected by the COLLAPSE clause.

Examples

In the following example, COLLAPSE (1) on affects the DO I loop. Therefore general directives before the DO J loop, which is at level 2, are allowed:

```
!$OMP SIMD collapse (1)
!dir$ prefetch  ...  ! this is allowed since it is before the start
   ! of the perfectly nested DO construct

do i = ...
   !dir$ loop count ...  ! this is allowed since collapse only applies
   ! to the i-loop, not the j-loop
      do j = _
         enddo                ! end for j-loop
      enddo                ! end for i-loop
enddo                     ! end for i-loop
```

In the following example, COLLAPSE (2) affects the DO I loop and the DO J loop but not the DO k loop.

```
!$OMP SIMD collapse (2)
!dir$ prefetch  ...  ! this is allowed since it is before the start
   ! of the perfectly nested DO construct

do i = ...
   do j = _
      !dir$ loop count ...  ! this is allowed since collapse only applies to
      ! the i-loop and the j-loop, not the k-loop
         do k= ...
            enddo                ! end for k-loop
         enddo                ! end for j-loop
      enddo                ! end for i-loop
enddo                 ! end for j-loop
enddo                     ! end for i-loop
```

In the following example, COLLAPSE (2) affects the DO I loop and the DO J loop so there can be no directives before the DO J loop.

```
!$OMP SIMD collapse (2)
!dir$ prefetch  ...  ! this is allowed since it is before the start
   ! of the perfectly nested DO construct

do i = ...
   !dir$ loop count ...  ! this is not allowed: it is breaks the perfectness
   ! of the i-loop and the nj-loop collapsing
      do j = _
         enddo                ! end for j-loop
      enddo                ! end for i-loop
enddo                     ! end for i-loop
```

Rules for General Directives that Affect DO Loops

Extended Range

A DO construct has an extended range if both of the following are true:
• The DO construct contains a control statement that transfers control out of the construct.
• Another control statement returns control back into the construct after execution of one or more statements.

The range of the construct is extended to include all executable statements between the destination statement of the first transfer and the statement that returns control to the construct.

The following rules apply to a DO construct with extended range:
• A transfer into the range of a DO statement is permitted only if the transfer is made from the extended range of that DO statement.
• The extended range of a DO statement must not change the control variable of the DO statement.

The following figure shows valid and invalid extended range control transfers:

Control Transfers and Extended Range

Image Control Statements

Execution of an image control statement divides the execution sequence on an image into segments. The following are image control statements:

• The SYNC ALL statement
• The SYNC IMAGES statement
• The SYNC MEMORY statement
• An ALLOCATE or DEALLOCATE statement that has a coarray allocatable object
• The CRITICAL or END CRITICAL statement
• The LOCK or UNLOCK statement
• Any statement that completes execution of a block or procedure and which results in the implicit deallocation of a coarray
• The STOP statement
• The END statement of a main program

A SYNC MEMORY statement is executed for all image control statements except CRITICAL, END CRITICAL, LOCK, and UNLOCK.

During an execution of a statement that invokes more than one procedure, at most one invocation can cause execution of an image control statement other than CRITICAL or END CRITICAL.

See Also
Execution Segments for Images

STAT= and ERRMSG= Specifiers in Image Control Statements

If the STAT= specifier appears, successful execution of the LOCK, SYNC ALL, SYNC IMAGES, SYNC MEMORY, or UNLOCK statement causes the specified variable to become defined with the value zero.

If the STAT= specifier appears in a SYNC ALL or SYNC IMAGES statement and execution of one of these statements involves synchronization with an image that has initiated termination, the variable becomes defined with the value of the constant STAT_STOPPED_IMAGE in the intrinsic module ISO_FORTRAN_ENV, and the effect of executing the statement is otherwise the same as that of executing the SYNC_MEMORY statement. If any other error condition occurs during execution of one of these statements, the variable becomes defined with a processor-dependent positive integer value that is different from the value of STAT_STOPPED_IMAGE.

If the STAT= specifier appears in a LOCK statement and the lock variable is locked by the executing image, the specified variable becomes defined with the value of STAT_LOCKED. If the STAT= specifier appears in an UNLOCK statement and the lock variable has the value unlocked, the variable specified by the STAT= specifier becomes defined with the value of STAT_UNLOCKED. If the STAT= specifier appears in an UNLOCK statement and the lock variable is locked by a different image, the specified variable becomes defined with the value STAT_LOCKED_OTHER_IMAGE. The named constants STAT_LOCKED, STAT_UNLOCKED, and STAT_LOCKED_OTHER_IMAGE are defined in the intrinsic module ISO_FORTRAN_ENV.

If any other error condition occurs during execution of a LOCK or UNLOCK statement, the specified variable becomes defined with a positive integer value that is different from STAT_LOCKED, STAT_UNLOCKED, and STAT_LOCKED_OTHER_IMAGE.

If an error condition occurs during execution of a LOCK, SYNC ALL, SYNC IMAGES, SYNC MEMORY, or UNLOCK statement that does not contain the STAT= specifier, error termination is initiated.
If an ERRMSG= specifier appears in a LOCK, SYNC ALL, SYNC IMAGES, SYNC MEMORY, or UNLOCK statement, and an error condition occurs during execution of that statement, the processor shall assign an explanatory message to the specified variable. If no such condition occurs, the processor shall not change the value of the variable.

The set of error conditions that can occur in an image control statement is processor dependent.

**Execution Segments for Images**

On each image, a segment is the sequence of statements executed before the first execution of an image control statement, between the execution of two image control statements, or after the last execution of an image control statement.

The segment executed immediately before the execution of an image control statement includes the evaluation of all expressions within that image control statement.

A coarray can be referenced or defined by execution of an atomic subroutine during the execution of a segment that is unordered, relative to the execution of a segment in which the coarray is referenced or defined by execution of an atomic subroutine. Otherwise, the following rules apply:

- If a variable is defined on an image in a segment, it must not be referenced, defined, or become undefined in a segment on another image unless the segments are ordered.
- If the allocation of an allocatable subobject of a coarray or the pointer association of a pointer subobject of a coarray is changed on an image in a segment, that subobject must not be referenced or defined in a segment on another image unless the segments are ordered.
- If a procedure invocation on image P is in execution in segments Pi, Pi+1, ..., Pk and defines a noncoarray dummy argument, the effective argument must not be referenced, defined, or become undefined on another image Q in a segment Qj unless Qj precedes Pi or succeeds Pk (because a copy of the actual argument may be passed to the procedure).

Incorrect sequencing of image control statements can suspend execution indefinitely. For example, one image might be executing a SYNC ALL statement while another is executing an ALLOCATE statement for a coarray.

Image Control Statements
Program Units and Procedures Overview

A Fortran program consists of one or more program units. There are four types of program units:

- **Main program**
  The program unit that denotes the beginning of execution. It may or may not have a PROGRAM statement as its first statement.

- **External procedures**
  Program units that are either user-written functions or subroutines.

- **Modules and submodules**
  Program units that contain declarations, type definitions, procedures, or interfaces that can be shared by other program units. A module can be extended by one or more program units called submodules. A submodule can in turn be extended by one or more submodules.

- **Block data program units**
  Program units that provide initial values for variables in named common blocks.

A program unit does not have to contain executable statements; for example, it can be a module containing interface blocks for subroutines.

A procedure can be invoked during program execution to perform a specific task. It specifies the EXTERNAL attribute for all procedure entities in the procedure declaration list. A procedure declaration is denoted by a PROCEDURE statement.

There are several kinds of procedures, as follows:

<table>
<thead>
<tr>
<th>Kind of Procedure</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>External Procedure</td>
<td>A procedure that is not part of any other program unit.</td>
</tr>
<tr>
<td>Module Procedure</td>
<td>A procedure defined within a module.</td>
</tr>
<tr>
<td>Internal Procedure[^1]</td>
<td>A procedure (other than a statement function) contained within a main program, function, or subroutine.</td>
</tr>
<tr>
<td>Intrinsic Procedure</td>
<td>A procedure defined by the Fortran language.</td>
</tr>
<tr>
<td>Dummy Procedure</td>
<td>A dummy argument specified as a procedure or appearing in a procedure reference. A dummy procedure with the POINTER attribute is a dummy procedure pointer.</td>
</tr>
<tr>
<td>Procedure Pointer</td>
<td>A procedure that has the EXTERNAL and POINTER attributes. It may be pointer associated with an external procedure, a module procedure, an intrinsic procedure, or a dummy procedure that is not a procedure pointer.</td>
</tr>
<tr>
<td>Statement function</td>
<td>A computing procedure defined by a single statement.</td>
</tr>
</tbody>
</table>

[^1] The program unit that contains an internal procedure is called its *host*. 
A function is invoked in an expression using the name of the function or a defined operator. It returns a single value (function result) that is used to evaluate the expression.

A subroutine is invoked in a CALL statement or by a defined assignment statement. It does not directly return a value, but values can be passed back to the calling program unit through arguments (or variables) known to the calling program.

Recursion (direct or indirect) is permitted for functions and subroutines.

A procedure interface refers to the properties of a procedure that interact with or are of concern to the calling program. A procedure interface can be explicitly defined in interface blocks. All program units, except block data program units, can contain interface blocks.

Program Units
Intrinsic Procedures Overview
Scope
RECURSIVE

Main Program
A main program is a program unit whose first statement is not a SUBROUTINE, FUNCTION, MODULE, SUBMODULE, or BLOCK DATA statement. Program execution always begins with the first executable statement in the main program, so there must be exactly one main program unit in every executable program. For more information, see PROGRAM.

Procedure Characteristics
The characteristics of a procedure are as follows:

- Whether it is classified as a function or subroutine
- The characteristics of its result value if it is a function
- The characteristics of its dummy arguments
- Whether it is pure
- Whether it is impure
- Whether it is elemental
- Whether it has the BIND attribute

Characteristics of Dummy Arguments
Each dummy argument has the characteristic that it is a dummy data object, a dummy procedure, or an asterisk indicating an alternate return indicator.

The characteristics of a dummy data object are as follows:

- Its type and type parameters (if any)
- Its shape
- Its intent
- Its corank
- Its codimensions
- Whether it is optional
- Whether it is allocatable
- Whether it has the ASYNCHRONOUS, CONTIGUOUS, VALUE, or VOLATILE attribute
- Whether it is a pointer or a target
- Whether it is polymorphic
- Whether or not it is assumed rank or assumed type
If a type parameter of an object or a bound of an array is not a constant expression, a characteristic is the exact dependence on the entities in the expression. Another characteristic is whether a shape, size, or type parameter is assumed or deferred.

The characteristics of a dummy procedure are as follows:

- Whether it is optional
- The explicitness of its interface
- Its characteristics as a procedure if the interface is explicit
- Whether it is a pointer

**Characteristics of Function Results**

The characteristics of a function result are as follows:

- Its type, type parameters (if any), and rank
- Whether it is allocatable
- Whether it has the CONTIGUOUS attribute
- Whether it is a pointer
- Whether it is a procedure pointer
- Whether it is polymorphic

If a function result is an array that is not allocatable or a pointer, a characteristic is its shape.

If a type parameter of a function result or a bound of a function result array is not a constant expression, a characteristic is the exact dependence on the entities in the expression.

If type parameters of a function result are deferred, a characteristic is which parameters are deferred. Another characteristic is whether the length of a character function result is assumed.

**Modules and Module Procedures**

A module program unit contains specifications and definitions that can be made accessible to other program units. There are two types of modules, intrinsic and nonintrinsic. Intrinsic modules are included in the Fortran library; nonintrinsic modules are user-defined.

For the module to be accessible, the other program units must reference its name in a USE statement, and the module entities must be public. This module reference lets the program unit access the public definitions, specifications, and procedures in the module. Entities in a module are public by default, unless the USE statement specifies otherwise or the PRIVATE attribute is specified for the module entities.

A module reference causes use association between the using program unit and the entities in the module.

A submodule extends a module or another submodule. It provides additional structuring facilities for modules. Data objects and procedure pointers declared in a module implicitly have the SAVE attribute.

For more information on module program units, see **MODULE**. For more information about submodule program units, see **SUBMODULE**.

A module procedure is a procedure declared and defined in a module, between its CONTAINS and END statements. For more information, see **MODULE PROCEDURE**.

**See Also**

PRIVATE Statement
PUBLIC
Use and Host Association Overview

**Separate Module Procedures**

A *separate module procedure* is a module procedure that is declared in a *separate interface body*. To denote separate module procedures, you must specify the keyword MODULE as a prefix in the initial statement of both of the following:
• A separate module procedure body
• A separate interface body

The interface block that contains the separate interface body must be nonabstract.

A separate interface body can be declared in a module or a submodule. The corresponding separate module procedure may be defined (implemented) in the same module or submodule or a descendent of the module or submodule. A separate module procedure can only be defined once.

Usually, the separate interface body is specified in a module and the separate module procedure is defined in a descendent submodule.

In the following example, FOO is a separate module procedure whose interface is specified in module M while the procedure body is defined in submodule A:

```fortran
module M
  type tt
    real r
  end type tt

  interface
    real module function FOO (arg)
      type(tt), intent(in) :: arg
    end function FOO
  end interface
end module M

submodule (M) A
  contains
    real module function FOO (arg) result(res)
      type(tt), intent(in) :: arg
      res = arg%r
    end function FOO
  end submodule A
```

A separate module procedure is accessible by use association only if its interface body is declared in a module and it is public (for example, FOO in the above example). If a separate module interface is declared in a submodule, the module procedure is only accessible in that submodule or its descendent submodules.

A separate module procedure interface body (either in a module or submodule) has access to entities in its host through host association.

**NOTE**

For an interface body that is not a separate interface body, IMPORT statements are required to make entities accessible by host association. However, IMPORT statements are not permitted in a separate interface body.

The initial statement of a separate module procedure body can take one of the two following forms:

**• MODULE appears as a prefix for a FUNCTION or SUBROUTINE statement**

The following shows an example using this form:

```fortran
submodule (M) A
  contains
    real module function foo (arg) result(res)
      type(tt), intent(in) :: arg
      res = arg%r
    end function foo
  end submodule A
```

With this form, a separate module procedure must specify the same characteristics and dummy argument names as its corresponding separate interface body.
They must both be functions or subroutines; they must both be pure or not; they must both be elemental or not. The characteristics of its dummy arguments and the characteristics of the function result must also be the same.

RECURSIVE can appear only if RECURSIVE appears as a prefix in the corresponding separate interface body.

Note that the restrictions of matching dummy argument names and matching PURE and RECURSIVE specifications only apply to separate module procedures. For an external procedure, the procedure definition and its interface body can differ with regard to dummy argument names, to whether it is pure, and to whether it is recursive.

A procedure defined in a submodule with the BIND attribute cannot have a binding label (that is, BIND(C, NAME="a-binding-label") unless it is a separate module procedure and its interface is declared in the ancestor module. The binding label specified in a separate module procedure definition must match the binding label specified in the separate interface body.

For this form, the result variable name for a function is determined by the FUNCTION statement in the module subprogram. The result variable name in the interface is ignored.

**MODULE PROCEDURE statement**

This has the following form:

```
MODULE PROCEDURE procedure-name
  [specification-part]
  [execution-part]
  [internal-subprogram-part]
END [PROCEDURE [procedure-name]]
```

The following shows an example using this form:

```fortran
submodule (M) A
contains
  module procedure foo
    foo = arg%r
  end procedure foo
end submodule A
```

This syntax avoids the redeclaration of the function or subroutine in the separate module procedure definition and just takes the characteristics, dummy argument names, and the function result variable name from the separate interface body.

A separate module procedure does not have to be defined. The separate module procedure interface can be used to specify an explicit interface; however, the procedure must not be called.

**NOTE**

Two modules cannot have USE statements that reference each other because circular reference is not allowed. However, you can solve that problem by putting at least one side of the USEs in submodules. This is because submodules cannot be referenced by use association and the USE statements in submodules are effectively hidden.

**Examples**

See the examples in **SUBMODULE**.

SUBMODULE

**Intrinsic Modules**

Intrinsic modules, like other module program units, contain specifications and definitions that can be made accessible to other program units. The intrinsic modules are part of the Fortran library.

An intrinsic module is specified in a USE statement, as follows:
USE, INTRINSIC :: mod-name [, rename-list] ...
USE, INTRINSIC :: mod-name, ONLY : [, only-list]

mod-name
Is the name of the intrinsic module.
ename-list
See the description in USE.

only-list
See the description in USE.

Procedures and types defined in an intrinsic module are not themselves intrinsic.

An intrinsic module can have the same name as other global entities, such as program units, common
blocks, or external procedures. A scoping unit must not be able to access both an intrinsic module and a non-
intrinsic module with the same name.

The following intrinsic modules are included in the Fortran library: ISO_C_BINDING, ISO_FORTRAN_ENV,
and IEEE Intrinsic Modules.

ISO_C_BINDING Module

The ISO_C_BINDING intrinsic module provides access to data entities that are useful in mixed-language
programming. It takes the following form:

USE, INTRINSIC :: ISO_C_BINDING

This intrinsic module provides access to the following data entities:

- Named Constants
- Derived Types
  - Derived type C_PTR is interoperable with any C object pointer type. Derived type C_FUNPTR is
    interoperable with any C function pointer type.
- Intrinsic Module Procedures

See Also
Standard Tools for Interoperability

Named Constants

The ISO_C_BINDING named constants represent kind type parameters of data representations compatible
with C types.

Intrinsic-Type Constants

The following table shows interoperable Fortran types and C Types.

<table>

**REAL**

| C_FLOAT | float |
| C_DOUBLE | double |
| C_LONG_DOUBLE | long double |

**COMPLEX**

| C_FLOAT_COMPLEX | float _Complex |
| C_DOUBLE_COMPLEX | double _Complex |
| C_LONG_DOUBLE_COMPLEX | long double _Complex |

**LOGICAL**¹

| C_BOOL | _Bool |

**CHARACTER**²

| C_CHAR | char |

¹ Use compiler option fpscomp logicals so that .TRUE. is 1 and .FALSE. is 0 as defined for C's _Bool.

² For character type, the length type parameter must be omitted or it must be specified by an initialization expression whose value is one.

For example, an integer type with the kind type parameter C_LONG is interoperable with the C integer type "long" or any C type derived from "long".

The value of C_INT will be a valid value for an integer kind type parameter on the processor. The values for the other integer named constants (C_INT*) will be a valid value for an integer kind type parameter on the processor, if any, or one of the following:

- -1 if the C processor defines the corresponding C type and there is no interoperating Fortran processor kind
- -2 if the C processor does not define the corresponding C type

The values of C_FLOAT, C_DOUBLE, and C_LONGDOUBLE will be a valid value for a real kind type parameter on the processor, if any, or one of the following:

- -1 if the C processor's type does not have a precision equal to the precision of any of the Fortran processor's real kinds
- -2 if the C processor's type does not have a range equal to the range of any of the Fortran processor's real kinds
-3 if the C processor’s type has neither the precision or range equal to the precision or range of any of the Fortran processor’s real kinds
-4 if there is no interoperating Fortran processor or kind for other reasons

The values of C_FLOAT_COMPLEX, C_DOUBLE_COMPLEX, and C_LONG_DOUBLE_COMPLEX will be the same as those of C_FLOAT, C_DOUBLE, and C_LONG_DOUBLE, respectively.

The value of C_BOOL will be a valid value for a logical kind parameter on the processor, if any, or -1.

The value of C_CHAR is the character kind.

### Character Constants

The following table shows interoperable named constants and C characters:

<table>
<thead>
<tr>
<th>Fortran Named Constant</th>
<th>Definition</th>
<th>C Character</th>
</tr>
</thead>
<tbody>
<tr>
<td>C_NULL_CHAR</td>
<td>null character</td>
<td>\0</td>
</tr>
<tr>
<td>C_ALERT</td>
<td>alert</td>
<td>\a</td>
</tr>
<tr>
<td>C_BACKSPACE</td>
<td>backspace</td>
<td>\b</td>
</tr>
<tr>
<td>C_FORM_FEED</td>
<td>form feed</td>
<td>\f</td>
</tr>
<tr>
<td>C_NEW_LINE</td>
<td>new line</td>
<td>\n</td>
</tr>
<tr>
<td>C_CARRIAGE_RETURN</td>
<td>carriage return</td>
<td>\r</td>
</tr>
<tr>
<td>C_HORIZONTAL_TAB</td>
<td>horizontal tab</td>
<td>\t</td>
</tr>
<tr>
<td>C_VERTICAL_TAB</td>
<td>vertical tab</td>
<td>\v</td>
</tr>
</tbody>
</table>

### Derived-Type Constants

The constant C_NULL_PTR is of type C_PTR; it has the value of a C null data pointer. The constant C_NULL_FUNPTR is of type C_FUNPTR; it has the value of a C null function pointer.

### Intrinsic Module Procedures

The following procedures are provided with the ISO_C_BINDING intrinsic module:
- C_ASSOCIATED
- C_F_POINTER
- C_F_PROCPOINTER
- C_FUNLOC
- C_LOC
- C_SIZEOF

None of the procedures are pure.

### ISO_FORTRAN_ENV Module

The ISO_FORTRAN_ENV intrinsic module provides information about the Fortran run-time environment. It takes the following form:

```
USE, INTRINSIC :: ISO_FORTRAN_ENV
```

This intrinsic module provides the following named constants you can use to get information on the Fortran environment. They are all scalars of type default integer.
<table>
<thead>
<tr>
<th>Named Constant</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>ATOMIC_INT_KIND</td>
<td>Is the kind type parameter used when defining integer variables used in atomic operations.</td>
</tr>
<tr>
<td>ATOMIC_LOGICAL_KIND</td>
<td>Is the kind type parameter used when defining logical variables used in atomic operations.</td>
</tr>
<tr>
<td>CHARACTER_KINDS</td>
<td>Is the kind type parameter supported by the processor that is used when defining variables of type character. This is a default integer array constant. The rank of the array is one, its lower bound is one, and its size is the number of character kinds supported. In Intel® Fortran, its value is [1].</td>

<tr>
<td>REAL_KINDS</td>
<td>Is the kind type parameter supported by the processor that is used when defining variables of type real. This is a default integer array constant. The rank of the array is one, its lower bound is one, and its size is the number of real kinds supported. In Intel Fortran its value is ([4, 8, 16]).</td>
</tr>
<tr>
<td>REAL32</td>
<td>Are the kind type parameters that specify a real type whose storage size is 32 bits, 64 bits, and 128 bits, respectively. If, for any of these constants, the processor supports more than one kind of that size, the kind value is determined by the processor. If the processor supports no kind of a particular size, that constant is equal to -2 if the processor supports kinds of a larger size; otherwise, -1. In Intel Fortran, their respective values are 4, 8, and 16.</td>
</tr>
<tr>
<td>REAL64</td>
<td></td>
</tr>
<tr>
<td>REAL128</td>
<td></td>
</tr>
<tr>
<td>STAT_LOCKED</td>
<td>The value assigned to the variable specified in a STAT= specifier of a LOCK statement if the lock variable is locked by the executing image.</td>
</tr>
<tr>
<td>STAT_LOCKED_OTHER_IMAGE</td>
<td>The value assigned to the variable specified in a STAT= specifier of an UNLOCK statement if the lock variable is locked by another image.</td>
</tr>
<tr>
<td>STAT_STOPPED_IMAGE</td>
<td>The value assigned to the variable specified in a STAT= specifier of a statement if execution of the statement requires synchronization with an image that has initiated termination of execution (ALLOCATE, DEALLOCATE, LOCK, SYNC ALL, SYNC IMAGES, SYNC MEMORY, or UNLOCK).</td>
</tr>
<tr>
<td>STAT_UNLOCKED</td>
<td>The value assigned to the variable specified in a STAT= specifier of an UNLOCK statement if the lock variable is unlocked.</td>
</tr>
</tbody>
</table>

The ISO_FORTRAN_ENV intrinsic module provides the following derived type:

LOCK_TYPE

This is a derived type with private components; none of the components can be allocatable or a pointer. It is an extensible type with no type parameters. It does not have the BIND (C) attribute or type parameters, and is not a sequence type. All components have default initialization.
A scalar variable of type LOCK_TYPE is a lock variable. A lock variable can have one of two states: locked or unlocked. The unlocked state is represented by the one value that is the initial value of a LOCK_TYPE variable. The locked state is represented by all other values. The value of a lock variable can be changed with the LOCK and UNLOCK statements.

A named variable of type LOCK_TYPE must be a coarray. A named variable with a noncoarray sub-component of type LOCK_TYPE must also be a coarray.

A lock variable must not appear in a variable definition context except as the lock-variable in a LOCK or UNLOCK statement, as an allocatable object, or as an actual argument in a reference to a procedure with an explicit interface where the corresponding dummy argument has INTENT (INOUT).

A variable with a subobject of type LOCK_TYPE must not appear in a variable definition context except as an allocatable object or as an actual argument in a reference to a procedure with an explicit interface where the corresponding dummy argument has INTENT (INOUT).

IEEE Intrinsic Modules and Procedures

Intel® Fortran includes IEEE intrinsic modules that support IEEE arithmetic and exception handling. The modules contain derived data types that include named constants for controlling the level of support, and intrinsic module procedures.

To include an IEEE module in your program, specify the intrinsic module name in a USE statement; for example:

USE, INTRINSIC :: IEEE_ARITHMETIC

You must include the INTRINSIC attribute or the processor will look for a non-intrinsic module. Once you include a module, all related intrinsic procedures are defined.

The following three IEEE intrinsic modules are described in this section:

- IEEE_ARITHMETIC
- IEEE_EXCEPTIONS
- IEEE_FEATURES

Determining Availability of IEEE Features

Before using a particular IEEE feature, you can determine whether your processor supports it by using the IEEE inquiry functions (listed in Table 1).

For example:

- To determine whether IEEE arithmetic is available for a particular kind of real, use intrinsic module function IEEE_SUPPORT_DATATYPE.
- To determine whether you can change a rounding mode, use intrinsic module function IEEE_SUPPORT_ROUNDING.
- To determine whether a divide operation will be supported with the accuracy specified by the IEEE standard, use intrinsic module function IEEE_SUPPORT_DIVIDE.
- To determine whether you can control halting after an exception has occurred, use intrinsic module function IEEE_SUPPORT_HALTING.
- To determine which exceptions are supported in a scoping unit, use intrinsic module function IEEE_SUPPORT_FLAG.
- To determine whether all IEEE features are supported, use intrinsic module function IEEE_SUPPORT_STANDARD.

Restrictions for IEEE Intrinsic Procedures

The following intrinsic procedures can only be invoked if IEEE_SUPPORT_DATATYPE is true for their arguments:

| IEEE_CLASS | IEEE_SUPPORT_DENORMAL |
IEEE_ARITHMETIC Intrinsic Module

The IEEE_ARITHMETIC module contains derived data types that include named constants for controlling the level of support, and intrinsic module procedures.

The derived types in the intrinsic modules have components that are private. The IEEE_ARITHMETIC intrinsic module supports IEEE arithmetic and features. It defines the following derived types:

- IEEE_CLASS_TYPE: Identifies a class of floating-point values. Its values are the following named constants:
IEEE_SIGNALING_NAN | IEEE_NEGATIVE_NORMAL
---|---
IEEE_QUIET_NAN | IEEE_POSITIVE_DENORMAL
IEEE_POSITIVE_INF | IEEE_NEGATIVE_DENORMAL
IEEE_NEGATIVE_INF | IEEE_POSITIVE_ZERO
IEEE_POSITIVE_NORMAL | IEEE_NEGATIVE_ZERO
IEEE_OTHER_VALUE

• IEEE_ROUND_TYPE: Identifies a rounding mode. Its values are the following named constants:

| IEEE_NEAREST | IEEE_TO_ZERO
---|---
IEEE_UP | IEEE_OTHER¹
IEEE_DOWN | ¹ Specifies the rounding mode does not conform to the IEEE standard.

The IEEE_ARITHMETIC intrinsic module also defines the following operators:

- Elemental operator `=` for two values of one of the above types to return true if the values are the same; otherwise, false.
- Elemental operator `=/` for two values of one of the above types to return true if the values differ; otherwise, false.

The IEEE_ARITHMETIC module includes support for IEEE_EXCEPTIONS module, and public entities in IEEE_EXCEPTIONS module are also public in the IEEE_ARITHMETIC module.

To see a summary of all the IEEE_ARITHMETIC intrinsic procedures, see IEEE Intrinsic Modules Quick Reference Tables.

### IEEE_EXCEPTIONS Intrinsic Module

The IEEE_EXCEPTIONS module contains derived data types that include named constants for controlling the level of support, and intrinsic module procedures.

The derived types in the intrinsic modules have components that are private. The IEEE_EXCEPTIONS intrinsic module supports the setting, clearing, saving, restoring, or testing of exception flags. It defines the following derived types:

- IEEE_FLAG_TYPE: Identifies an exception flag for errors that occur during an IEEE arithmetic operation or assignment. Its values are the following named constants:

| IEEE_INVALID | IEEE_DIVIDE_BY_ZERO
---|---
IEEE_OVERFLOW | IEEE_INEXACT
IEEE_UNDERFLOW |

Each of the above exceptions has a flag whose value is either quiet or signaling. The initial value is quiet and it signals when the associated exception occurs. To determine the value of a flag, use intrinsic module subroutine IEEE_GET_FLAG. To change the status for a flag, use intrinsic module subroutine IEEE_SET_FLAG or IEEE_SET_STATUS.

If a flag is signaling on entry to a procedure, the processor sets it to quiet on entry and restores it to signaling on return.

If a flag is quiet on entry to a procedure with access to modules IEEE_ARITHMETIC or IEEE_EXCEPTIONS, and is signaling on return, the processor will not restore it to quiet.

The IEEE_FLAG_TYPE module also defines the following named array constants:

- IEEE_USUAL=([IEEE_OVERFLOW,IEEE_DIVIDE_BY_ZERO, IEEE_INVALID])
- IEEE_ALL=([IEEE_USUAL,IEEE_UNDERFLOW,IEEE_INEXACT])
• **IEEE_STATUS_TYPE**: Saves the current floating-point status.

The **IEEE_ARITHMETIC** module includes support for **IEEE_EXCEPTIONS** module, and public entities in **IEEE_EXCEPTIONS** module are also public in the **IEEE_ARITHMETIC** module.

To see a summary of all the **IEEE_EXCEPTIONS** intrinsic procedures, see *IEEE Intrinsic Modules Quick Reference Tables*

**IEEE_FEATURES Intrinsic Module**

The **IEEE_FEATURES** module contains derived data types that include named constants for controlling the level of support, and intrinsic module procedures.

The derived types in the intrinsic modules have components that are private. The **IEEE_FEATURES** intrinsic module supports specification of essential IEEE features. It defines the following derived types:

• **IEEE_FEATURES_TYPE**: Specifies IEEE features. Its values are the following named constants:

<table>
<thead>
<tr>
<th>Derived Type</th>

Block Data Program Units Overview

A block data program unit provides initial values for nonpointer variables in named common blocks. For more information, see BLOCK DATA.

Examples

An example of a block data program unit follows:

```fortran
BLOCK DATA WORK
  COMMON /WRKCOM/ A, B, C (10,10)
  DATA A /1.0/, B /2.0/, C /100*0.0/
END BLOCK DATA WORK
```

Functions, Subroutines, and Statement Functions

Functions, subroutines, and statement functions are user-written subprograms that perform computing procedures. The computing procedure can be either a series of arithmetic operations or a series of Fortran statements. A single subprogram can perform a computing procedure in several places in a program, to avoid duplicating a series of operations or statements in each place.

The following table shows the statements that define these subprograms, and how control is transferred to the subprogram:

<table>
<thead>
<tr>
<th>Subprogram</th>

¹ A function can also be invoked by a defined operation (see Defining Generic Operators).
² A subroutine can also be invoked by a defined assignment (see Defining Generic Assignment).

A function reference is used in an expression to invoke a function; it consists of the function name and its actual arguments. The function reference returns a value to the calling expression that is used to evaluate the expression.

CALL

General Rules for Function and Subroutine Subprograms

A subprogram can be an external, module, or internal subprogram. The END statement for an internal or module subprogram must be END SUBROUTINE [name] for a subroutine, or END FUNCTION [name] for a function. In an external subprogram, the SUBROUTINE and FUNCTION keywords are optional.

If a subprogram name appears after the END statement, it must be the same as the name specified in the SUBROUTINE or FUNCTION statement.

Function and subroutine subprograms can change the values of their arguments, and the calling program can use the changed values.

A SUBROUTINE or FUNCTION statement can be optionally preceded by an OPTIONS statement.

Dummy arguments (except for dummy pointers or dummy procedures) can be specified with an intent and can be made optional.

RECURSIVE
PURE
Recursive Procedures
A recursive procedure is a function or subroutine that references itself, either directly or indirectly. For more information, see RECURSIVE.

Pure Procedures
A pure procedure is a user-defined procedure that has no side effects. For more information, see PURE.

Impure Procedures
An impure procedure is a user-defined procedure that has side effects. For more information, see IMPURE.

Elemental Procedures
An elemental procedure is a user-defined procedure defined on scalar arguments that may be called with array arguments. An elemental procedure is pure unless you specify that it is impure. For more information, see PURE, ELEMENTAL, and IMPURE.

Functions Overview
A function subprogram is invoked in an expression and returns a single value (a function result) that is used to evaluate the expression. For more information, see FUNCTION.

RESULT Keyword Overview
If you use the RESULT keyword in a FUNCTION statement, you can specify a local variable name for the function result. For more information, see RESULT.

Function References
Functions are invoked by a function reference in an expression or by a defined operation.

A function reference takes the following form:

$$\text{fun} \ ([\text{a-arg}, \text{a-arg}] \ldots)$$

- $\text{fun}$ is the name of the function subprogram or a procedure pointer.
- $\text{a-arg}$ is an actual argument optionally preceded by [keyword=], where $\text{keyword}$ is the name of a dummy argument in the explicit interface for the function. The keyword is assigned a value when the procedure is invoked.

Each actual argument must be a variable, an expression, or the name of a procedure. (It must not be the name of an internal procedure, statement function, or the generic name of a procedure.)

Description
When a function is referenced, each actual argument is associated with the corresponding dummy argument by its position in the argument list or by the name of its keyword. The arguments must agree in type and kind parameters.
Execution of the function produces a result that is assigned to the function name or to the result name, depending on whether the RESULT keyword was specified.

The program unit uses the result value to complete the evaluation of the expression containing the function reference.

If positional arguments and argument keywords are specified, the argument keywords must appear last in the actual argument list.

If a dummy argument is optional, the actual argument can be omitted.

If a dummy argument is specified with the INTENT attribute, its use may be limited. A dummy argument whose intent is not specified is subject to the limitations of its associated actual argument.

An actual argument associated with a dummy procedure must be the specific name of a procedure, or be another dummy procedure. Certain specific intrinsic function names must not be used as actual arguments (see table Specific Functions Not Allowed as Actual Arguments in Intrinsic Procedures Overview).

Examples
Consider the following example:

<table>
<thead>
<tr>
<th>X = 2.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>NEW_COS = COS(X) ! A function reference</td>
</tr>
</tbody>
</table>

Intrinsic function COS calculates the cosine of 2.0. The value -0.4161468 is returned (in place of COS(X)) and assigned to NEW_COS.

Subroutines Overview
A subroutine subprogram is invoked in a CALL statement or by a defined assignment statement, and does not return a particular value. For more information, see SUBROUTINE.

Statement Functions Overview
A statement function is a procedure defined by a single statement in the same program unit in which the procedure is referenced. For more information, see Statement Function.

Entry Points in Subprograms
The ENTRY statement provides multiple entry points within a subprogram. It is not executable and must precede any CONTAINS statement (if any) within the subprogram. For more information on the ENTRY statement, see ENTRY.

Entry Points in Function Subprograms
If the ENTRY statement is contained in a function subprogram, it defines an additional function. The name of the function is the name specified in the ENTRY statement, and its result variable is the entry name or the name specified by RESULT (if any).
If the entry result variable has the same characteristics as the FUNCTION statement's result variable, their result variables identify the same variable, even if they have different names. Otherwise, the result variables are storage associated and must all be nonpointer scalars of intrinsic type, in one of the following groups:

<table>
<thead>
<tr>
<th>Group</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>default integer, default real, double precision real, default complex, double complex, or default logical</td>
</tr>
<tr>
<td>2</td>
<td>REAL(16) and COMPLEX(16)</td>
</tr>
<tr>
<td>3</td>
<td>default character (with identical lengths)</td>
</tr>
</tbody>
</table>

All entry names within a function subprogram are associated with the name of the function subprogram. Therefore, defining any entry name or the name of the function subprogram defines all the associated names with the same data type. All associated names with different data types become undefined.

If RESULT is specified in the ENTRY statement and RECURSIVE is specified in the FUNCTION statement, the interface of the function defined by the ENTRY statement is explicit within the function subprogram.

**Examples**

The following example shows a function subprogram that computes the hyperbolic functions SINH, COSH, and TANH:

```fortran
REAL FUNCTION TANH(X)
    TSINH(Y) = EXP(Y) - EXP(-Y)
    TCOSH(Y) = EXP(Y) + EXP(-Y)
    TANH = TSINH(X)/TCOSH(X)
RETURN
END

ENTRY SINH(X)
    SINH = TSINH(X)/2.0
RETURN
END

ENTRY COSH(X)
    COSH = TCOSH(X)/2.0
RETURN
END
```

**See Also**

RESULT

**Entry Points in Subroutine Subprograms**

If the ENTRY statement is contained in a subroutine subprogram, it defines an additional subroutine. The name of the subroutine is the name specified in the ENTRY statement.

If RECURSIVE is specified on the SUBROUTINE statement, the interface of the subroutine defined by the ENTRY statement is explicit within the subroutine subprogram.

**Examples**

The following example shows a main program calling a subroutine containing an ENTRY statement:

```fortran
PROGRAM TEST
    ...
    CALL SUBA(A, B, C) ! A, B, and C are actual arguments
    ...
    ! passed to entry point SUBA
END

SUBROUTINE SUB(X, Y, Z)
    ...
ENTRY SUBA(Q, R, S) ! Q, R, and S are dummy arguments
    ...
    ! Execution starts with this statement
END SUBROUTINE
```
The following example shows an ENTRY statement specifying alternate returns:

```
CALL SUBC(M, N, *100, *200, P)
...
SUBROUTINE SUB(K, *, *)
  ...
ENTRY SUBC(J, K, *, *, X)
  ...
RETURN 1
RETURN 2
END
```

Note that the CALL statement for entry point SUBC includes actual alternate return arguments. The RETURN 1 statement transfers control to statement label 100 and the RETURN 2 statement transfers control to statement label 200 in the calling program.

**External Procedures**

External procedures are user-written functions or subroutines. They are located outside of the main program and can't be part of any other program unit.

External procedures can be invoked by the main program or any procedure of an executable program.

External procedures can include internal subprograms (defining internal procedures). Internal subprograms are placed after a CONTAINS statement.

An external procedure can reference itself (directly or indirectly).

The interface of an external procedure is implicit unless an interface block is supplied for the procedure.

**See Also**

*Functions, Subroutines, and Statement Functions*

*Procedure Interfaces*

**Internal Procedures**

Internal procedures are functions or subroutines that follow a CONTAINS statement in a program unit. The program unit in which the internal procedure appears is called its **host**.

Internal procedures can appear in the main program, in an external subprogram, or in a module subprogram.

An internal procedure takes the following form:

```
CONTAINS
  internal-subprogram
  [internal-subprogram] ...
```

*internal-subprogram* is a function or subroutine subprogram that defines the procedure. An internal subprogram must not contain any other internal subprograms.

**Description**

Internal procedures are the same as external procedures, except for the following:

- Only the host program unit can use an internal procedure.
- An internal procedure has access to host entities by host association; that is, names declared in the host program unit are useable within the internal procedure.
- In Standard Fortran, the name of an internal procedure must not be passed as an argument to another procedure. However, Intel® Fortran allows an internal procedure name to be passed as an actual argument to another procedure.
An internal procedure must not contain an ENTRY statement.

An internal procedure can reference itself (directly or indirectly); it can be referenced in the execution part of its host and in the execution part of any internal procedure contained in the same host (including itself).

The interface of an internal procedure is always explicit.

Examples

The following example shows an internal procedure:

```fortran
PROGRAM COLOR_GUIDE
    ...
    CONTAINS
    FUNCTION HUE(BLUE) ! An internal procedure
        ...
    END FUNCTION HUE
END PROGRAM
```

The following example program contains an internal subroutine `find`, which performs calculations that the main program then prints. The variables `a`, `b`, and `c` declared in the host program are also known to the internal subroutine.

```fortran
program INTERNAL
    ! shows use of internal subroutine and CONTAINS statement
    real a,b,c
    call find
    print *, c
contains
    subroutine find
        read *, a,b
        c = sqrt(a**2 + b**2)
    end subroutine find
end
```

CONTAINS

Argument Association in Procedures

Procedure arguments provide a way for different program units to access the same data.

When a procedure is referenced in an executable program, the program unit invoking the procedure can use one or more actual arguments to pass values to the procedure's dummy arguments. The dummy arguments are associated with their corresponding actual arguments when control passes to the subprogram.

In general, when control is returned to the calling program unit, the last value assigned to a dummy argument is assigned to the corresponding actual argument.

An actual argument can be a variable, expression, or procedure name. The type and kind parameters, and rank of the actual argument must match those of its associated dummy argument.

A dummy argument is either a dummy data object, a dummy procedure, or an alternate return specifier (*). Except for alternate return specifiers, dummy arguments can be optional.

If argument keywords are not used, argument association is positional. The first dummy argument becomes associated with the first actual argument, and so on. If argument keywords are used, arguments are associated by the keyword name, so actual arguments can be in a different order than dummy arguments.

A keyword is required for an argument only if a preceding optional argument is omitted or if the argument sequence is changed.

A scalar dummy argument can be associated with only a scalar actual argument.
If a dummy argument is an array, it must be no larger than the array that is the actual argument. You can use adjustable arrays to process arrays of different sizes in a single subprogram.

An actual argument associated with a dummy argument that is allocatable or a pointer must have the same type parameters as the dummy argument.

A dummy argument referenced as a subprogram must be associated with an actual argument that has been declared EXTERNAL or INTRINSIC in the calling routine.

If a scalar dummy argument is of type character, its length must not be greater than the length of its associated actual argument.

If the character dummy argument's length is specified as *(*) (assumed length), it uses the length of the associated actual argument.

Once an actual argument has been associated with a dummy argument, no action can be taken that affects the value or availability of the actual argument, except indirectly through the dummy argument. For example, if the following statement is specified:

```
CALL SUB_A (B(2:6), B(4:10))
```

B(4:6) must not be defined, redefined, or become undefined through either dummy argument, since it is associated with both arguments. However, B(2:3) is definable through the first argument, and B(7:10) is definable through the second argument.

Similarly, if any part of the actual argument is defined through a dummy argument, the actual argument can only be referenced through that dummy argument during execution of the procedure. For example, if the following statements are specified:

```fortran
MODULE MOD_A
  REAL :: A, B, C, D
END MODULE MOD_A

PROGRAM TEST
  USE MOD_A
  CALL SUB_1 (B)
  ...
END PROGRAM TEST

SUBROUTINE SUB_1 (F)
  USE MOD_A
  ...
  WRITE (*,*) F
END SUBROUTINE SUB_1
```

Variable B must not be directly referenced during the execution of SUB_1 because it is being defined through dummy argument F. However, B can be indirectly referenced through F (and directly referenced when SUB_1 completes execution).

The ultimate argument is the effective argument if the effective argument is not a dummy argument or a subobject of a dummy argument. If the effective argument is a dummy argument, the ultimate argument is the ultimate argument of that dummy argument. If the effective argument is a subobject of a dummy argument, the ultimate argument is the corresponding subobject of the ultimate argument of that dummy argument.

Consider the following sequence of subroutine calls:

```fortran
INTEGER :: X(100)
CALL SUBA (X)
...
SUBROUTINE SUBA(A)
INTEGER :: A(:)
CALL SUBB (A(1:5), A(5:1:-1))
...
SUBROUTINE SUBB(B, C)
INTEGER :: B(:), C(:)
```
The ultimate argument of B is X(1:5). The ultimate argument of C is X(5:1:-1), which is not the same object as the ultimate argument of B.

The following sections provide more details on arguments:

- Optional arguments
- The different kinds of arguments:
  - Array arguments
  - Pointer arguments
  - Passed-Object Dummy Arguments
  - Assumed-length character arguments
  - Character constant and Hollerith arguments
  - Alternate return arguments
  - Dummy procedure arguments
  - Coarray Dummy Arguments
- References to generic procedures
- References to non-Fortran procedures (%REF, %VAL, and %LOC)

See Also
CALL for details on argument keywords in subroutine references
Function References for details on argument keywords in function references

Optional Arguments

Dummy arguments can be made optional if they are declared with the OPTIONAL attribute. In this case, an actual argument does not have to be supplied for it in a procedure reference.

If argument keywords are not used, argument association is positional. The first dummy argument becomes associated with the first actual argument, and so on. If argument keywords are used, arguments are associated by the keyword name, so actual arguments can be in a different order than dummy arguments. A keyword is required for an argument only if a preceding optional argument is omitted or if the argument sequence is changed.

Positional arguments (if any) must appear first in an actual argument list, followed by keyword arguments (if any). If an optional argument is the last positional argument, it can simply be omitted if desired.

However, if the optional argument is to be omitted but it is not the last positional argument, keyword arguments must be used for any subsequent arguments in the list.

Optional arguments must have explicit procedure interfaces so that appropriate argument associations can be made.

The PRESENT intrinsic function can be used to determine if an actual argument is associated with an optional dummy argument in a particular reference.

A dummy argument or an entity that is host associated with a dummy argument is not present if any of the following are true for the dummy argument:

- It does not correspond to an actual argument.
- It corresponds to an actual argument that is not present.
- It does not have the ALLOCATABLE or POINTER attribute, and corresponds to one of the following:
  - An actual argument that has the ALLOCATABLE attribute and is not allocated
  - An actual argument that has the POINTER attribute and is disassociated

The following example shows optional arguments:

```fortran
PROGRAM RESULT
TEST_RESULT = LGFUNC(A, B=D)
...
CONTAINS
  FUNCTION LGFUNC(G, H, B)
    OPTIONAL H, B
```
In the function reference, A is a positional argument associated with required dummy argument G. The second actual argument D is associated with optional dummy argument B by its keyword name (B). No actual argument is associated with optional argument H.

The following shows another example:

```fortran
! Arguments can be passed out of order, but must be
! associated with the correct dummy argument.
CALL EXT1 (Z=C, X=A, Y=B)
... END

SUBROUTINE EXT1(X,Y,Z)
REAL X, Y
REAL, OPTIONAL :: Z
...
END SUBROUTINE
```

In this case, argument A is associated with dummy argument X by explicit assignment. Once EXT1 executes and returns, A is no longer associated with X, B is no longer associated with Y, and C is no longer associated with Z.

If you pass an omitted dummy argument as the actual argument to a procedure, the corresponding dummy argument is considered to be omitted as well. This applies to both intrinsic and non-intrinsic procedures. For example:

```fortran
CALL SUB1()
CONTAINS
  SUBROUTINE SUB1(B)
  LOGICAL, OPTIONAL :: B
  PRINT *, INDEX('Fortran','r',BACK=B) ! Prints 3
  CALL SUB2(B) ! Same as CALL SUB2()
  END SUBROUTINE SUB1
  
  SUBROUTINE SUB2(C)
  LOGICAL, OPTIONAL :: C
  PRINT *, PRESENT(C) ! Prints F
  END SUBROUTINE SUB2
END
```

CALL for details on argument keywords in subroutine references

Function References for details on argument keywords in function references

Array Arguments

Arrays are sequences of elements. Each element of an actual array is associated with the element of the dummy array that has the same position in array element order.

If the dummy argument is an explicit-shape or assumed-size array, the size of the dummy argument array must not exceed the size of the actual argument array.

The type and kind parameters of an explicit-shape or assumed-size dummy argument must match the type and kind parameters of the actual argument, but their ranks need not match.
If the dummy argument is an assumed-shape array, the size of the dummy argument array is equal to the size of the actual argument array. The associated actual argument must not be an assumed-size array or a scalar (including a designator for an array element or an array element substring).

If the actual argument is an array section with a vector subscript, the associated dummy argument must not be defined and it must not have the INTENT (OUT), INTENT (INOUT), VOLATILE, or ASYNCHRONOUS attribute.

If an actual argument is an array section or an assumed-shape array, and the corresponding dummy argument has either the VOLATILE or ASYNCHRONOUS attribute, that dummy argument must be an assumed-shape array.

If an actual argument is a pointer array, and the corresponding dummy argument has either the VOLATILE or ASYNCHRONOUS attribute, that dummy argument must be an assumed-shape array or a pointer array.

The declaration of an array used as a dummy argument can specify the lower bound of the array.

If a dummy argument is allocatable, the actual argument must be allocatable and the type parameters and ranks must agree. An example of an allocatable function with allocatable arrays appears in FUNCTION.

Dummy argument arrays declared as assumed-shape, deferred-shape, or pointer arrays require an explicit interface visible to the caller.

Array Elements for details on array element order
Explicit-Shape Specifications for details on explicit-shape arrays
Assumed-Shape Specifications for details on assumed-shape arrays
Assumed-Size Specifications for details on assumed-size arrays

**Pointer Arguments**

An argument is a pointer if it is declared with the POINTER attribute.

When a procedure is invoked, the dummy argument pointer receives the pointer association status of the actual argument. If the actual argument is currently associated, the dummy argument becomes associated with the same target.

The pointer association status of the dummy argument can change during the execution of the procedure, and any such changes are reflected in the actual argument.

If both the dummy and actual arguments are pointers, an explicit interface is required.

A dummy argument that is a pointer can be associated only with an actual argument that is a pointer. However, an actual argument that is a pointer can be associated with a nonpointer dummy argument. In this case, the actual argument is associated with a target and the dummy argument, through argument association, also becomes associated with that target.

If the dummy argument does not have the TARGET or POINTER attribute, any pointers associated with the actual argument do not become associated with the corresponding dummy argument when the procedure is invoked.

If the dummy argument has the TARGET attribute, and is either a scalar or assumed-shape array, and the corresponding actual argument has the TARGET attribute but is not an array section with a vector subscript, the following occurs:

- Any pointer associated with the actual argument becomes associated with the corresponding dummy argument when the procedure is invoked.
- Any pointers associated with the dummy argument remain associated with the actual argument when execution of the procedure completes.

If the dummy argument has the TARGET attribute, and is an explicit-shape or assumed-size array, and the corresponding actual argument has the TARGET attribute but is not an array section with a vector subscript, association of actual and corresponding dummy arguments when the procedure is invoked or when execution is completed is processor dependent.
If the dummy argument has the TARGET attribute and the corresponding actual argument does not have that attribute or is an array section with a vector subscript, any pointer associated with the dummy argument becomes undefined when execution of the procedure completes.

POINTER - Fortran
Pointer Assignments
TARGET Statement
Argument Association in Procedures for details on general rules for procedure argument association

Passed-Object Dummy Arguments
A procedure component or a binding procedure (type-bound procedure) can be declared to have a passed-object dummy argument. This kind of argument is associated with a special actual argument, which is not explicitly written in the actual argument list. The appropriate actual argument is then added to the argument list.

A passed-object dummy argument must be a scalar. It must not be a pointer, must not be allocatable, and all its length type parameters must be assumed. Its declared type must be the type in which the component or binding procedure appears.

The passed-object dummy argument must be a scalar, nonpointer, nonallocatable dummy data object. Its declared type must be the type in which the component or binding appears. All of its length type parameters must be assumed.

The determination of the passed-object dummy argument depends on the following:

- The PASS and NOPASS attributes specified or in effect
- The interface of the procedure component or binding procedure

The following rules apply to PASS and NOPASS:

- PASS and NOPASS are mutually exclusive. You can only specify one of these attributes for the same procedure component or binding.
- If you specify PASS (arg-name), dummy argument arg-name is the passed-object dummy argument. The interface of the procedure pointer component or binding procedure must have a dummy argument named arg-name.
- If NOPASS is specified, there is no passed-object dummy argument.
- NOPASS must be specified if the procedure component or binding procedure has an implicit interface.
- If you do not specify PASS or NOPASS, or you specify PASS without arg-name, the first dummy argument of a procedure pointer component or binding procedure is the passed-object dummy argument. In this case, there must be at least one dummy argument.

See Also
TYPE Statement (Derived Types)
Passed-Object Dummy Arguments

Assumed-Length Character Arguments
An assumed-length character argument is a dummy argument that assumes the length attribute of its corresponding actual argument. An asterisk (*) specifies the length of the dummy character argument.

A character array dummy argument can also have an assumed length. The length of each element in the dummy argument is the length of the elements in the actual argument. The assumed length and the array declarator together determine the size of the assumed-length character array.

The following example shows an assumed-length character argument:

```fortran
INTEGER FUNCTION ICMAX(CVAR)
    CHARACTER*(*) CVAR
    ICMAX = 1
    DO I=2,LEN(CVAR)
        IF (CVAR(I:I) .GT. CVAR(ICMAX:ICMAX)) ICMAX=I
    END DO
END FUNCTION ICMAX
```
The function ICMAX finds the position of the character with the highest ASCII code value. It uses the length of the assumed-length character argument to control the iteration. Intrinsic function LEN determines the length of the argument.

The length of the dummy argument is determined each time control transfers to the function. The length of the actual argument can be the length of a character variable, array element, substring, or expression. Each of the following function references specifies a different length for the dummy argument:

```
CHARACTER VAR*10, CARRAY(3,5)*20
...
I1 = ICMAX(VAR)
I2 = ICMAX(CARRAY(2,2))
I3 = ICMAX(VAR(3:8))
I4 = ICMAX(CARRAY(1,3)(5:15))
I5 = ICMAX(VAR(3:4)//CARRAY(3,5))
```

See Also
LEN
Argument Association in Procedures for details on general rules for procedure argument association

Character Constant and Hollerith Arguments

If an actual argument is a character constant (for example, 'ABCD'), the corresponding dummy argument must be of type character. If an actual argument is a Hollerith constant (for example, 4HABCD), the corresponding dummy argument must have a numeric data type.

The following example shows character and Hollerith constants being used as actual arguments:

```
SUBROUTINE S(CHARSUB, HOLLSUB, A, B)
EXTERNAL CHARSUB, HOLLSUB
...
CALL CHARSUB(A, 'STRING')
CALL HOLLSUB(B, 6HSTRING)
```

The subroutines CHARSUB and HOLLSUB are themselves dummy arguments of the subroutine S. Therefore, the actual argument 'STRING' in the call to CHARSUB must correspond to a character dummy argument, and the actual argument 6HSTRING in the call to HOLLSUB must correspond to a numeric dummy argument.

See Also
Argument Association in Procedures for details on general rules for procedure argument association

Alternate Return Arguments

Alternate return (dummy) arguments can appear in a subroutine argument list. They cause execution to transfer to a labeled statement rather than to the statement immediately following the statement that called the routine. The alternate return is indicated by an asterisk (*). (An alternate return is an obsolescent feature in Standard Fortran.)

There can be any number of alternate returns in a subroutine argument list, and they can be in any position in the list.

An actual argument associated with an alternate return dummy argument is called an alternate return specifier; it is indicated by an asterisk (*) or ampersand (&) followed by the label of an executable branch target statement in the same scoping unit as the CALL statement.

Alternate returns cannot be declared optional.

You can also use the RETURN statement to specify alternate returns.
The following example shows alternate return actual and dummy arguments:

```fortran
CALL MINN(X, Y, *300, *250, Z)
...
SUBROUTINE MINN(A, B, *, *, C)
```

See Also
Argument Association in Procedures for details on general rules for procedure argument association
SUBROUTINE
CALL
RETURN
Deleted and Obsolescent Language Features for details on obsolescent features in Standard Fortran

 Dummy Procedure Arguments

If an actual argument is a procedure, its corresponding dummy argument is a dummy procedure. Dummy procedures can appear in function or subroutine subprograms.

The actual argument must be the specific name of an external, module, intrinsic, or another dummy procedure. If the specific name is also a generic name, only the specific name is associated with the dummy argument. Not all specific intrinsic procedures can appear as actual arguments. (For more information, see table Specific Functions Not Allowed as Actual Arguments in Intrinsic Procedures Overview.)

The actual argument and corresponding dummy procedure must both be subroutines or both be functions.

If the interface of the dummy procedure is explicit, the type and kind parameters, and rank of the associated actual procedure must be the same as that of the dummy procedure.

If the interface of the dummy procedure is implicit and the procedure is referenced as a subroutine, the actual argument must be a subroutine or a dummy procedure.

If the interface of the dummy procedure is implicit and the procedure is referenced as a function or is explicitly typed, the actual argument must be a function or a dummy procedure.

Dummy procedures can be declared optional, but they must not be declared with an intent.

The following is an example of a procedure used as an argument:

```fortran
REAL FUNCTION LGFUNC(BAR)
  INTERFACE
    REAL FUNCTION BAR(Y)
      REAL, INTENT(IN) :: Y
    END
  END INTERFACE
  ...
LGFUNC = BAR(2.0)
...
END FUNCTION LGFUNC
```

See Also
Argument Association in Procedures for details on general rules for procedure argument association

 Coarray Dummy Arguments

If a dummy argument is a coarray, the corresponding actual argument must be a coarray and must have the VOLATILE attribute if and only if the dummy argument has the VOLATILE attribute.

If a dummy argument is an array coarray that has the CONTIGUOUS attribute or is not of assumed shape, the corresponding actual argument must be simply contiguous.
Examples

When a procedure is invoked on a particular image, each dummy coarray is associated with its ultimate argument on the image. During the execution of the procedure, this image can access the coarray corresponding to the ultimate argument on any other image. For example, consider the following:

```fortran
INTERFACE
   SUBROUTINE MY_SUB(Y)
      REAL :: Y[*]
   END SUBROUTINE MY_SUB
END INTERFACE
...
REAL :: B(700)[*]
...
CALL MY_SUB(B(10))
```

When subroutine `MY_SUB` is invoked, the executing image has access through the syntax `Y[P]` to `B(10)` on image `P`.

Each invocation of a procedure with a nonallocatable coarray dummy argument establishes a dummy coarray for the image with its own bounds and cobounds. During the execution of the procedure, this image may use its own bounds and cobounds to access the coarray corresponding to the ultimate argument on any other image. For example, consider the following:

```fortran
INTERFACE
   SUBROUTINE MY_SUB(Y,I)
      INTEGER :: I
      REAL :: Y(I,I)[I,*]
   END SUBROUTINE MY_SUB
END INTERFACE
...
REAL :: B(1000)[*]
...
CALL MY_SUB(B,10)
```

When subroutine `MY_SUB` is invoked, the executing image has access through the syntax `Y(1,2)[3,4]` to `B(11)` on the image with image index 33.

Image Control Statements

References to Generic Procedures

Generic procedures are procedures with different specific names that can be accessed under one generic (common) name. In FORTRAN 77, generic procedures were limited to intrinsic procedures. In the current Fortran standard, you can use generic interface blocks to specify generic properties for intrinsic and user-defined procedures.

If you refer to a procedure by using its generic name, the selection of the specific routine is based on the number of arguments and the type and kind parameters, and rank of each argument.

All procedures given the same generic name must be subroutines, or all must be functions. Any two must differ enough so that any invocation of the procedure is unambiguous.

The following sections describe references to generic intrinsic functions and show an example of using intrinsic function names.

Defining Generic Names for Procedures for details on user-defined generic procedures
References to Generic Intrinsic Functions

The generic intrinsic function name COS lists six specific intrinsic functions that calculate cosines: COS, DCOS, QCOS, CCOS, CDCOS, and CQCOS. These functions return different values: REAL(4), REAL(8), REAL(16), COMPLEX(4), COMPLEX(8), and COMPLEX(16) respectively.

If you invoke the cosine function by using the generic name COS, the compiler selects the appropriate routine based on the arguments that you specify. For example, if the argument is REAL(4), COS is selected; if it is REAL(8), DCOS is selected; and if it is COMPLEX(4), CCOS is selected.

You can also explicitly refer to a particular routine. For example, you can invoke the double-precision cosine function by specifying DCOS.

Procedure selection occurs independently for each generic reference, so you can use a generic reference repeatedly in the same program unit to access different intrinsic procedures.

You cannot use generic function names to select intrinsic procedures if you use them as follows:

- The name of a statement function
- A dummy argument name, a common block name, or a variable or array name

When an intrinsic function is passed as an actual argument to a procedure, its specific name must be used, and when called, its arguments must be scalar. Not all specific intrinsic functions can appear as actual arguments. (For more information, see table Specific Functions Not Allowed as Actual Arguments in Intrinsic Procedures Overview.)

A reference to a generic intrinsic procedure name in a program unit does not prevent use of the name for other purposes elsewhere in the program.

Normally, an intrinsic procedure name refers to the Fortran library procedure with that name. However, the name can refer to a user-defined procedure when the name appears in an EXTERNAL statement.

NOTE
If you call an intrinsic procedure by using the wrong number of arguments or an incorrect argument type, the compiler assumes you are referring to an external procedure. For example, intrinsic procedure SIN requires one argument; if you specify two arguments, such as SIN(10,4), the compiler assumes SIN is external and not intrinsic.

The data type of an intrinsic procedure does not change if you use an IMPLICIT statement to change the implied data type rules.

Intrinsic and user-defined procedures cannot have the same name if they appear in the same program unit.

Examples

The following example shows the local and global properties of an intrinsic function name. It uses the name SIN in different procedures as follows:

- The name of a statement function
- The generic name of an intrinsic function
- The specific name of an intrinsic function
- The name of a user-defined function

Using and Redefining an Intrinsic Function Name

! Compare ways of computing sine
PROGRAM SINES
    DOUBLE PRECISION X, PI
    PARAMETER (PI=3.141592653589793238D0)
    COMMON V(3)
!
! Define SIN as a statement function
    SIN(X) = COS(PI/2-X)
    print *, "Way of computing SIN(X)"
    print *
print *, "      X       Statement   Intrinsic   Intrinsic     User's "
print *, "              function      DSIN       SIN as arg     SIN "
print *
DO X = -PI, PI, PI/2
   CALL COMPUT(X)
END DO
! References the statement function SIN
WRITE (6,100) X, SIN(X), V
END
100      FORMAT (5F12.7)
END

SUBROUTINE COMPUT(Y)
DOUBLE PRECISION Y
! Use intrinsic function SIN - double-precision DSIN will be passed as an actual argument
INTRINSIC SIN
COMMON V(3)
! Makes the generic name SIN reference the double-precision sine DSIN
V(1) = SIN(Y)
! Use intrinsic function SIN as an actual argument - will pass DSIN
CALL SUB(REAL(Y),SIN)
END

SUBROUTINE SUB(A,S)
! Declare SIN as name of a user function
EXTERNAL SIN
! Declare SIN as type DOUBLE PRECISION
DOUBLE PRECISION SIN
COMMON V(3)
! Evaluate intrinsic function SIN passed as the dummy argument
V(2) = S(A)
! Evaluate user-defined SIN function
V(3) = SIN(A)
END

! Define the user SIN function
DOUBLE PRECISION FUNCTION SIN(X)
INTEGER FACTOR
   SIN = X - X**3/FACTOR(3) + X**5/FACTOR(5) - X**7/FACTOR(7)
END

! Compute the factorial of N
INTEGER FUNCTION FACTOR(N)
   FACTOR = 1
   DO I=N,1,-1
      FACTOR = FACTOR * I
   END DO
END
The statement function named SIN is defined in terms of the generic function name COS. Because the argument of COS is double precision, the double-precision cosine function is evaluated. The statement function SIN is itself single precision.

The statement function SIN is called.

The name SIN is declared intrinsic so that the single-precision intrinsic sine function can be passed as an actual argument at 5.

The generic function name SIN is used to refer to the double-precision sine function.

The single-precision intrinsic sine function is used as an actual argument.

The name SIN is declared a user-defined function name.

The type of SIN is declared double precision.

The single-precision sine function passed at 5 is evaluated.

The user-defined SIN function is evaluated.

The user-defined SIN function is defined as a simple Taylor series using a user-defined function FACTOR to compute the factorial function.

References to Elemental Intrinsic Procedures

An elemental intrinsic procedure has scalar dummy arguments that can be called with scalar or array actual arguments. If actual arguments are array-valued, they must have the same shape. There are many elemental intrinsic functions, but only one elemental intrinsic subroutine (MVBITS).

If the actual arguments are scalar, the result is scalar. If the actual arguments are array-valued, the scalar-valued procedure is applied element-by-element to the actual argument, resulting in an array that has the same shape as the actual argument.

The values of the elements of the resulting array are the same as if the scalar-valued procedure had been applied separately to the corresponding elements of each argument.

For example, if A and B are arrays of shape (5,6), MAX(A, 0.0, B) is an array expression of shape (5,6) whose elements have the value MAX(A(i, j), 0.0, B(i, j)), where i = 1, 2,..., 5, and j = 1, 2,..., 6.

A reference to an elemental intrinsic procedure is an elemental reference if one or more actual arguments are arrays and all array arguments have the same shape.

Examples

Consider the following:

```fortran
REAL, DIMENSION (2) :: a, b
a(1) = 4; a(2) = 9
b = SQRT(a) ! sets b(1) = SQRT(a(1)), and b(2) = SQRT(a(2))
```

  Arrays
  Intrinsic Procedures Overview for details on elemental procedures
References to Non-Fortran Procedures

When a procedure is called, Fortran (by default) passes the address of the actual argument, and its length if it is of type character. To call non-Fortran procedures, you may need to pass the actual arguments in a form different from that used by Fortran.

The built-in functions %REF and %VAL let you change the form of an actual argument. You must specify these functions in the actual argument list of a CALL statement or function reference. You cannot use them in any other context.

%LOC computes the internal address of a storage item.

Procedure Interfaces

Every procedure has an interface, which consists of the name and characteristics of a procedure, the name and characteristics of each dummy argument, and the generic identifier (if any) by which the procedure can be referenced. The characteristics of a procedure are fixed, but the remainder of the interface can change in different scoping units.

If these properties are all known within the scope of the calling program, the procedure interface is explicit; otherwise it is implicit (deduced from its reference and declaration). The following table shows which procedures have implicit or explicit interfaces:

<table>
<thead>
<tr>
<th>Kind of Procedure</th>
<th>Interface</th>
</tr>
</thead>
<tbody>
<tr>
<td>External procedure</td>
<td>Implicit</td>
</tr>
<tr>
<td>Module procedure</td>
<td>Explicit</td>
</tr>
<tr>
<td>Internal procedure</td>
<td>Explicit</td>
</tr>
<tr>
<td>Intrinsic procedure</td>
<td>Explicit</td>
</tr>
<tr>
<td>Dummy procedure</td>
<td>Implicit</td>
</tr>
<tr>
<td>Statement function</td>
<td>Implicit</td>
</tr>
</tbody>
</table>

1 This kind of procedure is explicit in a scoping unit other than its own if an interface body for the procedure is supplied or is accessible.

The interface of a recursive subroutine or function is explicit within the subprogram that defines it.

An explicit interface can appear in a procedure's definition, in an interface block, or both. (Internal procedures must not appear in an interface block.)

An abstract interface lets you give a name to a set of characteristics and argument keyword names that create an explicit interface to a procedure. It does not declare any actual procedure to have those characteristics.

You can use a procedure declaration statement to declare procedure pointers, dummy procedures, and external procedures. It specifies the EXTERNAL attribute for all procedure entities in the procedure declaration list.

You can use the IMPORT statement to make host entities accessible in the interface body of an interface block.

You can specify the ALLOCATABLE, OPTIONAL, or POINTER attributes for a dummy argument in a procedure interface that has the BIND attribute.

Examples

An example of an interface block follows:

```
INTERFACE
  SUBROUTINE Ext1 (x, y, z)
  REAL, DIMENSION (100,100) :: x, y, z
END SUBROUTINE Ext1
```
SUBROUTINE Ext2 (x, z)
  REAL x
  COMPLEX (KIND = 4) z (2000)
END SUBROUTINE Ext2

FUNCTION Ext3 (p, q)
  LOGICAL Ext3
  INTEGER p (1000)
  LOGICAL q (1000)
END FUNCTION Ext3
END INTERFACE

IMPORT

Procedures that Require Explicit Interfaces

When a procedure is referenced, it must have an explicit interface in the following cases:

- If a reference to the procedure appears in one of the following:
  - An actual argument that is specified with a keyword
  - In a context that requires it to be PURE
- If the procedure has a dummy argument that is one of the following:
  - An object that has the ALLOCATABLE, ASYNCHRONOUS, OPTIONAL, POINTER, TARGET, VALUE, or VOLATILE attribute
  - An assumed-shape array
  - A polymorphic object (an object declared with a CLASS statement)
  - A coarray (an object declared with a CODIMENSION attribute or statement)
  - An object of a parameterized derived type
  - An object of assumed-rank or assumed-type
- If the procedure has any of the following:
  - A result that is an array, or a pointer, or is allocatable (functions only)
  - A result whose length is neither assumed nor a constant (character functions only)
- If a reference to the procedure appears as follows:
  - With an argument keyword
  - As a reference by its generic name
  - As a defined assignment (subroutines only)
  - In an expression as a defined operator (functions only)
  - In a context that requires it to be pure
- If the procedure is elemental
- If the procedure has the BIND attribute

Statement functions do not require an explicit interface.

Explicit and Abstract Interfaces

An explicit interface defines characteristics for external or dummy procedures. It can also be used to define a generic name for procedures, a new operator for functions, and a new form of assignment for subroutines. For more information, see INTERFACE.

An abstract interface defines a subprogram whose name can be used in a PROCEDURE declaration statement to declare subprograms with identical arguments and characteristics. For more information, see ABSTRACT INTERFACE and PROCEDURE.

Defining Generic Names for Procedures

An interface block can be used to specify a generic name to reference all of the procedures within the interface block.

The initial line for such an interface block takes the following form:

```
INTERFACE generic-name
```

```
generic-name
```

Is the generic name. It can be the same as any of the procedure names in the interface block, or the same as any accessible generic name (including a generic intrinsic name).

A generic name can be the same as a derived-type name. In this case, all of the procedures in the interface block must be functions.

This kind of interface block can be used to extend or redefine a generic intrinsic procedure.

The procedures that are given the generic name must be the same kind of subprogram: all must be functions, or all must be subroutines.

Any procedure reference involving a generic procedure name must be resolvable to one specific procedure; it must be unambiguous. For more information, see Unambiguous Generic Procedure References.

The following is an example of a procedure interface block defining a generic name:

```
INTERFACE GROUP_SUBS
  SUBROUTINE INTEGER_SUB (A, B)
    INTEGER, INTENT(INOUT) :: A, B
  END SUBROUTINE INTEGER_SUB
  SUBROUTINE REAL_SUB (A, B)
    REAL, INTENT(INOUT) :: A, B
  END SUBROUTINE REAL_SUB
  SUBROUTINE COMPLEX_SUB (A, B)
    COMPLEX, INTENT(INOUT) :: A, B
  END SUBROUTINE COMPLEX_SUB
END INTERFACE
```

The three subroutines can be referenced by their individual specific names or by the group name GROUP_SUBS.

The following example shows a reference to INTEGER_SUB:

```
INTEGER V1, V2
CALL GROUP_SUBS (V1, V2)
```

Consider the following:

```
INTERFACE LINE_EQUATION
  SUBROUTINE REAL_LINE_EQ(X1,Y1,X2,Y2,M,B)
  END SUBROUTINE REAL_LINE_EQ
END INTERFACE
```

```
SUBROUTINE REAL_LINE_EQ(X1,Y1,X2,Y2,M,B)
```

```
INTEGER V1, V2
CALL GROUP_SUBS (V1, V2)
```

```
In this example, LINE_EQUATION is the generic name which can be used for either REAL_LINE_EQ or INT_LINE_EQ. Fortran selects the appropriate subroutine according to the nature of the arguments passed to LINE_EQUATION. Even when a generic name exists, you can always invoke a procedure by its specific name. In the previous example, you can call REAL_LINE_EQ by its specific name (REAL_LINE_EQ), or its generic name LINE_EQUATION.

See Also
INTERFACE statement for details on interface blocks

Defining Generic Operators

An interface block can be used to define a generic operator. The only procedures allowed in the interface block are functions that can be referenced as defined operations.

The initial line for such an interface block takes the following form:

```
INTERFACE OPERATOR (op)
```

Is one of the following:

- A defined unary operator (one argument)
- A defined binary operator (two arguments)
- An extended intrinsic operator (number of arguments must be consistent with the intrinsic uses of that operator)

The functions within the interface block must have one or two nonoptional arguments with intent IN, and the function result must not be of type character with assumed length. A defined operation is treated as a reference to the function.

The following shows the form (and an example) of a defined unary and defined binary operation:

<table>
<thead>
<tr>
<th>Operation</th>
<th>Form</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Defined Unary</td>
<td>.defined-operator. operand1</td>
<td>.MINUS. C</td>
</tr>
<tr>
<td>Defined Binary</td>
<td>operand2 .defined-operator. operand3</td>
<td>B .MINUS. C</td>
</tr>
</tbody>
</table>

1 The operand corresponds to the function's dummy argument.
2 The left operand corresponds to the first dummy argument of the function.
3 The right operand corresponds to the second argument.

For intrinsic operator symbols, the generic properties include the intrinsic operations they represent. Both forms of each relational operator have the same interpretation, so extending one form (such as >=) defines both forms (>= and .GE.).

The following is an example of a procedure interface block defining a new operator:

```
INTERFACE OPERATOR(.BAR.)
  FUNCTION BAR(A_1)
    INTEGER, INTENT(IN) :: A_1
    INTEGER :: BAR
  END FUNCTION BAR
END INTERFACE
```
The following example shows a way to reference function BAR by using the new operator:

```
INTEGER B
I = 4 + (.BAR. B)
```

The following is an example of a procedure interface block with a defined operator extending an existing operator:

```
INTERFACE OPERATOR(+)
  FUNCTION LGFUNC (A, B)
    LOGICAL, INTENT(IN) :: A(:), B(SIZE(A))
    LOGICAL :: LGFUNC(SIZE(A))
  END FUNCTION LGFUNC
END INTERFACE
```

The following example shows two equivalent ways to reference function LGFUNC:

```
LOGICAL, DIMENSION(1:10) :: C, D, E
N = 10
E = LGFUNC(C(1:N), D(1:N))
E = C(1:N) + D(1:N)
```

- Expressions for details on intrinsic operators
- Defined Operations for details on defined operators and operations

Defining Generic Assignment

An interface block can be used to define generic assignment. The only procedures allowed in the interface block are subroutines that can be referenced as defined assignments.

The initial line for such an interface block takes the following form:

```
INTERFACE ASSIGNMENT (=)
```

The subroutines within the interface block must have two nonoptional arguments, the first with intent OUT or INOUT, and the second with intent IN.

A defined assignment is treated as a reference to a subroutine. The left side of the assignment corresponds to the first dummy argument of the subroutine; the right side of the assignment corresponds to the second argument.

The ASSIGNMENT keyword extends or redefines an assignment operation if both sides of the equal sign are of the same derived type.

Defined elemental assignment is indicated by specifying ELEMENTAL in the SUBROUTINE statement.

Any procedure reference involving generic assignment must be resolvable to one specific procedure; it must be unambiguous. For more information, see Unambiguous Generic Procedure References.

The following is an example of a procedure interface block defining assignment:

```
INTERFACE ASSIGNMENT (=)
  SUBROUTINE BIT_TO_NUMERIC (NUM, BIT)
    INTEGER, INTENT(OUT) :: NUM
    LOGICAL, INTENT(IN)  :: BIT(:)
  END SUBROUTINE BIT_TO_NUMERIC

  SUBROUTINE CHAR_TO_STRING (STR, CHAR)
    USE STRING_MODULE   ! Contains definition of type STRING
    TYPE(STRING), INTENT(OUT) :: STR   ! A variable-length string
    CHARACTER(*), INTENT(IN)  :: CHAR
  END SUBROUTINE CHAR_TO_STRING
END INTERFACE
```
The following example shows two equivalent ways to reference subroutine BIT_TO_NUMERIC:

```
CALL BIT_TO_NUMERIC(X, (NUM(I:J)))
X = NUM(I:J)
```

The following example shows two equivalent ways to reference subroutine CHAR_TO_STRING:

```
CALL CHAR_TO_STRING(CH, '432C')
CH = '432C'
```

Defined Assignment Statements
INTENT
INTERFACE for details on interface blocks

Interoperability of Procedures and Procedure Interfaces

A Fortran procedure is interoperable if it has the BIND attribute.

A Fortran procedure interface is interoperable with a C function prototype if the following is true:

- The interface has the BIND attribute
- One of the following is true:
  - The interface describes a function whose result variable is a scalar that is interoperable with the result of the prototype.
  - The interface describes a subroutine and the prototype has a result type of void.
- The number of dummy arguments of the interface is equal to the number of formal parameters of the prototype.
- Any dummy argument with the VALUE attribute is interoperable with the corresponding formal parameter of the prototype.
- Any dummy argument without the VALUE attribute corresponds to a formal parameter of the prototype that is of a pointer type, and one of the following is true:
  - The dummy argument is interoperable with an entity of the referenced type of the formal parameter.
  - The dummy argument is a nonallocatable nonpointer variable of type CHARACTER with assumed character length and the formal parameter is a pointer to the C descriptor descriptor CFI_cdesc_t.
  - The dummy argument is allocatable, assumed-shape, assumed-rank, or a pointer without the CONTIGUOUS attribute, and the formal parameter is a pointer to the C descriptor descriptor CFI_cdesc_t.
  - The dummy argument is assumed-type and not allocatable, assumed-shape, assumed-rank, or a pointer, and the formal parameter is a pointer to void.
- Each allocatable or pointer dummy argument of type CHARACTER has deferred character length.
- The prototype does not have variable arguments as denoted by an ellipsis (...).

In an invocation of an interoperable procedure whose Fortran interface has an assumed-shape or assumed-rank dummy argument with the CONTIGUOUS attribute, the associated effective argument can be an array that is not contiguous or it can be the address of a C descriptor for such an array.

If the procedure is invoked from Fortran or the procedure is a Fortran procedure, the Fortran processor will handle the difference in contiguity.

If the procedure is invoked from C or the procedure is a C procedure, the C code within the procedure must be able to handle the situation of receiving a discontiguous argument.

An actual argument that is absent in a reference to an interoperable procedure is indicated by a corresponding formal parameter with the value of a null pointer. An optional dummy argument that is absent in a reference to an interoperable procedure from a C function is indicated by a corresponding argument with the value of a null pointer.

The following rules also apply:

- C functions must not invoke a function pointer whose value is the result of a reference to C_FUNLOC with a noninteroperable argument.
When passing an argument to a C procedure where the corresponding C formal parameter is a C descriptor, Fortran must pass a C descriptor and, on return, ensure that any updates to the C descriptor are reflected in Fortran.

If the interface specifies that the dummy argument is CONTIGUOUS, the passed argument (and the C descriptor’s description of that argument, if relevant) must be contiguous.

A Fortran procedure with BIND(C) that has a dummy argument that is assumed-length CHARACTER or is allocatable, assumed-shape, assumed-rank, or a pointer without CONTIGUOUS must accept that argument as a C descriptor and make sure that on return, the C descriptor reflects any changes made to the argument during execution of the Fortran procedure.

A Fortran procedure with one of the following arguments must accept that argument as a C descriptor and make sure that on return, the C descriptor reflects any changes made to the argument during execution of the Fortran procedure:

- A dummy argument that is assumed-length CHARACTER
- A dummy argument that is allocatable, assumed-shape, assumed-rank, or a pointer without CONTIGUOUS

**Procedure Pointers**

A procedure pointer has the POINTER attribute and points to a procedure instead of a data object. It can be associated with an external procedure, a module procedure, an intrinsic procedure, or a dummy procedure that is not a procedure pointer. It can have an implicit or explicit interface, but the interface cannot be generic or elemental.

A procedure pointer can be one of the following:

- A named pointer (described below)
- A derived-type component (See Procedure Pointers as Derived-Type Components.)

**Procedure Pointers as Named Pointers**

You can declare a procedure pointer in a procedure declaration statement by including the POINTER attribute. For example:

```fortran
PROCEDURE(QUARK), POINTER :: Q => NULL()
```

The above declares Q to be a procedure pointer with interface QUARK; it also initializes Q to be a disassociated pointer.

A named procedure pointer can also be declared by specifying the POINTER attribute in addition to the normal procedure declaration.

The following example uses a type declaration statement to declare a procedure pointer:

```fortran
POINTER :: MyP
INTERFACE
  SUBROUTINE MyP(c,d)
    REAL, INTENT(INOUT) :: c
    REAL, INTENT(IN) :: d
  END SUBROUTINE MyP
END INTERFACE
REAL, EXTERNAL, POINTER :: MyR
```

The above specifies that MyP is a pointer to a subroutine with an explicit interface. It also specifies that MyR is a pointer to a scalar REAL function with an implicit interface.

Note that in a type declaration statement, you must specify the EXTERNAL attribute as well as the POINTER attribute when declaring the procedure pointer.

ABSTRACT INTERFACE
PROCEDURE
Intrinsic Procedures

Intrinsic Procedures Overview

Intrinsic procedures are functions and subroutines that are included in the Fortran library. There are four classes of these intrinsic procedures, as follows:

- Elemental procedures

  These procedures have scalar dummy arguments that can be called with scalar or array actual arguments. There are many elemental intrinsic functions and one elemental intrinsic subroutine (MVBITS).

  If the arguments are all scalar, the result is scalar. If an actual argument is array-valued, the intrinsic procedure is applied to each element of the actual argument, resulting in an array that has the same shape as the actual argument.

  If there is more than one array-valued argument, they must all have the same shape.

  Many algorithms involving arrays can now be written conveniently as a series of computations with whole arrays. For example, consider the following:

  ```fortran
  a = b + c
  ...               ! a, b, c, and s are all arrays of similar shape
  s = sum(a)
  ```

  The above statements can replace entire DO loops.

- Inquiry functions

  These functions have results that depend on the properties of their principal argument, not the value of the argument (the argument value can be undefined).

- Transformational functions

  These functions have one or more array-valued dummy or actual arguments, an array result, or both. The intrinsic function is not applied elementally to an array-valued actual argument; instead it changes (transforms) the argument array into another array.

- Nonelemental procedures

  These procedures must be called with only scalar arguments; they return scalar results. All subroutines (except MVBITS) are nonelemental.

An atomic subroutine is an intrinsic subroutine that performs an action on a variable (its ATOM argument) atomically. When an atomic subroutine is executed, it is as if the subroutine were executed instantaneously without overlapping other atomic actions that might occur asynchronously.

Intrinsic procedures are invoked the same way as other procedures, and follow the same rules of argument association.

The intrinsic procedures have generic (or common) names, and many of the intrinsic functions have specific names. (Some intrinsic functions are both generic and specific.)

In general, generic functions accept arguments of more than one data type; the data type of the result is the same as that of the arguments in the function reference. For elemental functions with more than one argument, all arguments must be of the same type (except for the function MERGE).
When an intrinsic function is passed as an actual argument to a procedure, its specific name must be used, and when called, its arguments must be scalar. Some specific intrinsic functions are not allowed as actual arguments in all circumstances. The following table lists specific functions that cannot be passed as actual arguments or as targets in procedure pointer assignment statements.

**Specific Intrinsic Functions Not Allowed as Actual Arguments**

| AIMAX0 | FLOATJ | JFIX | MAX0 |
| AIMIN0 | FLOATK | JIDINT | MAX1 |
| AJMAX0 | FP_CLASS | JIFIX | MIN0 |
| AJMIN0 | HFIX | JINT | MIN1 |
| AKMAX0 | IADDR | JIQINT | NARGS |
| AKMIN0 | IARGC | JMAX0 | QCMLPX |
| AMAX0 | ICHAR | JMAX1 | QEXT |
| AMAX1 | IDINT | JMIN0 | QEXTD |
| AMIN0 | IFIX | JMIN1 | QMAX1 |
| AMIN1 | IIDINT | JNUM | QMIN1 |
| CHAR | IIFIX | JZEXT | QNUM |
| CMPLX | IINT | KIDINT | QREAL |
| DBLE | IIQINT | KIFIX | RAN |
| DBLEQ | IJINT | KINT | RANF |
| DCMPLX | IMAX0 | KIQINT | REAL |
| DFLOT1 | IMAX1 | KMAX0 | RNUM |
| DFLOTJ | IMIN0 | KMAX1 | SECNDS |
| DFLOTK | IMIN1 | KMIN0 | SHIFTL |
| DMAX1 | INT | KMIN1 | SHIFTR |
| DMIN1 | INT1 | KNUM | SNGL |
| DNUM | INT2 | KZEXT | SNGLQ |
| DREAL | INT4 | LGE | ZEXT |
| DSHIFTL | INT8 | LGT |
| DSHIFTR | NUM | LLE |
| FLOAT | IQINT | LLT |
| FLOATJ | IZEXT | LOC |

Note that none of the intrinsic subroutines can be passed as actual arguments or as targets in procedure pointer assignment statements.

The A to Z Reference contains the descriptions of all intrinsics listed in alphabetical order. Each reference entry indicates whether the procedure is inquiry, elemental, transformational, or nonelemental, and whether it is a function or a subroutine.

References to Elemental Intrinsic Procedures

Argument Keywords in Intrinsic Procedures

For all intrinsic procedures, the arguments shown are the names you must use as keywords when using the keyword form for actual arguments. For example, a reference to function CMPLX(X, Y, KIND) can be written as follows:

Using positional arguments: CMPLX(F, G, L)
Using argument keywords: CMPLX(KIND=L, Y=G, X=F)

1 Note that argument keywords can be written in any order.

Some argument keywords are optional (denoted by square brackets). The following describes some of the most commonly used optional arguments:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BACK</td>
<td>Specifies that a string scan is to be in reverse order (right to left).</td>
</tr>
<tr>
<td>DIM</td>
<td>Specifies a selected dimension of an array argument.</td>
</tr>
<tr>
<td>KIND</td>
<td>Specifies the kind type parameter of the function result.</td>
</tr>
<tr>
<td>MASK</td>
<td>Specifies that a mask can be applied to the elements of the argument array to exclude the elements that are not to be involved in an operation.</td>
</tr>
</tbody>
</table>

Examples

The syntax for the DATE_AND_TIME intrinsic subroutine shows four optional positional arguments: DATE, TIME, ZONE, and VALUES. The following shows some valid ways to specify these arguments:

```
! Keyword example
CALL DATE_AND_TIME (ZONE=Z)

! Positional example
CALL DATE_AND_TIME (DATE, TIME, ZONE)
```

Argument Association in Procedures

Overview of Bit Functions

Integer data types are represented internally in binary two’s complement notation. Bit positions in the binary representation are numbered from right (least significant bit) to left (most significant bit); the rightmost bit position is numbered 0.

The intrinsic functions IAND, IOR, IEOR, and NOT operate on all of the bits of their argument (or arguments). Bit 0 of the result comes from applying the specified logical operation to bit 0 of the argument. Bit 1 of the result comes from applying the specified logical operation to bit 1 of the argument, and so on for all of the bits of the result.

The functions ISHFT and ISHFTC shift binary patterns.

The functions IBSET, IBCLR, BTEST, and IBITS and the subroutine MVBITS operate on bit fields.
A bit field is a contiguous group of bits within a binary pattern. Bit fields are specified by a starting bit position and a length. A bit field must be entirely contained in its source operand.

For example, the integer 47 is represented by the following:

<table>
<thead>
<tr>
<th>Binary pattern:</th>
<th>0...0101111</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bit position:</td>
<td>n...6543210</td>
</tr>
</tbody>
</table>

Where \( n \) is the number of bit positions in the numeric storage unit.

You can refer to the bit field contained in bits 3 through 6 by specifying a starting position of 3 and a length of 4.

Negative integers are represented in two's complement notation. For example, the integer -47 is represented by the following:

<table>
<thead>
<tr>
<th>Binary pattern:</th>
<th>1...1010001</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bit position:</td>
<td>n...6543210</td>
</tr>
</tbody>
</table>

Where \( n \) is the number of bit positions in the numeric storage unit.

The value of bit position \( n \) is as follows:

- 1 for a negative number
- 0 for a non-negative number

All the high-order bits in the pattern from the last significant bit of the value up to bit \( n \) are the same as bit \( n \).

IBITS and MVBITS operate on general bit fields. Both the starting position of a bit field and its length are arguments to these intrinsics. IBSET, IBCLR, and BTEST operate on 1-bit fields. They do not require a length argument.

For IBSET, IBCLR, and BTEST, the bit position range is as follows:

- 0 to 63 for INTEGER(8) and LOGICAL(8)
- 0 to 31 for INTEGER(4) and LOGICAL(4)
- 0 to 15 for INTEGER(2) and LOGICAL(2)
- 0 to 7 for BYTE, INTEGER(1), and LOGICAL(1)

For IBITS, the bit position can be any number. The length range is 0 to 63 on Intel® 64 architecture; 0 to 31 on IA-32 architecture.

The following example shows IBSET, IBCLR, and BTEST:

```fortran
I = 4
J = IBSET (I, 5)
PRINT *, 'J = ', J
K = IBCLR (J, 2)
PRINT *, 'K = ', K
PRINT *, 'Bit 2 of K is ', BTEST(K, 2)
END
```

The results are: \( J = 36 \), \( K = 32 \), and Bit 2 of \( K \) is F.

For optimum selection of performance and memory requirements, Intel® Fortran provides the following integer data types:

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Storage Required (in bytes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER(1)</td>
<td>1</td>
</tr>
<tr>
<td>INTEGER(2)</td>
<td>2</td>
</tr>
<tr>
<td>INTEGER(4)</td>
<td>4</td>
</tr>
</tbody>
</table>
The bit manipulation functions each have a generic form that operates on all of these integer types and a specific form for each type.

When you specify the intrinsic functions that refer to bit positions or that shift binary patterns within a storage unit, be careful that you do not create a value that is outside the range of integers representable by the data type. If you shift by an amount greater than or equal to the size of the object you’re shifting, the result is 0.

Consider the following:

```fortran
INTEGER(2) I,J
I = 1
J = 17
I = ISHFT(I,J)
```

The variables I and J have INTEGER(2) type. Therefore, the generic function ISHFT maps to the specific function IISHFT, which returns an INTEGER(2) result. INTEGER(2) results must be in the range -32768 to 32767, but the value 1, shifted left 17 positions, yields the binary pattern 1 followed by 17 zeros, which represents the integer 131072. In this case, the result in I is 0.

The previous example would be valid if I was INTEGER(4), because ISHFT would then map to the specific function JISHFT, which returns an INTEGER(4) value.

If ISHFT is called with a constant first argument, the result will either be the default integer size or the smallest integer size that can contain the first argument, whichever is larger.

### Categories and Lists of Intrinsic Procedures

This section describes the categories of generic intrinsic functions (including a summarizing table) and lists the intrinsic subroutines.

Intrinsic procedures are fully described (in alphabetical order) in the A to Z Reference.

### Categories of Intrinsic Functions

Generic intrinsic functions can be divided into categories, as shown in the following table:

<table>
<thead>
<tr>
<th>Category</th>
<th>Subcategory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Numeric</td>
<td>Computation</td>
<td>Elemental functions that perform type conversions or simple numeric operations: ABS, AIMAG, AINT, AMAX0, AMIN0, ANINT, CEILING, CMPLX, CONJG, DBLE, DCMPLX, DFLOAT, DIM, DNUM, DPROD, DREAL, FLOOR, IFIX, IMAG, INT, JNUN, KNUM MAX, MAX1, MIN, MIN1, MOD, MODULO, NINT, QCPLAX, QEXT, QFLOAT, QNUM, QREAL, REAL, RNUM, SIGN, SNGL, ZEXT</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Nonelemental function that provides a pseudorandom number: RAN</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Elemental function that generates a random number: RANF</td>
</tr>
<tr>
<td>Category</td>
<td>Subcategory</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>---------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Manipulation</td>
<td>1</td>
<td>Elemental functions that return values related to the components of the model values associated with the actual value of the argument: EXPONENT, FRACTION, NEAREST, RRSPACING, SCALE, SET_EXPONENT, SPACING</td>
</tr>
<tr>
<td>Inquiry</td>
<td>1</td>
<td>Functions that return scalar values from the models associated with the type and kind parameters of their arguments: DIGITS, EPSILON, HUGE, ILEN, MAXEXPONENT, MINEXPONENT, PRECISION, RADIX, RANGE, SIZEOF, TINY</td>
</tr>
<tr>
<td>Transformational</td>
<td></td>
<td>Functions that perform vector and matrix multiplication: DOT_PRODUCT, MATMUL</td>
</tr>
<tr>
<td>System</td>
<td></td>
<td>Functions that return information about a process or processor: MCLOCK, SECNDS</td>
</tr>
<tr>
<td>Kind type</td>
<td></td>
<td>Functions that return kind type parameters: KIND, SELECTED_CHAR_KIND, SELECTED_INT_KIND, SELECTED_REAL_KIND</td>
</tr>
<tr>
<td>Mathematical</td>
<td></td>
<td>Elemental functions that perform mathematical operations: ACOS, ACOSD, ACOSH, ASIN, ASIND, ASINH, ATAN, ATAN2, ATAN2D, ATAND, ATANH, BESSEL_J0, BESSEL_J1, BESSEL_JN, BESSEL_Y0, BESSEL_Y1, BESSEL_YN, COS, COSD, COSH, COTAN, COTAND, EXP, GAMMA, HYPOT, LOG, LOG10, LOG_GAMMA, SIN, SIND, SINH, SQRT, TAN, TAND, TANH</td>
</tr>
<tr>
<td>Bit</td>
<td>Manipulation</td>
<td>Elemental functions that perform bit operations, such as single-bit processing, logical and shift operations, and allowing bit subfields to be referenced: AND, BGE, BGT, BLE, BLT, BTEST, DSHIFTL, DSHIFTR, IAND, IBCHNG, IBCLR, IBITS, IBSET, Ieor, IOR, ISHA, IHC, ISHFT, ISHTC, ISHL, IXOR, LSHIFT, MASKL, MASKR, MERGE_BITS, NOT, OR, RSHIFT, SHIFTA, SHIFTL, SHIFTR, XOR</td>
</tr>
<tr>
<td>Category</td>
<td>Subcategory</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>-------------</td>
<td>-------------</td>
</tr>
<tr>
<td>Inquiry</td>
<td>Function that lets you determine bit size and storage size: BIT_SIZE, STORAGE_SIZE</td>
<td></td>
</tr>
<tr>
<td>Representation</td>
<td>Elemental functions that return information on bit representation of integers: LEADZ, POPCNT, POPPAR, TRAILZ</td>
<td></td>
</tr>
<tr>
<td>Character</td>
<td>Comparison</td>
<td>Elemental functions that make a lexical comparison of the character-string arguments and return a default logical result: LGE, LGT, LLE, LLT</td>
</tr>
<tr>
<td>Conversion</td>
<td>Elemental functions that take character arguments and return integer, ASCII, or character values: ACHAR, CHAR, IACHAR, ICHAR</td>
<td></td>
</tr>
<tr>
<td>String handling</td>
<td>Functions that perform operations on character strings, return lengths of arguments, and search for certain arguments: Elemental: ADJUSTL, ADJUSTR, INDEX, LEN_TRIM, SCAN, VERIFY; Nonelemental: REPEAT, TRIM</td>
<td></td>
</tr>
<tr>
<td>Inquiry</td>
<td>Functions that return the length of an argument or information about command-line arguments: COMMAND_ARGUMENT_COUNT, IARG, IARGC, LEN, NARGS, NUMARG</td>
<td></td>
</tr>
<tr>
<td>Array</td>
<td>Construction</td>
<td>Functions that construct new arrays from the elements of existing arrays: Elemental: MERGE; Nonelemental: PACK, SPREAD, UNPACK</td>
</tr>
<tr>
<td>Inquiry</td>
<td>Functions that let you determine if an array argument is allocated, and return the size or shape of an array, and the lower and upper bounds of subscripts along each dimension: ALLOCATED, IS_CONTIGUOUS, LBOUND, RANK, SHAPE, SIZE, UBOUND</td>
<td></td>
</tr>
<tr>
<td>Location</td>
<td>Transformational functions that find the geometric locations of the maximum and minimum values of an array: MAXLOC, MINLOC</td>
<td></td>
</tr>
<tr>
<td>Category</td>
<td>Subcategory</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>-------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Manipulation</td>
<td></td>
<td>Transformational functions that shift an array, transpose an array, or change the shape of an array: CSHIFT, EOSHIFT, RESHAPE, TRANSPOSE</td>
</tr>
<tr>
<td>Reduction</td>
<td></td>
<td>Transformational functions that perform operations on arrays. The functions &quot;reduce&quot; elements of a whole array to produce a scalar result, or they can be applied to a specific dimension of an array to produce a result array with a rank reduced by one: ALL, ANY, COUNT, IALL, IANY, IPARITY, MAXVAL, MINVAL, NORM2, PARITY, PRODUCT, SUM</td>
</tr>
<tr>
<td>Coarray</td>
<td>Inquiry</td>
<td>Functions that convert cosubscripts or return lower or upper cobounds: IMAGE_INDEX, LCOBOUND, UCOBOUND</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Functions that return the number of images or cosubscripts: NUM.Images, THIS_IMAGE</td>
</tr>
<tr>
<td>Polymorphic</td>
<td>Inquiry</td>
<td>Functions that let you determine the dynamic type of an object: EXTENDS_TYPE_OF, SAME_TYPE_AS</td>
</tr>
<tr>
<td>Miscellaneous</td>
<td></td>
<td>Functions that do the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Check for pointer association (ASSOCIATED)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Return an address (BADDRESS or IADDR)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Return the size of a level of the memory cache (CACHESIZE)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Check for end-of-file (EOF)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Return error functions (ERF, ERFC, and ERFC_SCALED)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Return the class of a floating-point argument (FP_CLASS)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Return the INTEGER KIND that will hold an address (INT_PTR_KIND)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Test for Not-a-Number values (ISNAN)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Return the internal address of a storage item (LOC)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Return a logical value of an argument (LOGICAL)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Allocate memory (MALLOC)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Return a new line character (NEW_LINE)</td>
</tr>
</tbody>
</table>
All of the numeric manipulation, and many of the numeric inquiry functions are defined by the model sets for integers and reals.

The value of the argument does not have to be defined.

For more information on bit functions, see Bit functions.

The Intel® Fortran processor character set is ASCII, so ACHAR = CHAR and IACHAR = ICHAR.

The following table summarizes the generic intrinsic functions and indicates whether they are elemental, inquiry, or transformational functions. Optional arguments are shown within square brackets.

Some intrinsic functions are specific with no generic association. These functions are listed below.

### Summary of Generic Intrinsic Functions

<table>
<thead>
<tr>
<th>Generic Function</th>
<th>Class</th>
<th>Value Returned</th>
</tr>
</thead>
<tbody>
<tr>
<td>ABS (A)</td>
<td>E</td>
<td>The absolute value of an argument</td>
</tr>
<tr>
<td>ACHAR (I [,KIND])</td>
<td>E</td>
<td>The character in the specified position of the ASCII character set</td>
</tr>
<tr>
<td>ACOS (X)</td>
<td>E</td>
<td>The arccosine (in radians) of the argument</td>
</tr>
<tr>
<td>ACOSD (X)</td>
<td>E</td>
<td>The arccosine (in degrees) of the argument</td>
</tr>
<tr>
<td>ACOSH (X)</td>
<td>E</td>
<td>The hyperbolic arccosine of the argument</td>
</tr>
<tr>
<td>ADJUSTL (STRING)</td>
<td>E</td>
<td>The specified string with leading blanks removed and placed at the end of the string</td>
</tr>
<tr>
<td>ADJUSTR (STRING)</td>
<td>E</td>
<td>The specified string with trailing blanks removed and placed at the beginning of the string</td>
</tr>
<tr>
<td>AIMAG (Z)</td>
<td>E</td>
<td>The imaginary part of a complex argument</td>
</tr>
<tr>
<td>AINT (A [,KIND])</td>
<td>E</td>
<td>A real value truncated to a whole number</td>
</tr>
<tr>
<td>ALL (MASK [,DIM])</td>
<td>T</td>
<td>.TRUE. if all elements of the masked array are true</td>
</tr>
<tr>
<td>ALLOCATED ([ARRAY=]array)</td>
<td>I</td>
<td>The allocation status of the argument array or scalar</td>
</tr>
</tbody>
</table>

1 All of the numeric manipulation, and many of the numeric inquiry functions are defined by the model sets for integers and reals.

2 The value of the argument does not have to be defined.

3 For more information on bit functions, see Bit functions.

4 The Intel® Fortran processor character set is ASCII, so ACHAR = CHAR and IACHAR = ICHAR.
<table>
<thead>
<tr>
<th>Generic Function</th>
<th>Class</th>
<th>Value Returned</th>
</tr>
</thead>
<tbody>
<tr>
<td>AMAX0 (A1, A2 [, A3,...])</td>
<td>E</td>
<td>The maximum value in a list of integers (returned as a real value)</td>
</tr>
<tr>
<td>AMIN0 (A1, A2 [, A3,...])</td>
<td>E</td>
<td>The minimum value in a list of integers (returned as a real value)</td>
</tr>
<tr>
<td>AND (I, J)</td>
<td>E</td>
<td>See IAND</td>
</tr>
<tr>
<td>ANINT (A [, KIND])</td>
<td>E</td>
<td>A real value rounded to a whole number</td>
</tr>
<tr>
<td>ANY (MASK [, DIM])</td>
<td>T</td>
<td>.TRUE. if any elements of the masked array are true</td>
</tr>
<tr>
<td>ASIN (X)</td>
<td>E</td>
<td>The arcsine (in radians) of the argument</td>
</tr>
<tr>
<td>ASIND (X)</td>
<td>E</td>
<td>The arcsine (in degrees) of the argument</td>
</tr>
<tr>
<td>ASINH (X)</td>
<td>E</td>
<td>The hyperbolic arcsine of the argument</td>
</tr>
<tr>
<td>ASSOCIATED (POINTER [,TARGET])</td>
<td>I</td>
<td>.TRUE. if the pointer argument is associated or the pointer is associated with the specified target</td>
</tr>
<tr>
<td>ATAN (X)</td>
<td>E</td>
<td>The arctangent (in radians) of the argument</td>
</tr>
<tr>
<td>ATAN2 (Y, X)</td>
<td>E</td>
<td>The arctangent (in radians) of the arguments</td>
</tr>
<tr>
<td>ATAN2D (Y, X)</td>
<td>E</td>
<td>The arctangent (in degrees) of the arguments</td>
</tr>
<tr>
<td>ATAND (X)</td>
<td>E</td>
<td>The arctangent (in degrees) of the argument</td>
</tr>
<tr>
<td>ATANH (X)</td>
<td>E</td>
<td>The hyperbolic arctangent of the argument</td>
</tr>
<tr>
<td>BADDRESS (X)</td>
<td>I</td>
<td>The address of the argument</td>
</tr>
<tr>
<td>BESSEL_J0 (X)</td>
<td>E</td>
<td>A Bessel function of the first kind, order 0</td>
</tr>
<tr>
<td>BESSEL_J1 (X)</td>
<td>E</td>
<td>A Bessel function of the first kind, order 1</td>
</tr>
<tr>
<td>BESSEL_JN (N, X)</td>
<td>E</td>
<td>A Bessel function of the first kind, order N</td>
</tr>
<tr>
<td>BESSEL_JN (N1, N2, X)</td>
<td>T</td>
<td>A Bessel function of the first kind</td>
</tr>
<tr>
<td>BESSEL_Y0 (X)</td>
<td>E</td>
<td>A Bessel function of the second kind, order 0</td>
</tr>
<tr>
<td>BESSEL_Y1 (X)</td>
<td>E</td>
<td>A Bessel function of the second kind, order 1</td>
</tr>
<tr>
<td>Generic Function</td>
<td>Class</td>
<td>Value Returned</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------</td>
<td>-------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>BESSEL_YN (N, X)</td>
<td>E</td>
<td>A Bessel function of the second kind, order N</td>
</tr>
<tr>
<td>BESSEL_YN (N1, N2, X)</td>
<td>T</td>
<td>A Bessel function of the second kind</td>
</tr>
<tr>
<td>BGE (I, J)</td>
<td>E</td>
<td>Bitwise greater than or equal to</td>
</tr>
<tr>
<td>BGT (I, J)</td>
<td>E</td>
<td>Bitwise greater than</td>
</tr>
<tr>
<td>BIT_SIZE (I)</td>
<td>I</td>
<td>The number of bits (s) in the bit model</td>
</tr>
<tr>
<td>BLE (I, J)</td>
<td>E</td>
<td>Bitwise less than or equal to</td>
</tr>
<tr>
<td>BLT (I, J)</td>
<td>E</td>
<td>Bitwise less than</td>
</tr>
<tr>
<td>BTEST (I, POS)</td>
<td>E</td>
<td>.TRUE. if the specified position of argument I is one</td>
</tr>
<tr>
<td>CEILING (A [,KIND])</td>
<td>E</td>
<td>The smallest integer greater than or equal to the argument value</td>
</tr>
<tr>
<td>CHAR (I [,KIND])</td>
<td>E</td>
<td>The character in the specified position of the processor character set</td>
</tr>
<tr>
<td>COMMAND_ARGUMENT_COUNT ()</td>
<td>I</td>
<td>The number of command arguments</td>
</tr>
<tr>
<td>CONJG (Z)</td>
<td>E</td>
<td>The conjugate of a complex number</td>
</tr>
<tr>
<td>COS (X)</td>
<td>E</td>
<td>The cosine of the argument, which is in radians</td>
</tr>
<tr>
<td>COSD (X)</td>
<td>E</td>
<td>The cosine of the argument, which is in degrees</td>
</tr>
<tr>
<td>COSH (X)</td>
<td>E</td>
<td>The hyperbolic cosine of the argument</td>
</tr>
<tr>
<td>COTAN (X)</td>
<td>E</td>
<td>The cotangent of the argument, which is in radians</td>
</tr>
<tr>
<td>COTAND (X)</td>
<td>E</td>
<td>The cotangent of the argument, which is in degrees</td>
</tr>
<tr>
<td>COUNT (MASK [,DIM] [,KIND] )</td>
<td>T</td>
<td>The number of .TRUE. elements in the argument array</td>
</tr>
<tr>
<td>CSHIFT (ARRAY, SHIFT [,DIM])</td>
<td>T</td>
<td>An array that has the elements of the argument array circularly shifted</td>
</tr>
<tr>
<td>DBLE (A)</td>
<td>E</td>
<td>The corresponding double precision value of the argument</td>
</tr>
<tr>
<td>DFLOAT (A)</td>
<td>E</td>
<td>The corresponding double precision value of the integer argument</td>
</tr>
<tr>
<td>DIGITS (X)</td>
<td>I</td>
<td>The number of significant digits in the model for the argument</td>
</tr>
<tr>
<td>Generic Function</td>
<td>Class</td>
<td>Value Returned</td>
</tr>
<tr>
<td>------------------</td>
<td>-------</td>
<td>----------------</td>
</tr>
<tr>
<td>DIM (X, Y)</td>
<td>E</td>
<td>The positive difference between the two arguments</td>
</tr>
<tr>
<td>DOT_PRODUCT (VECTOR_A, VECTOR_B)</td>
<td>T</td>
<td>The dot product of two rank-one arrays (also called a vector multiply function)</td>
</tr>
<tr>
<td>DREAL (A)</td>
<td>E</td>
<td>The corresponding double-precision value of the double complex argument</td>
</tr>
<tr>
<td>DSHIFTL (ILEFT, IRIGHT, ISHIFT)</td>
<td>E</td>
<td>The upper (leftmost) 64 bits of a left-shifted 128-bit integer</td>
</tr>
<tr>
<td>DSHIFTR (ILEFT, IRIGHT, ISHIFT)</td>
<td>E</td>
<td>The lower (rightmost) 64 bits of a right-shifted 128-bit integer</td>
</tr>
<tr>
<td>EOF (A)</td>
<td>I</td>
<td>.TRUE. or .FALSE. depending on whether a file is beyond the end-of-file record</td>
</tr>
<tr>
<td>EOSHIFT (ARRAY, SHIFT [,BOUNDARY] [,DIM])</td>
<td>T</td>
<td>An array that has the elements of the argument array end-off shifted</td>
</tr>
<tr>
<td>EPSILON (X)</td>
<td>I</td>
<td>The number that is almost negligible when compared to one</td>
</tr>
<tr>
<td>ERF (X)</td>
<td>E</td>
<td>The error function of an argument</td>
</tr>
<tr>
<td>ERFC (X)</td>
<td>E</td>
<td>The complementary error function of an argument</td>
</tr>
<tr>
<td>ERFC_SCALED (X)</td>
<td>E</td>
<td>The scaled complementary error function of an argument</td>
</tr>
<tr>
<td>EXP (X)</td>
<td>E</td>
<td>The exponential $e^x$ for the argument x</td>
</tr>
<tr>
<td>EXPONENT (X)</td>
<td>E</td>
<td>The value of the exponent part of a real argument</td>
</tr>
<tr>
<td>EXTENDS_TYPE_OF (A, MOLD)</td>
<td>I</td>
<td>Whether one dynamic type is an extension of another dynamic type.</td>
</tr>
<tr>
<td>FLOAT (X)</td>
<td>E</td>
<td>The corresponding real value of the integer argument</td>
</tr>
<tr>
<td>FLOOR (A [,KIND])</td>
<td>E</td>
<td>The largest integer less than or equal to the argument value</td>
</tr>
<tr>
<td>FP_CLASS (X)</td>
<td>E</td>
<td>The class of the IEEE floating-point argument</td>
</tr>
<tr>
<td>FRACTION (X)</td>
<td>E</td>
<td>The fractional part of a real argument</td>
</tr>
<tr>
<td>GAMMA (X)</td>
<td>E</td>
<td>A gamma function</td>
</tr>
<tr>
<td>HUGE (X)</td>
<td>I</td>
<td>The largest number in the model for the argument</td>
</tr>
<tr>
<td>Generic Function</td>
<td>Class</td>
<td>Value Returned</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------</td>
<td>-------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>HYPOT (X, Y)</td>
<td>E</td>
<td>A Euclidean distance function</td>
</tr>
<tr>
<td>IACHAR (C [,KIND])</td>
<td>E</td>
<td>The position of the specified character in the ASCII character set</td>
</tr>
<tr>
<td>IADDR (X)</td>
<td>E</td>
<td>See BADDRESS</td>
</tr>
<tr>
<td>IAND (I, J)</td>
<td>E</td>
<td>The logical AND of the two arguments</td>
</tr>
<tr>
<td>IALL (ARRAY, DIM [, MASK]) or</td>
<td>T</td>
<td>The result of a bitwise AND operation</td>
</tr>
<tr>
<td>IALL (ARRAY [, MASK])</td>
<td></td>
<td></td>
</tr>
<tr>
<td>IANY (ARRAY, DIM [, MASK]) or</td>
<td>T</td>
<td>The result of a bitwise OR operation</td>
</tr>
<tr>
<td>IANY (ARRAY [, MASK])</td>
<td></td>
<td></td>
</tr>
<tr>
<td>IBCLR (I, POS)</td>
<td>E</td>
<td>The specified position of argument I cleared (set to zero)</td>
</tr>
<tr>
<td>IBCHNG (I, POS)</td>
<td>E</td>
<td>The reversed value of a specified bit</td>
</tr>
<tr>
<td>IBITS (I, POS, LEN)</td>
<td>E</td>
<td>The specified substring of bits of argument I</td>
</tr>
<tr>
<td>IBSET (I, POS)</td>
<td>E</td>
<td>The specified bit in argument I set to one</td>
</tr>
<tr>
<td>ICHAR (C [, KIND])</td>
<td>E</td>
<td>The position of the specified character in the processor character set</td>
</tr>
<tr>
<td>IEOR (I, J)</td>
<td>E</td>
<td>The logical exclusive OR of the corresponding bit arguments</td>
</tr>
<tr>
<td>IFIX (X)</td>
<td>E</td>
<td>The corresponding integer value of the real argument rounded as if it were an implied conversion in an assignment</td>
</tr>
<tr>
<td>ILEN (I)</td>
<td>I</td>
<td>The length (in bits) in the two's complement representation of an integer</td>
</tr>
<tr>
<td>IMAG (Z)</td>
<td>E</td>
<td>See AIMAG</td>
</tr>
<tr>
<td>IMAGE_INDEX (COARRAY, SUB)</td>
<td>I</td>
<td>The index of the corresponding image</td>
</tr>
<tr>
<td>INDEX (STRING, SUBSTRING [, BACK] [,KIND])</td>
<td>E</td>
<td>The position of the specified substring in a character expression</td>
</tr>
<tr>
<td>INT (A [, KIND])</td>
<td>E</td>
<td>The corresponding integer value (truncated) of the argument</td>
</tr>
<tr>
<td>IOR (I, J)</td>
<td>E</td>
<td>The logical inclusive OR of the corresponding bit arguments</td>
</tr>
<tr>
<td>IPARITY (ARRAY, DIM [, MASK]) or IPARITY (ARRAY [, MASK])</td>
<td>T</td>
<td>The result of a bitwise exclusive OR operation</td>
</tr>
<tr>
<td>IS_CONTIGUOUS (ARRAY)</td>
<td>I</td>
<td>The contiguity of an array</td>
</tr>
<tr>
<td>Generic Function</td>
<td>Class</td>
<td>Value Returned</td>
</tr>
<tr>
<td>---------------------------</td>
<td>-------</td>
<td>-------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>IS_IOSTAT_END (I)</td>
<td>E</td>
<td>.TRUE. for an end-of-file condition</td>
</tr>
<tr>
<td>IS_IOSTAT_EOR (I)</td>
<td>E</td>
<td>.TRUE. for an end-of-record condition</td>
</tr>
<tr>
<td>ISHA (I, SHIFT)</td>
<td>E</td>
<td>Argument I shifted left or right by a specified number of bits</td>
</tr>
<tr>
<td>ISHC (I, SHIFT)</td>
<td>E</td>
<td>Argument I rotated left or right by a specified number of bits</td>
</tr>
<tr>
<td>ISHFT (I, SHIFT)</td>
<td>E</td>
<td>The logical end-off shift of the bits in argument I</td>
</tr>
<tr>
<td>ISHTFC (I, SHIFT [,SIZE])</td>
<td>E</td>
<td>The logical circular shift of the bits in argument I</td>
</tr>
<tr>
<td>ISHL (I, SHIFT)</td>
<td>E</td>
<td>Argument I logically shifted left or right by a specified number of bits</td>
</tr>
<tr>
<td>ISNAN (X)</td>
<td>E</td>
<td>Tests for Not-a-Number (NaN) values</td>
</tr>
<tr>
<td>IXOR (I, J)</td>
<td>E</td>
<td>See IEOR</td>
</tr>
<tr>
<td>KIND (X)</td>
<td>I</td>
<td>The kind type parameter of the argument</td>
</tr>
<tr>
<td>LBOUND (ARRAY [,DIM] [,KIND])</td>
<td>I</td>
<td>The lower bounds of an array (or one of its dimensions)</td>
</tr>
<tr>
<td>LEADZ (I)</td>
<td>E</td>
<td>The number of leading zero bits in an integer</td>
</tr>
<tr>
<td>LEN (STRING [,KIND])</td>
<td>I</td>
<td>The length (number of characters) of the argument character string</td>
</tr>
<tr>
<td>LEN_TRIM (STRING [,KIND])</td>
<td>E</td>
<td>The length of the specified string without trailing blanks</td>
</tr>
<tr>
<td>LGE (STRING_A, STRING_B)</td>
<td>E</td>
<td>A logical value determined by a &gt; or = comparison of the arguments</td>
</tr>
<tr>
<td>LGT (STRING_A, STRING_B)</td>
<td>E</td>
<td>A logical value determined by a &gt; comparison of the arguments</td>
</tr>
<tr>
<td>LLE (STRING_A, STRING_B)</td>
<td>E</td>
<td>A logical value determined by a &lt; or = comparison of the arguments</td>
</tr>
<tr>
<td>LLT (STRING_A, STRING_B)</td>
<td>E</td>
<td>A logical value determined by a &lt; comparison of the arguments</td>
</tr>
<tr>
<td>LOC (A)</td>
<td>I</td>
<td>The internal address of the argument.</td>
</tr>
<tr>
<td>LOG (X)</td>
<td>E</td>
<td>The natural logarithm of the argument.</td>
</tr>
<tr>
<td>Generic Function</td>
<td>Class</td>
<td>Value Returned</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-------</td>
<td>-------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>LOG10 (X)</td>
<td>E</td>
<td>The common logarithm (base 10) of the argument</td>
</tr>
<tr>
<td>LOG_GAMMA (X)</td>
<td>E</td>
<td>The logarithm of the absolute value of the gamma function</td>
</tr>
<tr>
<td>LOGICAL (L [,KIND])</td>
<td>E</td>
<td>The logical value of the argument converted to a logical of type KIND</td>
</tr>
<tr>
<td>LSHIFT (I, POSITIVE_SHIFT)</td>
<td>E</td>
<td>See ISHFT</td>
</tr>
<tr>
<td>LSHFT (I, POSITIVE_SHIFT)</td>
<td>E</td>
<td>Same as LSHIFT; see ISHFT</td>
</tr>
<tr>
<td>MALLOC (I)</td>
<td>E</td>
<td>The starting address for the block of memory allocated</td>
</tr>
<tr>
<td>MASKL (I [,KIND])</td>
<td>E</td>
<td>A left-justified mask</td>
</tr>
<tr>
<td>MASKR (I [,KIND])</td>
<td>E</td>
<td>A right-justified mask</td>
</tr>
<tr>

Data Transfer I/O Statements

Data Transfer I/O Statements Overview

Input/Output (I/O) statements can be used for data transfer, file connection, file inquiry, and file positioning. This section discusses data transfer and contains information on the following topics:

- An overview of records and files
- Components of data transfer statements
- Data transfer input statements:
  - READ
    Data can be input from external sequential or direct-access records, or from internal records.
  - ACCEPT
    This statement is the same as a formatted, sequential READ statement, except that an ACCEPT statement must never be connected to user-specified I/O units.
- Data transfer output statements:
  - WRITE
    Data can be output to external sequential or direct-access records, or to internal records.
  - PRINT and TYPE
    The PRINT statement is the same as a formatted, sequential WRITE statement, except that the PRINT statement must never transfer data to user-specified I/O units.
    TYPE is a synonym for PRINT. All forms and rules for the PRINT statement also apply to the TYPE statement.
  - REWRITE
    It rewrites the current record and it can be formatted or unformatted.

File connection, file inquiry, and file positioning I/O statements are discussed in File Operation I/O Statements.

Records and Files

A record is a sequence of values or a sequence of characters. There are three kinds of Fortran records, as follows:

- Formatted
  A record containing formatted data that requires translation from internal to external form. Formatted I/O statements have explicit format specifiers (which can specify list-directed formatting) or namelist specifiers (for namelist formatting). Only formatted I/O statements can read formatted data.
- Unformatted
  A record containing unformatted data that is not translated from internal form. An unformatted record can also contain no data. The internal representation of unformatted data is processor-dependent. Only unformatted I/O statements can read unformatted data.
- Endfile
  The last record of a file. An endfile record can be explicitly written to a sequential file by an ENDFILE statement.

A file is a sequence of records. There are two types of Fortran files, as follows:
External

A file that exists in a medium (such as computer disks or terminals) external to the executable program.

Records in an external file must be either all formatted or all unformatted. There are two ways to access records in external files: sequential and direct access.

In sequential access, records are processed in the order in which they appear in the file. In direct access, records are selected by record number, so they can be processed in any order.

Internal

Memory (internal storage) that behaves like a file. This type of file provides a way to transfer and convert data in memory from one format to another. The contents of these files are stored as scalar character variables.

See Also

Unit Specifier (UNIT=)

Components of Data Transfer Statements

Data transfer statements take one of the following forms:

- `io-keyword (io-control-list) [io-list]`
- `io-keyword format [, io-list]`

`io-keyword`

Is one of the following: ACCEPT, PRINT (or TYPE), READ, REWRITE, or WRITE.

`io-control-list`

Is one or more of the following input/output (I/O) control specifiers:

<table>
<thead>
<tr>
<th>Specifier</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[UNIT=]io-unit</td>
<td>The I/O unit to act upon.</td>
</tr>
<tr>
<td>[FMT=]format</td>
<td>The format (explicit or list-directed) to use for data editing. If explicit, the keyword form must appear.</td>
</tr>
<tr>
<td>[NML=]group</td>
<td>A namelist specifier.</td>
</tr>
<tr>
<td>ADVANCE</td>
<td>Changes the record number used for direct-access I/O.</td>
</tr>
<tr>
<td>ERR</td>
<td>Error flag.</td>
</tr>
<tr>
<td>END</td>
<td>End-of-record flag.</td>
</tr>
<tr>
<td>IOMSG</td>
<td>Message flag.</td>
</tr>
<tr>
<td>IOSTAT</td>
<td>End-of-file flag.</td>
</tr>
<tr>
<td>POS</td>
<td>Position flag.</td>
</tr>
<tr>
<td>REC</td>
<td>Record flag.</td>
</tr>
</tbody>
</table>

`io-list`

Is an I/O list, which can contain variables (except for assumed-size arrays) or implied-DO lists. Output statements can contain constants or expressions.

`format`

Is the nonkeyword form of a control-list format specifier (no FMT=).

If a format specifier ([FMT=]format) or namelist specifier ([NML=]group) is present, the data transfer statement is called a formatted I/O statement; otherwise, it is an unformatted I/O statement.

If a record specifier (REC=) is present, the data transfer statement is a direct-access I/O statement; otherwise, it is a sequential-access I/O statement.

If an error, end-of-record, or end-of-file condition occurs during data transfer, file positioning and execution are affected, and certain control-list specifiers (if present) become defined. (For more information, see Branch Specifiers.)

Following sections describe the I/O control list and I/O lists.

I/O Control List

The I/O control list specifies one or more of the following:

- The I/O unit to act upon ([UNIT=]io-unit)
  
  This specifier must be present; the rest are optional.
- The format (explicit or list-directed) to use for data editing; if explicit, the keyword form must appear ([FMT=]
• The namelist group name to act upon ([NML=]group)
• The number of a record to access (REC=)
• The name of a variable that contains the completion status of an I/O operation (IOSTAT=)
• The label of the statement that receives control if an error (ERR=), end-of-file (END=), or end-of-record (EOR=) condition occurs
• Whether you want to use advancing or nonadvancing I/O (ADVANCE=)
• The number of characters read from a record (SIZE=)
• Whether you want to use asynchronous or synchronous I/O (ASYNCHRONOUS=)
• The identifier for a pending data transfer operation (ID=)
• The identifier for the file position in file storage units in a stream file (POS=)
• The name of a variable that contains an error message (IOMSG=)

No control specifier can appear more than once, and the list must not contain both a format specifier and namelist group name specifier.

Control specifiers can take any of the following forms:

• Keyword form
  When the keyword form (for example, UNIT=io-unit) is used for all control-list specifiers in an I/O statement, the specifiers can appear in any order.

• Nonkeyword form
  When the nonkeyword form (for example, io-unit) is used for all control-list specifiers in an I/O statement, the io-unit specifier must be the first item in the control list. If a format specifier or namelist group name specifier is used, it must immediately follow the io-unit specifier.

• Mixed form
  When a mix of keyword and nonkeyword forms is used for control-list specifiers in an I/O statement, the nonkeyword values must appear first. Once a keyword form of a specifier is used, all specifiers to the right must also be keyword forms.

**Unit Specifier (UNIT=)**

The unit specifier identifies the I/O unit to be accessed. It takes the following form:

[Unit=]io-unit

For external files, it identifies a logical unit and is one of the following:

• A scalar integer expression that refers to a specific file, I/O device, or pipe. If necessary, the value is converted to integer data type before use. The integer is in the range 0 through 2,147,483,643. Note that the predefined parameters FOR_K_PRINT_UNITNO, FOR_K_TYPE_UNITNO, FOR_K_ACCEPT_UNITNO, and FOR_K_READ_UNITNO may not be in that range.

  Units 5, 6, and 0 are associated with preconnected units.

• An asterisk (*). This is the default (or implicit) external unit, which is preconnected for formatted sequential access. You can also preconnect files by using an environment variable.

For internal files, it identifies a scalar or array character variable that is an internal file. An internal file is designated internal storage space (a variable buffer) that is used with formatted (including list-directed) sequential READ and WRITE statements.

The io-unit must be specified in a control list. If the keyword UNIT is omitted, the io-unit must be first in the control list.

A unit number is assigned either explicitly through an OPEN statement or implicitly by the system. If a READ statement implicitly opens a file, the file’s status is STATUS='OLD'. If a WRITE statement implicitly opens a file, the file’s status is STATUS='UNKNOWN'.

If the internal file is a scalar character variable, the file has only one record; its length is equal to that of the variable.
If the internal file is an array character variable, the file has a record for each element in the array; each record’s length is equal to one array element.

An internal file can be read only if the variable has been defined and a value assigned to each record in the file. If the variable representing the internal file is a pointer, it must be associated; if the variable is an allocatable array, it must be currently allocated.

Before data transfer, an internal file is always positioned at the beginning of the first character of the first record.

**See Also**

**OPEN**

**Format Specifier (FMT=)**

The format specifier indicates the format to use for data editing. It takes the following form:

```
[FMT=] format
```

is one of the following:

- The statement label of a FORMAT statement
  - The FORMAT statement must be in the same scoping unit as the data transfer statement.
- An asterisk (*), indicating list-directed formatting
- A scalar default integer variable that has been assigned the label of a FORMAT statement (through an ASSIGN statement)
  - The FORMAT statement must be in the same scoping unit as the data transfer statement.
- A character expression (which can be an array or character constant) containing the run-time format
  - A default character expression must evaluate to a valid format specification. If the expression is an array, it is treated as if all the elements of the array were specified in array element order and were concatenated.
- The name of a numeric array (or array element) containing the format

If the keyword FMT is omitted, the format specifier must be the second specifier in the control list; the io-unit specifier must be first.

If a format specifier appears in a control list, a namelist group specifier must not appear.

**See Also**

**FORMAT**

**Interaction Between Format Specifications and I/O Lists**

**Rules for List-Directed Sequential READ Statements** for details on list-directed input

**Rules for List-Directed Sequential WRITE Statements** for details on list-directed output

**Namelist Specifier (NML=)**

The namelist specifier indicates namelist formatting and identifies the namelist group for data transfer. It takes the following form:

```
[NML=] group
```

is the name of a namelist group previously declared in a `NAMELIST` statement.

If the keyword NML is omitted, the namelist specifier must be the second specifier in the control list; the io-unit specifier must be first.

If a namelist specifier appears in a control list, a format specifier must *not* appear.
**See Also**
*Rules for Namelist Sequential READ Statement* for details on namelist input
*Rules for Namelist Sequential WRITE Statements* for details on namelist output
READ Statement
WRITE Statement

**Record Specifier (REC=)**
The record specifier identifies the number of the record for data transfer in a file connected for direct access. It takes the following form:

```
REC=r
```

*r* is a scalar numeric expression indicating the record number. The value of the expression must be greater than or equal to 1, and less than or equal to the maximum number of records allowed in the file.

If necessary, the value is converted to integer data type before use.

If REC is present, no END specifier, * format specifier, or namelist group name can appear in the same control list.

**See Also**
*Alternative Syntax for a Record Specifier*

**I/O Status Specifier (IOSTAT=)**
The I/O status specifier designates a variable to store a value indicating the status of a data transfer operation. It takes the following form:

```
IOSTAT=i-var
```

*i-var* is a scalar integer variable. When a data transfer statement is executed, *i-var* is set to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>A positive integer</td>
<td>Indicating an error condition occurred.</td>
</tr>
<tr>
<td>A negative integer</td>
<td>Indicating an end-of-file or end-of-record condition occurred. The negative integers differ depending on which condition occurred.</td>
</tr>
<tr>
<td>Zero</td>
<td>Indicating no error, end-of-file, or end-of-record condition occurred.</td>
</tr>
</tbody>
</table>

Execution continues with the statement following the data transfer statement, or the statement identified by a branch specifier (if any).

An end-of-file condition occurs only during execution of a sequential READ statement; an end-of-record condition occurs only during execution of a nonadvancing READ statement.

READ Statement
WRITE Statement
Branch Specifiers (END=, EOR=, ERR=)

A branch specifier identifies a branch target statement that receives control if an error, end-of-file, or end-of-record condition occurs. There are three branch specifiers, taking the following forms:

ERR=label
END=label
EOR=label

label Is the label of the branch target statement that receives control when the specified condition occurs.
The branch target statement must be in the same scoping unit as the data transfer statement.

The following rules apply to these specifiers:

- **ERR**
  The error specifier can appear in a sequential access READ or WRITE statement, a direct-access READ statement, or a REWRITE statement.
  If an error condition occurs, the position of the file is indeterminate, and execution of the statement terminates.
  If IOSTAT was specified, the IOSTAT variable becomes defined as a positive integer value. If SIZE was specified (in a nonadvancing READ statement), the SIZE variable becomes defined as an integer value. If a label was specified, execution continues with the labeled statement.

- **END**
  The end-of-file specifier can appear only in a sequential access READ statement.
  An end-of-file condition occurs when no more records exist in a file during a sequential read, or when an end-of-file record produced by the ENDFILE statement is encountered. End-of-file conditions do not occur in direct-access READ statements.
  If an end-of-file condition occurs, the file is positioned after the end-of-file record, and execution of the statement terminates.
  If IOSTAT was specified, the IOSTAT variable becomes defined as a negative integer value. If a label was specified, execution continues with the labeled statement.

- **EOR**
  The end-of-record specifier can appear only in a formatted, sequential access READ statement that has the specifier ADVANCE='NO'(nonadvancing input).
  An end-of-record condition occurs when a nonadvancing READ statement tries to transfer data from a position after the end of a record.
  If an end-of-record condition occurs, the file is positioned after the current record, and execution of the statement terminates.
  If IOSTAT was specified, the IOSTAT variable becomes defined as a negative integer value. If PAD='YES' was specified for file connection, the record is padded with blanks (as necessary) to satisfy the input item list and the corresponding data edit descriptor. If SIZE was specified, the SIZE variable becomes defined as an integer value. If a label was specified, execution continues with the labeled statement.

If one of the conditions occurs, no branch specifier appears in the control list, but an IOSTAT specifier appears, execution continues with the statement following the I/O statement. If neither a branch specifier nor an IOSTAT specifier appears, the program terminates.

I/O Status Specifier (IOSTAT=)
Branch Statements Overview

Compiler Reference section: *Error Handling* for details on error processing
Advance Specifier (ADVANCE=)
The advance specifier determines whether nonadvancing I/O occurs for a data transfer statement. It takes the following form:

ADVANCE=c-expr

c-expr

Is a scalar character expression that evaluates to 'YES' for advancing I/O or 'NO' for nonadvancing I/O. The default value is 'YES'.

Trailing blanks in the expression are ignored. The values specified are without regard to case.

The ADVANCE specifier can appear only in a formatted, sequential data transfer statement that specifies an external unit. It must not be specified for list-directed or namelist data transfer.

Advancing I/O always positions a file at the end of a record, unless an error condition occurs. Nonadvancing I/O can position a file at a character position within the current record.

See Also
Compiler Reference: Data and I/O: Fortran I/O: Advancing and Nonadvancing Record I/O

Asynchronous Specifier (ASYNCHRONOUS=)
The asynchronous specifier determines whether asynchronous I/O occurs for a data transfer statement. It takes the following form:

ASYNCHRONOUS=i-expr

i-expr

Is a scalar character initialization expression that evaluates to 'YES' for asynchronous I/O or 'NO' for synchronous I/O. The value 'YES' should not appear unless the data transfer statement specifies a file unit number for io-unit. The default value is 'NO'.

Trailing blanks in the expression are ignored. The values specified are without regard to case.

Asynchronous I/O is permitted only for external files opened with an OPEN statement that specifies ASYNCHRONOUS='YES'.

When an asynchronous I/O statement is executed, the pending I/O storage sequence for the data transfer operation is defined to be:

- The set of storage units specified by the I/O item list or by the NML= specifier
- The storage units specified by the SIZE= specifier

Character Count Specifier (SIZE=)
The character count specifier defines a variable to contain the count of the characters transferred by data edit descriptors during execution of the current input statement. It takes the following form:

SIZE=i-var

i-var

Is a scalar integer variable.

If PAD='YES' was specified for file connection, blanks inserted as padding are not counted.

For input statements, the SIZE= specifier can appear only in a formatted, sequential READ statement that has the specifier ADVANCE='NO' (nonadvancing input). It must not be specified for list-directed or namelist data transfer.

For asynchronous nonadvancing input, the storage units specified in the SIZE= specifier become defined with the count of the characters transferred when the corresponding wait operation is executed.

ID Specifier (ID=)
The ID specifier identifies a pending data transfer operation for a specified unit. It takes the following form:
ID=id-var

The ID specifier is a scalar integer variable to be used as an identifier. This specifier can only be used if the value of ASYNCHRONOUS=i-expr is "YES".

If an ID specifier is used in a data transfer statement, a wait operation is performed for the operation. If it is omitted, wait operations are performed for all pending data transfers for the specified unit.

If an error occurs during the execution of a data transfer statement containing an ID specifier, the variable specified becomes undefined.

In an INQUIRE statement, the ID= specifier identifies a pending asynchronous data transfer. It is used with the PENDING specifier to determine whether a specific asynchronous pending data transfer is completed.

**POS Specifier (POS=)**

The POS specifier identifies the file position in file storage units in a stream file (ACCESS='STREAM'). It takes the following form:

POS=p

p

Is a scalar integer expression that specifies the file position. It can only be specified on a file opened for stream access. If omitted, the stream I/O occurs starting at the next file position after the current file position.

Each file storage unit has a unique file position, represented by a positive integer. The first file storage unit is a file at file position 1. The position of each subsequent file storage unit is one greater than that of its preceding file storage unit.

For a formatted file, the file storage unit is an eight-bit byte. For an unformatted file, the file storage unit is an eight-bit byte (if option assume byterecl is specified) or a 32-bit word (if option assume nobyterecl, the default, is specified).

**I/O Message Specifier (IOMSG=)**

The I/O message specifier designates a variable to contain the message to be returned when an I/O error occurs. It takes the following form:

IOMSG=msg-var

msg-var

Is a scalar default character variable.

If an error (ERR=), end-of-file (END=), or end-of-record (EOR=) condition occurs during execution of an I/O statement, msg-var is assigned an explanatory message.

If no error occurs, the value of the variable remains unchanged.

**I/O Lists**

In a data transfer statement, the I/O list specifies the entities whose values will be transferred. An input list is made up of implied-do lists and simple lists of variables (except for assumed-size arrays). An output list is made up of implied-do lists, expressions, and simple lists of variables (except for assumed-size arrays).

In input statements, the I/O list cannot contain constants and expressions because these do not specify named memory locations that can be referenced later in the program.

However, constants and expressions can appear in the I/O lists for output statements because the compiler can use temporary memory locations to hold these values during the execution of the I/O statement.

If an input item is a pointer, it must be currently associated with a definable target; data is transferred from the file to the associated target. If an output item is a pointer, it must be currently associated with a target; data is transferred from the target to the file.
If an input or output item is an array, it is treated as if the elements (if any) were specified in array element order. For example, if ARRAY_A is an array of shape (2,1), the following input statements are equivalent:

```plaintext
READ *, ARRAY_A
READ *, ARRAY_A(1,1), ARRAY_A(2,1)
```

However, no element of that array can affect the value of any expression in the input list, nor can any element appear more than once in an input list. For example, the following input statements are invalid:

```plaintext
INTEGER B(50)
...
READ *, B(B)
READ *, B(B(1):B(10))
```

If an input or output item is an allocatable array, it must be currently allocated.

If an input or output item is a derived type, the following rules apply:

- Any derived-type component must be in the scoping unit containing the I/O statement.
- The derived type must not have a pointer component.
- In a formatted I/O statement, a derived type is treated as if all of the components of the structure were specified in the same order as in the derived-type definition.
- In an unformatted I/O statement, a derived type is treated as a single object.

**See Also**

Simple List Items in I/O Lists
Implied-DO Lists in I/O Lists

**Simple List Items in I/O Lists**

In a data transfer statement, a simple list of items takes the following form:

```plaintext
item [, item] ...
```

`item` is one of the following:

- For input statements: a variable name
  - The variable must not be an assumed-size array, unless one of the following appears in the last dimension: a subscript, a vector subscript, or a section subscript specifying an upper bound.
- For output statements: a variable name, expression, or constant
  - Any expression must not attempt further I/O operations on the same logical unit. For example, it must not refer to a function subprogram that performs I/O on the same logical unit.

The data transfer statement assigns values to (or transfers values from) the list items in the order in which the items appear, from left to right.

When multiple array names are used in the I/O list of an unformatted input or output statement, only one record is read or written, regardless of how many array name references appear in the list.

**Examples**

The following example shows a simple I/O list:

```plaintext
WRITE (6,10) J, K(3), 4, (L+4)/2, N
```

When you use an array name reference in an I/O list, an input statement reads enough data to fill every item of the array. An output statement writes all of the values in the array.

Data transfer begins with the initial item of the array and proceeds in the order of subscript progression, with the leftmost subscript varying most rapidly. The following statement defines a two-dimensional array:

```plaintext
DIMENSION ARRAY(3,3)
```

If the name ARRAY appears with no subscripts in a READ statement, that statement assigns values from the input record(s) to ARRAY(1,1), ARRAY(2,1), ARRAY(3,1), ARRAY(1,2), and so on through ARRAY(3,3).
An input record contains the following values:

1,3,721.73

The following example shows how variables in the I/O list can be used in array subscripts later in the list:

```fortran
DIMENSION ARRAY(3,3)
...
READ (1,30) J, K, ARRAY(J,K)
```

When the READ statement is executed, the first input value is assigned to J and the second to K, establishing the subscript values for ARRAY(J,K). The value 721.73 is then assigned to ARRAY(1,3). Note that the variables must appear before their use as array subscripts.

Consider the following derived-type definition and structure declaration:

```fortran
TYPE EMPLOYEE
  INTEGER ID
  CHARACTER(LEN=40) NAME
END TYPE EMPLOYEE
...
TYPE(EMPLOYEE) :: CONTRACT   ! A structure of type EMPLOYEE
```

The following statements are equivalent:

```fortran
READ *, CONTRACT
READ *, CONTRACT%ID, CONTRACT%NAME
```

The following shows more examples:

```fortran
! A variable and array element in iolist:
REAL b(99)
READ (*, 300) n, b(n) ! n and b(n) are the iolist
300 FORMAT (I2, F10.5) ! FORMAT statement telling what form the input data has

! A derived type and type element in iolist:
TYPE YOUR_DATA
  REAL a
  CHARACTER(30) info
  COMPLEX cx
END TYPE YOUR_DATA
TYPE (YOUR_DATA) yd1, yd2
yd1.a = 2.3
yd1.info = "This is a type demo."
yd2.cx = (3.0, 4.0)
yd2.cx = (4.5, 6.7)
! The iolist follows the WRITE (*,500).
WRITE (*, 500) yd1, yd2.cx
! The format statement tells how the iolist will be output.
500 FORMAT (F5.3, A21, F5.2, ',', F5.2, ' yd2.cx = (', F5.2, ',', F5.2, ' )')
! The output looks like:
! 2.300This is a type demo 3.00, 4.00 yd2.cx = ( 4.50, 6.70 )
```

The following example uses an array and an array section:

```fortran
! An array in the iolist:
INTEGER handle(5)
DATA handle / 5*0 /
WRITE (*, 99) handle
99 FORMAT (5I5)
! An array section in the iolist.
WRITE (*, 100) handle(2:3)
100 FORMAT (2I5)
```
The following shows another example:

```fortran
PRINT *, '(I5)', 2*3 ! The iolist is the expression 2*3.
```

The following example uses a namelist:

```fortran
! Namelist I/O:
    INTEGER int1
    LOGICAL log1
    REAL r1
    CHARACTER (20) char20
    NAMELIST /mylist/ int1, log1, r1, char20
int1 = 1
log1 = .TRUE.
r1 = 1.0
char20 = 'NAMELIST demo'
OPEN (UNIT = 4, FILE = 'MYFILE.DAT', DELIM = 'APOSTROPHE')
WRITE (UNIT = 4, NML = mylist)
! Writes the following:
! &MYLIST
! INT1 = 1,
! LOG1 = T,
! R1 = 1.000000,
! CHAR20 = 'NAMELIST demo'
! /
REWIND(4)
READ (4, mylist)
```

- I/O Lists for details on the general rules for I/O lists
- Implied-DO Lists in I/O Lists

Implied-DO Lists in I/O Lists

In a data transfer statement, an implied-DO list acts as though it were a part of an I/O statement within a DO loop. It takes the following form:

```
(list, do-var = expr 1, expr 2 [, expr 3])
```

- **list** Is a list of variables, expressions, or constants (see Simple List Items in I/O Lists).
- **do-var** Is the name of a scalar integer or real variable. The variable must not be one of the input items in *list*.
- **expr** Are scalar numeric expressions of type integer or real. They do not all have to be the same type, or the same type as the DO variable.

The implied-DO loop is initiated, executed, and terminated in the same way as a DO construct.

The *list* is the range of the implied-DO loop. Items in that list can refer to *do-var*, but they must not change the value of *do-var*.

Two nested implied-DO lists must not have the same (or an associated) DO variable.

Use an implied-DO list to do the following:

- Specify iteration of part of an I/O list
- Transfer part of an array
- Transfer array items in a sequence different from the order of subscript progression

If the I/O statement containing an implied-DO list terminates abnormally (with an END, EOR, or ERR branch or with an IOSTAT value other than zero), the DO variable becomes undefined.
Examples

The following two output statements are equivalent:

- WRITE (3,200) (A,B,C, I=1,3)   ! An implied-DO list

The following example shows nested implied-DO lists. Execution of the innermost list is repeated most often:

- WRITE (6,150) ((FORM(K,L), L=1,10), K=1,10,2)

The inner DO loop is executed 10 times for each iteration of the outer loop; the second subscript (L) advances from 1 through 10 for each increment of the first subscript (K). This is the reverse of the normal array element order. Note that K is incremented by 2, so only the odd-numbered rows of the array are output.

In the following example, the entire list of the implied-DO list (P(1), Q(1,1), Q(1,2)...,Q(1,10)) are read before I is incremented to 2:

- READ (5,999) (P(I), (Q(I,J), J=1,10), I=1,5)

The following example uses fixed subscripts and subscripts that vary according to the implied-DO list:

- READ (3,5555) (BOX(1,J), J=1,10)

Input values are assigned to BOX(1,1) through BOX(1,10), but other elements of the array are not affected.

The following example shows how a DO variable can be output directly:

- WRITE (6,1111) (I, I=1,20)

Integers 1 through 20 are written.

Consider the following:

```fortran
INTEGER mydata(25)
READ (10, 9000) (mydata(I), I=6,10,1)
9000  FORMAT (5I3)
```

In this example, the `io/list` specifies to put the input data into elements 6 through 10 of the array called `mydata`. The third value in the implied-DO loop, the increment, is optional. If you leave it out, the increment value defaults to 1.

I/O Lists for details on the general rules for I/O lists

Forms for READ Statements

Forms for Sequential READ Statements

Sequential READ statements transfer input data from external sequential-access records. The statements can be formatted with format specifiers (which can use list-directed formatting) or namelist specifiers (for namelist formatting), or they can be unformatted.

A sequential READ statement takes one of the following forms:

**Formatted:**

- READ form [, io-list]
**Formatted - List-Directed:**

```
READ * [, io-list]
```

**Formatted - Namelist:**

```
READ nml
```

**Unformatted:**

```
```

**See Also**

READ Statement
I/O Control List
I/O Lists

**Rules for Formatted Sequential READ Statements**

Formatted, sequential READ statements translate data from character to binary form by using format specifications for editing (if any). The translated data is assigned to the entities in the I/O list in the order in which the entities appear, from left to right.

Values can be transferred to objects of intrinsic or derived types. For derived types, values of intrinsic types are transferred to the components of intrinsic types that ultimately make up these structured objects.

For data transfer, the file must be positioned so that the record read is a formatted record or an end-of-file record.

If the number of I/O list items is less than the number of fields in an input record, the statement ignores the excess fields.

If the number of I/O list items is greater than the number of fields in an input record, the input record is padded with blanks. However, if PAD='NO' was specified for file connection, the input list and file specification must not require more characters from the record than it contains. If more characters are required and nonadvancing input is in effect, an end-of-record condition occurs.

If the file is connected for unformatted I/O, formatted data transfer is prohibited.

**Examples**

The following example shows formatted, sequential READ statements:

```
READ (*, '(B)', ADVANCE='NO') C
READ (FMT="(E2.4)", UNIT=6, IOSTAT=IO_STATUS) A, B, C
```

**See Also**

READ Statement
Forms for Sequential READ Statements

**Rules for List-Directed Sequential READ Statements**

List-directed, sequential READ statements translate data from character to binary form by using the data types of the corresponding I/O list item to determine the form of the data. The translated data is then assigned to the entities in the I/O list in the order in which they appear, from left to right.

If a slash ( / ) is encountered during execution, the READ statement is terminated, and any remaining input list items are unchanged.

If the file is connected for unformatted I/O, list-directed data transfer is prohibited.
List-Directed Records

A list-directed external record consists of a sequence of values and value separators. A value can be any of the following:

- A constant

  Each constant must be a literal constant of type integer, real, complex, logical, or character; or a nondelimited character string. Binary, octal, hexadecimal, Hollerith, and named constants are not permitted.

  In general, the form of the constant must be acceptable for the type of the list item. The data type of the constant determines the data type of the value and the translation from external to internal form. The following rules also apply:

  - A numeric list item can correspond only to a numeric constant, and a character list item can correspond only to a character constant. If the data types of a numeric list element and its corresponding numeric constant do not match, conversion is performed according to the rules for arithmetic assignment (see the table in Numeric Assignment Statements).
  
  - A complex constant has the form of a pair of real or integer constants separated by a comma and enclosed in parentheses. Blanks can appear between the opening parenthesis and the first constant, before and after the separating comma, and between the second constant and the closing parenthesis.
  
  - A logical constant represents true values (.TRUE. or any value beginning with T, .T, t, or .t) or false values (.FALSE. or any value beginning with F, .F, f, or .f).

  A character string does not need delimiting apostrophes or quotation marks if the corresponding I/O list item is of type default character, and the following is true:

    - The character string does not contain a blank, comma (,), or slash (/).
    - The character string is not continued across a record boundary.
    - The first nonblank character in the string is not an apostrophe or a quotation mark.
    - The leading character is not a string of digits followed by an asterisk.

  A nondelimited character string is terminated by the first blank, comma, slash, or end-of-record encountered. Apostrophes and quotation marks within nondelimited character strings are transferred as is.

- A null value

  A null value is specified by two consecutive value separators (such as,,) or a nonblank initial value separator. (A value separator before the end of the record does not signify a null value.)

  A null value indicates that the corresponding list element remains unchanged. A null value can represent an entire complex constant, but cannot be used for either part of a complex constant.

  - A repetition of a null value (r*) or a constant (r*constant), where r is an unsigned, nonzero, integer literal constant with no kind parameter, and no embedded blanks.

  A value separator is any number of blanks, or a comma or slash, preceded or followed by any number of blanks. When any of these appear in a character constant, they are considered part of the constant, not value separators.

  The end of a record is equivalent to a blank character, except when it occurs in a character constant. In this case, the end of the record is ignored, and the character constant is continued with the next record (the last character in the previous record is immediately followed by the first character of the next record).

  Blanks at the beginning of a record are ignored unless they are part of a character constant continued from the previous record. In this case, the blanks at the beginning of the record are considered part of the constant.
Examples

Suppose the following statements are specified:

```plaintext
CHARACTER*14 C
DOUBLE PRECISION T
COMPLEX D,E
LOGICAL L,M
READ (1,*) I,R,D,E,L,M,J,K,S,T,C,A,B
```

Then suppose the following external record is read:

```plaintext
4 6.3 (3.4,4.2), (3, 2 ), T,F,,3*14.6,'ABC,DEF/GHI''JK'/
```

The following values are assigned to the I/O list items:

<table>
<thead>
<tr>
<th>I/O List Item</th>
<th>Value Assigned</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>4</td>
</tr>
<tr>
<td>R</td>
<td>6.3</td>
</tr>
<tr>
<td>D</td>
<td>(3.4,4.2)</td>
</tr>
<tr>
<td>E</td>
<td>(3.0,2.0)</td>
</tr>
<tr>
<td>L</td>
<td>.TRUE.</td>
</tr>
<tr>
<td>M</td>
<td>.FALSE.</td>
</tr>
<tr>
<td>J</td>
<td>Unchanged</td>
</tr>
<tr>
<td>K</td>
<td>14</td>
</tr>
<tr>
<td>S</td>
<td>14.6</td>
</tr>
<tr>
<td>T</td>
<td>14.6D0</td>
</tr>
<tr>
<td>C</td>
<td>ABC,DEF/GHI' JK</td>
</tr>
<tr>
<td>A</td>
<td>Unchanged</td>
</tr>
<tr>
<td>B</td>
<td>Unchanged</td>
</tr>
</tbody>
</table>

The following example shows list-directed input and output:

```plaintext
REAL    a
INTEGER i
COMPLEX c
LOGICAL up, down
DATA a /2358.2E-8/, i /91585/, c /(705.60,819.60)/
DATA up /.TRUE./, down /.FALSE./
OPEN (UNIT = 9, FILE = 'listout', STATUS = 'NEW')
WRITE  (9, *) a, i
WRITE  (9, *) c, up, down
REWIND (9)
READ   (9, *) a, i
READ   (9, *) c, up, down
WRITE  (*, *) a, i
WRITE  (*, *) c, up, down
END
```

The preceding program produces the following output:

```plaintext
2.3582001E-05     91585
(705.6000,819.6000) T F
```

READ Statement
Forms for Sequential READ Statements
Intrinsic Data Types for details on the literal constant forms of intrinsic data types
Rules for List-Directed Sequential WRITE Statements for details on list-directed output

Rules for Namelist Sequential READ Statement

Namelist, sequential READ statements translate data from external to internal form by using the data types of the objects in the corresponding NAMELIST statement to determine the form of the data. The translated data is assigned to the specified objects in the namelist group in the order in which they appear, from left to right.

If a slash ( / ) is encountered during execution, the READ statement is terminated, and any remaining input list items are unchanged. An ampersand (&) encountered during input is treated the same as a slash (/).

If the file is connected for unformatted I/O, namelist data transfer is prohibited.

Namelist Records

A namelist external record takes the following form:
&group-nameobject = value [, object = value] .../

\texttt{group-name} Is the name of the group containing the objects to be given values. The name must have been previously defined in a NAMELIST statement in the scoping unit. The name cannot contain embedded blanks and must be contained within a single record.

\texttt{object} Is the name (or subobject designator) of an entity defined in the NAMELIST declaration of the group name. The object name must not contain embedded blanks except within the parentheses of a subscript or substring specifier. Each object must be contained in a single record.

\texttt{value} Is any of the following:

\begin{itemize}
  \item A constant
    
    Each constant must be a literal constant of type integer, real, complex, logical, or character; or a nondelimited character string. Binary, octal, hexadecimal, Hollerith, and named constants are not permitted.
    
    In general, the form of the constant must be acceptable for the type of the list item. The data type of the constant determines the data type of the value and the translation from external to internal form. The following rules also apply:
    
    \begin{itemize}
      \item A numeric list item can correspond only to a numeric constant, and a character list item can correspond only to a character constant. If the data types of a numeric list element and its corresponding numeric constant do not match, conversion is performed according to the rules for arithmetic assignment (see the table in Numeric Assignment Statements). Logical list items and logical constants are not considered numeric, unless the compiler option assume old_logical ldio is specified.
    \end{itemize}
\end{itemize}
• A complex constant has the form of a pair of real or integer constants separated by a comma and enclosed in parentheses. Blanks can appear between the opening parenthesis and the first constant, before and after the separating comma, and between the second constant and the closing parenthesis.

• A logical constant represents true values (.TRUE. or any value beginning with T, .T, t, or .t) or false values (.FALSE. or any value beginning with F, .F, f, or .f).

A character string does not need delimiting apostrophes or quotation marks if the corresponding NAMELIST item is of type default character, and the following is true:

• The character string does not contain a blank, comma (,), slash (/), exclamation point(!), ampersand (&), dollar sign ($), left parenthesis, equal sign (=), percent sign (%), or period (.).

The character string is not continued across a record boundary.

• The first nonblank character in the string is not an apostrophe or a quotation mark.

• The leading characters are not a string of digits followed by an asterisk.

A nondelimited character string is terminated by the first blank, comma, slash, end-of-record, exclamation, ampersand, or dollar sign encountered. Apostrophes and quotation marks within nondelimited character strings are transferred as is.

If an equal sign, percent sign, or period is encountered while scanning for a nondelimited character string, the string is treated as a variable name (or part of one) and not as a nondelimited character string.

• A null value

A null value is specified by two consecutive value separators (such as two adjacent commas ",," ) or a nonblank initial value separator. (A value separator before the end of the record does not signify a null value.)

A null value indicates that the corresponding list element remains unchanged. A null value can represent an entire complex constant, but cannot be used for either part of a complex constant.

• A repetition of a null value (r*) or a constant (r*constant), where r is an unsigned, nonzero, integer literal constant with no kind parameter, and no embedded blanks.

Blanks can precede or follow the beginning ampersand (&), follow the group name, precede or follow the equal sign, or precede the terminating slash.

Comments (beginning with ! only) can appear anywhere in namelist input. The comment extends to the end of the source line.

If an entity appears more than once within the input record for a namelist data transfer, the last value is the one that is used.

If there is more than one object = value pair, they must be separated by value separators.

A value separator is any number of blanks, or a comma or slash, preceded or followed by any number of blanks. When any of these appear in a character constant, they are considered part of the constant, not value separators.
The end of a record is equivalent to a blank character, except when it occurs in a character constant. In this case, the end of the record is ignored, and the character constant is continued with the next record (the last character in the previous record is immediately followed by the first character of the next record).

Blanks at the beginning of a record are ignored unless they are part of a character constant continued from the previous record. In this case, the blanks at the beginning of the record are considered part of the constant.

When the name in the input record is an array variable or a variable of derived type, the effect is as if the variable represented were expanded into a sequence of scalar list items of intrinsic data types. Each input value following the equal sign must comply with format specifications for the intrinsic type of the list item in the corresponding position in the expanded sequence.

The number of values following the equal sign must be equal to or less than the number of list items in the expanded sequence. In the latter case (less than), the effect is as if null values have been added to match any remaining list items in the expanded sequence.

In Intel® Fortran, a list of values may follow the equal sign when the object is a single array element. In this case, values are assigned to the specified array element and subsequent elements, in element sequence order. For example, suppose the following input is read:

```
&ELEM
ARRAY_A(3)=34.54, 45.34, 87.63, 3*20.00
/
```

New values are assigned only to array `ARRAY_A` elements 3 through 8. The other element values are unchanged.

Prompting for Namelist Group Information

During execution of a program containing a namelist READ statement, you can specify a question mark character (?) or a question mark character preceded by an equal sign (=?) to get information about the namelist group. The ? or =? must follow one or more blanks.

If specified for a unit capable of both input and output, the ? causes display of the group name and the objects in that group. The =? causes display of the group name, objects within that group, and the current values for those objects (in namelist output form). If specified for another type of unit, the symbols are ignored.

For example, consider the following statements:

```
NAMELIST /NLIST/ A,B,C
REAL A /1.5/
INTEGER B /2/
CHARACTER*5 C /'ABCDE'/
READ (5,NML=NLIST)
WRITE (6,NML=NLIST)
END
```

During execution, if a blank followed by ? is entered on a terminal device, the following values are displayed:

```
&NLIST
  A
  B
  C
/
```

If a blank followed by =? is entered, the following values are displayed:

```
&NLIST
  A  =   1.500000,
  B  =           2,
  C  = ABCDE
/
```
Examples

Suppose the following statements are specified:

```
NAMELIST /CONTROL/ TITLE, RESET, START, STOP, INTERVAL
CHARACTER*10 TITLE
REAL(KIND=8) START, STOP
LOGICAL(KIND=4) RESET
INTEGER(KIND=4) INTERVAL
READ (UNIT=1, NML=CONTROL)
```

The NAMELIST statement associates the group name CONTROL with a list of five objects. The corresponding READ statement reads the following input data from unit 1:

```
&CONTROL
    TITLE='TESTT002AA',
    INTERVAL=1,
    RESET=.TRUE.,
    START=10.2,
    STOP =14.5
/
```

The following values are assigned to objects in group CONTROL:

<table>
<thead>
<tr>
<th>Namelist Object</th>
<th>Value Assigned</th>
</tr>
</thead>
<tbody>
<tr>
<td>TITLE</td>
<td>TESTT002AA</td>
</tr>
<tr>
<td>RESET</td>
<td>T</td>
</tr>
<tr>
<td>START</td>
<td>10.2</td>
</tr>
<tr>
<td>STOP</td>
<td>14.5</td>
</tr>
<tr>
<td>INTERVAL</td>
<td>1</td>
</tr>
</tbody>
</table>

It is not necessary to assign values to all of the objects declared in the corresponding NAMELIST group. If a namelist object does not appear in the input statement, its value (if any) is unchanged.

Similarly, when character substrings and array elements are specified, only the values of the specified variable substrings and array elements are changed. For example, suppose the following input is read:

```
&CONTROL TITLE(9:10)='BB' /
```

The new value for TITLE is TESTT002BB; only the last two characters in the variable change.

The following example shows an array as an object:

```
DIMENSION ARRAY_A(20)
NAMELIST /ELEM/ ARRAY_A
READ (UNIT=1, NML=ELEM)
```

Suppose the following input is read:

```
&ELEM
    ARRAY_A=1.1, 1.2,, 1.4
/
```

The following values are assigned to the ARRAY_A elements:

<table>
<thead>
<tr>
<th>Array Element</th>
<th>Value Assigned</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARRAY_A(1)</td>
<td>1.1</td>
</tr>
<tr>
<td>ARRAY_A(2)</td>
<td>1.2</td>
</tr>
<tr>
<td>ARRAY_A(3)</td>
<td>Unchanged</td>
</tr>
</tbody>
</table>
Nondelimited character strings that are written out by using a NAMELIST write may not be read in as expected by a corresponding NAMELIST read. Consider the following:

```
NAMELIST/TEST/ CHARR
CHARACTER*3 CHARR(4)
DATA CHARR/'AAA', 'BBB', 'CCC', 'DDD'/
OPEN (UNIT=1, FILE='NMLTEST.DAT')
WRITE (1, NML=TEST)
END
```

The output file NMLTEST.DAT will contain:

```
&TEST CHARR   = AAABBBCCCDDD/
```

If an attempt is then made to read the data in NMLTEST.DAT with a NAMELIST read using nondelimited character strings, as follows:

```
NAMELIST/TEST/ CHARR
CHARACTER*3 CHARR(4)
DATA CHARR/4*'   '/
OPEN (UNIT=1, FILE='NMLTEST.DAT')
READ (1, NML=TEST)
PRINT *, 'CHARR read in >', CHARR(1),'<  >', CHARR(2),'<  >', CHARR(3), '<  >', CHARR(4), '<'
END
```

The result is the following:

```
CHARR read in >AAA<  >  <  >  <  >  <
```

NAMELIST
Alternative Form for Namelist External Records
Rules for Formatted Sequential READ Statements
Rules for Namelist Sequential WRITE Statements

Rules for Unformatted Sequential READ Statements

Unformatted, sequential READ statements transfer binary data (without translation) between the current record and the entities specified in the I/O list. The value transferred from the file is called a field. Only one record is read.

Objects of intrinsic or derived types can be transferred.

For data transfer, the file must be positioned so that the record read is an unformatted record or an end-of-file record.

The unformatted, sequential READ statement reads a single record. Each field value in the record must be of the same type as the corresponding entity in the input list, unless the field value is real or complex.

If the field value is real or complex, one complex field value can correspond to two real list entities, or two real values can correspond to one complex list entity. The corresponding values and entities must have the same kind parameter.

If the number of I/O list items is less than or equal to the number of fields in an input record, the READ statement ignores the excess fields. If the number of I/O list items is greater than the number of fields in an input record, an error occurs.

If a READ statement contains no I/O list, it skips over one full record, positioning the file to read the following record on the next execution of a READ statement.

If the file is connected for formatted, list-directed, or namelist I/O, unformatted data transfer is prohibited.
You have previously been able to buffer the output (WRITEs) of variable length, unformatted, sequential files, by specifying certain values for an OPEN statement, environment variable, or compiler option. You can now do the same buffering for input (READs) of records. To enable buffering for the input of records, you can specify any of the following:

- BUFFERED=YES in the file's OPEN statement
- Value YES (Y or y), or TRUE (T or t), or a number > 0 for the environment variable FORT_BUFFERED
- Setting `buffered_io` for the `assume` option

When any of the above are specified, the Fortran Runtime Library buffers all input records from variable length, unformatted, sequential files, regardless of the size of the records in the file. In addition, if the environment variable FORT_BUFFERING_THRESHOLD has a positive value \( n \), the following occurs:

- I/O list items with a size \( \leq n \) are buffered and are moved one at a time from the runtime buffer to the I/O list item
- I/O list items with a size \( > n \) are not buffered and are moved one at a time from the file to the I/O list item

**Determining the Size of I/O Buffers**

If both the block size and the buffer count have been specified with positive values, their product determines the size in bytes of the buffer for that I/O unit. If neither is specified, the default size of the buffer is 8KB (8192 bytes). This is the initial size of the I/O buffer; the buffer may be expanded to hold a larger record.

If block size is not specified, the following occurs:

- The block size defaults to 128KB
- If the buffer count is not specified, it defaults to 1
- The initial default buffer size is 8KB
- If buffer count is specified, then the initial default buffer size is (8KB \( \times \) buffercount)

If a block size is specified, the following occurs:

- The block size is the specified value, rounded up to 512-byte boundary
- If the buffer count is not specified, it defaults to 1
- The initial default buffer size is the block size, rounded up to 512-byte boundary
- If buffer count is specified, then the initial default buffer size is (block size \( \times \) buffer count)

**Optimizing for Time or Space**

When reading variable length, unformatted sequential records, the runtime system may optimize for time or for space.

This optimization decision is made during runtime on a record-by-record basis using specifications made by the program and the length of a given record. That is, one record may be optimized for time while another record from the same file may be optimized for space.

The default behavior when reading records of this type whose length exceeds the specified block size, is to not buffer the input records. You can override this default behavior by requesting that the input be buffered.

The following table shows the relationship between a file's specified block size and the length of its variable length records. Note that the length of the individual record is the key:

<table>
<thead>
<tr>
<th>Buffering</th>
<th>record length ( \geq ) block size</th>
<th>record length &lt; block size</th>
</tr>
</thead>
<tbody>
<tr>
<td>buffering unspecified</td>
<td>Optimizes for space</td>
<td>Optimizes for time</td>
</tr>
<tr>
<td>OPEN (BUFFERED='YES')</td>
<td>Optimizes for time</td>
<td>Optimizes for time</td>
</tr>
<tr>
<td>OPEN (BUFFERED='NO')</td>
<td>Optimizes for space</td>
<td>Optimizes for time</td>
</tr>
</tbody>
</table>

If an input record's length is *less than or equal to* the specified block size, then by default, the runtime system always optimizes for time rather than for space and the input is buffered.
If an input record's length is greater than the specified block size, then the following occurs:

- By default, the runtime system always optimizes for space rather than time and the input is not buffered.
- If you request buffering of input, then the runtime system optimizes for time and the input is buffered.
- If you request no buffering of input, then the runtime system optimizes for space rather than time and the input is not buffered.
- If you request dynamic buffering of input, the runtime system optimizes based on the size of the I/O list item and some items are buffered and some are not.

**Optimizing for time:**

Traditionally, optimizing for time comes at the expense of using more memory.

When the runtime system optimizes for time, it buffers input. It reads as much data as possible during one disk access into the runtime's internal buffer, extending it if necessary to hold the file's largest record. Fields within the record are then moved to the user space in response to READs from the file. Typically, minimizing file accesses is faster.

However, there are circumstances when optimizing for space can actually be faster than optimizing for time. For example, consider you are reading records whose length exceeds the block size and the data is being read into a contiguous array. Reading this huge array directly into a user's space is going to be faster than reading it first into the runtime system's internal buffer, then moving the data to the user's space. In this case, it is better to optimize for space; that is, you should not buffer the input record.

On the other hand, if the READ is being done into non-contiguous elements of an array, the traditional method of optimizing for time becomes a huge win. Data being read into non-contiguous array elements must be moved, or read, into the user's space one element at a time. In this case, you always want to optimize for time; that is, you should buffer the input data.

If you are reading large, variable length, unformatted records, you should try both buffered and unbuffered I/O to determine which delivers the better performance.

**Optimizing for space:**

Traditionally, optimizing for space comes at the expense of time.

When the runtime system optimizes for space, it wants to avoid creating a huge internal buffer in order to hold a "very large" record. The size of a "very large" record is clearly subjective, but the rule of thumb here is whether or not a record's size is greater than the specified block size.

If this is the case, the runtime system will read one field at a time from the record, directly into the I/O list items. The optimal record for this optimization is one whose record length exceeds the default block size of 128 KB (or a user-specified block size) and contains "very large" fields.

Note that because fields are read one at a time from the file to the user space, very large records that contain very small fields may see a serious performance issue. In these cases, it may be better to buffer the input. If you are reading large, variable length, unformatted records, you should try both buffered and unbuffered I/O to determine which delivers the better performance.

**Optimizing unformatted sequential input based on field size - dynamic buffering:**

Dynamic buffering is a hybrid solution that chooses the time/space trade-off on a per field basis. The decision is based on a "field size threshold" supplied by the user, deciding, for every field in every record in the file, regardless of the record length, whether or not to buffer a field from the file to the I/O list item. The runtime system can do this because it knows the size of a field that is being requested before actually attempting to read the field.

When a READ statement is first executed, a read from the file is issued to fill the buffer, regardless of its size. This is necessary so that the runtime system can extract the record size from the first length control field. (Each unformatted sequential record has 4-byte leading and trailing record lengths to facilitate reading both forwards and backwards in the file.) From that point on, dynamic buffering decides whether or not to buffer a field or to read it directly from the file to the I/O list item. If the buffer holds the beginning portion of a large field, it will be moved to the start of the I/O list item and the remainder will be read directly from the file.
The following table shows the various buffering options for unformatted, sequential input:

<table>
<thead>
<tr>
<th>Buffering Option</th>
<th>How do I get this?</th>
<th>What happens?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-buffered</td>
<td>You get this kind of buffering by default, or by specifying:</td>
<td>When non-buffered is in effect:</td>
</tr>
<tr>
<td></td>
<td>• OPEN (BUFFERED=NO)</td>
<td>• The runtime system does not re-allocate its buffer to accommodate large records.</td>
</tr>
<tr>
<td></td>
<td>• FORT_BUFFERED=NO</td>
<td>• Records with lengths &gt; the block size:</td>
</tr>
<tr>
<td></td>
<td>• assume nobuffered_io</td>
<td>• Are not buffered.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• All fields are moved one at a time from the file to the I/O list item.</td>
</tr>
<tr>
<td>Buffered</td>
<td>You get this kind of buffering by specifying:</td>
<td>When buffered is in effect:</td>
</tr>
<tr>
<td></td>
<td>• OPEN (BUFFERED=YES)</td>
<td>• The runtime system re-allocates its buffer to accommodate the largest record read.</td>
</tr>
<tr>
<td></td>
<td>• FORT_BUFFERED=YES</td>
<td>• All input records are buffered.</td>
</tr>
<tr>
<td></td>
<td>• assume buffered_io</td>
<td>• All fields are moved one at a time from the buffer to the I/O list item.</td>
</tr>
<tr>
<td>Dynamic buffering</td>
<td>You get this kind of buffering by specifying:</td>
<td>When dynamic buffering is in effect:</td>
</tr>
<tr>
<td></td>
<td>• FORT_BUFFERING_THRESHOLD D=n and one of -</td>
<td>• The runtime system does not re-allocate its buffer to accommodate large records.</td>
</tr>
<tr>
<td></td>
<td>• OPEN (BUFFERED=YES)</td>
<td>• All fields with a size &lt;= n are buffered and are moved one at a time from the buffer to the I/O list item.</td>
</tr>
<tr>
<td></td>
<td>• FORT_BUFFERED=YES</td>
<td>• Fields with a size &gt; n are not buffered and are moved one at a time from the file to the I/O list item.</td>
</tr>
<tr>
<td></td>
<td>• assume buffered_io</td>
<td></td>
</tr>
</tbody>
</table>

**Examples**

The following example shows an unformatted, sequential READ statement:

```plaintext
READ (UNIT=6, IOSTAT=IO_STATUS) A, B, C
```

READ Statement  
Forms for Sequential READ Statements
Record Types

Forms for Direct-Access READ Statements

Direct-access READ statements transfer input data from external records with direct access. (The attributes of a direct-access file are established by the OPEN statement.)

A direct-access READ statement can be formatted or unformatted, and takes one of the following forms:

**Formatted:**

```
```

**Unformatted:**

```
```

See Also

READ Statement
I/O Control List
I/O Lists

Rules for Formatted Direct-Access READ Statements

Formatted, direct-access READ statements translate data from character to binary form by using format specifications for editing (if any). The translated data is assigned to the entities in the I/O list in the order in which the entities appear, from left to right.

Values can be transferred to objects of intrinsic or derived types. For derived types, values of intrinsic types are transferred to the components of intrinsic types that ultimately make up these structured objects.

For data transfer, the file must be positioned so that the record read is a formatted record or an end-of-file record.

If the number of I/O list items is less than the number of fields in an input record, the statement ignores the excess fields.

If the number of I/O list items is greater than the number of fields in an input record, the input record is padded with blanks. However, if PAD='NO' was specified for file connection, the input list and file specification must not require more characters from the record than it contains. If more characters are required and nonadvancing input is in effect, an end-of-record condition occurs.

If the format specification specifies another record, the record number is increased by one as each subsequent record is read by that input statement.

Examples

The following example shows a formatted, direct-access READ statement:

```
READ (2, REC=35, FMT=10) (NUM(K), K=1,10)
```

Rules for Unformatted Direct-Access READ Statements

Unformatted, direct-access READ statements transfer binary data (without translation) between the current record and the entities specified in the I/O list. Only one record is read.

Objects of intrinsic or derived types can be transferred.

For data transfer, the file must be positioned so that the record read is an unformatted record or an end-of-file record.

The unformatted, direct-access READ statement reads a single record. Each value in the record must be of the same type as the corresponding entity in the input list, unless the value is real or complex.

If the value is real or complex, one complex value can correspond to two real list entities, or two real values can correspond to one complex list entity. The corresponding values and entities must have the same kind parameter.
If the number of I/O list items is less than the number of fields in an input record, the statement ignores the excess fields. If the number of I/O list items is greater than the number of fields in an input record, an error occurs.

If the file is connected for formatted, list-directed, or namelist I/O, unformatted data transfer is prohibited.

**Examples**

The following example shows unformatted, direct-access READ statements:

```plaintext
READ (1, REC=10) LIST(1), LIST(8)
READ (4, REC=58, IOSTAT=I, ERR=500) (RHO(N), N=1,5)
```

**Forms for Stream READ Statements**

The forms for stream READ statements take the same forms as sequential READ statements. A POS specifier may be present to specify at what file position the READ will start.

You can impose a record structure on a formatted, sequential stream by using a new-line character as a record terminator (see intrinsic function `NEW_LINE`). There is no record structure in an unformatted, sequential stream.

The INQUIRE statement can be used with the POS specifier to determine the current file position in a stream file.

**Examples**

The following example shows stream READ statements:

```plaintext
READ (12 ) I  !stream reading without POS= specifier
READ (12,POS=10) J !stream reading with POS= specifier
```

**See Also**

NEW_LINE

**Forms and Rules for Internal READ Statements**

Internal READ statements transfer input data from an internal file.

An internal READ statement can only be formatted. It must include format specifiers (which can use list-directed formatting). Namelist formatting is also permitted.

An internal READ statement takes one of the following forms:

```plaintext
READ (iunit, format [, nml-group] [, iostat] [, err] [, end] [, iomsg]) [io-list]
```

For more information on syntax, see READ.

Formatted, internal READ statements translate data from character to binary form by using format specifications for editing (if any). The translated data is assigned to the entities in the I/O list in the order in which the entities appear, from left to right.

This form of READ statement behaves as if the format begins with a BN edit descriptor. (You can override this behavior by explicitly specifying the BZ edit descriptor.)

Values can be transferred to objects of intrinsic or derived types. For derived types, values of intrinsic types are transferred to the components of intrinsic types that ultimately make up these structured objects.

Before data transfer occurs, the file is positioned at the beginning of the first record. This record becomes the current record.

If the number of I/O list items is less than the number of fields in an input record, the statement ignores the excess fields.

If the number of I/O list items is greater than the number of fields in an input record, the input record is padded with blanks. However, if PAD='NO' was specified for file connection, the input list and file specification must not require more characters from the record than it contains.

In list-directed and namelist formatting, character strings have no delimiters.
Examples

The following program segment reads a record and examines the first character to determine whether the remaining data should be interpreted as decimal, octal, or hexadecimal. It then uses internal READ statements to make appropriate conversions from character string representations to binary.

```fortran
INTEGER IVAL
CHARACTER TYPE, RECORD*80
CHARACTER*(*) AFMT, IFMT, OFMT, ZFMT
PARAMETER (AFMT='(Q,A)', IFMT= '(I10)', OFMT= '(O11)', & ZFMT= '(Z8)')
ACCEPT AFMT, ILEN, RECORD
TYPE = RECORD(1:1)
IF (TYPE .EQ. 'D') THEN
   READ (RECORD(2:MIN(ILEN, 11)), IFMT) IVAL
ELSE IF (TYPE .EQ. 'O') THEN
   READ (RECORD(2:MIN(ILEN, 12)), OFMT) IVAL
ELSE IF (TYPE .EQ. 'X') THEN
   READ (RECORD(2:MIN(ILEN, 9)),ZFMT) IVAL
ELSE
   PRINT *, 'ERROR'
END IF
END
```

I/O Lists
Rules for List-Directed Sequential READ Statements for details on list-directed input
Rules for Namelist Sequential READ Statement for details on namelist input

Forms for WRITE Statements

Forms for Sequential WRITE Statements

Sequential WRITE statements transfer output data to external sequential access records. The statements can be formatted by using format specifiers (which can use list-directed formatting) or namelist specifiers (for namelist formatting), or they can be unformatted.

A sequential WRITE statement takes one of the following forms:

**Formatted:**

```
```

**Formatted - List-Directed:**

```
```

**Formatted - Namelist:**

```
```

**Unformatted:**

```
```
Rules for Formatted Sequential WRITE Statements

Formatted, sequential WRITE statements translate data from binary to character form by using format specifications for editing (if any). The translated data is written to an external file that is connected for sequential access.

Values can be transferred from objects of intrinsic or derived types. For derived types, values of intrinsic types are transferred from the components of intrinsic types that ultimately make up these structured objects.

The output list and format specification must not specify more characters for a record than the record size. (Record size is specified by RECL in an OPEN statement.)

If the file is connected for unformatted I/O, formatted data transfer is prohibited.

Examples

The following example shows formatted, sequential WRITE statements:

```
WRITE (UNIT=8, FMT='(B)', ADVANCE='NO') C
WRITE (*, "(F6.5)", ERR=25, IOSTAT=IO_STATUS) A, B, C
```

See Also
- WRITE Statement
- Forms for Sequential WRITE Statements

Rules for List-Directed Sequential WRITE Statements

List-directed, sequential WRITE statements transfer data from binary to character form by using the data types of the corresponding I/O list item to determine the form of the data. The translated data is then written to an external file.

In general, values transferred as output have the same forms as values transferred as input. However, there is no guarantee that a REAL internal value transferred as output and then transferred as input as a REAL value will be the same internal value.

The following table shows the default output formats for each intrinsic data type:

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Output Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>BYTE</td>
<td>I5</td>
</tr>
<tr>

</tr>
<tr>
<td>CHARACTER</td>
<td>Aw</td>
</tr>
</tbody>
</table>

1 Where w is the length of the character expression.

2 If option assume noold_ldout_format is in effect, the compiler uses Fortran 2003 standard semantics for output of integer and real values in list-directed and namelisted-directed output. This means that for real and complex values, the output is in E or F format depending on the magnitude of the value. For more information, see the description of option assume.

By default, character constants are not delimited by apostrophes or quotation marks, and each internal apostrophe or quotation mark is represented externally by one apostrophe or quotation mark.

This behavior can be changed by the DELIM specifier (in an OPEN statement) as follows:

- If the file is opened with the DELIM='QUOTE' specifier, character constants are delimited by quotation marks and each internal quotation mark is represented externally by two consecutive quotation marks.
- If the file is opened with the DELIM='APOSTROPHE' specifier, character constants are delimited by apostrophes and each internal apostrophe is represented externally by two consecutive apostrophes.

Each output statement writes one or more complete records.

A literal character constant or complex constant can be longer than an entire record. For complex constants, the end of the record can occur between the comma and the imaginary part, if the imaginary part and closing right parenthesis cannot fit in the current record. For literal constants that are longer than an entire record, the constant is continued onto as many records as necessary.

Each output record begins with a blank character for carriage control.

Slashes, octal values, null values, and repeated forms of values are not output.

If the file is connected for unformatted I/O, list-directed data transfer is prohibited.

**Examples**

Suppose the following statements are specified:

```fortran
DIMENSION A(4)
DATA A/4*3.4/
WRITE (1,*), 'ARRAY VALUES FOLLOW'
WRITE (1,*), A, 4
```

The following records are then written to external unit 1:

```
ARRAY VALUES FOLLOW
3.400000  3.400000  3.400000  3.400000  4
```

The following shows another example:

```fortran
INTEGER i, j
REAL a, b
LOGICAL on, off
CHARACTER(20) c
DATA i /123456/, j /500/, a /28.22/, b / .0015555/
DATA on /.TRUE./, off/.FALSE./
DATA c /'Here''s a string'/
WRITE (*, *) i, j
```
\begin{verbatim}
WRITE (*, *)  a, b, on, off
WRITE (*, *)  c
END
\end{verbatim}

The preceding example produces the following output:

\begin{verbatim}
  123456         500
  28.22000      1.5555E-03 T F
Here's a string
\end{verbatim}

\section*{See Also}

\textbf{Rules for Formatted Sequential WRITE Statements}

\textbf{Rules for List-Directed Sequential READ Statements} for details on list-directed input

\section*{Rules for Namelist Sequential WRITE Statements}

Namelist, sequential WRITE statements translate data from internal to external form by using the data types of the objects in the corresponding NAMELIST statement to determine the form of the data. The translated data is then written to an external file.

In general, values transferred as output have the same forms as values transferred as input. However, there is no guarantee that a REAL internal value transferred as output and then transferred as input as a REAL value will be the same internal value.

By default, character constants are not delimited by apostrophes or quotation marks, and each internal apostrophe or quotation mark is represented externally by one apostrophe or quotation mark.

This behavior can be changed by the DELIM specifier (in an OPEN statement) as follows:

- If the file is opened with the DELIM='QUOTE' specifier, character constants are delimited by quotation marks and each internal quotation mark is represented externally by two consecutive quotation marks.
- If the file is opened with the DELIM='APOSTROPHE' specifier, character constants are delimited by apostrophes and each internal apostrophe is represented externally by two consecutive apostrophes.

Each output statement writes one or more complete records.

A literal character constant or complex constant can be longer than an entire record. In the case of complex constants, the end of the record can occur between the comma and the imaginary part, if the imaginary part and closing right parenthesis cannot fit in the current record.

Each output record begins with a blank character for carriage control, except for literal character constants that are continued from the previous record.

Slashes, octal values, null values, and repeated forms of values are not output.

If the file is connected for unformatted I/O, namelist data transfer is prohibited.

\section*{Examples}

Consider the following statements:

\begin{verbatim}
CHARACTER*19 NAME(2)/2*' '/
REAL PITCH, ROLL, YAW, POSITION(3)
LOGICAL DIAGNOSTICS
INTEGER ITERATIONS
TYPE MYTYPE
    INTEGER X
    REAL Y
    CHARACTER(5)Z
END TYPE MYTYPE
TYPE(MYTYPE) :: TYPEVAR = MYTYPE(1,2.0,'ABCDE')
NAMELIST /PARAM/ NAME, PITCH, ROLL, TYPEVAR, YAW, POSITION, &
    DIAGNOSTICS, ITERATIONS
... READ (UNIT=1,NML=PARAM)
WRITE (UNIT=2,NML=PARAM)
\end{verbatim}
Suppose the following input is read:

```fortran
&PARAM
    NAME(2)(10:)='HEISENBERG',
    PITCH=5.0, YAW=0.0, ROLL=5.0,
    DIAGNOSTICS=.TRUE.,
    ITERATIONS=10
/
```

The following is then written to the file connected to unit 2:

```fortran
&PARAM
NAME    = '                         ', '        HEISENBERG',
PITCH   =    5.000000,
ROLL    =    5.000000,
TYPEVAR = 1, 2.0, 'ABCDE'
YAW     =   0.0000000E+00,
POSITION        = 3*0.0000000E+00,
DIAGNOSTICS     = T,
ITERATIONS      =                10
/
```

Note that character values are not enclosed in apostrophes unless the output file is opened with `DELIM='APOSTROPHE'`. The value of `POSITION` is not defined in the namelist input, so the current value of `POSITION` is written.

The following example declares a number of variables, which are placed in a namelist, initialized, and then written to the screen with namelist I/O:

```fortran
INTEGER(1) int1
INTEGER    int2, int3, array(3)
LOGICAL(1) log1
LOGICAL log2, log3
REAL    real1
REAL(8) real2
COMPLEX z1, z2
CHARACTER(1)  char1
CHARACTER(10) char2

NAMELIST /example/ int1, int2, int3, log1, log2, log3, 
            &
            real1, real2, z1, z2, char1, char2, array

int1     = 11
int2     = 12
int3     = 14
log1     = .TRUE.
log2     = .TRUE.
log3     = .TRUE.
real1    = 24.0
real2    = 28.0d0
z1       = (38.0,0.0)
z2       = (316.0d0,0.0d0)
char1    = 'A'
char2    = '0123456789'
array(1) = 41
array(2) = 42
array(3) = 43
WRITE (*, example)
```

The preceding example produces the following output:

```fortran
&EXAMPLE
INT1 =   11,
INT2 =          12,
```
INT3 = 14,
LOG1 = T,
LOG2 = T,
LOG3 = T,
REAL1 = 24.00000,
REAL2 = 28.0000000000000,
Z1 = (38.00000,0.0000000E+00),
Z2 = (316.0000,0.0000000E+00),
CHAR1 = A,
CHAR2 = 0123456789,
ARRAY = 41, 42, 43
/

NAMELIST
Rules for Formatted Sequential WRITE Statements
Rules for Namelist Sequential READ Statement

Rules for Unformatted Sequential WRITE Statements
Unformatted, sequential WRITE statements transfer binary data (without translation) between the entities specified in the I/O list and the current record. Only one record is written.

Objects of intrinsic or derived types can be transferred.
This form of WRITE statement writes exactly one record. If there is no I/O item list, the statement writes one null record.
If the file is connected for formatted, list-directed, or namelist I/O, unformatted data transfer is prohibited.
For a discussion of I/O buffering, see Rules for Unformatted Sequential READ Statements.

Examples
The following example shows an unformatted, sequential WRITE statement:

```
WRITE (UNIT=6, IOSTAT=IO_STATUS) A, B, C
```

Forms for Direct-Access WRITE Statements
Direct-access WRITE statements transfer output data to external records with direct access. (The attributes of a direct-access file are established by the OPEN statement.)

A direct-access WRITE statement can be formatted or unformatted, and takes one of the following forms:

**Formatted:**

```
```

**Unformatted:**

```
```

See Also
WRITE Statement
I/O Control List
I/O Lists

Rules for Formatted Direct-Access WRITE Statements

Formatted, direct-access WRITE statements translate data from binary to character form by using format specifications for editing (if any). The translated data is written to an external file that is connected for direct access.
Values can be transferred from objects of intrinsic or derived types. For derived types, values of intrinsic types are transferred from the components of intrinsic types that ultimately make up these structured objects.

If the values specified by the I/O list do not fill a record, blank characters are added to fill the record. If the I/O list specifies too many characters for the record, an error occurs.

If the format specification specifies another record, the record number is increased by one as each subsequent record is written by that output statement.

**Examples**

The following example shows a formatted, direct-access WRITE statement:

```fortran
WRITE (2, REC=35, FMT=10) (NUM(K), K=1,10)
```

**Rules for Unformatted Direct-Access WRITE Statements**

Unformatted, direct-access WRITE statements transfer binary data (without translation) between the entities specified in the I/O list and the current record. Only one record is written.

Objects of intrinsic or derived types can be transferred.

If the values specified by the I/O list do not fill a record, blank characters are added to fill the record. If the I/O list specifies too many characters for the record, an error occurs.

If the file is connected for formatted, list-directed, or namelist I/O, unformatted data transfer is prohibited.

**Examples**

The following example shows unformatted, direct-access WRITE statements:

```fortran
WRITE (1, REC=10) LIST(1), LIST(8)
WRITE (4, REC=58, IOSTAT=K, ERR=500) (RHO(N), N=1,5)
```

**Forms for Stream WRITE Statements**

The forms for stream WRITE statements take the same forms as sequential WRITE statements. A POS specifier may be present to specify at what file position the WRITE will start.

You can impose a record structure on a formatted, sequential stream by using a new-line character as a record terminator (see intrinsic function NEW_LINE). There is no record structure in an unformatted, sequential stream.

The INQUIRE statement can be used with the POS specifier to determine the current file position in a stream file.

**See Also**

NEW_LINE

**Forms and Rules for Internal WRITE Statements**

Internal WRITE statements transfer output data to an internal file.

An internal WRITE statement can only be formatted. It must include format specifiers (which can use list-directed formatting). Namelist formatting is also permitted.

An internal WRITE statement takes one of the following forms:

```fortran
WRITE (iunit, format [, iostat] [, err] [, iomsg]) [io-list]
WRITE (iunit, nml-group [, iostat] [, err] [, iomsg]) [io-list]
```

For more information on syntax, see WRITE.

Formatted, internal WRITE statements translate data from binary to character form by using format specifications for editing (if any). The translated data is written to an internal file.
Values can be transferred from objects of intrinsic or derived types. For derived types, values of intrinsic types are transferred from the components of intrinsic types that ultimately make up these structured objects.

If the number of characters written in a record is less than the length of the record, the rest of the record is filled with blanks. The number of characters to be written must not exceed the length of the record.

Character constants are not delimited by apostrophes or quotation marks, and each internal apostrophe or quotation mark is represented externally by one apostrophe or quotation mark.

**Examples**

The following example shows an internal WRITE statement:

```
INTEGER J, K, STAT_VALUE
CHARACTER*50 CHAR_50
...
WRITE (FMT=*, UNIT=CHAR_50, IOSTAT=STAT_VALUE) J, K
```

**User-Defined Derived-Type I/O**

**User-Defined Derived-Type I/O Overview**

By default, when a derived-type object is in a formatted I/O statement, it is treated as if all of its components were specified in the component order. The components must be accessible in the scope of the I/O statement and they cannot be pointers or allocatables. In an unformatted I/O statement, a derived-type object is treated as a single value in a processor-dependent form.

User-defined derived-type I/O lets you replace the default I/O processing for a derived-type object. For both unformatted and formatted I/O, a procedures can be invoked that will handle the I/O of the derived type. This is similar to defined operators and defined assignment.

For formatted I/O, the replacement occurs for list-directed formatting, namelist formatting, and for an explicit format with the DT edit descriptor. Other edit descriptors in the explicit format do not have any effect on user-defined I/O.

A procedure can be associated with defined I/O through generic bindings or generic interface blocks. The procedure must conform to the interface that specifies its characteristics. It cannot directly or indirectly use OpenMP* constructs. A defined I/O procedure can also call itself recursively.

An I/O statement that includes a derived-type object and causes a defined I/O procedure to be invoked is called a parent I/O statement. An I/O statement that is executed while a parent statement is being processed, and specifies the unit passed to a defined I/O procedure, is called a child I/O statement.

A defined I/O procedure can be invoked as a parent I/O statement for an external or internal file opened for sequential, direct, or stream access.

This section also has information about how to resolve user-defined I/O procedure references.

**Specifying the User-Defined Derived Type**

**DT Edit Descriptor in User-Defined I/O**

The DT edit descriptor passes a character string and integer array to a defined I/O procedure. It takes the following form:

```
DT [string] [(v-list)]
```
The _string_ is a default character literal constant delimited by single quotes (' ') or double quotes (" "); no kind parameter can be specified. Its length is the number of characters between the delimiters; two consecutive delimiters are counted as one character. If _string_ is not specified, a character string of length zero is passed.

The _v-list_ is a list of one or more signed or unsigned integer literal constants; no kind parameter can be specified. If _v-list_ is not specified, an integer array of length zero is passed.

A DT edit descriptor must correspond to a list item of a derived type. Also, there should be an accessible interface to a corresponding defined FORMATTED I/O procedure for that derived type.

In a format statement, if the last closing parenthesis of the format string is reached and there are no effective items left, then format processing terminates. But, if there are more items to be processed, then format control reverts to the beginning of the format item which was terminated by the next-to-last right parenthesis.

If there is no such preceding right parenthesis, it reverts to the first left parenthesis of the format specification. During this format reversion, the right parenthesis that is part of a DT edit descriptor is not considered as the next-to-last parenthesis. For example, consider the following:

```fortran
write (10, '(F10.3, I5, 'DT "sample" (1, 2) )' ) 10.1, 3, obj1, 4.7, 1, obj2
```

In the above case, format control reverts to the left parenthesis before F10.3 and not to DT.

### Examples

The following are valid ways to specify the DT edit descriptor:

- DT
- DT "z8, i4, e10.2"
- DT (1, -1, +1000)
- DT 'my type' (0)

### Associating a Procedure with Defined I/O

#### Defined I/O Procedures

For a particular derived type and a particular set of kind-type parameter values, there are four possible sets of characteristics for defined I/O procedures: formatted input, formatted output, unformatted input, and unformatted output.

To specify that an I/O procedure should be used for derived-type I/O, specify one of the following with a defined-io-generic-spec:

- A generic binding
- An interface block

A defined-io-generic-spec is one of the following statements:

- READ (FORMATTED)
- READ (UNFORMATTED)
- WRITE (FORMATTED)
- WRITE (UNFORMATTED)

#### Generic Bindings

User-defined I/O procedures can be type-bound procedures that use a defined-io-generic-spec (see Defined I/O Procedures).

Consider the following:

```fortran
TYPE LIST
  TYPE(NODE), POINTER :: FIRST
CONTAINS
  PROCEDURE :: FMTREAD => LIST_FMTREAD
  PROCEDURE :: FMTWRITE => LIST_FMTWRITE
```

902
In the above, LIST_FMTREAD and LIST_FMTWRITE are the type-bound defined I/O procedures. If an object of type LIST is an effective item in a formatted READ statement, LIST_FMTREAD will be called to perform the read operation.

See Also
Type-Bound Procedures
Resolving Defined I/O Procedure References

Generic Interface Block

A generic interface block can be used to associate procedures with defined I/O. The generic identifier should be the defined-io-generic-spec (see Defined I/O Procedures). This is the only option for sequence or BIND(C) types.

Consider the following:

```fortran
MODULE EXAMPLE

TYPE LIST
  INTEGER :: X
END TYPE

INTERFACE READ (FORMATTED)
  MODULE PROCEDURE R1
END INTERFACE

CONTAINS

  SUBROUTINE R1 (DTV, UNIT, IOTYPE, V_LIST, IOSTAT, IOMSG)
    CLASS(LIST), INTENT(INOUT) :: DTV
    INTEGER, INTENT(IN) :: UNIT
    CHARACTER(*), INTENT(IN) :: IOTYPE
    INTEGER, INTENT(IN) :: V_LIST(:)
    INTEGER, INTENT(OUT) :: IOSTAT
    CHARACTER(*), INTENT(INOUT) :: IOMSG
    READ (UNIT, FMT=*, IOSTAT=IOSTAT, IOMSG=IOMSG) DTV%X
  END SUBROUTINE R1

END MODULE EXAMPLE
```

In the above, R1 is the READ (FORMATTED) defined I/O procedure. If an object of type LIST is an effective item in a formatted READ statement, R1 will be called.

See Also
TYPE Statement (Derived Types)
Defining Generic Names for Procedures

Characteristics of Defined I/O Procedures

Shown below are the four interfaces that specify the characteristics of the user-defined I/O procedures. The actual specific procedure names and the names of the dummy arguments in these interfaces are arbitrary. The following names are used in the interfaces:

- `dtv-type-spec` is one of the following:
  - TYPE(`d-name`) for a sequence or BIND(C) type
  - CLASS(`d-name`) for an extensible type
d-name is the name of the derived type. It cannot be an abstract type. All length type parameters of the derived type must be assumed.

var
Is a scalar of the derived type. For output, it holds the value to be written. For input, it will be altered in accordance with the values read.

unit
Is the scalar integer value of the I/O unit on which input or output is taking place. It is a negative number for an internal file or for an external unit that is a NEWUNIT value. It is a processor-dependent number (which may be negative) for the '*-' unit.

iotype
Is the value 'LISTDIRECTED', 'NAMELIST', or 'DT'//string, where string is the character string from the DT edit descriptor.

vlist
Is a rank-one assumed-shape integer array whose value comes from the parenthetical list of integers from the DT edit descriptor. For list-directed formatting and namelist formatting, vlist is a zero-sized integer array.

iostat
Is a scalar integer variable that must be given a positive value if an error condition occurs. If an end-of-file or end-of-record condition occurs, it must be given the value IOSTAT_END or IOSTAT_EOR (from the intrinsic module ISO_FORTRAN_ENV). In all other cases, it must be given the value zero.

iomsg
Is an assumed-length scalar character variable that must be set to an explanatory message if iostat is given a nonzero value. Otherwise, it must not be altered.

The following interfaces specify the characteristics of the user-defined I/O procedures:

SUBROUTINE my_read_formatted (var,unit,iotype,vlist,iostat,iomsg)
dtv-type-spec,INTENT(INOUT) :: var
INTEGER,INTENT(IN) :: unit
CHARACTER(*),INTENT(IN) :: iotype
INTEGER,INTENT(IN) :: vlist(:)
INTEGER,INTENT(OUT) :: iostat
CHARACTER(*),INTENT(INOUT) :: iomsg
END

SUBROUTINE my_read_unformatted (var,unit,iostat,iomsg)
dtv-type-spec,INTENT(INOUT) :: var
INTEGER,INTENT(IN) :: unit
INTEGER,INTENT(OUT) :: iostat
CHARACTER(*),INTENT(INOUT) :: iomsg
END

SUBROUTINE my_write_formatted (var,unit,iotype,vlist,iostat,iomsg)
dtv-type-spec,INTENT(IN) :: var
INTEGER,INTENT(IN) :: unit
CHARACTER(*),INTENT(IN) :: iotype
INTEGER,INTENT(IN) :: vlist(:)
INTEGER,INTENT(OUT) :: iostat
CHARACTER(*),INTENT(INOUT) :: iomsg
END

SUBROUTINE my_write_unformatted (var,unit,iostat,iomsg)
dtv-type-spec,INTENT(IN) :: var
See Also
ISO_FORTRAN_ENV Module

Defined I/O Data Transfers

The following rules apply to defined I/O data transfers:

- During execution of a defined I/O procedure, there must be no I/O for an external unit except for the unit argument. However, I/O is permitted for internal files.
- You cannot use user-defined I/O in combination with asynchronous I/O.
- No file-positioning commands are permitted in the defined I/O procedure. OPEN, CLOSE, BACKSPACE, ENDFILE, and REWIND statements will not be executed. Any ADVANCE= specifier in a child statement is ignored.
- A record positioning edit descriptor, such as TL and TR, used on the unit by a child data transfer statement will not cause the record position to be positioned before the record position at the time the defined I/O procedure was invoked.
- A child data transfer statement must not specify the ID=, POS=, or REC= specifier in an I/O control list.
- The file position on entry is treated as a left tab limit and there is no record termination on return. However, a child statement with slash (/) edit descriptor, or explicit record termination by a list-directed child I/O, is allowed.
- If the unit is associated with an external file (for example, non-negative, or equal to one of the constants ERROR_UNIT, INPUT_UNIT, or OUTPUT_UNIT from the intrinsic module ISO_FORTRAN_ENV), the current settings for the pad mode, sign mode, etc., can be discovered by using INQUIRE with PAD=, SIGN=, etc. on the unit argument.

Note that INQUIRE must not be used if the unit is an internal unit passed to a user-defined derived-type I/O procedure from a parent I/O statement. When an internal unit is used with the INQUIRE statement, an error condition will occur, and the variable specified in an IOSTAT= specifier in the INQUIRE statement will be assigned the value IOSTAT_INQUIRE_INTERNAL_UNIT from the intrinsic module ISO_FORTRAN_ENV.

ISO_FORTRAN_ENV Module
User-Defined Derived-Type I/O Overview

Resolving Defined I/O Procedure References

A generic interface for defined I/O of a derived-type object is one that has both of the following:

- A defined-io-generic-spec that is appropriate to the READ or WRITE direction and the form (formatted or unformatted) of the data transfer (see Defined IO Procedures, Generic Bindings, and Generic Interface Block).
- A specific interface whose var argument is compatible with the derived-type item.

Within the scope of a defined-io-generic-spec, if two procedures have that generic identifier, they must be distinguishable.

For defined I/O procedures, only the var argument corresponds to something explicitly written in the program, so it is the var that must be distinguishable.

Because var arguments are required to be scalar, they cannot differ in rank. So, the var must be distinguishable in the type and kind type parameters.

You cannot have two procedures with the same defined-io-generic-spec.

See Also
Characteristics of Defined I/O Procedures
Recursive Defined I/O

A defined I/O procedure can invoke itself indirectly. It can have an I/O statement that includes a derived-type object that results in the invocation of the same procedure. In this case, the defined I/O procedure must be declared RECURSIVE.

Consider the following:

```fortran
MODULE LIST_MODULE
  IMPLICIT NONE
  TYPE NODE
    ! This type declaration represents a singly-linked list that also
    ! contains a user-defined i/o procedure. The name of the procedure
    ! is arbitrary, but the order of arguments must conform to the
    ! standard definition.
    INTEGER :: VALUE = -1
    TYPE(NODE), POINTER :: NEXT_NODE => NULL()
  CONTAINS
    PROCEDURE :: PWF
      GENERIC :: WRITE(FORMATTED) => PWF ! <=== GENERIC BINDING.
  END TYPE NODE
  CONTAINS
    RECURSIVE SUBROUTINE PWF( DTV, UNIT, IOTYPE, V_LIST, IOSTAT, IOMSG )
      ! These arguments are defined in the standard.
      CLASS(NODE), INTENT(IN) :: DTV
      INTEGER, INTENT(IN) :: UNIT
      CHARACTER(LEN=*) :: IOTYPE
      INTEGER, DIMENSION(:), INTENT(IN) :: V_LIST
      INTEGER :: IOSTAT
      CHARACTER(LEN=*) :: IOMSG
      ! The following is a child i/o statement that is called when user-defined i/o
      ! statement is invoked.
      WRITE( UNIT=UNIT, FMT='(I9)', IOSTAT=IOSTAT ) DTV%VALUE
      PRINT *, ASSOCIATED(DTV%NEXT_NODE)
      IF(IOSTAT /= 0)RETURN
      ! It is possible to recursively call the user-defined i/o routine.
      IF(ASSOCIATED(DTV%NEXT_NODE)
        WRITE(UNIT=UNIT, FMT='(/,DT)', IOSTAT=IOSTAT) DTV%NEXT_NODE
      END IF
    END SUBROUTINE PWF
  END MODULE LIST_MODULE

PROGRAM LISTE
  USE LIST_MODULE
  IMPLICIT NONE
  INTEGER :: UNIT, IOSTAT, I
  TYPE(NODE), POINTER :: CUR, TO_PRINT
  ! Create the linked list
  ALLOCATE(CUR)
  CUR % VALUE = 999
  ALLOCATE(TO_PRINT)
  TO_PRINT => CUR
  DO I = 1,10
```

---

The module `LIST_MODULE` defines a type `NODE` that represents a singly-linked list. The module also contains a recursive subroutine `PWF` that prints the value of the current node and recursively calls itself on the next node if it exists. The program `LISTE` creates a linked list by allocating nodes and calling the `PWF` subroutine to print the list.
ALLOCATE(CUR%NEXT_NODE)
CUR % VALUE = I
CUR => CUR%NEXT_NODE
END DO
CUR % NEXT_NODE => NULL()
! END CREATION OF LINKED LIST

DO I = 1,15
  IF(ASSOCIATED(TO_PRINT)) THEN
    PRINT *, I, TO_PRINT%VALUE
    TO_PRINT => TO_PRINT % NEXT_NODE
  END IF
END DO

! Call the user-defined i/o routine with dt format descriptor.
WRITE( UNIT=UNIT, FMT='(DT)', IOSTAT=IOSTAT ) CUR
END PROGRAM LISTE

RECURSIVE

Examples of User-Defined Derived-Type I/O

Example 1
The following example shows formatted defined I/O using the DT edit descriptor and both generic type-bound and explicit interface procedures:

MODULE TYPES
  TYPE T
    INTEGER :: K(10)
  CONTAINS

! a generic type-bound procedure
  PROCEDURE :: UDIO_READ_ARRAY
    GENERIC :: READ (FORMATTED) => UDIO_READ_ARRAY
  END TYPE T

! an explicit interface
  INTERFACE WRITE(FORMATTED)
    MODULE PROCEDURE UDIO_WRITE_ARRAY
  END INTERFACE
  CONTAINS
  SUBROUTINE UDIO_READ_ARRAY (DTV, UNIT, IOTYPE, V_LIST, IOSTAT, IOMSG)
    CLASS(T), INTENT(INOUT) :: DTV
    INTEGER, INTENT(IN) :: UNIT
    CHARACTER(*), INTENT(IN) :: IOTYPE
    INTEGER, INTENT(IN) :: V_LIST (:)
    INTEGER, INTENT(OUT) :: IOSTAT
    CHARACTER(*), INTENT(INOUT) :: IOMSG
    ! This is the child I/O that gets performed when the procedure
    ! is called from a parent I/O - it uses list-directed input to read
    ! the array K
    READ (UNIT, FMT=*, IOSTAT=IOSTAT, IOMSG=IOMSG) DTV%K
  END SUBROUTINE UDIO_READ_ARRAY

  SUBROUTINE UDIO_WRITE_ARRAY (DTV, UNIT, IOTYPE, V_LIST, IOSTAT, IOMSG)
    CLASS(T), INTENT(IN) :: DTV
INTEGER, INTENT(IN) :: UNIT
CHARACTER(*), INTENT(IN) :: IOTYPE
INTEGER, INTENT(IN) :: V_LIST (:)
INTEGER, INTENT(OUT) :: IOSTAT
CHARACTER(*), INTENT(INOUT) :: IOMSG

! This is the child I/O that gets performed when the procedure
! is called from a parent I/O – it uses list-directed output to write
! the array K

WRITE (UNIT, FMT=*, IOSTAT=IOSTAT, IOMSG=IOMSG) DTV%K

END SUBROUTINE UDIO_WRITE_ARRAY

END MODULE TYPES

PROGRAM TEST1
USE TYPES
TYPE (T) :: V
INTEGER :: COUNTCHAR
OPEN (1, FILE='TEST.INPUT', FORM='FORMATTED')
READ (1, FMT='(DT)', ADVANCE='NO', SIZE=COUNTCHAR) V
CLOSE(UNIT=1)
WRITE(6, '(DT)') V
END PROGRAM TEST1

Consider that procedure UDIO_READ_ARRAY reads an input file named TEST.INPUT that contains the following:
1, 3, 5, 7, 9, 2, 4, 6, 8, 10

In this case, the program TEST1 in procedure UDIO_WRITE_ARRAY prints:

<p>| | | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>3</td>
<td>5</td>
<td>7</td>
<td>9</td>
<td>2</td>
</tr>
<tr>
<td>4</td>
<td>6</td>
<td>8</td>
<td>10</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Example 2

The following example shows list-directed formatted output and user-defined I/O:

MODULE M
TYPE T
  REAL, POINTER :: R (:)
CONTAINS
  PROCEDURE :: UDIO_WRITE_LD
  GENERIC :: WRITE(FORMATTED) => UDIO_WRITE_LD
END TYPE T

CONTAINS
SUBROUTINE UDIO_WRITE_LD (DTV, UNIT, IOTYPE, V_LIST, IOSTAT, IOMSG)

I/O Formatting

I/O Formatting Overview

A format appearing in an input or output (I/O) statement specifies the form of data being transferred and the data conversion (editing) required to achieve that form. The format specified can be explicit or implicit.

Explicit format is indicated in a format specification that appears in a FORMAT statement or a character expression (the expression must evaluate to a valid format specification).

The format specification contains edit descriptors, which can be data edit descriptors, control edit descriptors, or string edit descriptors.

Implicit format is determined by the processor and is specified using list-directed or namelist formatting.

List-directed formatting is specified with an asterisk (*); namelist formatting is specified with a namelist group name.

List-directed formatting can be specified for advancing sequential files and internal files. Namelist formatting can be specified only for advancing sequential files.

Rules for Namelist Sequential READ Statement for details on namelist input
Rules for Namelist Sequential WRITE Statements for details on namelist output

Format Specifications

A format specification can appear in a FORMAT statement or character expression. In a FORMAT statement, it is preceded by the keyword FORMAT. A format specification takes one of the following forms:

( [format-items format-items, ])
( [format-items, ] unlimited-format-item)

format-items Is format-items [[,] format-item]...

where format-item is one of the following:

[r] data-edit-desc
control-edit-desc
char-string-edit-desc
[r] (format-items)

r (Optional) Is an integer literal constant. This is called a repeat specification. The range of r is 1 through 2147483647 (2**31-1). If r is omitted, it is assumed to be 1.

data-edit-desc Is one of the data edit descriptors: I, B, O, Z, F, E, EN, ES, D, DT, G, L, or A.

A repeat specification can precede any data edit descriptor.

control-edit-desc Is one of the control edit descriptors: T, TL, TR, X, S, SP, SS, BN, BZ, P, :, /, $, \, and Q.

A repeat specification can precede the slash (/) edit descriptor.
char-string-edit-desc Is one of the string edit descriptors: H, 'c', and "c", where c is a character constant.

unlimited-format-item Is * (format-items). The * indicates an unlimited repeat count.

If more than one edit descriptor is specified, they must be separated by commas or slashes (/).

A comma can be omitted in the following cases:

- Between a P edit descriptor and an immediately following F, E, EN, ES, D, or G edit descriptor
- Before a slash (/) edit descriptor when the optional repeat specification is not present
- After a slash (/) edit descriptor
- Before or after a colon (:) edit descriptor

Description

A FORMAT statement must be labeled.

Named constants are not permitted in format specifications.

If the associated I/O statement contains an I/O list, the format specification must contain at least one data edit descriptor or the control edit descriptor Q.

Blank characters can precede the initial left parenthesis, and additional blanks can appear anywhere within the format specification. These blanks have no meaning unless they are within a character string edit descriptor.

When a formatted input statement is executed, the setting of the BLANK specifier (for the relevant logical unit) determines the interpretation of blanks within the specification. If the BN or BZ edit descriptors are specified for a formatted input statement, they supersede the default interpretation of blanks. (For more information on BLANK defaults, see BLANK Specifier in OPEN statements.)

For formatted input, use the comma as an external field separator. The comma terminates the input of fields (for noncharacter data types) that are shorter than the number of characters expected. It can also designate null (zero-length) fields.

The first character of a record transmitted to a line printer or terminal is typically used for carriage control; it is not printed. The first character of such a record should be a blank, 0, 1, $, +, or ASCII NUL. Any other character is treated as a blank.

A format specification cannot specify more output characters than the external record can contain. For example, a line printer record cannot contain more than 133 characters, including the carriage control character.

The following table summarizes the edit descriptors that can be used in format specifications.

<table>
<thead>
<tr>
<th>Code</th>
<th>Form</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>A[w]</td>
<td>Transfers character or Hollerith values.</td>
</tr>
<tr>
<td>B</td>
<td>Bw[.m]</td>
<td>Transfers binary values.</td>
</tr>
<tr>
<td>BN</td>
<td>BN</td>
<td>Ignores embedded and trailing blanks in a numeric input field.</td>
</tr>
<tr>
<td>BZ</td>
<td>BZ</td>
<td>Treats embedded and trailing blanks in a numeric input field as zeros.</td>
</tr>
<tr>
<td>D</td>
<td>Dw.d</td>
<td>Transfers real values with D exponents.</td>
</tr>
<tr>
<td>Code</td>
<td>Form</td>
<td>Effect</td>
</tr>
<tr>
<td>------</td>
<td>------</td>
<td>--------</td>
</tr>
<tr>
<td>DT</td>
<td>DT [string] [(v-list)]</td>
<td>Passes a character string and integer array to a defined I/O procedure.</td>
</tr>
<tr>
<td>E</td>
<td>Ew.d[Ee]</td>
<td>Transfers real values with E exponents.</td>
</tr>
<tr>
<td>EN</td>
<td>ENw.d[Ee]</td>
<td>Transfers real values with engineering notation.</td>
</tr>
<tr>
<td>ES</td>
<td>ESw.d[Ee]</td>
<td>Transfers real values with scientific notation.</td>
</tr>
<tr>
<td>F</td>
<td>Fw.d</td>
<td>Transfers real values with no exponent.</td>
</tr>
<tr>
<td>G</td>
<td>Gw.d[Ee]</td>
<td>Transfers values of all intrinsic types.</td>
</tr>
<tr>
<td>H</td>
<td>nHch[ch...]</td>
<td>Transfers characters following the H edit descriptor to an output record.</td>
</tr>
<tr>
<td>I</td>
<td>Iw[.m]</td>
<td>Transfers decimal integer values.</td>
</tr>
<tr>
<td>L</td>
<td>Lw</td>
<td>Transfers logical values: on input, transfers characters; on output, transfers T or F.</td>
</tr>
<tr>
<td>O</td>
<td>Ow[.m]</td>
<td>Transfers octal values.</td>
</tr>
<tr>
<td>P</td>
<td>kP</td>
<td>Interprets certain real numbers with a specified scale factor.</td>
</tr>
<tr>
<td>Q</td>
<td>Q</td>
<td>Returns the number of characters remaining in an input record.</td>
</tr>
<tr>
<td>S</td>
<td>S</td>
<td>Reinvokes optional plus sign (+) in numeric output fields; counters the action of SP and SS.</td>
</tr>
<tr>
<td>SP</td>
<td>SP</td>
<td>Writes optional plus sign (+) into numeric output fields.</td>
</tr>
<tr>
<td>SS</td>
<td>SS</td>
<td>Suppresses optional plus sign (+) in numeric output fields.</td>
</tr>
<tr>
<td>T</td>

<td>Tabs right the specified number of positions.</td>
</tr>
<tr>
<td>X</td>
<td>nX</td>
<td>Skips the specified number of positions.</td>
</tr>
<tr>
<td>Z</td>
<td>Zw[.m]</td>
<td>Transfers hexadecimal values.</td>
</tr>
</tbody>
</table>
Character Format Specifications

In data transfer I/O statements, a format specifier ([FMT=]format) can be a character expression that is a character array, character array element, or character constant. This type of format is also called a run-time format because it can be constructed or altered during program execution.

The expression must evaluate to a character string whose leading part is a valid format specification (including the enclosing parentheses).

If the expression is a character array element, the format specification must be contained entirely within that element.

If the expression is a character array, the format specification can continue past the first element into subsequent consecutive elements.

If the expression is a character constant delimited by apostrophes, use two consecutive apostrophes ("'" ) to represent an apostrophe character in the format specification; for example:

```
PRINT "("NUM can''t be a real number")"
```

Similarly, if the expression is a character constant delimited by quotation marks, use two consecutive quotation marks ("" ) to represent a quotation mark character in the format specification.

To avoid using consecutive apostrophes or quotation marks, you can put the character constant in an I/O list instead of a format specification, as follows:

```
PRINT "(A)", "NUM can't be a real number"
```

The following shows another character format specification:

```
WRITE (6, "'(I12, I4, I12)'") I, J, K
```

In the following example, the format specification changes with each iteration of the DO loop:

```
SUBROUTINE PRINT(TABLE)
REAL TABLE(10,5)
CHARACTER*5 FORCHR(0:5), RPAR*1, FBIG, FMED, FSML
DATA FORCHR(0), RPAR /'(',')'/
DATA FBIG,FMED,FSML /'F8.2,','F9.4,','F9.6,'/
DO I=1,10
DO J=1,5
IF (TABLE(I,J) .GE. 100.) THEN
    FORCHR(J) = FBIG
ELSE IF (TABLE(I,J) .GT. 0.1) THEN
    FORCHR(J) = FMED
```

1 These delimiters can also be quotation marks ("" ).
The DATA statement assigns a left parenthesis to character array element FORCHR(0), and (for later use) a right parenthesis and three F edit descriptors to character variables.

Next, the proper F edit descriptors are selected for inclusion in the format specification. The selection is based on the magnitude of the individual elements of array TABLE.

A right parenthesis is added to the format specification just before the WRITE statement uses it.

**NOTE**

Format specifications stored in arrays are recompiled at run time each time they are used. If a Hollerith or character run-time format is used in a READ statement to read data into the format itself, that data is not copied back into the original array, and the array is unavailable for subsequent use as a run-time format specification.

### Examples

The following example shows a format specification:

```fortran
WRITE (*, 9000) int1, real1(3), char1
9000 FORMAT (I5, 3F4.5, A16)
! I5, 3F5.2, A16 is the format list.
```

The following shows a format example using a character expression:

```fortran
WRITE (*, '(I5, 3F5.2, A16)')iolist
! I5, 3F5.2, A16 is the format list.
```

In the following example, the format list is put into an 80-character variable called MYLIST:

```fortran
CHARACTER(80) MYLIST
MYLIST = '(I5, 3F5.2, A16)'
WRITE (*, MYLIST) iolist
```

Consider the following two-dimensional array:

1  2  3
4  5  6

In this case, the elements are stored in memory in the order: 1, 4, 2, 5, 3, 6 as follows:

```fortran
CHARACTER(6) array(3)
DATA array / '(I5', ',3F5.2', ',A16)' /
WRITE (*, array) iolist
```

In the following example, the WRITE statement uses the character array element array(2) as the format specifier for data transfer:

```fortran
CHARACTER(80) array(5)
array(2) = '(I5, 3F5.2, A16)'
WRITE (*, array(2)) iolist
```

Data Edit Descriptors  
Control Edit Descriptors  
Character Constant Editing
Data Edit Descriptors

A data edit descriptor causes the transfer or conversion of data to or from its internal representation. The part of a record that is input or output and formatted with data edit descriptors (or character string edit descriptors) is called a *field*.

Forms for Data Edit Descriptors

A data edit descriptor takes one of the following forms:

\[\text{[r]c}\]
\[\text{[r]cw}\]
\[\text{[r]cw.m}\]
\[\text{[r]cw.d}\]
\[\text{[r]cw.d[Ee]}\]

- \(r\) is a repeat specification. The range of \(r\) is 1 through 2147483647 (2**31-1). If \(r\) is omitted, it is assumed to be 1.
- \(c\) is one of the following format codes: I, B, O, Z, F, E, EN, ES, D, G, L, or A.
- \(w\) is the total number of digits in the field (the field width). If omitted, the system applies default values (see Default Widths for Data Edit Descriptors). The range of \(w\) is 1 through 2147483647 (2**31-1) on Intel® 64 architecture; 1 through 32767 (2**15-1) on IA-32 architecture. For I, B, O, Z, and F, the range can start at zero.
- \(m\) is the minimum number of digits that must be in the field (including leading zeros). The range of \(m\) is 0 through 32767 (2**15-1) on Intel® 64 architecture; 0 through 255 (2**8-1) on IA-32 architecture.
- \(d\) is the number of digits to the right of the decimal point (the significant digits). The range of \(d\) is 0 through 32767 (2**15-1) on Intel® 64 architecture; 0 through 255 (2**8-1) on IA-32 architecture. The number of significant digits is affected if a scale factor is specified for the data edit descriptor.
- \(E\) identifies an exponent field.
- \(e\) is the number of digits in the exponent. The range of \(e\) is 1 through 32767 (2**15-1) on Intel® 64 architecture; 1 through 255 (2**8-1) on IA-32 architecture.

Description

Standard Fortran allows the field width to be omitted only for the A descriptor. However, Intel® Fortran allows the field width to be omitted for any data edit descriptor.

The \(r\), \(w\), \(m\), \(d\), and \(e\) must all be positive, unsigned, integer literal constants; or variable format expressions -- no kind parameter can be specified. They must not be named constants.

Actual useful ranges for \(r\), \(w\), \(m\), \(d\), and \(e\) may be constrained by record sizes (RECL) and the file system.

The data edit descriptors have the following specific forms:
Integer: $Iw[m], Bw[m], Ow[m], \text{ and } Zw[m]$  
Real and complex: $Fw.d, Ew.d[Ee], ENw.d[Ee], ESw.d[Ee], Dw.d, \text{ and } Gw.d[Ee]$  
Logical: $Lw$  
Character: $A[w]$  

The $d$ must be specified with F, E, D, and G field descriptors even if $d$ is zero. The decimal point is also required. You must specify both $w$ and $d$, or omit them both.

A repeat specification can simplify formatting. For example, the following two statements are equivalent:

```
20 FORMAT (E12.4, E12.4, E12.4, I5, I5, I5, I5)
20 FORMAT (3E12.4, 4I5)
```

Examples

```plaintext
! This WRITE outputs three integers, each in a five-space field
! and four reals in pairs of F7.2 and F5.2 values.
INTEGER(2) int1, int2, int3
REAL(4) r1, r2, r3, r4
DATA int1, int2, int3 /143, 62, 999/
DATA r1, r2, r3, r4 /2458.32, 43.78, 664.55, 73.8/
WRITE (*,9000) int1, int2, int3, r1, r2, r3, r4
9000 FORMAT (3I5, 2(1X, F7.2, 1X, F5.2))
```

The following output is produced from the above code:

```
143  62  999 2458.32 43.78  664.55 73.80
```

See Also

- General Rules for Numeric Editing
- Nested and Group Repeat Specifications

General Rules for Numeric Editing

The following rules apply to input and output data for numeric editing (data edit descriptors I, B, O, Z, F, E, EN, ES, D, and G).

Rules for Input Processing

Leading blanks in the external field are ignored. If BLANK='NULL' is in effect (or the BN edit descriptor has been specified) embedded and trailing blanks are ignored; otherwise, they are treated as zeros. An all-blank field is treated as a value of zero.

The following table shows how blanks are interpreted by default:

<table>
<thead>
<tr>
<th>Type of Unit or File</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>An explicitly OPENed unit</td>
<td>BLANK='NULL'</td>
</tr>
<tr>
<td>An internal file</td>
<td>BLANK='NULL'</td>
</tr>
<tr>
<td>A preconnected file¹</td>
<td>BLANK='NULL'</td>
</tr>
</tbody>
</table>

¹ For interactive input from preconnected files, you should explicitly specify the BN or BZ edit descriptor to ensure desired behavior.

A minus sign must precede a negative value in an external field; a plus sign is optional before a positive value.

In input records, constants can include any valid kind parameter. Named constants are not permitted.
If the data field in a record contains fewer than \( w \) characters, an input statement will read characters from the next data field in the record. You can prevent this by padding the short field with blanks or zeros, or by using commas to separate the input data. The comma terminates the data field, and can also be used to designate null (zero-length) fields. For more information, see Terminating Short Fields of Input Data.

**Rules for Output Processing**

The field width \( w \) must be large enough to include any leading plus or minus sign, and any decimal point or exponent. For example, the field width for an E data edit descriptor must be large enough to contain the following:

- For positive numbers: \( d + 5 \) or \( d + e + 3 \) characters
- For negative numbers: \( d + 6 \) or \( d + e + 4 \) characters

A positive or zero value (zero is allowed for I, B, O, Z, F, and G descriptors) can have a plus sign, depending on which sign edit descriptor is in effect. If a value is negative, the leftmost nonblank character is a minus sign.

If the value is smaller than the field width specified, leading blanks are inserted (the value is right-justified). If the value is too large for the field width specified, the entire output field is filled with asterisks (*).

When the value of the field width is zero, the compiler selects the smallest possible positive actual field width that does not result in the field being filled with asterisks.

**See Also**

Forms for Data Edit Descriptors
Format Specifications

**Integer Editing**

Integer editing is controlled by the I (decimal), B (binary), O (octal), and Z (hexadecimal) data edit descriptors.

**I Editing**

The I edit descriptor transfers decimal integer values. It takes the following form:

\[ Iw[,m] \]

The value of \( m \) (the minimum number of digits in the constant) must not exceed the value of \( w \) (the field width), unless \( w \) is zero. The \( m \) has no effect on input, only output.

The specified I/O list item must be of type integer; logical and real items are also allowed if the compiler option check format is not specified.

The G edit descriptor can be used to edit integer data; it follows the same rules as \( Iw \).

**Rules for Input Processing**

On input, the I data edit descriptor transfers \( w \) characters from an external field and assigns their integer value to the corresponding I/O list item. The external field data must be an integer constant. \( w \) must not be zero.

If the value exceeds the range of the corresponding input list item, an error occurs.

The following shows input using the I edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Input</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>I4</td>
<td>2788</td>
<td>2788</td>
</tr>
<tr>
<td>I3</td>
<td>-26</td>
<td>-26</td>
</tr>
<tr>
<td>I9</td>
<td>^^^^^^312</td>
<td>312</td>
</tr>
</tbody>
</table>
Rules for Output Processing

On output, the I data edit descriptor transfers the value of the corresponding I/O list item, right-justified, to an external field that is \( w \) characters long.

The field consists of zero or more blanks, followed by a sign (a plus sign is optional for positive values, a minus sign is required for negative values), followed by an unsigned integer constant with no leading zeros.

If \( m \) is specified, the unsigned integer constant will have at least \( m \) digits, padded with leading zeros if necessary.

If the output list item has the value zero, and \( m \) is zero, the external field is filled with blanks; if \( w \) is also zero, the external field is one blank.

If \( w \) is zero, the external field has the minimum number of characters necessary to represent the value, left justifying the value with no leading blanks. If both \( w \) and \( m \) are zero and the internal value is zero, the external field is one blank.

The following shows output using the I edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Value</th>
<th>Output</th>
</tr>
</thead>

Forms for Data Edit Descriptors
General Rules for Numeric Editing

B Editing

The B data edit descriptor transfers binary (base 2) values. It takes the following form:

\[ B^w[m] \]

The value of \( m \) (the minimum number of digits in the constant) must not exceed the value of \( w \) (the field width), unless \( w \) is zero. The \( m \) has no effect on input, only output.

The specified I/O list item can be of type integer, real, or logical.

Rules for Input Processing

On input, the B data edit descriptor transfers \( w \) characters from an external field and assigns their binary value to the corresponding I/O list item. The external field must contain only binary digits (0 or 1) or blanks. \( w \) must not be zero.

If \( w \) is zero, the external field has the minimum number of characters necessary to represent the value. If both \( w \) and \( m \) are zero and the internal value is zero, the external field is one blank.

If the value exceeds the range of the corresponding input list item, an error occurs.
The following shows input using the B edit descriptor:

<table>
<thead>
<tr>
<th>Format</th>
<th>Input</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>B4</td>
<td>1001</td>
<td>9</td>
</tr>
<tr>
<td>B1</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>B2</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>B0</td>
<td>11</td>
<td>1011</td>
</tr>
</tbody>
</table>

**Rules for Output Processing**

On output, the B data edit descriptor transfers the binary value of the corresponding I/O list item, right-justified, to an external field that is \( w \) characters long.

The field consists of zero or more blanks, followed by an unsigned integer constant (consisting of binary digits) with no leading zeros. A negative value is transferred in internal form.

If \( m \) is specified, the unsigned integer constant must have at least \( m \) digits. If necessary, it is padded with leading zeros.

If \( m \) is zero, and the output list item has the value zero, the external field is filled with blanks.

The following shows output using the B edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Value</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>B4</td>
<td>9</td>
<td>1001</td>
</tr>
<tr>
<td>B2</td>
<td>0</td>
<td>^0</td>
</tr>
</tbody>
</table>

**See Also**

- Forms for Data Edit Descriptors

**O Editing**

The O data edit descriptor transfers octal (base 8) values. It takes the following form:

\[ Ow[.m] \]

The value of \( m \) (the minimum number of digits in the constant) must not exceed the value of \( w \) (the field width), unless \( w \) is zero. The \( m \) has no effect on input, only output.

The specified I/O list item can be of type integer, real, or logical.

**Rules for Input Processing**

On input, the O data edit descriptor transfers \( w \) characters from an external field and assigns their octal value to the corresponding I/O list item. The external field must contain only octal digits (0 through 7) or blanks. \( w \) must not be zero.

If \( w \) is zero, the external field has the minimum number of characters necessary to represent the value. If both \( w \) and \( m \) are zero and the internal value is zero, the external field is one blank.

If the value exceeds the range of the corresponding input list item, an error occurs.

The following shows input using the O edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Input</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>05</td>
<td>32767</td>
<td>32767</td>
</tr>
<tr>
<td>04</td>
<td>16234</td>
<td>1623</td>
</tr>
<tr>
<td>03</td>
<td>9^</td>
<td>An error; the 9 is invalid in octal notation</td>
</tr>
<tr>
<td>00</td>
<td>11</td>
<td>13</td>
</tr>
</tbody>
</table>

**Rules for Output Processing**

On output, the O data edit descriptor transfers the octal value of the corresponding I/O list item, right-justified, to an external field that is \( w \) characters long.
The field consists of zero or more blanks, followed by an unsigned integer constant (consisting of octal digits) with no leading zeros. A negative value is transferred in internal form without a leading minus sign.

If \( m \) is specified, the unsigned integer constant must have at least \( m \) digits. If necessary, it is padded with leading zeros.

If \( m \) is zero, and the output list item has the value zero, the external field is filled with blanks.

The following shows output using the \( O \) edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Value</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>06</td>
<td>32767</td>
<td>^77777</td>
</tr>
<tr>
<td>012</td>
<td>-32767</td>
<td>^37777700001</td>
</tr>
<tr>
<td>02</td>

Forms for Data Edit Descriptors  
General Rules for Numeric Editing  

**Z Editing**

The \( Z \) data edit descriptor transfers hexadecimal (base 16) values. It takes the following form:

\[
Zw[m]
\]

The value of \( m \) (the minimum number of digits in the constant) must not exceed the value of \( w \) (the field width), unless \( w \) is zero. The \( m \) has no effect on input, only output.

The specified I/O list item can be of type integer, real, or logical.

**Rules for Input Processing**

On input, the \( Z \) data edit descriptor transfers \( w \) characters from an external field and assigns their hexadecimal value to the corresponding I/O list item. The external field must contain only hexadecimal digits (0 through 9 and A (a) through F(f)) or blanks. \( w \) must not be zero.

If \( w \) is zero, the external field has the minimum number of characters necessary to represent the value. If both \( w \) and \( m \) are zero and the internal value is zero, the external field is one blank.

If the value exceeds the range of the corresponding input list item, an error occurs.

The following shows input using the \( Z \) edit descriptor:

<table>
<thead>
<tr>
<th>Format</th>
<th>Input</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>23</td>
<td>A94</td>
<td>A94</td>
</tr>
<tr>
<td>25</td>
<td>A23DEF</td>
<td>A23DE</td>
</tr>
<tr>
<td>25</td>
<td>95.AF2</td>
<td>An error; the decimal point is invalid</td>
</tr>
<tr>
<td>20</td>
<td>42</td>
<td>2A</td>
</tr>
</tbody>
</table>

**Rules for Output Processing**

On output, the \( Z \) data edit descriptor transfers the hexadecimal value of the corresponding I/O list item, right-justified, to an external field that is \( w \) characters long.

The field consists of zero or more blanks, followed by an unsigned integer constant (consisting of hexadecimal digits) with no leading zeros. A negative value is transferred in internal form without a leading minus sign.

If \( m \) is specified, the unsigned integer constant must have at least \( m \) digits. If necessary, it is padded with leading zeros.

If \( m \) is zero, and the output list item has the value zero, the external field is filled with blanks.

Forms for Data Edit Descriptors
General Rules for Numeric Editing

Real and Complex Editing

Real and complex editing is controlled by the F, E, D, EN, ES, and G data edit descriptors.
If no field width (w) is specified for a real data edit descriptor, the system supplies default values.
Real data edit descriptors can be affected by specified scale factors.

NOTE
Do not use the real data edit descriptors when attempting to parse textual input. These descriptors accept some forms that are purely textual as valid numeric input values. For example, input values T and F are treated as values -1.0 and 0.0, respectively, for .TRUE. and .FALSE.

See Also
Forms for Data Edit Descriptors
General Rules for Numeric Editing
Scale-Factor Editing (P)
Default Widths for Data Edit Descriptors for details on system default values for data edit descriptors

F Editing

The F data edit descriptor transfers real values. It takes the following form:

Fw.d

The value of d (the number of places after the decimal point) must not exceed the value of w (the field width) unless w is zero. When w is zero, the processor selects the field width. On input, w must not be zero.
The specified I/O list item must be of type real, or it must be the real or imaginary part of a complex type.

Rules for Input Processing

On input, the F data edit descriptor transfers w characters from an external field and assigns their real value to the corresponding I/O list item. The external field data must be an integer or real constant.

An input field is one of the following:
- An IEEE exception specification
- An optional sign, followed by a string of one or more digits optionally containing a decimal symbol; any blanks are interpreted as zeros.

The basic form can be followed by an exponent in one of the following forms:
- A sign followed by one or more digits
- An E or D followed by zero or more blanks, followed by an optional sign and one or more digits
An exponent containing a D is processed in the same way as an exponent containing an E.
If the input field contains only an exponent letter or decimal point, it is treated as a zero value.

If the input field does not contain a decimal point or an exponent, it is treated as a real number of \( w \) digits, with \( d \) digits to the right of the decimal point. (Leading zeros are added, if necessary.)

If the input field contains a decimal point, the location of that decimal point overrides the location specified by the F descriptor.

If the field contains an exponent, that exponent is used to establish the magnitude of the value before it is assigned to the list element.

An input field that is an IEEE exception specification consists of optional blanks, followed by either of the following:

- An optional sign, followed by the string 'INF' or the string 'INFINITY'; this is an IEEE infinity
  
  This form can not be used if the processor does not support IEEE infinities for the input variable.

- An optional sign, followed by the string 'NAN', optionally followed by zero or more alphanumeric characters enclosed in parentheses, optionally followed by blanks; this is an IEEE Nan
  
  This form can not be used if the processor does not support IEEE Nans for the input variable.

The NaN value is a quiet NaN if the only nonblank characters in the field are 'NAN' or 'NAN(').

The following shows input using the F edit descriptor:

<table>
<thead>
<tr>
<th>Format</th>
<th>Input</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>F8.5</td>
<td>123456789</td>
<td>123.45678</td>
</tr>
<tr>
<td>F8.5</td>
<td>-1234.567</td>
<td>-1234.56</td>
</tr>
<tr>
<td>F8.5</td>
<td>24.77E+2</td>
<td>2477.0</td>
</tr>
<tr>
<td>F5.2</td>
<td>1234567.89</td>
<td>123.45</td>
</tr>
</tbody>
</table>

**Rules for Output Processing**

On output, the F data edit descriptor transfers the real value of the corresponding I/O list item, right-justified and rounded to \( d \) decimal positions, to an external field that is \( w \) characters long.

For an internal value that is an IEEE infinity, the output field consists of blanks, if needed, followed by a sign (optional if the value is positive and descriptor SP is not in effect), followed by the letters 'Inf' or 'Infinity', right justified within the field.

If \( w \) is less than 3, the field is filled with asterisks; otherwise, if \( w \) is less than 8, 'Inf' is produced.

For an internal value that is an IEEE NaN, the output field consists of blanks, if necessary, followed by the letters 'NaN' and optionally followed by one to \( w-5 \) alphanumeric characters enclosed in parentheses, right justified within the field.

If \( w \) is less than 3, the field is filled with asterisks.

For an internal value that is neither an IEEE infinity nor an IEEE NaN, the \( w \) must be greater than or equal to \( d+3 \) to allow for the following:

- A sign (optional if the value is positive and descriptor SP is not in effect)
- At least one digit to the left of the decimal point
- The decimal point
- The \( d \) digits to the right of the decimal point

A negative value that is not zero but rounds to zero on output is displayed with a leading minus sign. For example, the value -0.00000001 in F5.1 format will be displayed as -0.0 rather than as 0.0. The setting of compiler option assume [no]std_minus0_rounding can affect this behavior.

The following shows output using the F edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Value</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>F8.5</td>
<td>2.3547188</td>
<td>^2.35472</td>
</tr>
<tr>
<td>F9.3</td>
<td>8789.7361</td>
<td>^8789.736</td>
</tr>
<tr>
<td>F2.1</td>
<td>51.44</td>
<td>**</td>
</tr>
</tbody>
</table>
### E and D Editing

The E and D data edit descriptors transfer real values in exponential form. They take the following form:

**Ew.d[Ee]**

**Dw.d**

For the E edit descriptor, the value of \(d\) (the number of places after the decimal point) plus \(e\) (the number of digits in the exponent) must not exceed the value of \(w\) (the field width).

For the D edit descriptor, the value of \(d\) must not exceed the value of \(w\).

The specified I/O list item must be of type real, or it must be the real or imaginary part of a complex type.

### Rules for Input Processing

On input, the E and D data edit descriptors transfer \(w\) characters from an external field and assigns their real value to the corresponding I/O list item. The E and D descriptors interpret and assign input data in the same way as the F data edit descriptor.

The following shows input using the E and D edit descriptors (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Input</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>E9.3</td>
<td>734.432E3</td>
<td>734432.0</td>
</tr>
<tr>
<td>E12.4</td>
<td>^1022.43E</td>
<td>1022.43E-6</td>
</tr>
<tr>
<td>E15.3</td>
<td>52.3759663^</td>
<td>52.3759663</td>
</tr>
<tr>
<td>E12.5</td>
<td>210.5271D+10</td>
<td>210.5271E10</td>
</tr>
<tr>
<td>BZ,D10.2</td>
<td>12345^</td>
<td>1234500.0D0</td>
</tr>
<tr>
<td>D10.2</td>
<td>^123.45^</td>
<td>123.45D0</td>
</tr>
<tr>
<td>D15.3</td>
<td>367.4981763D+04</td>
<td>3.674981763D+06</td>
</tr>
</tbody>
</table>

If the I/O list item is single-precision real, the E edit descriptor treats the D exponent indicator as an E indicator.

### Rules for Output Processing

On output, the E and D data edit descriptors transfer the real value of the corresponding I/O list item, right-justified and rounded to \(d\) decimal positions, to an external field that is \(w\) characters long.

The \(w\) should be greater than or equal to \(d+7\) to allow for the following:

- A sign (optional if the value is positive and descriptor SP is not in effect)
- An optional zero to the left of the decimal point
- The decimal point
- The \(d\) digits to the right of the decimal point
- The exponent

The exponent takes one of the following forms:

<table>
<thead>
<tr>
<th>Edit Descriptor</th>
<th>Absolute Value of Exponent</th>
<th>Positive Form of Exponent</th>
<th>Negative Form of Exponent</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ew.d</td>
<td>(</td>
<td>\exp</td>
<td>) 99</td>
</tr>
</tbody>
</table>
The exponent field width (e) is optional for the E edit descriptor; if omitted, the default value is 2. If e is specified, the w should be greater than or equal to d+e+5.

NOTE
The w can be as small as d + 5 or d + e + 3, if the optional fields for the sign and the zero are omitted.

For an internal value that is an IEEE infinity or an IEEE NaN, the form of the output field is the same as for Fw.d.

A negative value that is not zero but rounds to zero on output is displayed with a leading minus sign. For example, the value -0.01 in "-5P,E20.5" format will be displayed as -0.00 rather than as 0.00. The setting of compiler option assume [no]std_minus0_rounding can affect this behavior.

The following shows output using the E and D edit descriptors (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Value</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>E11.2</td>
<td>475867.222</td>

assume

EN Editing
The EN data edit descriptor transfers values by using engineering notation. It takes the following form:

ENw.d[Ee]

The value of d (the number of places after the decimal point) plus e (the number of digits in the exponent) must not exceed the value of w (the field width).

The specified I/O list item must be of type real, or it must be the real or imaginary part of a complex type.
Rules for Input Processing

On input, the EN data edit descriptor transfers \( w \) characters from an external field and assigns their real value to the corresponding I/O list item. The EN descriptor interprets and assigns input data in the same way as the F data edit descriptor.

The following shows input using the EN edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Input</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>EN11.3</td>
<td>^^5.321E+00</td>
<td>5.32100</td>
</tr>
<tr>
<td>EN11.3</td>
<td>-600.00E-03</td>
<td>-.60000</td>
</tr>
<tr>
<td>EN12.3</td>
<td>^^^3.150E-03</td>
<td>00315</td>
</tr>
<tr>
<td>EN12.3</td>
<td>^^^3.829E+03</td>
<td>3829.0</td>
</tr>
</tbody>
</table>

Rules for Output Processing

On output, the EN data edit descriptor transfers the real value of the corresponding I/O list item, right-justified and rounded to \( d \) decimal positions, to an external field that is \( w \) characters long. The real value is output in engineering notation, where the decimal exponent is divisible by 3 and the absolute value of the significand is greater than or equal to 1 and less than 1000 (unless the output value is zero).

The \( w \) should be greater than or equal to \( d+9 \) to allow for the following:

- A sign (optional if the value is positive and descriptor SP is not in effect)
- One to three digits to the left of the decimal point
- The decimal point
- The \( d \) digits to the right of the decimal point
- The exponent

The exponent takes one of the following forms:

<table>
<thead>
<tr>
<th>Edit Descriptor</th>
<th>Absolute Value of Exponent</th>
<th>Positive Form of Exponent</th>
<th>Negative Form of Exponent</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENw.d</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>99</td>
<td></td>
<td>E+nn</td>
<td>E-nn</td>
</tr>
<tr>
<td>99 &lt;</td>
<td>exp</td>

<td>+nnn</td>
</tr>
<tr>
<td>ENw.dEe</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>exp</td>
<td>10(^e) - 1</td>
<td>E+n_1n_2...n_e</td>
</tr>
</tbody>
</table>

If an exponent exceeds its specified or implied width, or the number of characters produced exceeds the field width, the entire field of width \( w \) is filled with asterisks. However, the field width is not filled with asterisks if the field width is exceeded when optional characters are omitted.

The exponent field width \((e)\) is optional; if omitted, the default value is 2. If \( e \) is specified, the \( w \) should be greater than or equal to \( d + e + 5 \).

For an internal value that is an IEEE infinity or an IEEE NaN, the form of the output field is the same as for Fw.d.

The following shows output using the EN edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Value</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>EN11.2</td>

Forms for Data Edit Descriptors
General Rules for Numeric Editing

G Editing

The G data edit descriptor generally transfers values of real type, but it can be used to transfer values of any intrinsic type. It takes the following form:

\[ \text{Gw.d[Ee]} \]

The value of \( d \) (the number of places after the decimal point) plus \( e \) (the number of digits in the exponent) must not exceed the value of \( w \) (the field width), unless \( w \) is zero. If \( w \) is zero, you can only specify forms G0 or G0.d.

When \( w \) is zero, the processor selects the field width. On input, \( w \) must not be zero.

The specified I/O list item can be of any intrinsic type.

When used to specify I/O for integer, logical, or character data, the edit descriptor follows the same rules as Iw, Lw, and Aw, respectively, and \( d \) and \( e \) have no effect.

Rules for Real Input Processing

On input, the G data edit descriptor transfers \( w \) characters from an external field and assigns their real value to the corresponding I/O list item. The G descriptor interprets and assigns input data in the same way as the F data edit descriptor.

Rules for Real Output Processing

The form in which the value is written depends on the magnitude of the internal value being edited. \( N \) is the magnitude of the internal value and \( r \) is the rounding mode value defined in the table below. If \( 0 < N < 0.1 - r \times 10^{-d-1} \) or \( N >= 10^d - r \), or \( N \) is identically 0 and \( d \) is 0, Gw.d output editing is the same as k PEw.d output editing and Gw.d Ee output editing is the same as k PEw.d Ee output editing, where \( k \) is the scale factor. If \( 0.1 - r \times 10^{-d-1} \leq N < 10^d - r \) or \( N \) is identically 0 and \( d \) is not zero, the scale factor has no effect, and the value of \( N \) determines the editing as follows:

<table>
<thead>
<tr>
<th>Data Magnitude</th>
<th>Effective Conversion</th>
</tr>
</thead>
<tbody>
<tr>
<td>( N = 0 )</td>
<td>F(w - n).(d -1), n('b')</td>
</tr>
<tr>
<td>( 0.1 - r \times 10^{-d-1} \leq N &lt; 1 - r \times 10^{-d} )</td>
<td>F(w - n).d, n('b')</td>
</tr>
<tr>
<td>( 1 - r \times 10^{-d} \leq N &lt; 10 - r \times 10^{d+1} )</td>
<td>F(w - n).(d -1), n('b')</td>
</tr>
<tr>
<td>( 10 - r \times 10^{d+1} \leq N &lt; 100 - r \times 10^{d+2} )</td>
<td>F(w - n).(d -2), n('b')</td>
</tr>
<tr>
<td>.</td>
<td>.</td>
</tr>
<tr>
<td>.</td>
<td>.</td>
</tr>
<tr>
<td>( 10^{-2} - r \times 10^{-2} \leq N &lt; 10^{-1} - r \times 10^{-1} )</td>
<td>F(w - n).1, n('b')</td>
</tr>
<tr>
<td>( 10^{-1} - r \times 10^{-1} \leq N &lt; 10^{-d} - r )</td>
<td>(w - n).0, n('b')</td>
</tr>
</tbody>
</table>

The 'b' is a blank following the numeric data representation. For Gw.d, n('b') is 4 blanks. For Gw.dEe, n('b') is \( e+2 \) blanks.

The \( r \) is defined for each I/O rounding mode as follows:
Rounding Mode | r
---|---
COMPATIBLE | 0.5
NEAREST | 0.5 if the higher value is even
| -0.5 if the lower value is even
UP | 1
DOWN | 0
ZERO | 1 if the internal value is negative
| 0 if the internal value is positive

Note that the scale factor has no effect on output unless the magnitude of the datum to be edited is outside the range that permits effective use of F editing.

The \( w \) should be greater than or equal to \( d + 7 \) to allow for the following:

- A sign (optional if the value is positive and descriptor SP is not in effect)
- One digit to the left of the decimal point
- The decimal point
- The \( d \) digits to the right of the decimal point
- The 4-digit or \( e + 2 \)-digit exponent

If \( e \) is specified, the \( w \) should be greater than or equal to \( d + e + 5 \).

If an exponent exceeds its specified or implied width, or the number of characters produced exceeds the field width, the entire field of width \( w \) is filled with asterisks. However, the field width is not filled with asterisks if the field width is exceeded when optional characters are omitted.

For an internal value that is an IEEE infinity or an IEEE NaN, the form of the output field is the same as for Fw.d.

The following shows output using the G edit descriptor and compares it to output using equivalent F editing (the symbol ^ represents a nonprinting blank character):

<table>
<thead>

I Editing
Logical Editing (L)
Character Editing (A)
Scale-Factor Editing (P)

Complex Editing
A complex value is an ordered pair of real values. Complex editing is specified by a pair of real edit descriptors, using any combination of the forms: Fw.d, Ew.d[EE], Dw.d, Ew.d[EE], ESw.d[EE], or Gw.d[EE].
Rules for Input Processing

On input, the two successive fields are read and assigned to the corresponding complex I/O list item as its real and imaginary part, respectively.

The following shows input using complex editing:

<table>
<thead>
<tr>
<th>Format</th>
<th>Input</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>F8.5,F8.5</td>
<td>1234567812345.67</td>
<td>123.45678, 12345.67</td>
</tr>
<tr>
<td>E9.1,F9.3</td>
<td>734.432E8123456789</td>
<td>734.432E8, 123456.789</td>
</tr>
</tbody>
</table>

Rules for Output Processing

On output, the two parts of the complex value are transferred under the control of repeated or successive real edit descriptors. The two parts are transferred consecutively without punctuation or blanks, unless control or character string edit descriptors are specified between the pair of real edit descriptors.

The following shows output using complex editing (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Value</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>2F8.5</td>
<td>2.3547188, 3.456732</td>
<td>^2.35472 ^3.45673</td>
</tr>
<tr>
<td>E9.2,'^',^',E5.3</td>
<td>47587.222, 56.123</td>
<td>^0.48E+06 ^,*****</td>
</tr>
</tbody>
</table>

Forms for Data Edit Descriptors
General Rules for Numeric Editing
General Rules for Complex Constants for details on complex constants

Logical Editing (L)

The L data edit descriptor transfers logical values. It takes the following form:

Lw

The specified I/O list item must be of type logical or integer.

The G edit descriptor can be used to edit logical data; it follows the same rules as Lw.

Rules for Input Processing

On input, the L data edit descriptor transfers w characters from an external field and assigns their logical value to the corresponding I/O list item. The value assigned depends on the external field data, as follows:

- .TRUE. is assigned if the first nonblank character is .T, T, .t, or t. The logical constant .TRUE. is an acceptable input form.
- .FALSE. is assigned if the first nonblank character is .F, F, .f, or f, or the entire field is filled with blanks. The logical constant .FALSE. is an acceptable input form.

If an other value appears in the external field, an error occurs.

Rules for Output Processing

On output, the L data edit descriptor transfers the following to an external field that is w characters long: w - 1 blanks, followed by a T or F (if the value is .TRUE. or .FALSE., respectively).

The following shows output using the L edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Value</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>L5</td>
<td>.TRUE.</td>
<td>^^^^T</td>
</tr>
<tr>
<td>L1</td>
<td>.FALSE.</td>
<td>F</td>
</tr>
</tbody>
</table>

See Also
Forms for Data Edit Descriptors
Character Editing (A)
The A data edit descriptor transfers character or Hollerith values. It takes the following form:

A[w]

If the corresponding I/O list item is of type character, character data is transferred. If the list item is of any other type, Hollerith data is transferred.

The G edit descriptor can be used to edit character data; it follows the same rules as A[w].

Rules for Input Processing
On input, the A data edit descriptor transfers w characters from an external field and assigns them to the corresponding I/O list item.

The maximum number of characters that can be stored depends on the size of the I/O list item, as follows:

• For character data, the maximum size is the length of the corresponding I/O list item.
• For noncharacter data, the maximum size depends on the data type, as shown in the following table:

<table>
<thead>
<tr>
<th>I/O List Element</th>
<th>Maximum Number of Characters</th>
</tr>
</thead>
<tbody>
<tr>
<td>BYTE</td>
<td>1</td>
</tr>
<tr>
<td>LOGICAL(1) or LOGICAL*1</td>
<td>1</td>
</tr>
<tr>
<td>LOGICAL(2) or LOGICAL*2</td>
<td>2</td>
</tr>
<tr>
<td>LOGICAL(4) or LOGICAL*4</td>
<td>4</td>
</tr>
<tr>
<td>LOGICAL(8) or LOGICAL*8</td>
<td>8</td>
</tr>
<tr>
<td>INTEGER(1) or INTEGER*1</td>
<td>1</td>
</tr>
<tr>
<td>INTEGER(2) or INTEGER*2</td>
<td>2</td>
</tr>
<tr>
<td>INTEGER(4) or INTEGER*4</td>
<td>4</td>
</tr>
<tr>
<td>INTEGER(8) or INTEGER*8</td>
<td>8</td>
</tr>
<tr>
<td>REAL(4) or REAL*4</td>
<td>4</td>
</tr>
<tr>
<td>DOUBLE PRECISION</td>
<td>8</td>
</tr>
<tr>
<td>REAL(8) or REAL*8</td>
<td>8</td>
</tr>
<tr>
<td>REAL(16) or REAL*16</td>
<td>16</td>
</tr>
<tr>
<td>COMPLEX(4) or COMPLEX*81</td>
<td>8</td>
</tr>
<tr>
<td>DOUBLE COMPLEX1</td>
<td>16</td>
</tr>
<tr>
<td>COMPLEX(8) or COMPLEX*161</td>
<td>16</td>
</tr>
<tr>
<td>COMPLEX(16) or COMPLEX*321</td>
<td>32</td>
</tr>
</tbody>
</table>

Complex values are treated as pairs of real numbers, so complex editing requires a pair of edit descriptors. (See Complex Editing.)

If w is equal to or greater than the length (len) of the input item, the rightmost characters are assigned to that item. The leftmost excess characters are ignored.

If w is less than len, or less than the number of characters that can be stored, w characters are assigned to the list item, left-justified, and followed by trailing blanks.
The following shows input using the A edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Input</th>
<th>Value</th>
<th>Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>A6</td>
<td>PAGE^#</td>
<td>#</td>
<td>CHARACTER (LEN=1)</td>
</tr>
<tr>
<td>A6</td>

<td>GE^#</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>A6</td>
<td>PAGE^#</td>
<td>PAGE^#^^</td>
<td>REAL(8)</td>
</tr>
</tbody>
</table>

Rules for Output Processing

On output, the A data edit descriptor transfers the contents of the corresponding I/O list item to an external field that is \( w \) characters long.

If \( w \) is greater than the size of the list item, the data is transferred to the output field, right-justified, with leading blanks. If \( w \) is less than or equal to the size of the list item, the leftmost \( w \) characters are transferred.

The following shows output using the A edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Value</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>A5</td>
<td>OHMS</td>
<td>^OHMS</td>

Forms for Data Edit Descriptors

Defined I/O Editing (DT)

The DT edit descriptor passes a character string and integer array to a defined I/O procedure. It takes the following form:

\[
\text{DT } [\text{string}] [(\text{v-list})]
\]

For more information on this edit descriptor, see DT Edit Descriptor in User-Defined I/O.

Default Widths for Data Edit Descriptors

If \( w \) (the field width) is omitted for the data edit descriptors, the system applies default values. For the real data edit descriptors, the system also applies default values for \( d \) (the number of characters to the right of the decimal point), and \( e \) (the number of characters in the exponent).

These defaults are based on the data type of the I/O list item, and are listed in the following table:

<table>
<thead>
<tr>
<th>Edit Descriptor</th>
<th>Data Type of I/O List Item</th>
<th>( w )</th>
</tr>
</thead>
<tbody>
<tr>
<td>I, B, O, Z, G</td>
<td>BYTE</td>
<td>7</td>
</tr>
<tr>
<td></td>
<td>INTEGER(1), LOGICAL(1)</td>
<td>7</td>
</tr>
<tr>
<td></td>
<td>INTEGER(2), LOGICAL(2)</td>
<td>7</td>
</tr>
<tr>
<td></td>
<td>INTEGER(4), LOGICAL(4)</td>
<td>12</td>
</tr>
<tr>
<td></td>
<td>INTEGER(8), LOGICAL(8)</td>
<td>23</td>
</tr>
<tr>
<td>O, Z</td>
<td>REAL(4)</td>
<td>12</td>
</tr>
</tbody>
</table>
Terminating Short Fields of Input Data

On input, an edit descriptor such as Fw.d specifies that \( w \) characters (the field width) are to be read from the external field.

If the field contains fewer than \( w \) characters, the input statement will read characters from the next data field in the record. You can prevent this by padding the short field with blanks or zeros, or by using commas to separate the input data.

Padding Short Fields

You can use the OPEN statement specifier PAD='YES' to indicate blank padding for short fields of input data. However, blanks can be interpreted as blanks or zeros, depending on which default behavior is in effect at the time. Consider the following:

```fortran
READ (2, '(I5)') J
```

If 3 is input for \( J \), the value of \( J \) will be 30000 or 3 depending on which default behavior is in effect (BLANK='NULL' or BLANK='ZERO'). This can give unexpected results.

To ensure that the desired behavior is in effect, explicitly specify the BN or BZ edit descriptor. For example, the following ensures that blanks are interpreted as blanks (and not as zeros):

```fortran
READ (2, '(BN, I5)') J
```
Using Commas to Separate Input Data

You can use a comma to terminate a short data field. The comma has no effect on the \( d \) part (the number of characters to the right of the decimal point) of the specification.

The comma overrides the \( w \) specified for the I, B, O, Z, F, E, D, EN, ES, G, and L edit descriptors. For example, suppose the following statements are executed:

```
READ (5,100) I,J,A,B
100  FORMAT (2I6,2F10.2)
```

Suppose a record containing the following values is read:

```
1, -2, 1.0, 35
```

The following assignments occur:

```
I = 1  
J = -2  
A = 1.0  
B = 0.35
```

A comma can only terminate fields less than \( w \) characters long. If a comma follows a field of \( w \) or more characters, the comma is considered part of the next field.

A null (zero-length) field is designated by two successive commas, or by a comma after a field of \( w \) characters. Depending on the field descriptor specified, the resulting value assigned is 0, 0.0, 0.0D0, 0.0Q0, or .FALSE..

General Rules for Numeric Editing

Control Edit Descriptors

A control edit descriptor either directly determines how text is displayed or affects the conversions performed by subsequent data edit descriptors.

Forms for Control Edit Descriptors

A control edit descriptor takes one of the following forms:

\( c \)  
\( cn \)  
\( nc \)  
\( c \)  
\( n \)

Is one of the following format codes: T, TL, TR, X, S, SP, SS, BN, BZ, P, RU, RD, RZ, RN, RC, RP, DC, DP, :, /, \, $, and Q.

Is a number of character positions. It must be a positive integer literal constant or a variable format expression. No kind parameter can be specified. It cannot be a named constant.

The range of \( n \) is 1 through 2147483647 (2**31-1) on Intel® 64 architecture; 1 through 32767 (2**15-1) on IA-32 architecture. Actual useful ranges may be constrained by record sizes (RECL) and the file system.

Description

In general, control edit descriptors are nonrepeatable. The only exception is the slash (/) edit descriptor, which can be preceded by a repeat specification or a * indicating an unlimited repeat count.

The control edit descriptors have the following specific forms:
The P edit descriptor is an exception to the general control edit descriptor syntax. It is preceded by a scale factor, rather than a character position specifier.

Control edit descriptors can be grouped in parentheses and preceded by a group repeat specification.

See Also
Nested and Group Repeat Specifications
Format Specifications

Positional Editing
The T, TL, TR, and X edit descriptors specify the position where the next character is transferred to or from a record.

On output, these descriptors do not themselves cause characters to be transferred and do not affect the length of the record. If characters are transferred to positions at or after the position specified by one of these descriptors, positions skipped and not previously filled are filled with blanks. The result is as if the entire record was initially filled with blanks.

The TR and X edit descriptors produce the same results.

See Also
Forms for Control Edit Descriptors

T Editing
The T edit descriptor specifies a character position in an I/O record. It takes the following form:

Tn

The n is a positive integer literal constant (with no kind parameter) indicating the character position of the record, relative to the left tab limit.

On input, the T descriptor positions the external record at the character position specified by \( n \). On output, the T descriptor indicates that data transfer begins at the \( n \)th character position of the external record.

Examples
In the following examples, the symbol \(^\) represents a nonprinting blank character.

Suppose a file has a record containing the value ABC\(^\)\(^\)\(^\)XYZ, and the following statements are executed:

```
READ (11,10) VALUE1, VALUE2
10   FORMAT (T7,A3,T1,A3)
```

The values read first are XYZ, then ABC.

Suppose the following statements are executed:

```
PRINT 25
25   FORMAT (T51,'COLUMN 2',T21,'COLUMN 1')
```
Note that the first character of the record printed was reserved as a control character.

See Also
Printing of Formatted Records

TL Editing
The TL edit descriptor specifies a character position to the left of the current position in an I/O record. It takes the following form:

TLn
The n is a positive integer literal constant (with no kind parameter) indicating the nth character position to the left of the current character.
If n is greater than or equal to the current position, the next character accessed is the first character of the record.

TR Editing
The TR edit descriptor specifies a character position to the right of the current position in an I/O record. It takes the following form:

TRn
The n is a positive integer literal constant (with no kind parameter) indicating the nth character position to the right of the current character.

X Editing
The X edit descriptor specifies a character position to the right of the current position in an I/O record. It takes the following form:

nX
The n is a positive integer literal constant (with no kind parameter) indicating the nth character position to the right of the current character.
On output, the X edit descriptor does not output any characters when it appears at the end of a format specification; for example:

WRITE (6,99) K
99 FORMAT (^K=,'I6,5X)

Note that the symbol ^ represents a nonprinting blank character. This example writes a record of only 9 characters. To cause n trailing blanks to be output at the end of a record, specify a format of n('^').

Sign Editing
The SP, SS and S edit descriptors control the output of the optional plus (+) sign within numeric output fields. These descriptors have no effect during execution of input statements.
These specifiers correspond to the SIGN= specifier values PLUS, SUPPRESS, and PROCESSOR_DEFINED, respectively.
Within a format specification, a sign editing descriptor affects all subsequent I, F, E, EN, ES, D, and G descriptors until another sign editing descriptor occurs.

Examples

| INTEGER i |
| REAL r |
The following statements write:

```plaintext
! 251 +251 251 +251 251
i = 251
WRITE (*, 100) i, i, i, i, i
100 FORMAT (I5, SP, I5, SS, I5, SP, I5, S, I5)
```

The following statements write:

```plaintext
! 0.673E+4 +.673E+4 +0.673E+4 +.673E+4 +0.673E+4
r = 67.3E2
WRITE (*, 200) r, r, r, r, r
200 FORMAT (E8.3E1, 1X, SP, E8.3E1, SS, E8.3E1, 1X, SP, &
            E8.3E1, S, E8.3E1)
```

See Also
Forms for Control Edit Descriptors

**SP Editing**
The SP edit descriptor causes the processor to produce a plus sign in any subsequent position where it would be otherwise optional. It takes the following form:

SP

**SS Editing**
The SS edit descriptor causes the processor to *suppress* a plus sign in any subsequent position where it would be otherwise optional. It takes the following form:

SS

**S Editing**
The S edit descriptor restores the plus sign as optional for all subsequent positive numeric fields. It takes the following form:

S

The S edit descriptor restores to the processor the discretion of producing plus characters on an optional basis.

**Blank Editing**
The BN and BZ descriptors control the interpretation of embedded and trailing blanks within numeric input fields. These descriptors have no effect during execution of output statements.

Within a format specification, a blank editing descriptor affects all subsequent I, B, O, Z, F, E, EN, ES, D, and G descriptors until another blank editing descriptor occurs.

The blank editing descriptors override the effect of the BLANK specifier during execution of a particular input data transfer statement. (For more information, see the BLANK specifier in OPEN statements.)

See Also
Forms for Control Edit Descriptors

**BN Editing**
The BN edit descriptor causes the processor to *ignore* all embedded and trailing blanks in numeric input fields. It takes the following form:

BN

The input field is treated as if all blanks have been removed and the remainder of the field is right-justified. An all-blank field is treated as zero.
Examples

If an input field formatted as a six-digit integer (I6) contains '2 3 4', it is interpreted as ' 234'.

Consider the following code:

```
READ (*, 100) n
100 FORMAT (BN, I6)
```

If you enter any one of the following three records and terminate by pressing Enter, the READ statement interprets that record as the value 123:

```
123
123
123  456
```

Because the repeatable edit descriptor associated with the I/O list item n is I6, only the first six characters of each record are read (three blanks followed by 123 for the first record, and 123 followed by three blanks for the last two records). Because blanks are ignored, all three records are interpreted as 123.

The following example shows the effect of BN editing with an input record that has fewer characters than the number of characters specified by the edit descriptors and `iolist`. Suppose you enter 123 and press Enter in response to the following READ statement:

```
READ (*, '(I6)') n
```

The I/O system is looking for six characters to interpret as an integer number. You have entered only three, so the first thing the I/O system does is to pad the record 123 on the right with three blanks. With BN editing in effect, the nonblank characters (123) are right-aligned, so the record is equal to 123.

BZ Editing

The BZ edit descriptor causes the processor to interpret all embedded and trailing blanks in numeric input fields as zeros. It takes the following form:

```
BZ
```

Examples

The input field ' 23 4 ' is interpreted as ' 23040'. If ' 23 4 ' is entered, the formatter adds one blank to pad the input to the six-digit integer format (I6), but this extra space is ignored, and the input is interpreted as '2304 '. The blanks following the E or D in real-number input are ignored, regardless of the form of blank interpretation in effect.

Suppose you enter 123 and press Enter in response to the following READ statement:

```
READ (*, '(I6)') n
```

The I/O system is looking for six characters to interpret as an integer number. You have entered only three, so the first thing the I/O system does is to pad the record 123 on the right with three blanks. If BZ editing is in effect, those three blanks are interpreted as zeros, and the record is equal to 123000.

Round Editing

The RU, RD, RZ, RN, RC, and RP edit descriptors temporarily change the I/O rounding mode for a connection. These specifiers correspond to the ROUND= specifier values UP, DOWN, ZERO, NEAREST, COMPATIBLE, and PROCESSOR DEFINED, respectively.

The I/O rounding mode affects the conversion of real and complex values in formatted I/O. It affects only D, E, EN, ES, F, and G editing.

Each descriptor continues to be in effect until a different round editing descriptor is encountered or until the end of the current I/O statement.

See Also

Forms for Control Edit Descriptors
RU Editing
The RU edit descriptor causes rounding to the smallest value that is greater than or equal to the original value. It takes the following form:

RU

RD Editing
The RD edit descriptor causes rounding to the largest representable value that is less than or equal to the original value. It takes the following form:

RD

RZ Editing
The RZ edit descriptor causes rounding to the value closest to the original value, but not greater in magnitude. It takes the following form:

RZ

RN Editing
The RN edit descriptor causes rounding to the closer of the two nearest representable values, if one is closer than the other. If both values are equally close then the even value is chosen. It takes the following form:

RN

RC Editing
The RC edit descriptor causes rounding to the closer of the two nearest representable values. If the value is halfway between the two values, the one chosen is the one farther from zero. It takes the following form:

RC

RP Editing
The RP edit descriptor causes rounding to be determined by the default settings in the processor, which may correspond to one of the other modes. It takes the following form:

RP

Decimal Editing
The DC and DP edit descriptors temporarily change the decimal edit mode for a connection. These specifiers correspond to the DECIMAL= specifier values COMMA and POINT, respectively. The decimal editing mode controls the representation of the decimal symbol during conversion of real and complex values in formatted I/O. It affects only D, E, EN, ES, F, and G editing. Each descriptor continues to be in effect until a different decimal editing descriptor is encountered or until the end of the current I/O statement.

See Also
Forms for Control Edit Descriptors

DC Editing
The DC edit descriptor changes the decimal editing mode for a connection to a decimal comma. It takes the following form:

DC

Note that during list-directed I/O, a semicolon is used as a value separator in place of a comma.
**DP Editing**

The DP edit descriptor causes rounding to be determined by the default settings in the processor, which may correspond to one of the other modes. It takes the following form:

\[ \text{DP} \]

**Scale-Factor Editing (P)**

The P edit descriptor specifies a scale factor, which moves the location of the decimal point in real values and the two real parts of complex values. It takes the following form:

\[ kP \]

The \( k \) is a signed (sign is optional if positive), integer literal constant specifying the number of positions, to the left or right, that the decimal point is to move (the scale factor). The range of \( k \) is -128 to 127.

At the beginning of a formatted I/O statement, the value of the scale factor is zero. If a scale editing descriptor is specified, the scale factor is set to the new value, which affects all subsequent real edit descriptors until another scale editing descriptor occurs.

To reinstate a scale factor of zero, you must explicitly specify \( 0P \).

Format reversion does not affect the scale factor. (For more information on format reversion, see Interaction Between Format Specifications and I/O Lists.)

**Rules for Input Processing**

On input, a positive scale factor moves the decimal point to the left, and a negative scale factor moves the decimal point to the right. (On output, the effect is the reverse.)

On input, when an input field using an F, E, D, EN, ES, or G real edit descriptor contains an explicit exponent, the scale factor has no effect. Otherwise, the internal value of the corresponding I/O list item is equal to the external field data multiplied by \( 10^{-k} \). For example, a 2P scale factor multiplies an input value by .01, moving the decimal point two places to the left. A -2P scale factor multiplies an input value by 100, moving the decimal point two places to the right.

The following shows input using the P edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Input</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>3PE10.5</td>
<td>^^^37.614^</td>
<td>.037614</td>
</tr>
<tr>
<td>3PE10.5</td>
<td>^^37.614E2</td>
<td>3761.4</td>
</tr>
<tr>
<td>-3PE10.5</td>
<td>^^^^37.614</td>
<td>37614.0</td>
</tr>
</tbody>
</table>

The scale factor must precede the first real edit descriptor associated with it, but it need not immediately precede the descriptor. For example, the following all have the same effect:

\[ (3P, I6, F6.3, E8.1) \]
\[ (I6, 3P, F6.3, E8.1) \]
\[ (I6, 3PF6.3, E8.1) \]

Note that if the scale factor immediately precedes the associated real edit descriptor, the comma separator is optional.

**Rules for Output Processing**

On output, a positive scale factor moves the decimal point to the right, and a negative scale factor moves the decimal point to the left. (On input, the effect is the reverse.)

On output, the effect of the scale factor depends on which kind of real editing is associated with it, as follows:

- For F editing, the external value equals the internal value of the I/O list item multiplied by \( 10^k \). This changes the magnitude of the data.
- For E and D editing, the external decimal field of the I/O list item is multiplied by \( 10^k \), and \( k \) is subtracted from the exponent. This changes the form of the data.
A positive scale factor decreases the exponent; a negative scale factor increases the exponent.

For a positive scale factor, \( k \) must be less than \( d + 2 \) or an output conversion error occurs.

- For G editing, the scale factor has no effect if the magnitude of the data to be output is within the effective range of the descriptor (the G descriptor supplies its own scaling).

  If the magnitude of the data field is outside G descriptor range, E editing is used, and the scale factor has the same effect as E output editing.

- For EN and ES editing, the scale factor has no effect.

The following shows output using the P edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Value</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>1PE12.3</td>
<td>-270.139</td>
<td>^^-2.701E+02</td>
</tr>
<tr>
<td>1P,E12.2</td>
<td>-270.139</td>
<td>^^^-2.70E+02</td>
</tr>
<tr>
<td>-1PE12.2</td>
<td>-270.139</td>
<td>^^^-0.03E+04</td>
</tr>
</tbody>
</table>

**Examples**

The following shows a FORMAT statement containing a scale factor:

```plaintext
DIMENSION A(6)
DO 10 I=1,6
  A(I) = 25.
  WRITE (6, 100) A
100  FORMAT(' ', F8.2, 2PF8.2, F8.2)
```

The preceding statements produce the following results:

```
25.00  2500.00  2500.00
2500.00  2500.00  2500.00
```

The following code uses scale-factor editing when reading:

```plaintext
READ (*, 100) a, b, c, d
100  FORMAT (F10.6, 1P, F10.6, F10.6, -2P, F10.6)
```

The program's output is:

```
12.340      1.234      1.234   1234.000
12.340      1.234      1.234   1234.000
12340.000  12340.000  12340.000  12340.000
```

The next code shows scale-factor editing when writing:

```plaintext
a = 12.34

WRITE (*, 100) a, a, a, a, a
100  FORMAT (IX, F9.4, E11.4E2, 1P, F9.4, E11.4E2, &
          & -2P, F9.4, E11.4E2)
```

This program's output is:

```
12.3400 0.1234E+02 123.4000 1.2340E+01  0.1234 0.0012E+04
```
Slash Editing (/)

The slash edit descriptor terminates data transfer for the current record and starts data transfer for a new record. It takes the following form:

\[ [r] / \]

The \( r \) is a repeat specification. It must be a positive default integer literal constant; no kind parameter can be specified.

The range of \( r \) is 1 through 2147483647 (2**31-1) on Intel® 64 architecture; 1 through 32767 (2**15-1) on IA-32 architecture. If \( r \) is omitted, it is assumed to be 1.

Multiple slashes cause the system to skip input records or to output blank records, as follows:

- When \( n \) consecutive slashes appear between two edit descriptors, \( n - 1 \) records are skipped on input, or \( n - 1 \) blank records are output. The first slash terminates the current record. The second slash terminates the first skipped or blank record, and so on.
- When \( n \) consecutive slashes appear at the beginning or end of a format specification, \( n \) records are skipped or \( n \) blank records are output, because the opening and closing parentheses of the format specification are themselves a record initiator and terminator, respectively. For example, suppose the following statements are specified:

```fortran
WRITE (6,99)
99 FORMAT ('1','T51','HEADING LINE'//T51,'SUBHEADING LINE'//)
```

The following lines are written:

<table>
<thead>
<tr>
<th>Column 50, top of page</th>
<th>HEADING LINE</th>
</tr>
</thead>
<tbody>
<tr>
<td>(blank line)</td>
<td>SUBHEADING LINE</td>
</tr>
<tr>
<td>(blank line)</td>
<td></td>
</tr>
<tr>
<td>(blank line)</td>
<td></td>
</tr>
</tbody>
</table>

Note that the first character of the record printed was reserved as a control character (see Printing of Formatted Records).

Examples

The following statements write spreadsheet column and row labels:

```fortran
WRITE (*,100)
100 FORMAT ('   A     B     C     D     E'                             &
&        /,' 1',/,' 2',/,' 3',/,' 4',/,' 5')
```

This example generates the following output:

<p>| | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>B</td>
<td>C</td>
<td>D</td>
<td>E</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>3</td>
<td>4</td>
<td>5</td>
</tr>
</tbody>
</table>

See Also

Forms for Control Edit Descriptors

Colon Editing (:)

The colon edit descriptor terminates format control if no more items are in the I/O list.
**Examples**

Suppose the following statements are specified:

```fortran
PRINT 1,3
PRINT 2,13
1 FORMAT (' I=',I2,' J=',I2)
2 FORMAT (' K=',I2,:, ' L=',I2)
```

The following lines are written (the symbol ^ represents a nonprinting blank character):

```fortran
I=^3^J=
K=13
```

The following example writes a = 3.20 b = .99

```fortran
REAL a, b, c, d
DATA a /3.2/, b /.9871515/
WRITE (*, 100) a, b
100 FORMAT (' a=', F5.2, :, ' b=', F5.2, :, &
        ' c=', F5.2, :, ' d=', F5.2)
END
```

See Also

Forms for Control Edit Descriptors

**Dollar-Sign ($) and Backslash ( \ ) Editing**

The dollar sign and backslash edit descriptors modify the output of carriage control specified by the first character of the record. They only affect carriage control for formatted files, and have no effect on input.

If the first character of the record is a blank or a plus sign (+), the dollar sign and backslash descriptors suppress carriage return (after printing the record).

For terminal device I/O, when this trailing carriage return is suppressed, a response follows output on the same line. For example, suppose the following statements are specified:

The following prompt is displayed:

```
ENTER RADIUS VALUE
```

Any response (for example, "12.") is then displayed on the same line:

```
ENTER RADIUS VALUE 12.
```

If the first character of the record is 0, 1, or ASCII NUL, the dollar sign and backslash descriptors have no effect.

Consider the following:

This example advances two lines, prompts for input, awaits input on the same line as the prompt, and prints the input.

The following shows the same example using Fortran standard constructs:

See Also

Forms for Control Edit Descriptors

**Character Count Editing (Q)**

The character count edit descriptor returns the remaining number of characters in the current input record. The corresponding I/O list item must be of type integer or logical. For example, suppose the following statements are specified:

```fortran
READ (4,1000) XRAY, KK, NCHRS, (ICHR(I), I=1,NCHRS)
1000 FORMAT (E15.7,I4,Q,(80A1))
```

Two fields are read into variables XRAY and KK. The number of characters remaining in the record is stored in NCHRS, and exactly that many characters are read into the array ICHR. (This instruction can fail if the record is longer than 80 characters.)
If you place the character count descriptor first in a format specification, you can determine the length of an input record.

On output, the character count edit descriptor causes the corresponding I/O list item to be skipped.

**Examples**

Consider the following:

```fortran
CHARACTER ICHAR(80)
READ (4, 1000) XRAY, K, NCHAR, (ICHAR(I), I= 1, NCHAR)
1000 FORMAT (E15.7, I4, Q, 80A1)
```

The preceding input statement reads the variables XRAY and K. The number of characters remaining in the record is NCHAR, specified by the Q edit descriptor. The array ICHAR is then filled by reading exactly the number of characters left in the record. (Note that this instruction will fail if NCHAR is greater than 80, the length of the array ICHAR.) By placing Q in the format specification, you can determine the actual length of an input record.

Note that the length returned by Q is the number of characters left in the record, not the number of reals or integers or other data types. The length returned by Q can be used immediately after it is read and can be used later in the same format statement or in a variable format expression. (See Variable Format Expressions.)

Assume the file Q.DAT contains:

```
1234.567Hello, Q Edit
```

The following program reads in the number REAL1, determines the characters left in the record, and reads those into STR:

```fortran
CHARACTER STR(80)
INTEGER LENGTH
REAL REAL1
OPEN (UNIT = 10, FILE = 'Q.DAT')
100 FORMAT (F8.3, Q, 80A1)
READ (10, 100) REAL1, LENGTH, (STR(I), I=1, LENGTH)
WRITE(*,'(F8.3,2X,I2,2X,<LENGTH>A1)') REAL1, LENGTH, (STR(I), &
& I= 1, LENGTH)
END
```

The output on the screen is:

```
1234.567  13  Hello, Q Edit
```

A READ statement that contains only a Q edit descriptor advances the file to the next record. For example, consider that Q.DAT contains the following data:

```
abcdefg
abcd
```

Consider it is then READ with the following statements:

```fortran
OPEN (10, FILE = "Q.DAT")
READ(10, 100) LENGTH
100 FORMAT(Q)
WRITE(*,'(I2)') LENGTH
READ(10, 100) LENGTH
WRITE(*,'(I2)') LENGTH
END
```

The output to the screen would be:

```
7
4
```

**See Also**

Forms for Control Edit Descriptors
**Character String Edit Descriptors**

Character string edit descriptors control the output of character strings. The character string edit descriptors are the **character constant** and **H** edit descriptor.

Although no string edit descriptor can be preceded by a repeat specification, a parenthesized group of string edit descriptors can be preceded by a repeat specification or a * indicating an unlimited repeat count.

**See Also**

**Nested and Group Repeat Specifications**

**Character Constant Editing**

The character constant edit descriptor causes a character string to be output to an external record. It takes one of the following forms:

- `'string'`
- `"string"

The **string** is a character literal constant; no kind parameter can be specified. Its length is the number of characters between the delimiters; two consecutive delimiters are counted as one character.

To include an apostrophe in a character constant that is enclosed by apostrophes, place two consecutive apostrophes (``) in the format specification; for example:

```plaintext
50   FORMAT ("TODAY''S DATE IS:"',I2,'/',I2,'/',I2)
```

Note that the symbol ^ represents a nonprinting blank character.

Similarly, to include a quotation mark in a character constant that is enclosed by quotation marks, place two consecutive quotation marks (``) in the format specification.

On input, the character constant edit descriptor transfers length of string characters to the edit descriptor.

**Examples**

Consider the following '(3I5)' format in the WRITE statement:

```plaintext
WRITE (10, '(3I5)') I1, I2, I3
```

This is equivalent to:

```plaintext
WRITE (10, 100) I1, I2, I3
100   FORMAT( 3I5)
```

The following shows another example:

```plaintext
! These WRITE statements both output ABC'DEF
! (The leading blank is a carriage-control character).
   WRITE (*, 970)
   WRITE (*, '" ABC''''DEF"')
   WRITE (*, '" ABC"''DEF"')
!
   The following WRITE also outputs ABC'DEF. No carriage-
! control character is necessary for list-directed I/O.
   WRITE (*,*) 'ABC''DEF'
```

Alternatively, if the delimiter is quotation marks, the apostrophe in the character constant ABC'DEF requires no special treatment:

```plaintext
WRITE (*,*) "ABC'DEF"
```

**See Also**

**Character Constants**

**Format Specifications**
H Editing

The H edit descriptor transfers data between the external record and the H edit descriptor itself. The H edit descriptor is a deleted feature in the Fortran Standard. Intel® Fortran fully supports features deleted in the Fortran Standard.

An H edit descriptor has the form of a Hollerith constant, as follows:

\[ n \text{H} \text{string} \]

- \( n \) is an unsigned, positive default integer literal constant (with no kind parameter) indicating the number of characters in \( \text{string} \) (including blanks and tabs).
- The range of \( n \) is 1 through 2147483647 (\( 2^{31} \)-1) on Intel® 64 architecture; 1 through 32767 (\( 2^{15} \)-1) on IA-32 architecture. Actual useful ranges may be constrained by record sizes (RECL) and the file system.

- \( \text{string} \) is a string of printable ASCII characters.

On input, the H edit descriptor transfers \( n \) characters from the external field to the edit descriptor. The first character appears immediately after the letter H. Any characters in the edit descriptor before input are replaced by the input characters. If the edit descriptor appears in a FORMAT statement, the replaced characters are preserved for future uses of that FORMAT statement; otherwise, the replacement is discarded.

On output, the H edit descriptor causes \( n \) characters following the letter H to be output to an external record.

Examples

```
! These WRITE statements both print "Don't misspell 'Hollerith'"
! (The leading blanks are carriage-control characters).
! Hollerith formatting does not require you to embed additional
! single quotation marks as shown in the second example.
! WRITE (*, 960)
960 FORMAT (27H Don't misspell 'Hollerith')
WRITE (*, 961)
961 FORMAT (' Don''t misspell ''Hollerith''')
```

Deleted and Obsolescent Language Features
Format Specifications

Nested and Group Repeat Specifications

Format specifications can include nested format specifications enclosed in parentheses; for example:

```
15 FORMAT (E7.2,I8,12,(A5,16))
35 FORMAT (A6,(L8(312)),A)
```

A group repeat specification can precede a nested group of edit descriptors; it can be an unsigned integer literal constant, a variable format expression, or * to indicate an unlimited repeat count. For example, the following statements are equivalent, and the second statement shows a group repeat specification:

```
50 FORMAT (I8,18,F8.3,E15.7,F8.3,E15.7,I5,I5)
50 FORMAT (2I8,3(F8.3,E15.7),2I5)
```

If a nested group does not show a repeat count, a default count of 1 is assumed.

Normally, the string edit descriptors and control edit descriptors cannot be repeated (except for slash), but any of these descriptors can be enclosed in parentheses and preceded by a group repeat specification. For example, the following statements are valid:

```
76 FORMAT ('MONTHLY',3('TOTAL'))
100 FORMAT (I8,4(T7),A4)
```
Each of the following can be used to read data at the end of an input record into N elements of array A:

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>read (10,‘(&lt;N&gt;F8.2)’) A(1:N)</code></td>
<td>Variable format expression</td>
</tr>
<tr>
<td><code>read(10,’(*F8.2)’) A(1:N)</code></td>
<td>Unlimited repeat count</td>
</tr>
</tbody>
</table>

**See Also**

- Character String Edit Descriptors
- Control Edit Descriptors
- Forms for Data Edit Descriptors for details on repeat specifications for data edit descriptors
- Interaction Between Format Specifications and I/O Lists for details on group repeat specifications and format reversion

**Variable Format Expressions**

A variable format expression is a numeric expression enclosed in angle brackets (`< >`) that can be used in a FORMAT statement or in a character format specification.

The numeric expression can be any valid Fortran expression, including function calls and references to dummy arguments.

If the expression is not of type integer, it is converted to integer type before being used.

If the value of a variable format expression does not obey the restrictions on magnitude applying to its use in the format, an error occurs.

Variable format expressions cannot be used with the H edit descriptor, and they are not allowed in character format specifications that are not character constant expressions.

Variable format expressions are evaluated each time they are encountered in the scan of the format. If the value of the variable used in the expression changes during the execution of the I/O statement, the new value is used the next time the format item containing the expression is processed.

**Examples**

Consider the following statement:

```fortran
FORMAT (I<J+1>)
```

When the format is scanned, the preceding statement performs an I (integer) data transfer with a field width of J+1. The expression is reevaluated each time it is encountered in the normal format scan.

Consider the following statements:

```fortran
DIMENSION A(5)
DATA A/1.,2.,3.,4.,5./

DO 10 I=1,10
  WRITE (6,100) I
100   FORMAT (I<MAX(I,5)>)
10 CONTINUE

DO 20 I=1,5
  WRITE (6,101) (A(I), J=1,I)
101   FORMAT (<I>F10.<I-1>)
20 CONTINUE
END
```

On execution, these statements produce the following output:

```
1
2
3
4
5
6
7
```
The following shows another example:

```fortran
WRITE(6,20) INT1
20     FORMAT(I<MAX(20,5)>)
WRITE(6,FMT=30) REAL2(10), REAL3
30     FORMAT(<J+K>X, <2*M>F8.3)
```

The value of the expression is reevaluated each time an input/output item is processed during the execution of the READ, WRITE, or PRINT statement. For example:

```fortran
INTEGER width, value
width=2
READ (*,10) width, value
10     FORMAT(I1, I <width>)
PRINT *, value
END
```

When given input 3123, the program will print 123 and not 12.

**See Also**

*Interaction Between Format Specifications and I/O Lists* for details on the synchronization of I/O lists with formats

### Printing of Formatted Records

On output, if a file was opened with CARRIAGECONTROL='FORTRAN' in effect or the file is being processed by the `fortpr` format utility, the first character of a record transmitted to a line printer or terminal is typically a character that is not printed, but used to control vertical spacing.

The following table lists the valid control characters for printing:

**Control Characters for Printing**

<table>
<thead>
<tr>
<th>Character</th>
<th>Meaning</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>+</td>
<td>Overprinting</td>
<td>Outputs the record (at the current position in the current line) and a carriage return.</td>
</tr>
<tr>
<td>-</td>
<td>One line feed</td>
<td>Outputs the record (at the beginning of the following line) and a carriage return.</td>
</tr>
<tr>
<td>0</td>
<td>Two line feeds</td>
<td>Outputs the record (after skipping a line) and a carriage return.</td>
</tr>
<tr>
<td>1</td>
<td>Next page</td>
<td>Outputs the record (at the beginning of a new page) and a carriage return.</td>
</tr>
<tr>
<td>$</td>
<td>Prompting</td>
<td>Outputs the record (at the beginning of the following line), but no carriage return.</td>
</tr>
</tbody>
</table>
### Interaction Between Format Specifications and I/O Lists

Format control begins with the execution of a formatted I/O statement. Each action of format control depends on information provided jointly by the next item in the I/O list (if one exists) and the next edit descriptor in the format specification.

Both the I/O list and the format specification are interpreted from left to right, unless repeat specifications or implied-DO lists appear.

If an I/O list specifies at least one list item, at least one data edit descriptor (I, B, O, Z, F, E, EN, ES, D, G, L, or A) or the Q edit descriptor must appear in the format specification; otherwise, an error occurs.

Each data edit descriptor (or Q edit descriptor) corresponds to one item in the I/O list, except that an I/O list item of type complex requires the interpretation of two F, E, EN, ES, D, or G edit descriptors. No I/O list item corresponds to a control edit descriptor (X, P, T, TL, TR, SP, SS, S, BN, BZ, $, or :), or a character string edit descriptor (H and character constants). For character string edit descriptors, data transfer occurs directly between the external record and the format specification.

When format control encounters a data edit descriptor in a format specification, it determines whether there is a corresponding I/O list item specified. If there is such an item, it is transferred under control of the edit descriptor, and then format control proceeds. If there is no corresponding I/O list item, format control terminates.

If there are no other I/O list items to be processed, format control also terminates when the following occurs:

- A colon edit descriptor is encountered.
- The end of the format specification is reached.

If additional I/O list items remain, part or all of the format specification is reused in format reversion.

In format reversion, the current record is terminated and a new one is initiated. Format control then reverts to one of the following (in order) and continues from that point:

1. The group repeat specification whose opening parenthesis matches the next-to-last closing parenthesis of the format specification
2. The initial opening parenthesis of the format specification

Format reversion has no effect on the scale factor (P), the sign control edit descriptors (S, SP, or SS), or the blank interpretation edit descriptors (BN or BZ).

### Examples

The data in file FOR002.DAT is to be processed 2 records at a time. Each record starts with a number to be put into an element of a vector B, followed by 5 numbers to be put in a row in matrix A.

FOR002.DAT contains the following data:

```
001 0101 0102 0103 0104 0105
002 0201 0202 0203 0204 0205
003 0301 0302 0303 0304 0305
004 0401 0402 0403 0404 0405
005 0501 0502 0503 0504 0505
006 0601 0602 0603 0604 0605
007 0701 0702 0703 0704 0705
```
The following example shows how several different format specifications interact with I/O lists to process data in file FOR002.DAT:

**Interaction Between Format Specifications and I/O Lists**

```
INTEGER I, J, A(2,5), B(2)
OPEN (unit=2, access='sequential', file='FOR002.DAT')

READ (2,100) (B(I), (A(I,J), J=1,5), I=1,2)  
100   FORMAT (2 (I3, X, 5(I4,X), /) )  
      WRITE (6,999) B, ((A(I,J),J=1,5),I=1,2)  
999   FORMAT (' B is ', 2(I3, X), ';  A is', /  
            (' ', 5 (I4, X)) )
      READ (2,200) (B(I), (A(I,J), J=1,5), I=1,2)  
200   FORMAT (2 (I3, X, 5(I4,X), :/) ) 
      WRITE (6,999) B, ((A(I,J),J=1,5),I=1,2)  
      READ (2,300) (B(I), (A(I,J), J=1,5), I=1,2)  
300   FORMAT ( (I3, X, 5(I4,X)) ) 
      WRITE (6,999) B, ((A(I,J),J=1,5),I=1,2)  
      READ (2,400) (B(I), (A(I,J), J=1,5), I=1,2)  
400   FORMAT ( I3, X, 5(I4,X) )
```
This statement reads B(1); then A(1,1) through A(1,5); then B(2) and A(2,1) through A(2,5).

The first record read (starting with 001) starts the processing of the I/O list.

There are two records, each in the format I3, X, 5(I4, X). The slash (/) forces the reading of the second record after A(1,5) is processed. It also forces the reading of the third record after A(2,5) is processed; no data is taken from that record.

This statement produces the following output:

\[
\begin{array}{c}
B \\
\end{array}
\begin{array}{c}
is \\
1 & 2 \\
\end{array}
\begin{array}{c}
A \\
101 & 102 & 103 & 104 & 105 & 201 & 202 & 203 & 204 & 205
\end{array}
\]

This statement reads the record starting with 004. The slash (/) forces the reading of the next record after A(1,5) is processed. The colon (:) stops the reading after A(2,5) is processed, but before the slash (/) forces another read.

This statement produces the following output:

\[
\begin{array}{c}
B \\
\end{array}
\begin{array}{c}
is \\
4 & 5 \\
\end{array}
\begin{array}{c}
A \\
401 & 402 & 403 & 404 & 405 & 501 & 502 & 503 & 504 & 505
\end{array}
\]

This statement reads the record starting with 006. After A(1,5) is processed, format reversion causes the next record to be read and starts format processing at the left parenthesis before the I3.

This statement produces the following output:

\[
\begin{array}{c}
B \\
\end{array}
\begin{array}{c}
is \\
6 & 7 \\
\end{array}
\begin{array}{c}
A \\
601 & 602 & 603 & 604 & 605 & 701 & 702 & 703 & 704 & 705
\end{array}
\]

This statement reads the record starting with 008. After A(1,5) is processed, format reversion causes the next record to be read and starts format processing at the left parenthesis before the I4.

This statement produces the following output:

\[
\begin{array}{c}
B \\
\end{array}
\begin{array}{c}
is \\
8 & 90 \\
\end{array}
\begin{array}{c}
A \\
801 & 802 & 803 & 804 & 805 & 9010 & 9020 & 9030 & 9040 & 100
\end{array}
\]

The record 009 0901 0902 0903 0904 0905 is processed with I4 as "009 " for B(2), which is 90. X skips the next "0". Then "901 " is processed for A(2,1), which is 9010, "902 " for A(2,2), "903 " for A(2,3), and "904 " for A(2,4). The repeat specification of 5 is now exhausted and the format ends. Format reversion causes another record to be read and starts format processing at the left parenthesis before the I4, so "010 " is read for A(2,5), which is 100.

File Operation I/O Statements Overview

The following are file connection, inquiry, and positioning I/O statements:

- **BACKSPACE**
  Positions a sequential file at the beginning of the preceding record, making it available for subsequent I/O processing.

- **CLOSE**
  Terminates the connection between a logical unit and a file or device.

- **DELETE**
  Deletes a record from a relative file.

- **ENDFILE**
  Writes an end-of-file record to a sequential file and positions the file after this record (the terminal point). For direct access files, truncates the file after the current record.

- **FLUSH**
  Causes data written to a file to become available to other processes or causes data written to a file outside of Fortran to be accessible to a READ statement.

- **INQUIRE**
  Requests information on the status of specified properties of a file or logical unit. For more information on specifiers you can use in INQUIRE statements, see INQUIRE Statement Specifiers.

- **OPEN**
  Connects a Fortran logical unit to a file or device; declares attributes for read and write operations. For more information on specifiers you can use in OPEN statements, see OPEN Statement Specifiers.

- **REWIND**
  Positions a sequential or direct access file at the beginning of the file (the initial point).

- **WAIT**
  Performs a wait operation for a specified pending asynchronous data transfer operation.

The following table summarizes I/O statement specifiers:

<table>
<thead>
<tr>
<th>Specifier</th>
<th>Values</th>
<th>Description</th>
<th>Used with:</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACCESS=access</td>
<td>'SEQUENTIAL', 'DIRECT', 'STREAM', or 'APPEND'</td>
<td>Specifies the method of file access.</td>
<td>INQUIRE, OPEN</td>
</tr>
<tr>
<td>ACTION=permission</td>
<td>'READ', 'WRITE' or 'READWRITE' (default is 'READWRITE')</td>
<td>Specifies file I/O mode.</td>
<td>INQUIRE, OPEN</td>
</tr>
<tr>
<td>ADVANCE=c-expr</td>
<td>'NO' or 'YES' (default is 'YES')</td>
<td>Specifies formatted sequential data input as advancing, or non-advancing.</td>
<td>READ</td>
</tr>
<tr>
<td>Specifier</td>
<td>Values</td>
<td>Description</td>
<td>Used with:</td>
</tr>
<tr>
<td>------------------------</td>
<td>-----------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>--------------</td>
</tr>
<tr>
<td>ASSOCIATEVARIABLE=var</td>
<td>Integer variable</td>
<td>Specifies a variable to be updated to reflect the record number of the next sequential record in the file.</td>
<td>OPEN</td>
</tr>
<tr>
<td>ASYNCHRONOUS=async</td>
<td>'YES' or 'NO' (default is 'NO')</td>
<td>Specifies whether or not the I/O is done asynchronously</td>
<td>INQUIRE, OPEN</td>
</tr>
<tr>
<td>BINARY=bin</td>
<td>'NO' or 'YES'</td>
<td>Returns whether file format is binary.</td>
<td>INQUIRE</td>
</tr>
<tr>
<td>BLANK=blank_control</td>
<td>'NULL' or 'ZERO' (default is 'NULL')</td>
<td>Specifies whether blanks are ignored in numeric fields or interpreted as zeros.</td>
<td>INQUIRE, OPEN</td>
</tr>
<tr>
<td>BLOCKSIZE=blocksize</td>
<td>Positive integer variable or expression</td>
<td>Specifies or returns the internal buffer size used in I/O.</td>
<td>INQUIRE, OPEN</td>
</tr>
<tr>
<td>BUFFERCOUNT=bc</td>
<td>Numeric expression</td>
<td>Specifies the number of buffers to be associated with the unit for multibuffered I/O.</td>
<td>OPEN</td>
</tr>
<tr>
<td>BUFFERED=bf</td>
<td>'YES' or 'NO' (default is 'NO')</td>
<td>Specifies run-time library behavior following WRITE operations.</td>
<td>INQUIRE, OPEN</td>
</tr>
<tr>
<td>CARRIAGECONTROL=control</td>
<td>'FORTRAN', 'LIST', or 'NONE'</td>
<td>Specifies carriage control processing.</td>
<td>INQUIRE, OPEN</td>
</tr>
<tr>
<td>CONVERT=form</td>
<td>'LITTLE_ENDIAN', 'BIG_ENDIAN', 'CRAY', 'FDX', 'FGX', 'IBM', 'VAXD', 'VAXG', or 'NATIVE' (default is 'NATIVE')</td>
<td>Specifies a numeric format for unformatted data.</td>
<td>INQUIRE, OPEN</td>
</tr>
<tr>
<td>DEFAULTFILE=var</td>
<td>Character expression</td>
<td>Specifies a default file pathname string.</td>
<td>INQUIRE, OPEN</td>
</tr>
<tr>
<td>DELIM=delimiter</td>
<td>'APOSTROPHE', 'QUOTE' or 'NONE' (default is 'NONE')</td>
<td>Specifies the delimiting character for list-directed or namelist data.</td>
<td>INQUIRE, OPEN</td>
</tr>
<tr>
<td>DIRECT=dir</td>
<td>'NO' or 'YES'</td>
<td>Returns whether file is connected for direct access.</td>
<td>INQUIRE</td>
</tr>
<tr>
<td>DISPOSE=dis (or DISP=dis)</td>
<td>'KEEP', 'SAVE', 'DELETE', 'PRINT', 'PRINT/DELETE', 'SUBMIT', or 'SUBMIT/DELETE'</td>
<td>Specifies the status of a file after the unit is closed.</td>
<td>OPEN, CLOSE</td>
</tr>
<tr>
<td>Specifier</td>
<td>Values</td>
<td>Description</td>
<td>Used with:</td>
</tr>
<tr>
<td>-------------</td>
<td>------------------------------------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------------------------</td>
</tr>
<tr>
<td>formatlist</td>
<td>Character variable or expression</td>
<td>Lists edit descriptors. Used in FORMAT statements and format specifiers (the FMT=fmt option) to describe the format of data.</td>
<td>FORMAT, PRINT, READ, WRITE</td>
</tr>
<tr>
<td>END=endlabel</td>
<td>Integer between 1 and 99999</td>
<td>When an end of file is encountered, transfers control to the statement whose label is specified.</td>
<td>READ</td>
</tr>
<tr>
<td>EOR=eorlabel</td>
<td>Integer between 1 and 99999</td>
<td>When an end of record is encountered, transfers to the statement whose label is specified.</td>
<td>READ</td>
</tr>
<tr>
<td>ERR=errlabel</td>
<td>Integer between 1 and 99999</td>
<td>Specifies the label of an executable statement where execution is transferred after an I/O error.</td>
<td>All except PRINT</td>
</tr>
<tr>
<td>EXIST=ex</td>
<td>.TRUE. or .FALSE.</td>
<td>Returns whether a file exists and can be opened.</td>
<td>INQUIRE</td>
</tr>
<tr>
<td>FILE=file(or NAME=name)</td>
<td>Character variable or expression. Length and format of the name are determined by the operating system</td>
<td>Specifies the name of a file</td>
<td>INQUIRE, OPEN</td>
</tr>
<tr>
<td>[FMT=]fmt</td>
<td>Character variable or expression</td>
<td>Specifies an editlist to use to format data.</td>
<td>PRINT, READ, WRITE</td>
</tr>
<tr>
<td>FORM=form</td>
<td>'FORMATTED', 'UNFORMATTED', or 'BINARY'</td>
<td>Specifies a file's format.</td>
<td>INQUIRE, OPEN</td>
</tr>
<tr>
<td>FORMATTED=fmt</td>
<td>'NO' or 'YES'</td>
<td>Returns whether a file is connected for formatted data transfer.</td>
<td>INQUIRE</td>
</tr>
<tr>
<td>IOFOCUS=iof</td>
<td>.TRUE. or .FALSE.</td>
<td>Specifies whether a unit is the active window in a QuickWin application.</td>
<td>INQUIRE, OPEN</td>
</tr>
<tr>
<td>iolist</td>
<td>List of variables of any type, character expression, or NAMELIST</td>
<td>Specifies items to be input or output.</td>
<td>PRINT, READ, WRITE</td>
</tr>
<tr>
<td>Specifier</td>
<td>Values</td>
<td>Description</td>
<td>Used with:</td>
</tr>
<tr>
<td>-----------------</td>
<td>-------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------------------</td>
</tr>
<tr>
<td>IOSTAT=istat</td>
<td>Integer variable</td>
<td>Specifies a variable whose value indicates whether an I/O error has occurred.</td>
<td>All except PRINT</td>
</tr>
<tr>
<td>MAXREC=var</td>
<td>Numeric expression</td>
<td>Specifies the maximum number of records that can be transferred to or from a direct access file.</td>
<td>OPEN</td>
</tr>
<tr>
<td>MODE=permission</td>
<td>'READ', 'WRITE' or 'READWRITE' (default is 'READWRITE')</td>
<td>Same as ACTION.</td>
<td>INQUIRE, OPEN</td>
</tr>
<tr>
<td>NAMED=var</td>
<td>.TRUE. or .FALSE.</td>
<td>Returns whether a file is named.</td>
<td>INQUIRE</td>
</tr>
<tr>
<td>NEWUNIT=u-var</td>
<td>Scalar integer variable</td>
<td>Is assigned an unused unit number that is automatically chosen. It is always a negative integer.</td>
<td>OPEN</td>
</tr>
<tr>
<td>NEXTREC=nr</td>
<td>Integer variable</td>
<td>Returns where the next record can be read or written in a file.</td>
<td>INQUIRE</td>
</tr>
<tr>
<td>[NML=]nmIspec</td>
<td>Namelist name</td>
<td>Specifies a namelist group to be input or output.</td>
<td>PRINT, READ, WRITE</td>
</tr>
<tr>
<td>NUMBER=num</td>
<td>Integer variable</td>
<td>Returns the number of the unit connected to a file.</td>
<td>INQUIRE</td>
</tr>
<tr>
<td>OPENED=od</td>
<td>.TRUE. or .FALSE.</td>
<td>Returns whether a file is connected.</td>
<td>INQUIRE</td>
</tr>
<tr>
<td>ORGANIZATION=org</td>
<td>'SEQUENTIAL' or 'RELATIVE' (default is 'SEQUENTIAL')</td>
<td>Specifies the internal organization of a file.</td>
<td>INQUIRE, OPEN</td>
</tr>
<tr>
<td>PAD=pad_switch</td>
<td>'YES' or 'NO' (default is 'YES')</td>
<td>Specifies whether an input record is padded with blanks when the input list or format requires more data than the record holds, or whether the input record is required to contain the data indicated.</td>
<td>INQUIRE, OPEN</td>
</tr>
<tr>
<td>POS=pos</td>
<td>Positive integer</td>
<td>Specifies the file storage unit position in a stream file.</td>
<td>INQUIRE, READ, WRITE</td>
</tr>
<tr>
<td>POSITION=file_pos</td>
