If \( isgn = -1 \), \( \text{op}(A)*X - X*\text{op}(B) = \alpha * C \).

**m**
The order of \( A \), and the number of rows in \( X \) and \( C \) \((m \geq 0)\).

**n**
The order of \( B \), and the number of columns in \( X \) and \( C \) \((n \geq 0)\).

**a, b, c**
Arrays:
\( a \) (size \( \max(1, \text{lda}*m) \)) contains the matrix \( A \).
\( b \) (size \( \max(1, \text{ldb}*n) \)) contains the matrix \( B \).
\( c \) (size \( \max(1, \text{ldc}*n) \) for column major layout and \( \max(1, \text{ldc}*m \) for row major layout) contains the matrix \( C \).

**lda**
The leading dimension of \( a \); at least \( \max(1, m) \) for column major layout and \( \max(1, n) \) for row major layout.

**ldb**
The leading dimension of \( b \); at least \( \max(1, n) \).

**ldc**
The leading dimension of \( c \); at least \( \max(1, m) \) for column major layout and at least \( \max(1, n) \) for row major layout.

**Output Parameters**

**c**
Overwritten by the solution matrix \( X \).

**scale**
The value of the scale factor \( \alpha \).

**Return Values**
This function returns a value \( info \).
If \( info = 0 \), the execution is successful.
If \( info = -i \), the \( i \)-th parameter had an illegal value.
If \( info = 1 \), \( A \) and \( B \) have common or close eigenvalues; perturbed values were used to solve the equation.

**Application Notes**
Let \( X \) be the exact, \( Y \) the corresponding computed solution, and \( R \) the residual matrix: \( R = C - (AY \pm YB) \).
Then the residual is always small:
\[
||R||_F = O(\varepsilon) \cdot (||A||_F + ||B||_F) \cdot ||Y||_F,
\]
However, \( Y \) is not necessarily the exact solution of a slightly perturbed equation; in other words, the solution is not backwards stable.
For the forward error, the following bound holds:
\[
||Y - X||_F \leq ||R||_F / \text{sep}(A, B)
\]
but this may be a considerable overestimate. See [Golub96] for a definition of \( \text{sep}(A, B) \).
The approximate number of floating-point operations for real flavors is \( mn^* (m + n) \). For complex flavors it is 4 times greater.
Generalized Nonsymmetric Eigenvalue Problems: LAPACK Computational Routines

This section describes LAPACK routines for solving generalized nonsymmetric eigenvalue problems, reordering the generalized Schur factorization of a pair of matrices, as well as performing a number of related computational tasks.

A generalized nonsymmetric eigenvalue problem is as follows: given a pair of nonsymmetric (or non-Hermitian) \( n \times n \) matrices \( A \) and \( B \), find the generalized eigenvalues \( \lambda \) and the corresponding generalized eigenvectors \( x \) and \( y \) that satisfy the equations

\[
Ax = \lambda Bx \quad (\text{right generalized eigenvectors } x)
\]

and

\[
y^H A = \lambda y^H B \quad (\text{left generalized eigenvectors } y).
\]

Table "Computational Routines for Solving Generalized Nonsymmetric Eigenvalue Problems" lists LAPACK routines used to solve the generalized nonsymmetric eigenvalue problems and the generalized Sylvester equation.

Description

The routine reduces a pair of real/complex matrices \((A, B)\) to generalized upper Hessenberg form using orthogonal/unitary transformations, where \(A\) is a general matrix and \(B\) is upper triangular. The form of the generalized eigenvalue problem is \(A x = \lambda B x\), and \(B\) is typically made upper triangular by computing its QR factorization and moving the orthogonal matrix \(Q\) to the left side of the equation.

This routine simultaneously reduces \(A\) to a Hessenberg matrix \(H:\)
\[ Q^H A Z = H \]
and transforms \(B\) to another upper triangular matrix \(T:\)
\[ Q^H B Z = T \]
in order to reduce the problem to its standard form \(H^* y = \lambda^* T^* y\), where \(y = Z^H x\).

The orthogonal/unitary matrices \(Q\) and \(Z\) are determined as products of Givens rotations. They may either be formed explicitly, or they may be postmultiplied into input matrices \(Q_1\) and \(Z_1\), so that
\[
Q_1^* A Z_1^H = (Q_1^* Q)^* (Z_1^* Z)^H \\
Q_1^* B Z_1^H = (Q_1^* Q)^* (Z_1^* Z)^H 
\]

If \(Q_1\) is the orthogonal/unitary matrix from the QR factorization of \(B\) in the original equation \(A x = \lambda B x\), then the routine \(gghrd\) reduces the original problem to generalized Hessenberg form.

Input Parameters

matrix_layout

- Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

compq

- Must be 'N', 'I', or 'V'.
- If compq = 'N', matrix \(Q\) is not computed.
- If compq = 'I', \(Q\) is initialized to the unit matrix, and the orthogonal/unitary matrix \(Q\) is returned;
- If compq = 'V', \(Q\) must contain an orthogonal/unitary matrix \(Q_1\) on entry, and the product \(Q_1^* Q\) is returned.

compz

- Must be 'N', 'I', or 'V'.
- If compz = 'N', matrix \(Z\) is not computed.
- If compz = 'I', \(Z\) is initialized to the unit matrix, and the orthogonal/unitary matrix \(Z\) is returned;
If \( \text{compz} = 'V' \), \( Z \) must contain an orthogonal/unitary matrix \( Z_1 \) on entry, and the product \( Z_1^*Z \) is returned.

The order of the matrices \( A \) and \( B \) (\( n \geq 0 \)).

\( \text{ilo}, \text{ihi} \)

\( \text{ilo} \) and \( \text{ihi} \) mark the rows and columns of \( A \) which are to be reduced. It is assumed that \( A \) is already upper triangular in rows and columns 1:\( \text{ilo} \)-1 and \( \text{ihi}+1:n \). Values of \( \text{ilo} \) and \( \text{ihi} \) are normally set by a previous call to \text{ggbal}; otherwise they should be set to 1 and \( n \) respectively.

Constraint:

If \( n > 0 \), then \( 1 \leq \text{ilo} \leq \text{ihi} \leq n \);
if \( n = 0 \), then \( \text{ilo} = 1 \) and \( \text{ihi} = 0 \).

\( a, b, q, z \)

Arrays:

\( a \) (size \( \max(1, lda*n) \)) contains the \( n \)-by-\( n \) general matrix \( A \).
\( b \) (size \( \max(1, ldb*n) \)) contains the \( n \)-by-\( n \) upper triangular matrix \( B \).
\( q \) (size \( \max(1, ldq*n) \))

If \( \text{compq} = 'N' \), then \( q \) is not referenced.
If \( \text{compq} = 'V' \), then \( q \) must contain the orthogonal/unitary matrix \( Q_1 \), typically from the \( QR \) factorization of \( B \).

\( z \) (size \( \max(1, ldz*n) \))

If \( \text{compz} = 'N' \), then \( z \) is not referenced.
If \( \text{compz} = 'V' \), then \( z \) must contain the orthogonal/unitary matrix \( Z_1 \).

\( lda \)

The leading dimension of \( a \); at least \( \max(1, n) \).

\( ldb \)

The leading dimension of \( b \); at least \( \max(1, n) \).

\( ldq \)

The leading dimension of \( q \);
If \( \text{compq} = 'N' \), then \( ldq \geq 1 \).
If \( \text{compq} = 'I' \) or \( 'V' \), then \( ldq \geq \max(1, n) \).

\( ldz \)

The leading dimension of \( z \);
If \( \text{compz} = 'N' \), then \( ldz \geq 1 \).
If \( \text{compz} = 'I' \) or \( 'V' \), then \( ldz \geq \max(1, n) \).

Output Parameters

\( a \)

On exit, the upper triangle and the first subdiagonal of \( A \) are overwritten with the upper Hessenberg matrix \( H \), and the rest is set to zero.

\( b \)

On exit, overwritten by the upper triangular matrix \( T = \text{Q}^H B Z \). The elements below the diagonal are set to zero.

\( q \)

If \( \text{compq} = 'I' \), then \( q \) contains the orthogonal/unitary matrix \( Q_1 \);
If \( \text{compq} = 'V' \), then \( q \) is overwritten by the product \( Q_1^*Q \).

\( z \)

If \( \text{compz} = 'I' \), then \( z \) contains the orthogonal/unitary matrix \( Z_1 \);
If \( \text{compz} = 'V' \), then \( z \) is overwritten by the product \( Z_1^* Z \).

**Return Values**

This function returns a value \( \text{info} \).

If \( \text{info} = 0 \), the execution is successful.

If \( \text{info} = -i \), the \( i \)-th parameter had an illegal value.

**ggbal**

*Balances a pair of general real or complex matrices.*

**Syntax**

```c
lapack_int LAPACKE_sggbal( int matrix_layout, char job, lapack_int n, float* a, lapack_int lda, float* b, lapack_int ldb, lapack_int* ilo, lapack_int* ihi, float* lscale, float* rscale );
```

```c
lapack_int LAPACKE_dggbal( int matrix_layout, char job, lapack_int n, double* a, lapack_int lda, double* b, lapack_int ldb, lapack_int* ilo, lapack_int* ihi, double* lscale, double* rscale );
```

```c
lapack_int LAPACKE_cggbal( int matrix_layout, char job, lapack_int n, lapack_complex_float* a, lapack_int lda, lapack_complex_float* b, lapack_int ldb, lapack_int* ilo, lapack_int* ihi, float* lscale, float* rscale );
```

```c
lapack_int LAPACKE_zggbal( int matrix_layout, char job, lapack_int n, lapack_complex_double* a, lapack_int lda, lapack_complex_double* b, lapack_int ldb, lapack_int* ilo, lapack_int* ihi, double* lscale, double* rscale );
```

**Include Files**

- mkl.h

**Description**

The routine balances a pair of general real/complex matrices \((A, B)\). This involves, first, permuting \( A \) and \( B \) by similarity transformations to isolate eigenvalues in the first \( 1 \) to \( \text{ilo} - 1 \) and last \( \text{ihi} + 1 \) to \( n \) elements on the diagonal; and second, applying a diagonal similarity transformation to rows and columns \( \text{ilo} \) to \( \text{ihi} \) to make the rows and columns as close in norm as possible. Both steps are optional. Balancing may reduce the 1-norm of the matrices, and improve the accuracy of the computed eigenvalues and/or eigenvectors in the generalized eigenvalue problem \( A^* x = \lambda B^* x \).

**Input Parameters**

- **matrix_layout**
  
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **job**
  
  Specifies the operations to be performed on \( A \) and \( B \). Must be 'N' or 'P' or 'S' or 'B'.
  
  If \( \text{job} = 'N' \), then no operations are done; simply set \( \text{ilo} = 1, \text{ihi} = n \), \( \text{lscale}[i] = 1.0 \) and \( \text{rscale}[i] = 1.0 \) for \( i = 0, \ldots, n - 1 \).
  
  If \( \text{job} = 'P' \), then permute only.
  
  If \( \text{job} = 'S' \), then scale only.
If \( \text{job} = \text{'B'} \), then both permute and scale.

The order of the matrices \( A \) and \( B \) (\( n \geq 0 \)).

Arrays:

- \( a \) (size \( \max(1, \text{lda}^*n) \)) contains the matrix \( A \).
- \( b \) (size \( \max(1, \text{ldb}^*n) \)) contains the matrix \( B \).

If \( \text{job} = \text{'N'} \), \( a \) and \( b \) are not referenced.

The leading dimension of \( a \); at least \( \max(1, n) \).

The leading dimension of \( b \); at least \( \max(1, n) \).

Output Parameters

- \( a, b \) Overwritten by the balanced matrices \( A \) and \( B \), respectively.
- \( i lo, \text{hi} \) are set to integers such that on exit \( A_{i,j} = 0 \) and \( B_{i,j} = 0 \) if \( i > j \) and \( j=1, \ldots, i lo -1 \) or \( i = i hi + 1, \ldots, n \).

If \( \text{job} = \text{'N'} \) or \( \text{'S'} \), then \( i lo = 1 \) and \( i hi = n \).

- \( \text{lscale, rscale} \)

\( \text{lscale} \) contains details of the permutations and scaling factors applied to the left side of \( A \) and \( B \).

If \( P_j \) is the index of the row interchanged with row \( j \), and \( D_j \) is the scaling factor applied to row \( j \), then

\[
\text{lscale}[j - 1] = P_j, \text{ for } j = 1, \ldots, i lo -1
\]
\[
= D_j, \text{ for } j = i lo, \ldots, i hi
\]
\[
= P_j, \text{ for } j = i hi + 1, \ldots, n.
\]

\( \text{rscale} \) contains details of the permutations and scaling factors applied to the right side of \( A \) and \( B \).

If \( P_j \) is the index of the column interchanged with column \( j \), and \( D_j \) is the scaling factor applied to column \( j \), then

\[
\text{rscale}[j - 1] = P_j, \text{ for } j = 1, \ldots, i lo -1
\]
\[
= D_j, \text{ for } j = i lo, \ldots, i hi
\]
\[
= P_j, \text{ for } j = i hi + 1, \ldots, n
\]

The order in which the interchanges are made is \( n \) to \( i hi + 1 \), then \( 1 \) to \( i lo -1 \).

Return Values

This function returns a value \( \text{info} \).

If \( \text{info} = 0 \), the execution is successful.

If \( \text{info} = -i \), the \( i \)-th parameter had an illegal value.

\texttt{?ggbak}

Forms the right or left eigenvectors of a generalized eigenvalue problem.
Syntax

```c
lapack_int LAPACKE_sggbak( int matrix_layout, char job, char side, lapack_int n, 
  lapack_int ilo, lapack_int ihi, const float* lscale, const float* rscale, lapack_int m, 
  float* v, lapack_int ldv );

lapack_int LAPACKE_dggbak( int matrix_layout, char job, char side, lapack_int n, 
  lapack_int ilo, lapack_int ihi, const double* lscale, const double* rscale, lapack_int m, 
  double* v, lapack_int ldv );

lapack_int LAPACKE_cggbak( int matrix_layout, char job, char side, lapack_int n, 
  lapack_int ilo, lapack_int ihi, const float* lscale, const float* rscale, lapack_int m, 
  lapack_complex_float* v, lapack_int ldv );

lapack_int LAPACKE_zggbak( int matrix_layout, char job, char side, lapack_int n, 
  lapack_int ilo, lapack_int ihi, const double* lscale, const double* rscale, lapack_int m, 
  lapack_complex_double* v, lapack_int ldv );
```

Include Files
- `mkl.h`

Description

The routine forms the right or left eigenvectors of a real/complex generalized eigenvalue problem

\[ A^*x = \lambda^*B^*x \]

by backward transformation on the computed eigenvectors of the balanced pair of matrices output by `ggbal`.

Input Parameters

- **matrix_layout**
  - Specifies whether matrix storage layout is row major (`LAPACK_ROW_MAJOR`) or column major (`LAPACK_COL_MAJOR`).

- **job**
  - Specifies the type of backward transformation required. Must be 'N', 'P', 'S', or 'B'.
    - If `job` = 'N', then no operations are done; return.
    - If `job` = 'P', then do backward transformation for permutation only.
    - If `job` = 'S', then do backward transformation for scaling only.
    - If `job` = 'B', then do backward transformation for both permutation and scaling. This argument must be the same as the argument `job` supplied to `ggbal`.

- **side**
  - Must be 'L' or 'R'.
    - If `side` = 'L', then `v` contains left eigenvectors.
    - If `side` = 'R', then `v` contains right eigenvectors.

- **n**
  - The number of rows of the matrix `V` \( (n \geq 0) \).

- **ilo, ihi**
  - The integers `ilo` and `ihi` determined by `ggbal`. Constraint:
    - If `n > 0`, then \( 1 \leq ilo \leq ihi \leq n \);
    - if `n = 0`, then `ilo = 1` and `ihi = 0`.

- **lscale, rscale**
  - Arrays, size at least `max(1, n)`. 
The array `lscale` contains details of the permutations and/or scaling factors applied to the left side of `A` and `B`, as returned by ?ggbal.

The array `rscale` contains details of the permutations and/or scaling factors applied to the right side of `A` and `B`, as returned by ?ggbal.

The number of columns of the matrix `V` ($m \geq 0$).

Array `v` (size max(1, `ldv`*`m`) for column major layout and max(1, `ldv`*`n`) for row major layout). Contains the matrix of right or left eigenvectors to be transformed, as returned by tgevc.

The leading dimension of `v`; at least max(1, `n`) for column major layout and at least max(1, `m`) for row major layout.

Output Parameters

`v` Overwritten by the transformed eigenvectors

Return Values

This function returns a value `info`.

If `info`=0, the execution is successful.

If `info` = `-i`, the `i`-th parameter had an illegal value.

?gghd3

Reduces a pair of matrices to generalized upper Hessenberg form.

Syntax

```c
lapack_int LAPACKE_sgghd3 (int matrix_layout, char compq, char compz, lapack_int n,
lapack_int ilo, lapack_int ihi, float * a, lapack_int lda, float * b, lapack_int ldb,
float * q, lapack_int ldq, float * z, lapack_int ldz);

lapack_int LAPACKE_dgghd3 (int matrix_layout, char compq, char compz, lapack_int n,
lapack_int ilo, lapack_int ihi, double * a, lapack_int lda, double * b, lapack_int ldb,
double * q, lapack_int ldq, double * z, lapack_int ldz);

lapack_int LAPACKE_cgghd3 (int matrix_layout, char compq, char compz, lapack_int n,
lapack_int ilo, lapack_int ihi, lapack_complex_float * a, lapack_int lda,
lapack_complex_float * b, lapack_int ldb, lapack_complex_float * q, lapack_int ldq,
lapack_complex_float * z, lapack_int ldz);

lapack_int LAPACKE_zgghd3 (int matrix_layout, char compq, char compz, lapack_int n,
lapack_int ilo, lapack_int ihi, lapack_complex_double * a, lapack_int lda,
lapack_complex_double * b, lapack_int ldb, lapack_complex_double * q, lapack_int ldq,
lapack_complex_double * z, lapack_int ldz);
```

Include Files

- mkl.h
Description

?gghd3 reduces a pair of real or complex matrices \((A, B)\) to generalized upper Hessenberg form using orthogonal/unitary transformations, where \(A\) is a general matrix and \(B\) is upper triangular. The form of the generalized eigenvalue problem is

\[ A^*x = \lambda^*B^*x, \]

and \(B\) is typically made upper triangular by computing its QR factorization and moving the orthogonal/unitary matrix \(Q\) to the left side of the equation.

This subroutine simultaneously reduces \(A\) to a Hessenberg matrix \(H\):

\[ Q^T A^* Z = H \] for real flavors

or

\[ Q^T A^* Z = H \] for complex flavors

and transforms \(B\) to another upper triangular matrix \(T\):

\[ Q^T B^* Z = T \] for real flavors

or

\[ Q^T B^* Z = T \] for complex flavors

in order to reduce the problem to its standard form

\[ H^*y = \lambda^*T^*y \]

where \(y = Z^T x\) for real flavors

or

\(y = Z^T x\) for complex flavors.

The orthogonal/unitary matrices \(Q\) and \(Z\) are determined as products of Givens rotations. They may either be formed explicitly, or they may be postmultiplied into input matrices \(Q_1\) and \(Z_1\), so that

for real flavors:

\[ Q_1 \ast A \ast Z_1^T = (Q_1 \ast Q) \ast H \ast (Z_1 \ast Z)^T \]

\[ Q_1 \ast B \ast Z_1^T = (Q_1 \ast Q) \ast T \ast (Z_1 \ast Z)^T \]

for complex flavors:

\[ Q_1 \ast A \ast Z_1^H = (Q_1 \ast Q) \ast H \ast (Z_1 \ast Z)^T \]

\[ Q_1 \ast B \ast Z_1^T = (Q_1 \ast Q) \ast T \ast (Z_1 \ast Z)^T \]

If \(Q_1\) is the orthogonal/unitary matrix from the QR factorization of \(B\) in the original equation \(A^*x = \lambda^*B^*x\), then ?gghd3 reduces the original problem to generalized Hessenberg form.

This is a blocked variant of ?gghrd, using matrix-matrix multiplications for parts of the computation to enhance performance.

Input Parameters

\(matrix\_layout\)

Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

\(compq\)

\(= 'N':\) do not compute \(Q\);

\(= 'I':\) \(Q\) is initialized to the unit matrix, and the orthogonal/unitary matrix \(Q\) is returned;
= 'V': q must contain an orthogonal/unitary matrix $Q_1$ on entry, and the product $Q_1^*q$ is returned.

$compz$  
= 'N': do not compute $z$;  
= 'I': $z$ is initialized to the unit matrix, and the orthogonal/unitary matrix $Z$ is returned;  
= 'V': $z$ must contain an orthogonal/unitary matrix $Z_1$ on entry, and the product $Z_1^*z$ is returned.

$n$  
The order of the matrices $A$ and $B$.  
$n \geq 0$.

$ilo, ihi$  
$ilo$ and $ihi$ mark the rows and columns of $a$ which are to be reduced. It is assumed that $a$ is already upper triangular in rows and columns $1:ilo - 1$ and $ihi + 1:n$. $ilo$ and $ihi$ are normally set by a previous call to $?ggbal$; otherwise they should be set to 1 and $n$, respectively.  
$1 \leq ilo \leq ihi \leq n$, if $n > 0$; $ilo = 1$ and $ihi = 0$, if $n = 0$.

$a$  
Array, size ($lda \times n$).  
On entry, the $n$-by-$n$ general matrix to be reduced.

$lda$  
The leading dimension of the array $a$.  
$lda \geq \max(1,n)$.

$b$  
Array, ($ldb \times n$).  
On entry, the $n$-by-$n$ upper triangular matrix $B$.

$ldb$  
The leading dimension of the array $b$.  
$ldb \geq \max(1,n)$.

$q$  
Array, size ($ldq \times n$).  
On entry, if $compq = 'V$', the orthogonal/unitary matrix $Q_1$, typically from the QR factorization of $b$.

$ldq$  
The leading dimension of the array $q$.  
$ldq \geq n$ if $compq = 'V'$ or 'I'; $ldq \geq 1$ otherwise.

$z$  
Array, size ($ldz \times n$).  
On entry, if $compz = 'V$', the orthogonal/unitary matrix $Z_1$.  
Not referenced if $compz = 'N$'.

$ldz$  
The leading dimension of the array $z$.  $ldz \geq n$ if $compz = 'V'$ or 'I'; $ldz \geq 1$ otherwise.

**Output Parameters**

$a$  
On exit, the upper triangle and the first subdiagonal of $a$ are overwritten with the upper Hessenberg matrix $H$, and the rest is set to zero.
On exit, the upper triangular matrix $T = Q^T B Z$ for real flavors or $T = Q^H B Z$ for complex flavors. The elements below the diagonal are set to zero.

On exit, if $\text{compq} = 'I'$, the orthogonal/unitary matrix $Q$, and if $\text{compq} = 'V'$, the product $Q_1^* Q$.
Not referenced if $\text{compq} = 'N'$.

On exit, if $\text{compz} = 'I'$, the orthogonal/unitary matrix $Z$, and if $\text{compz} = 'V'$, the product $Z_1^* Z$.
Not referenced if $\text{compz} = 'N'$.

Return Values
This function returns a value $\text{info}$.

= 0: successful exit.
< 0: if $\text{info} = -i$, the $i$-th argument had an illegal value.

Application Notes
This routine reduces $A$ to Hessenberg form and maintains $B$ in using a blocked variant of Moler and Stewart's original algorithm, as described by Kagstrom, Kressner, Quintana-Orti, and Quintana-Orti (BIT 2008).

$hgeqz$
Implements the QZ method for finding the generalized eigenvalues of the matrix pair $(H, T)$.

Syntax

```c

- mkl.h
Description

The routine computes the eigenvalues of a real/complex matrix pair \((H, T)\), where \(H\) is an upper Hessenberg matrix and \(T\) is upper triangular, using the double-shift version (for real flavors) or single-shift version (for complex flavors) of the QZ method. Matrix pairs of this type are produced by the reduction to generalized upper Hessenberg form of a real/complex matrix pair \((A, B)\):

\[
A = Q_1^* H Z_1^H, \quad B = Q_1^* T Z_1^H,
\]

as computed by ?gghrd.

For real flavors:

If \(job = 'S'\), then the Hessenberg-triangular pair \((H, T)\) is reduced to generalized Schur form,

\[
H = Q^* S Z^T, \quad T = Q^* P Z^T,
\]

where \(Q\) and \(Z\) are orthogonal matrices, \(P\) is an upper triangular matrix, and \(S\) is a quasi-triangular matrix with 1-by-1 and 2-by-2 diagonal blocks. The 1-by-1 blocks correspond to real eigenvalues of the matrix pair \((H, T)\) and the 2-by-2 blocks correspond to complex conjugate pairs of eigenvalues.

Additionally, the 2-by-2 upper triangular diagonal blocks of \(P\) corresponding to 2-by-2 blocks of \(S\) are reduced to positive diagonal form, that is, if \(S_{j+1,j}\) is non-zero, then \(P_{j+1,j} = P_{j,j+1} = 0\), \(P_{j,j} > 0\), and \(P_{j+1,j+1} > 0\).

For complex flavors:

If \(job = 'S'\), then the Hessenberg-triangular pair \((H, T)\) is reduced to generalized Schur form,

\[
H = Q^* S Z_H^T, \quad T = Q^* P Z_H^T,
\]

where \(Q\) and \(Z\) are unitary matrices, and \(S\) and \(P\) are upper triangular.

For all function flavors:

Optionally, the orthogonal/unitary matrix \(Q\) from the generalized Schur factorization may be post-multiplied by an input matrix \(Q_1\), and the orthogonal/unitary matrix \(Z\) may be post-multiplied by an input matrix \(Z_1\).

If \(Q_1\) and \(Z_1\) are the orthogonal/unitary matrices from ?gghrd that reduced the matrix pair \((A, B)\) to generalized upper Hessenberg form, then the output matrices \(Q_1 Q\) and \(Z_1 Z\) are the orthogonal/unitary factors from the generalized Schur factorization of \((A, B)\):

\[
A = (Q_1 Q)^* S^* (Z_1 Z)^H, \quad B = (Q_1 Q)^* P^* (Z_1 Z)^H.
\]

To avoid overflow, eigenvalues of the matrix pair \((H, T)\) (equivalently, of \((A, B)\)) are computed as a pair of values \((\alpha, \beta)\). For chgeqz/zhgeqz, \(\alpha\) and \(\beta\) are complex, and for shgeqz/dhgeqz, \(\alpha\) is complex and \(\beta\) real. If \(\beta\) is nonzero, \(\lambda = \alpha/\beta\) is an eigenvalue of the generalized nonsymmetric eigenvalue problem (GNEP)

\[
A^* x = \lambda B^* x
\]

and if \(\alpha\) is nonzero, \(\mu = \beta/\alpha\) is an eigenvalue of the alternate form of the GNEP

\[
\mu A^* y = B^* y.
\]

Real eigenvalues (for real flavors) or the values of \(\alpha\) and \(\beta\) for the \(i\)-th eigenvalue (for complex flavors) can be read directly from the generalized Schur form:

\[
\alpha_i = S_{i,i}, \quad \beta_i = P_{i,i}.
\]

Input Parameters

\[
\text{matrix\_layout}
\]

Specifies whether matrix storage layout is row major \((\text{LAPACK\_ROW\_MAJOR})\) or column major \((\text{LAPACK\_COL\_MAJOR})\).

\[
\text{job}
\]

Specifies the operations to be performed. Must be \('E'\) or \('S'\).
If $job = 'E'$, then compute eigenvalues only;
If $job = 'S'$, then compute eigenvalues and the Schur form.

**compq**
Must be 'N', 'I', or 'V'.
If $compq = 'N'$, left Schur vectors ($q$) are not computed;
If $compq = 'I'$, $q$ is initialized to the unit matrix and the matrix of left
Schur vectors of $(H,T)$ is returned;
If $compq = 'V'$, $q$ must contain an orthogonal/unitary matrix $Q_1$ on entry
and the product $Q_1^*Q$ is returned.

**compz**
Must be 'N', 'I', or 'V'.
If $compz = 'N'$, right Schur vectors ($z$) are not computed;
If $compz = 'I'$, $z$ is initialized to the unit matrix and the matrix of right
Schur vectors of $(H,T)$ is returned;
If $compz = 'V'$, $z$ must contain an orthogonal/unitary matrix $Z_1$ on entry
and the product $Z_1^*Z$ is returned.

**n**
The order of the matrices $H$, $T$, $Q$, and $Z$
$(n \geq 0)$.

**ilo, ihi**
$ilo$ and $ihi$ mark the rows and columns of $H$ which are in Hessenberg form.
It is assumed that $H$ is already upper triangular in rows and columns $1:ilo-1$ and
$ihi+1:n$.
Constraint:
If $n > 0$, then $1 \leq ilo \leq ihi \leq n$;
if $n = 0$, then $ilo = 1$ and $ihi = 0$.

**h, t, q, z**
Arrays:
On entry, $h$ (size max(1, $ldh*n$)) contains the $n$-by-$n$ upper Hessenberg
matrix $H$.
On entry, $t$ (size max(1, $ldt*n$)) contains the $n$-by-$n$ upper triangular
matrix $T$.
$q$ (size max(1, $ldq*n$)) :
On entry, if $compq = 'V'$, this array contains the orthogonal/unitary matrix
$Q_1$ used in the reduction of $(A,B)$ to generalized Hessenberg form.
If $compq = 'N'$, then $q$ is not referenced.
$z$ (size max(1, $ldz*n$)) :
On entry, if $compz = 'V'$, this array contains the orthogonal/unitary matrix
$Z_1$ used in the reduction of $(A,B)$ to generalized Hessenberg form.
If $compz = 'N'$, then $z$ is not referenced.

**ldh**
The leading dimension of $h$; at least max(1, $n$).

**ldt**
The leading dimension of $t$; at least max(1, $n$).

**ldq**
The leading dimension of $q$;
If $\text{compq} = 'N'$, then $\text{ldq} \geq 1$.
If $\text{compq} = 'I'$ or 'V', then $\text{ldq} \geq \max(1, n)$.

$\text{ldz}$

The leading dimension of $z$;
If $\text{compq} = 'N'$, then $\text{ldz} \geq 1$.
If $\text{compq} = 'I'$ or 'V', then $\text{ldz} \geq \max(1, n)$.

**Output Parameters**

$h$

*For real flavors:*
If $\text{job} = 'S'$, then on exit $h$ contains the upper quasi-triangular matrix $S$ from the generalized Schur factorization.
If $\text{job} = 'E'$, then on exit the diagonal blocks of $h$ match those of $S$, but the rest of $h$ is unspecified.

*For complex flavors:*
If $\text{job} = 'S'$, then, on exit, $h$ contains the upper triangular matrix $S$ from the generalized Schur factorization.
If $\text{job} = 'E'$, then on exit the diagonal of $h$ matches that of $S$, but the rest of $h$ is unspecified.

$t$

If $\text{job} = 'S'$, then, on exit, $t$ contains the upper triangular matrix $P$ from the generalized Schur factorization.

*For real flavors:*
2-by-2 diagonal blocks of $P$ corresponding to 2-by-2 blocks of $S$ are reduced to positive diagonal form, that is, if $h(j+1,j)$ is non-zero, then $t(j+1,j) = t(j,j+1) = 0$ and $t(j,j)$ and $t(j+1,j+1)$ will be positive.
If $\text{job} = 'E'$, then on exit the diagonal blocks of $t$ match those of $P$, but the rest of $t$ is unspecified.

*For complex flavors:*
if $\text{job} = 'E'$, then on exit the diagonal of $t$ matches that of $P$, but the rest of $t$ is unspecified.

$\text{alphan, alphei}$

Arrays, size at least $\max(1, n)$. The real and imaginary parts, respectively, of each scalar $\text{alpha}$ defining an eigenvalue of GNEP.

If $\text{alphei}[j - 1]$ is zero, then the $j$-th eigenvalue is real; if positive, then the $j$-th and $(j+1)$-th eigenvalues are a complex conjugate pair, with $\text{alphei}[j] = -\text{alphei}[j - 1]$.

$\text{alpha}$

Array, size at least $\max(1, n)$.
The complex scalars $\text{alpha}$ that define the eigenvalues of GNEP. $\text{alphei}[i - 1] = S_i, i$ in the generalized Schur factorization.

$\text{beta}$

Array, size at least $\max(1, n)$.
*For real flavors:*
The scalars $\text{beta}$ that define the eigenvalues of GNEP.
Together, the quantities \( \alpha = (\alpha_j[j - 1], \alpha_i[j - 1]) \) and \( \beta = \beta[j - 1] \) represent the \( j \)-th eigenvalue of the matrix pair \((A, B)\), in one of the forms \( \lambda = \alpha / \beta \) or \( \mu = \beta / \alpha \). Since either \( \lambda \) or \( \mu \) may overflow, they should not, in general, be computed.

For complex flavors:

The real non-negative scalars \( \beta \) that define the eigenvalues of GNEP.

\( \beta[i - 1] = P_{i, j} \) in the generalized Schur factorization. Together, the quantities \( \alpha = \alpha[j - 1] \) and \( \beta = \beta[j - 1] \) represent the \( j \)-th eigenvalue of the matrix pair \((A, B)\), in one of the forms \( \lambda = \alpha / \beta \) or \( \mu = \beta / \alpha \). Since either \( \lambda \) or \( \mu \) may overflow, they should not, in general, be computed.

On exit, if \( \text{compq} = 'I' \), \( q \) is overwritten by the orthogonal/unitary matrix of left Schur vectors of the pair \((H, T)\), and if \( \text{compq} = 'V' \), \( q \) is overwritten by the orthogonal/unitary matrix of left Schur vectors of \((A, B)\).

On exit, if \( \text{compz} = 'I' \), \( z \) is overwritten by the orthogonal/unitary matrix of right Schur vectors of the pair \((H, T)\), and if \( \text{compz} = 'V' \), \( z \) is overwritten by the orthogonal/unitary matrix of right Schur vectors of \((A, B)\).

Return Values

This function returns a value \( \text{info} \).

If \( \text{info} = 0 \), the execution is successful.

If \( \text{info} = -i \), the \( i \)-th parameter had an illegal value.

If \( \text{info} = 1, \ldots, n \), the QZ iteration did not converge.

\((H, T)\) is not in Schur form, but \( \alpha[i - 1], \alpha[i - 1] \) (for real flavors), \( \alpha[i - 1] \) (for complex flavors), and \( \beta[i - 1], i = \text{info}+1, \ldots, n \) should be correct.

If \( \text{info} = n+1, \ldots, 2n \), the shift calculation failed.

\((H, T)\) is not in Schur form, but \( \alpha[i - 1], \alpha[i - 1] \) (for real flavors), \( \alpha[i - 1] \) (for complex flavors), and \( \beta[i - 1], i = \text{info}-n+1, \ldots, n \) should be correct.

\texttt{tgevc}

Computes some or all of the right and/or left generalized eigenvectors of a pair of upper triangular matrices.

Syntax

\[
\begin{align*}
\text{lapack_int LAPACKE_stgevc (int matrix_layout, char side, char howmny, const} \\

Include Files
• mkl.h

Description
The routine computes some or all of the right and/or left eigenvectors of a pair of real/complex matrices
$(S,P)$, where $S$ is quasi-triangular (for real flavors) or upper triangular (for complex flavors) and $P$ is upper triangular.

Matrix pairs of this type are produced by the generalized Schur factorization of a real/complex matrix pair
$(A,B)$:
$$A = Q*Z^H, B = Q*Z^H$$
as computed by ?gghrd plus ?hgeqz.

The right eigenvector $x$ and the left eigenvector $y$ of $(S,P)$ corresponding to an eigenvalue $w$ are defined by:
$$S*x = w*P*y, y^H*S = w*y^H*P$$

The eigenvalues are not input to this routine, but are computed directly from the diagonal blocks or diagonal
elements of $S$ and $P$.

This routine returns the matrices $X$ and/or $Y$ of right and left eigenvectors of $(S,P)$, or the products $Z*X$
and/or $Q*Y$, where $Z$ and $Q$ are input matrices.

If $Q$ and $Z$ are the orthogonal/unitary factors from the generalized Schur factorization of a matrix pair $(A,B)$,
then $Z*X$ and $Q*Y$ are the matrices of right and left eigenvectors of $(A,B)$.

Input Parameters

matrix_layout Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR)
or column major (LAPACK_COL_MAJOR).

side Must be 'R', 'L', or 'B'.
If side = 'R', compute right eigenvectors only.
If side = 'L', compute left eigenvectors only.
If side = 'B', compute both right and left eigenvectors.

howmny Must be 'A', 'B', or 'S'.
If howmny = 'A', compute all right and/or left eigenvectors.
If howmny = 'B', compute all right and/or left eigenvectors, backtransformed by the matrices in $vr$ and/or $vl$.
If howmny = 'S', compute selected right and/or left eigenvectors, specified by the logical array select.

select
Array, size at least max (1, n).

If howmny = 'S', select specifies the eigenvectors to be computed.

If howmny = 'A' or 'B', select is not referenced.

For real flavors:

If \( w[j] \) is a real eigenvalue, the corresponding real eigenvector is computed if select\([j]\) is 1.

If \( w[j] \) and omega\([j + 1]\) are the real and imaginary parts of a complex eigenvalue, the corresponding complex eigenvector is computed if either select\([j]\) or select\([j + 1]\) is 1, and on exit select\([j]\) is set to 1 and select\([j + 1]\) is set to 0.

For complex flavors:

The eigenvector corresponding to the \( j \)-th eigenvalue is computed if select\([j]\) is 1.

The order of the matrices \( S \) and \( P \) \((n \geq 0)\).

Arrays:

\( s \) (size max(1, \( lds*n \))) contains the matrix \( S \) from a generalized Schur factorization as computed by ?hgeqz. This matrix is upper quasi-triangular for real flavors, and upper triangular for complex flavors.

\( p \) (size max(1, \( ldp*n \))) contains the upper triangular matrix \( P \) from a generalized Schur factorization as computed by ?hgeqz.

For real flavors, 2-by-2 diagonal blocks of \( P \) corresponding to 2-by-2 blocks of \( S \) must be in positive diagonal form.

For complex flavors, \( P \) must have real diagonal elements.

If \( side = 'L' \) or 'B' and howmny = 'B', \( vl \)(size max(1, \( ldvl*mm \))) for column major layout and max(1, \( ldvl*n \)) for row major layout must contain an \( n \)-by-\( n \) matrix \( Q \) (usually the orthogonal/unitary matrix \( Q \) of left Schur vectors returned by ?hgeqz).

If \( side = 'R' \), \( vl \) is not referenced.

If \( side = 'R' \) or 'B' and howmny = 'B', \( vr \)(size max(1, \( ldvr*mm \))) for column major layout and max(1, \( ldvr*n \)) for row major layout must contain an \( n \)-by-\( n \) matrix \( Z \) (usually the orthogonal/unitary matrix \( Z \) of right Schur vectors returned by ?hgeqz).

If \( side = 'L' \), \( vr \) is not referenced.

\( lds \)

The leading dimension of \( s \); at least max(1, n).

\( ldp \)

The leading dimension of \( p \); at least max(1, n).

\( ldvl \)

The leading dimension of \( vl \);

If \( side = 'L' \) or 'B', then \( ldvl \geq n \) for column major layout and \( ldvl \geq \text{max}(1, \text{mm}) \) for row major layout.

If \( side = 'R' \), then \( ldvl \geq 1 \).

\( ldvr \)

The leading dimension of \( vr \);
If \( side = 'R' \) or \( 'B' \), then \( ldvr \geq n \) for column major layout and \( ldvr \geq \max(1, mm) \) for row major layout.

If \( side = 'L' \), then \( ldvr \geq 1 \).

\( mm \)

The number of columns in the arrays \( vl \) and/or \( vr \) (\( mm \geq m \)).

**Output Parameters**

\( vl \)

On exit, if \( side = 'L' \) or \( 'B' \), \( vl \) contains:

- if \( howmny = 'A' \), the matrix \( Y \) of left eigenvectors of \((S,P)\);
- if \( howmny = 'B' \), the matrix \( Q^*Y \);
- if \( howmny = 'S' \), the left eigenvectors of \((S,P)\) specified by \select\, stored consecutively in the columns of \( vl \), in the same order as their eigenvalues.

*For real flavors:*

A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part, and the second the imaginary part.

\( vr \)

On exit, if \( side = 'R' \) or \( 'B' \), \( vr \) contains:

- if \( howmny = 'A' \), the matrix \( X \) of right eigenvectors of \((S,P)\);
- if \( howmny = 'B' \), the matrix \( Z^*X \);
- if \( howmny = 'S' \), the right eigenvectors of \((S,P)\) specified by \select\, stored consecutively in the columns of \( vr \), in the same order as their eigenvalues.

*For real flavors:*

A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part, and the second the imaginary part.

\( m \)

The number of columns in the arrays \( vl \) and/or \( vr \) actually used to store the eigenvectors.

If \( howmny = 'A' \) or \( 'B' \), \( m \) is set to \( n \).

*For real flavors:*

Each selected real eigenvector occupies one column and each selected complex eigenvector occupies two columns.

*For complex flavors:*

Each selected eigenvector occupies one column.

**Return Values**

This function returns a value \( info \).

If \( info=0 \), the execution is successful.

If \( info = -i \), the \( i \)-th parameter had an illegal value.

*For real flavors:*

if \( info = i>0 \), the \( (i:i+1) \) does not have a complex eigenvalue.
Reorders the generalized Schur decomposition of a pair of matrices \((A,B)\) so that one diagonal block of \((A,B)\) moves to another row index.

**Syntax**

```c
lapack_int LAPACKE_stgexc (int matrix_layout, lapack_logical wantq, lapack_logical wantz, lapack_int n, float* a, lapack_int lda, float* b, lapack_int ldb, float* q, lapack_int ldq, float* z, lapack_int ldz, lapack_int* ifst, lapack_int* ilst);

lapack_int LAPACKE_dtgexc (int matrix_layout, lapack_logical wantq, lapack_logical wantz, lapack_int n, double* a, lapack_int lda, double* b, lapack_int ldb, double* q, lapack_int ldq, double* z, lapack_int ldz, lapack_int* ifst, lapack_int* ilst);

lapack_int LAPACKE_ctgexc (int matrix_layout, lapack_logical wantq, lapack_logical wantz, lapack_int n, lapack_complex_float* a, lapack_int lda, lapack_complex_float* b, lapack_int ldb, lapack_complex_float* q, lapack_int ldq, lapack_complex_float* z, lapack_int ldz, lapack_int* ifst, lapack_int* ilst);

lapack_int LAPACKE_ztgexc (int matrix_layout, lapack_logical wantq, lapack_logical wantz, lapack_int n, lapack_complex_double* a, lapack_int lda, lapack_complex_double* b, lapack_int ldb, lapack_complex_double* q, lapack_int ldq, lapack_complex_double* z, lapack_int ldz, lapack_int* ifst, lapack_int* ilst);
```

**Include Files**

- mkl.h

**Description**

The routine reorders the generalized real-Schur/Schur decomposition of a real/complex matrix pair \((A,B)\) using an orthogonal/unitary equivalence transformation

\[
(A,B) = Q^* (A,B) Z^H,
\]

so that the diagonal block of \((A, B)\) with row index \(ifst\) is moved to row \(ilst\). Matrix pair \((A, B)\) must be in a generalized real-Schur/Schur canonical form (as returned by gges), that is, \(A\) is block upper triangular with 1-by-1 and 2-by-2 diagonal blocks and \(B\) is upper triangular. Optionally, the matrices \(Q\) and \(Z\) of generalized Schur vectors are updated.

\[
\begin{align*}
Q_{in}^* A_{in}^* Z_{in}^T &= Q_{out}^* A_{out}^* Z_{out}^T, \\
Q_{in}^* B_{in}^* Z_{in}^T &= Q_{out}^* B_{out}^* Z_{out}^T.
\end{align*}
\]

**Input Parameters**

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **wantq, wantz**
  If \(wantq = 1\), update the left transformation matrix \(Q\);
  If \(wantq = 0\), do not update \(Q\);
  If \(wantz = 1\), update the right transformation matrix \(Z\);
  If \(wantz = 0\), do not update \(Z\).

- **n**
  The order of the matrices \(A\) and \(B\) \((n \geq 0)\).

- **a, b, q, z**
  Arrays:
a (size max(1, lda*n)) contains the matrix A.
b (size max(1, ldb*n)) contains the matrix B.
q (size at least 1 if wantq = 0 and at least max(1, ldq*n) if wantq = 1)
If wantq = 0, then q is not referenced.
If wantq = 1, then q must contain the orthogonal/unitary matrix Q.
z (size at least 1 if wantz = 0 and at least max(1, ldz*n) if wantz = 1)
If wantz = 0, then z is not referenced.
If wantz = 1, then z must contain the orthogonal/unitary matrix Z.

lda
The leading dimension of a; at least max(1, n).

ldb
The leading dimension of b; at least max(1, n).

ldq
The leading dimension of q;
If wantq = 0, then ldq ≥ 1.
If wantq = 1, then ldq ≥ max(1, n).

ldz
The leading dimension of z;
If wantz = 0, then ldz ≥ 1.
If wantz = 1, then ldz ≥ max(1, n).

ifst, ilst
Specify the reordering of the diagonal blocks of (A, B). The block with row index ifst is moved to row ilst, by a sequence of swapping between adjacent blocks. Constraint: 1 ≤ ifst, ilst ≤ n.

Output Parameters

a, b, q, z
Overwritten by the updated matrices A, B, Q, and Z respectively.

ifst, ilst
Overwritten for real flavors only.
If ifst pointed to the second row of a 2 by 2 block on entry, it is changed to point to the first row; ilst always points to the first row of the block in its final position (which may differ from its input value by ±1).

Return Values
This function returns a value info.
If info=0, the execution is successful.
If info = −i, the i-th parameter had an illegal value.
If info = 1, the transformed matrix pair (A, B) would be too far from generalized Schur form; the problem is ill-conditioned. (A, B) may have been partially reordered, and ilst points to the first row of the current position of the block being moved.

?tgsen
Reorders the generalized Schur decomposition of a pair of matrices (A, B) so that a selected cluster of eigenvalues appears in the leading diagonal blocks of (A, B).

Include Files
- mkl.h

Description

The routine reorders the generalized real-Schur/Schur decomposition of a real/complex matrix pair \((A, B)\) (in terms of an orthogonal/unitary equivalence transformation \(Q^* (A, B) \cdot Z\) for real flavors or \(Q^* (A, B) \cdot Z\) for complex flavors), so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the pair \((A, B)\). The leading columns of \(Q\) and \(Z\) form orthonormal/unitary bases of the corresponding left and right eigenspaces (deflating subspaces).

\((A, B)\) must be in generalized real-Schur/Schur canonical form (as returned by `gges`), that is, \(A\) and \(B\) are both upper triangular.

`tgsen` also computes the generalized eigenvalues

\[ \omega_j = (\text{alphar}(j) + \text{alphai}(j) \cdot i)/\text{beta}(j) \] (for real flavors)

\[ \omega_j = \text{alpha}(j)/\text{beta}(j) \] (for complex flavors)

of the reordered matrix pair \((A, B)\).

Optionally, the routine computes the estimates of reciprocal condition numbers for eigenvalues and eigenspaces. These are \(\text{Difu}[A_{11}, B_{11}], (A_{22}, B_{22})\) and \(\text{Difl}[A_{11}, B_{11}], (A_{22}, B_{22})\), that is, the separation(s) between the matrix pairs \((A_{11}, B_{11})\) and \((A_{22}, B_{22})\) that correspond to the selected cluster and the eigenvalues outside the cluster, respectively, and norms of "projections" onto left and right eigenspaces with respect to the selected cluster in the \((1,1)\)-block.
Input Parameters

**matrix_layout**
Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

**ijob**
Specifies whether condition numbers are required for the cluster of eigenvalues (pl and pr) or the deflating subspaces Difu and Difl.
- If ijob = 0, only reorder with respect to select;
- If ijob = 1, reciprocal of norms of "projections" onto left and right eigenspaces with respect to the selected cluster (pl and pr);
- If ijob = 2, compute upper bounds on Difu and Difl, using F-norm-based estimate (dif (1:2));
- If ijob = 3, compute estimate of Difu and Difl, using 1-norm-based estimate (dif (1:2)). This option is about 5 times as expensive as ijob = 2;
- If ijob = 4, compute pl, pr and dif (i.e., options 0, 1 and 2 above). This is an economic version to get it all;
- If ijob = 5, compute pl, pr and dif (i.e., options 0, 1 and 3 above).

**wantq, wantz**
- If wantq = 1, update the left transformation matrix Q;
- If wantq = 0, do not update Q;
- If wantz = 1, update the right transformation matrix Z;
- If wantz = 0, do not update Z.

**select**
Array, size at least max (1, n). Specifies the eigenvalues in the selected cluster.
- To select an eigenvalue \( \omega_j \), select[j-1] must be 1.
- For real flavors: to select a complex conjugate pair of eigenvalues \( \omega_j \) and \( \omega_j + 1 \) (corresponding 2 by 2 diagonal block), select[j-1] and/or select[j] must be set to 1; the complex conjugate \( \omega_j \) and \( \omega_j + 1 \) must be either both included in the cluster or both excluded.

**n**
The order of the matrices A and B (\( n \geq 0 \)).

**a, b, q, z**
Arrays:
- a (size max(1, lda*n)) contains the matrix A.
  - For real flavors: A is upper quasi-triangular, with (A, B) in generalized real Schur canonical form.
  - For complex flavors: A is upper triangular, in generalized Schur canonical form.
- b (size max(1, ldb*n)) contains the matrix B.
  - For real flavors: B is upper triangular, with (A, B) in generalized real Schur canonical form.
  - For complex flavors: B is upper triangular, in generalized Schur canonical form.
- q (size at least 1 if wantq = 0 and at least max(1, ldq*n) if wantq = 1)
  - If wantq = 1, then q is an \( n \)-by-\( n \) matrix;
If $wantq = 0$, then $q$ is not referenced.

$z$ (size at least 1 if $wantz = 0$ and at least $\max(1, ldz \times n)$ if $wantz = 1$)

If $wantz = 1$, then $z$ is an $n$-by-$n$ matrix;
If $wantz = 0$, then $z$ is not referenced.

$lda$
The leading dimension of $a$; at least $\max(1, n)$.

$ldb$
The leading dimension of $b$; at least $\max(1, n)$.

$ldq$
The leading dimension of $q$; $ldq \geq 1$.

If $wantq = 1$, then $ldq \geq \max(1, n)$.

$ldz$
The leading dimension of $z$; $ldz \geq 1$.

If $wantz = 1$, then $ldz \geq \max(1, n)$.

Output Parameters

$a, b$
Overwritten by the reordered matrices $A$ and $B$, respectively.

$\text{alphan, alphi}$
Arrays, size at least $\max(1, n)$. Contain values that form generalized eigenvalues in real flavors.
See $beta$.

$\text{alpha}$
Array, size at least $\max(1, n)$. Contain values that form generalized eigenvalues in complex flavors.
See $beta$.

$beta$
Array, size at least $\max(1, n)$.

For real flavors:
On exit, $(\text{alphan}[j] + \text{alphi}[j] \times i) / \text{beta}[j], j=0,\ldots, n-1$, will be the generalized eigenvalues.

$\text{alphan}[j] + \text{alphi}[j] \times i$ and $\text{beta}[j], j=0,\ldots, n-1$ are the diagonals of the complex Schur form $(S,T)$ that would result if the 2-by-2 diagonal blocks of the real generalized Schur form of $(A,B)$ were further reduced to triangular form using complex unitary transformations.

If $\text{alphi}[j-1]$ is zero, then the $j$-th eigenvalue is real; if positive, then the $j$-th and $(j+1)$-st eigenvalues are a complex conjugate pair, with $\text{alphi}[j]$ negative.

For complex flavors:
The diagonal elements of $A$ and $B$, respectively, when the pair $(A,B)$ has been reduced to generalized Schur form. $\text{alpha}[i] / \text{beta}[i], i=0,\ldots, n-1$ are the generalized eigenvalues.

$q$
If $wantq = 1$, then, on exit, $Q$ has been postmultiplied by the left orthogonal transformation matrix which reorder $(A, B)$. The leading $m$ columns of $Q$ form orthonormal bases for the specified pair of left eigenspaces (deflating subspaces).
If `wantz = 1`, then, on exit, \( Z \) has been postmultiplied by the left orthogonal transformation matrix which reorder \((A, B)\). The leading \( m \) columns of \( Z \) form orthonormal bases for the specified pair of left eigenspaces (deflating subspaces).

\( m \)

The dimension of the specified pair of left and right eigen-spaces (deflating subspaces); \( 0 \leq m \leq n \).

\( pl, pr \)

If \( ijob = 1, 4, \) or \( 5, \) \( pl \) and \( pr \) are lower bounds on the reciprocal of the norm of "projections" onto left and right eigenspaces with respect to the selected cluster.

\( 0 < pl, pr \leq 1 \). If \( m = 0 \) or \( m = n, pl = pr = 1 \).

If \( ijob = 0, 2 \) or \( 3, \) \( pl \) and \( pr \) are not referenced

\( dif \)

Array, size (2).

If \( ijob \geq 2, \) \( dif(1:2) \) store the estimates of \( Difu \) and \( Difl \).

If \( ijob = 2 \) or \( 4, \) \( dif(1:2) \) are F-norm-based upper bounds on \( Difu \) and \( Difl \).

If \( ijob = 3 \) or \( 5, \) \( dif(1:2) \) are 1-norm-based estimates of \( Difu \) and \( Difl \).

If \( m = 0 \) or \( m = n, dif(1:2) = F\text{-}\text{norm}([A, B]). \)

If \( ijob = 0 \) or \( 1, \) \( dif \) is not referenced

**Return Values**

This function returns a value \( info \).

If \( info=0, \) the execution is successful.

If \( info = -i, \) the \( i \)-th parameter had an illegal value.

If \( info = 1, \) Reordering of \((A, B)\) failed because the transformed matrix pair \((A, B)\) would be too far from generalized Schur form; the problem is very ill-conditioned. \((A, B)\) may have been partially reordered.

If \( ijob > 0, 0 \) is returned in \( dif, pl \) and \( pr \).

**tgsyl**

Solves the generalized Sylvester equation.

**Syntax**

```c
lapack_int LAPACKE_stgsyl( int matrix_layout, char trans, lapack_int ijob, lapack_int m, lapack_int n, const float* a, lapack_int lda, const float* b, lapack_int ldb, float* c, lapack_int ldc, const float* d, lapack_int ldd, const float* e, lapack_int lde, float* f, lapack_int ldf, float* scale, float* dif );

lapack_int LAPACKE_dtgsyl( int matrix_layout, char trans, lapack_int ijob, lapack_int m, lapack_int n, const double* a, lapack_int lda, const double* b, lapack_int ldb, double* c, lapack_int ldc, const double* d, lapack_int ldd, const double* e, lapack_int lde, double* f, lapack_int ldf, double* scale, double* dif );
```
Include Files

- mkl.h

Description

The routine solves the generalized Sylvester equation:

\[ A \cdot R - L \cdot B = \text{scale} \cdot C \]
\[ D \cdot R - L \cdot E = \text{scale} \cdot F \]

where \( R \) and \( L \) are unknown \( m \)-by-\( n \) matrices, \((A, D), (B, E)\) and \((C, F)\) are given matrix pairs of size \( m \)-by-\( m \), \( n \)-by-\( n \) and \( m \)-by-\( n \), respectively, with real/complex entries. \((A, D)\) and \((B, E)\) must be in generalized real-Schur/Schur canonical form, that is, \( A, B \) are upper quasi-triangular/triangular and \( D, E \) are upper triangular.

The solution \((R, L)\) overwrites \((C, F)\). The factor \( \text{scale} \), \( 0 \leq \text{scale} \leq 1 \), is an output scaling factor chosen to avoid overflow.

In matrix notation the above equation is equivalent to the following: solve \( Z^T x = \text{scale} \cdot b \), where \( Z \) is defined as

\[
Z = \begin{pmatrix}
\text{kron}(I_k, A) & -\text{kron}(B^T, I_k) \\
\text{kron}(I_k, D) & -\text{kron}(E^T, I_k)
\end{pmatrix}
\]

Here \( I_k \) is the identity matrix of size \( k \) and \( X^T \) is the transpose/conjugate-transpose of \( X \). \( \text{kron}(X, Y) \) is the Kronecker product between the matrices \( X \) and \( Y \).

If \( \text{trans} = 'T' \) (for real flavors), or \( \text{trans} = 'C' \) (for complex flavors), the routine \( ?\text{tgsyl} \) solves the transposed/conjugate-transposed system \( Z^T y = \text{scale} \cdot b \), which is equivalent to solve for \( R \) and \( L \) in

\[ A^T \cdot R + D^T \cdot L = \text{scale} \cdot C \]
\[ R \cdot B^T + L \cdot E^T = \text{scale} \cdot (-F) \]

This case (\( \text{trans} = 'T' \) for \( \text{stgsyl/dtgsyl} \) or \( \text{trans} = 'C' \) for \( \text{ctgsyl/ztgsyl} \)) is used to compute an one-norm-based estimate of \( \text{Dif}[(A, D), (B, E)] \), the separation between the matrix pairs \((A, D)\) and \((B, E)\).

If \( \text{ijob} \geq 1 \), \( ?\text{tgsyl} \) computes a Frobenius norm-based estimate of \( \text{Dif}[(A, D), (B, E)] \). That is, the reciprocal of a lower bound on the reciprocal of the smallest singular value of \( Z \). This is a level 3 BLAS algorithm.

Input Parameters

- \text{matrix_layout} \quad \text{Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).}
**trans**

Must be 'N', 'T', or 'C'.

If \( \text{trans} = \text{'N'} \), solve the generalized Sylvester equation.

If \( \text{trans} = \text{'T'} \), solve the 'transposed' system (for real flavors only).

If \( \text{trans} = \text{'C'} \), solve the 'conjugate transposed' system (for complex flavors only).

**ijob**

Specifies what kind of functionality to be performed:

If \( \text{ijob} = 0 \), solve the generalized Sylvester equation only;

If \( \text{ijob} = 1 \), perform the functionality of \( \text{ijob} = 0 \) and \( \text{ijob} = 3 \);

If \( \text{ijob} = 2 \), perform the functionality of \( \text{ijob} = 0 \) and \( \text{ijob} = 4 \);

If \( \text{ijob} = 3 \), only an estimate of \( \text{Dif}([A, D], [B, E]) \) is computed (look ahead strategy is used);

If \( \text{ijob} = 4 \), only an estimate of \( \text{Dif}([A, D], [B, E]) \) is computed (?gecon on sub-systems is used). If \( \text{trans} = \text{'T'} \) or \( \text{'C'} \), \( \text{ijob} \) is not referenced.

**m**

The order of the matrices \( A \) and \( D \), and the row dimension of the matrices \( C, F, R \) and \( L \).

**n**

The order of the matrices \( B \) and \( E \), and the column dimension of the matrices \( C, F, R \) and \( L \).

**a, b, c, d, e, f**

Arrays:

- \( a \) (size \( \text{max}(1, \text{lda} \times m) \)) contains the upper quasi-triangular (for real flavors) or upper triangular (for complex flavors) matrix \( A \).
- \( b \) (size \( \text{max}(1, \text{ldb} \times n) \)) contains the upper quasi-triangular (for real flavors) or upper triangular (for complex flavors) matrix \( B \).
- \( c \) (size \( \text{max}(1, \text{ldc} \times n) \) for column major layout and \( \text{max}(1, \text{ldc} \times m) \) for row major layout) contains the right-hand-side of the first matrix equation in the generalized Sylvester equation (as defined by \( \text{trans} \)).
- \( d \) (size \( \text{max}(1, \text{ldd} \times m) \)) contains the upper triangular matrix \( D \).
- \( e \) (size \( \text{max}(1, \text{lde} \times n) \)) contains the upper triangular matrix \( E \).
- \( f \) (size \( \text{max}(1, \text{ldf} \times n) \) for column major layout and \( \text{max}(1, \text{ldf} \times m) \) for row major layout) contains the right-hand-side of the second matrix equation in the generalized Sylvester equation (as defined by \( \text{trans} \)).

**lda**

The leading dimension of \( a \); at least \( \text{max}(1, m) \).

**ldb**

The leading dimension of \( b \); at least \( \text{max}(1, n) \).

**ldc**

The leading dimension of \( c \); at least \( \text{max}(1, m) \) for column major layout and at least \( \text{max}(1, n) \) for row major layout.

**ldd**

The leading dimension of \( d \); at least \( \text{max}(1, m) \).

**lde**

The leading dimension of \( e \); at least \( \text{max}(1, n) \).

**ldf**

The leading dimension of \( f \); at least \( \text{max}(1, m) \) for column major layout and at least \( \text{max}(1, n) \) for row major layout.
Output Parameters

\( c \)

If \( ijob=0, 1, \) or \( 2, \) overwritten by the solution \( R. \)

If \( ijob=3 \) or \( 4 \) and \( trans = 'N', \) \( c \) holds \( R, \) the solution achieved during the computation of the Dif-estimate.

\( f \)

If \( ijob=0, 1, \) or \( 2, \) overwritten by the solution \( L. \)

If \( ijob=3 \) or \( 4 \) and \( trans = 'N', \) \( f \) holds \( L, \) the solution achieved during the computation of the Dif-estimate.

\( dif \)

On exit, \( dif \) is the reciprocal of a lower bound of the reciprocal of the Dif-function, that is, \( dif \) is an upper bound of \( \text{Dif}[(A, D), (B, E)] = \sigma_{\text{min}}(Z), \) where \( Z \) as defined in the description.

If \( ijob = 0, \) or \( trans = 'T' \) (for real flavors), or \( trans = 'C' \) (for complex flavors), \( dif \) is not touched.

\( scale \)

On exit, \( scale \) is the scaling factor in the generalized Sylvester equation.

If \( 0 < scale < 1, \) \( c \) and \( f \) hold the solutions \( R \) and \( L, \) respectively, to a slightly perturbed system but the input matrices \( A, B, D \) and \( E \) have not been changed.

If \( scale = 0, \) \( c \) and \( f \) hold the solutions \( R \) and \( L, \) respectively, to the homogeneous system with \( C = F = 0. \) Normally, \( scale = 1. \)

Return Values

This function returns a value \( info. \)

If \( info=0, \) the execution is successful.

If \( info = -i, \) the \( i-th \) parameter had an illegal value.

If \( info > 0, (A, D) \) and \( (B, E) \) have common or close eigenvalues.

?tgsna

Estimates reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a pair of matrices in generalized real Schur canonical form.

Syntax

\[
\text{lapack_int LAPACKE_stgsna}(\text{int} \text{ matrix_layout}, \text{char} \text{ job}, \text{char} \text{ howmny}, \text{const lapack_logical* select}, \text{lapack_int n}, \text{const float* a, lapack_int lda}, \text{const float* b, lapack_int ldb, const float* vl, lapack_int ldvl, const float* vr, lapack_int ldvr, float* s, float* dif, lapack_int mm, lapack_int* m});
\]

\[

\]

\[
\text{lapack_int LAPACKE_ctgsna}(\text{int} \text{ matrix_layout}, \text{char} \text{ job}, \text{char} \text{ howmny}, \text{const lapack_logical* select}, \text{lapack_int n}, \text{const lapack_complex_float* a, lapack_int lda}, \text{const lapack_complex_float* b, lapack_int ldb, const lapack_complex_float* vl, lapack_int ldvl, const lapack_complex_float* vr, lapack_int ldvr, float* s, float* dif, lapack_int mm, lapack_int* m});
\]
lapack_int LAPACKE_ztgsna( int matrix_layout, char job, char howmny, const
lapack_logical* select, lapack_int n, const lapack_complex_double* a, lapack_int lda,
const lapack_complex_double* b, lapack_int ldb, const lapack_complex_double* vl,
lapack_int ldvl, const lapack_complex_double* vr, lapack_int ldvr, double* s, double* dif, lapack_int mm,
lapack_int* m );

Include Files
• mkl.h

Description
The real flavors stgsna/dtgsna of this routine estimate reciprocal condition numbers for specified
eigenvalues and/or eigenvectors of a matrix pair (A, B) in generalized real Schur canonical form (or of any
matrix pair (Q*A*Z^T, Q*B*Z^T) with orthogonal matrices Q and Z.

(A, B) must be in generalized real Schur form (as returned by gges/gges), that is, A is block upper triangular
with 1-by-1 and 2-by-2 diagonal blocks. B is upper triangular.

The complex flavors ctgsna/ztgsna estimate reciprocal condition numbers for specified eigenvalues and/or
eigenvectors of a matrix pair (A, B). (A, B) must be in generalized Schur canonical form, that is, A and B are
both upper triangular.

Input Parameters

matrix_layout specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR)
or column major (LAPACK_COL_MAJOR).

job specifies whether condition numbers are required for eigenvalues or
eigenvectors. Must be 'E' or 'V' or 'B'.

If job = 'E', for eigenvalues only (compute s ).
If job = 'V', for eigenvectors only (compute dif ).
If job = 'B', for both eigenvalues and eigenvectors (compute both s and
dif ).

howmny must be 'A' or 'S'.
If howmny = 'A', compute condition numbers for all eigenpairs.
If howmny = 'S', compute condition numbers for selected eigenpairs
specified by the logical array select.

select array, size at least max (1, n).
If howmny = 'S', select specifies the eigenpairs for which condition
numbers are required.
If howmny = 'A', select is not referenced.

For real flavors:
To select condition numbers for the eigenpair corresponding to a real
eigenvalue \( \omega_j \), select[j - 1] must be set to 1; to select condition numbers corresponding to a complex conjugate pair of eigenvalues \( \omega_j \) and \( \omega_j + 1 \),
either select[j - 1] or select[j] must be set to 1.

For complex flavors:
To select condition numbers for the corresponding \( j \)-th eigenvalue and/or eigenvector, \( \text{select}[j - 1] \) must be set to 1.

The order of the square matrix pair \((A, B)\) \((n \geq 0)\).

Arrays:

- \( a \) (size \( \max(1, lda*\nu) \)) contains the upper quasi-triangular (for real flavors) or upper triangular (for complex flavors) matrix \( A \) in the pair \((A, B)\).
- \( b \) (size \( \max(1, ldb*\nu) \)) contains the upper triangular matrix \( B \) in the pair \((A, B)\).

If \( \text{job} = 'E' \) or \( 'B' \), \( vl \) (size \( \max(1, ldvl*\mu) \)) for column major layout and \( \max(1, ldvl*\nu) \) for row major layout) must contain left eigenvectors of \((A, B)\), corresponding to the eigenpairs specified by \( \text{howmny} \) and \( \text{select} \). The eigenvectors must be stored in consecutive columns of \( vl \), as returned by \(? \text{tgevc}\).

If \( \text{job} = 'V' \), \( vl \) is not referenced.

If \( \text{job} = 'E' \) or \( 'B' \), \( vr \) (size \( \max(1, ldvr*\mu) \)) for column major layout and \( \max(1, ldvr*\nu) \) for row major layout) must contain right eigenvectors of \((A, B)\), corresponding to the eigenpairs specified by \( \text{howmny} \) and \( \text{select} \). The eigenvectors must be stored in consecutive columns of \( vr \), as returned by \(? \text{tgevc}\).

If \( \text{job} = 'V' \), \( vr \) is not referenced.

- \( lda \) The leading dimension of \( a \); at least \( \max(1, n) \).
- \( ldb \) The leading dimension of \( b \); at least \( \max(1, n) \).
- \( ldvl \) The leading dimension of \( vl \); \( ldvl \geq 1 \).
- \( ldvr \) The leading dimension of \( vr \); \( ldvr \geq 1 \).

The number of elements in the arrays \( s \) and \( \text{dif} (mm \geq m) \).

Output Parameters

- \( s \) Array, size \( mm \).

  If \( \text{job} = 'E' \) or \( 'B' \), contains the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of the array.

  If \( \text{job} = 'V' \), \( s \) is not referenced.

  For real flavors:

  For a complex conjugate pair of eigenvalues two consecutive elements of \( s \) are set to the same value. Thus, \( s[j - 1] \), \( \text{dif}[j - 1] \), and the \( j \)-th columns of \( vl \) and \( vr \) all correspond to the same eigenpair (but not in general the \( j \)-th eigenpair, unless all eigenpairs are selected).
$dif$

Array, size $mm$.

If $job = 'V' \text{ or } 'B'$, contains the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array.

If the eigenvalues cannot be reordered to compute $dif[j]$, $dif[j]$ is set to 0; this can only occur when the true value would be very small anyway.

If $job = 'E'$, $dif$ is not referenced.

For real flavors:

For a complex eigenvector, two consecutive elements of $dif$ are set to the same value.

For complex flavors:

For each eigenvalue/vector specified by $select$, $dif$ stores a Frobenius norm-based estimate of $Difl$.

$m$

The number of elements in the arrays $s$ and $dif$ used to store the specified condition numbers; for each selected eigenvalue one element is used.

If $howmny = 'A'$, $m$ is set to $n$.

Return Values

This function returns a value $info$.

If $info = 0$, the execution is successful.

If $info = -i$, the $i$-th parameter had an illegal value.

Generalized Singular Value Decomposition: LAPACK Computational Routines

This section describes LAPACK computational routines used for finding the generalized singular value decomposition (GSVD) of two matrices $A$ and $B$ as

\[ U^H A Q = D_1 \begin{pmatrix} 0 & R \end{pmatrix}, \]
\[ V^H B Q = D_2 \begin{pmatrix} 0 & R \end{pmatrix}, \]

where $U$, $V$, and $Q$ are orthogonal/unitary matrices, $R$ is a nonsingular upper triangular matrix, and $D_1$, $D_2$ are “diagonal” matrices of the structure detailed in the routines description section.

Table “Computational Routines for Generalized Singular Value Decomposition” lists LAPACK routines that perform generalized singular value decomposition of matrices.

**Computational Routines for Generalized Singular Value Decomposition**

<table>
<thead>
<tr>
<th>Routine name</th>
<th>Operation performed</th>
</tr>
</thead>
<tbody>
<tr>
<td>ggsvp</td>
<td>Computes the preprocessing decomposition for the generalized SVD</td>
</tr>
<tr>
<td>ggsvp3</td>
<td>Performs preprocessing for a generalized SVD.</td>
</tr>
<tr>
<td>ggsvd3</td>
<td>Computes generalized SVD.</td>
</tr>
<tr>
<td>tgsja</td>
<td>Computes the generalized SVD of two upper triangular or trapezoidal matrices</td>
</tr>
</tbody>
</table>

You can use routines listed in the above table as well as the driver routine $ggsvd$ to find the GSVD of a pair of general rectangular matrices.
?ggsvp

Computes the preprocessing decomposition for the generalized SVD (deprecated).

Syntax

```c
lapack_int LAPACKE_sggsvp(int matrix_layout, char jobu, char jobv, char jobq,

Description

This routine is deprecated; use ggsvp3.

The routine computes orthogonal matrices $U$, $V$ and $Q$ such that

$$
U^H A Q = egin{cases}
  \begin{pmatrix}
    k & 0 & A_{12} & A_{13} \\
    0 & 0 & A_{23}
  \end{pmatrix}, & \text{if } m - k - l > 0 \\
  \begin{pmatrix}
    0 & A_{12} & A_{13} \\
    0 & 0 & A_{23}
  \end{pmatrix}, & \text{if } m - k - l < 0
  \end{cases}
$$

$$
V^H B Q = \begin{pmatrix}
  l & 0 & B_{13} \\
  0 & 0 & 0
  \end{pmatrix}
$$
where the $k$-by-$k$ matrix $A_{12}$ and $l$-by-$l$ matrix $B_{13}$ are nonsingular upper triangular; $A_{23}$ is $l$-by-$l$ upper triangular if $m-k-l \geq 0$, otherwise $A_{23}$ is $(m-k)$-by-$l$ upper trapezoidal. The sum $k+l$ is equal to the effective numerical rank of the $(m+p)$-by-$n$ matrix $(A^H, B^H)^H$.

This decomposition is the preprocessing step for computing the Generalized Singular Value Decomposition (GSVD), see subroutine ?tgsja.

**Input Parameters**

*matrix_layout* Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

*jobu* Must be ‘U’ or ‘N’.

  - If *jobu* = ‘U’, orthogonal/unitary matrix $U$ is computed.
  - If *jobu* = ‘N’, $U$ is not computed.

*jobv* Must be ‘V’ or ‘N’.

  - If *jobv* = ‘V’, orthogonal/unitary matrix $V$ is computed.
  - If *jobv* = ‘N’, $V$ is not computed.

*jobq* Must be ‘Q’ or ‘N’.

  - If *jobq* = ‘Q’, orthogonal/unitary matrix $Q$ is computed.
  - If *jobq* = ‘N’, $Q$ is not computed.

*m* The number of rows of the matrix $A$ ($m \geq 0$).

*p* The number of rows of the matrix $B$ ($p \geq 0$).

*n* The number of columns of the matrices $A$ and $B$ ($n \geq 0$).

*a, b* Arrays:

  - $a$ (size at least $\max(1, \text{lda} \times n)$ for column major layout and $\max(1, \text{lda} \times m)$ for row major layout) contains the $m$-by-$n$ matrix $A$.
  - $b$ (size at least $\max(1, \text{ldb} \times n)$ for column major layout and $\max(1, \text{ldb} \times p)$ for row major layout) contains the $p$-by-$n$ matrix $B$.

*lda* The leading dimension of $a$; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout.

*ldb* The leading dimension of $b$; at least $\max(1, p)$ for column major layout and $\max(1, n)$ for row major layout.

*tola, tolb* $tola$ and $tolb$ are the thresholds to determine the effective numerical rank of matrix $B$ and a subblock of $A$. Generally, they are set to

  - $tola = \max(m, n) \times \|A\| \times \text{MACHEPS}$,
  - $tolb = \max(p, n) \times \|B\| \times \text{MACHEPS}$.

The size of $tola$ and $tolb$ may affect the size of backward errors of the decomposition.

*ldu* The leading dimension of the output array $U$. $ldu \geq \max(1, m)$ if *jobu* = ‘U’; $ldu \geq 1$ otherwise.
The leading dimension of the output array $v$. $ldv \geq \max(1, p)$ if $jobv = 'V' ; ldv \geq 1$ otherwise.

The leading dimension of the output array $q$. $ldq \geq \max(1, n)$ if $jobq = 'Q' ; ldq \geq 1$ otherwise.

Output Parameters

- $a$  
  Overwritten by the triangular (or trapezoidal) matrix described in the Description section.

- $b$  
  Overwritten by the triangular matrix described in the Description section.

- $k$, $l$  
  On exit, $k$ and $l$ specify the dimension of subblocks. The sum $k + l$ is equal to effective numerical rank of $(A^H, B^H)^H$.

- $u$, $v$, $q$  
  Arrays:
  
  - If $jobu = 'U'$, $u$ (size max(1, $ldu$*$m$)) contains the orthogonal/unitary matrix $U$.
  - If $jobu = 'N'$, $u$ is not referenced.
  - If $jobv = 'V'$, $v$ (size max(1, $ldv$*$p$)) contains the orthogonal/unitary matrix $V$.
  - If $jobv = 'N'$, $v$ is not referenced.
  - If $jobq = 'Q'$, $q$ (size max(1, $ldq$*$n$)) contains the orthogonal/unitary matrix $Q$.
  - If $jobq = 'N'$, $q$ is not referenced.

Return Values

This function returns a value $info$.

- If $info=0$, the execution is successful.
- If $info = -i$, the $i$-th parameter had an illegal value.

$\text{ggsvp3}$

Performs preprocessing for a generalized SVD.

Include Files
• mkl.h

Description
?ggsvp3 computes orthogonal or unitary matrices \( U, V, \) and \( Q \) such that for real flavors:

For \( \text{m} - \text{k} - \text{l} \geq 0 \):

\[
U^T AQ = \begin{pmatrix}
A_{12} & A_{13} \\
0 & A_{23}
\end{pmatrix}
\]

For \( \text{m} - \text{k} - \text{l} < 0 \):

\[
U^T AQ = \begin{pmatrix}
0 & A_{12} & A_{13} \\
0 & 0 & A_{23}
\end{pmatrix}
\]

\[
V^T BQ = \begin{pmatrix}
0 & 0 & B_{13} \\
0 & 0 & 0
\end{pmatrix}
\]

For complex flavors:

For \( \text{m} - \text{k} - \text{l} \geq 0 \):

\[
U^H AQ = \begin{pmatrix}
A_{12} & A_{13} \\
0 & A_{23}
\end{pmatrix}
\]

For \( \text{m} - \text{k} - \text{l} < 0 \):

\[
U^H AQ = \begin{pmatrix}
0 & A_{12} & A_{13} \\
0 & 0 & A_{23}
\end{pmatrix}
\]

\[
V^H BQ = \begin{pmatrix}
0 & 0 & B_{13} \\
0 & 0 & 0
\end{pmatrix}
\]

where the \( k \)-by-\( k \) matrix \( A_{12} \) and \( l \)-by-\( l \) matrix \( B_{13} \) are nonsingular upper triangular; \( A_{23} \) is \( l \)-by-\( l \) upper triangular if \( \text{m} - \text{k} - \text{l} \geq 0 \), otherwise \( A_{23} \) is \( (m-k) \)-by-\( l \) upper trapezoidal. \( k + l \) is the effective numerical rank of the \( (m+p) \)-by-\( n \) matrix \( (A^T,B^T)^T \) for real flavors or \( (A^H,B^H)^H \) for complex flavors.

This decomposition is the preprocessing step for computing the Generalized Singular Value Decomposition (GSVD), see ?ggsvd3.
Input Parameters

matrix_layout
Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

jobu
= 'U': Orthogonal/unitary matrix $U$ is computed;
= 'N': $U$ is not computed.

jobv
= 'V': Orthogonal/unitary matrix $V$ is computed;
= 'N': $V$ is not computed.

jobq
= 'Q': Orthogonal/unitary matrix $Q$ is computed;
= 'N': $Q$ is not computed.

m
The number of rows of the matrix $A$.
$m \geq 0$.

p
The number of rows of the matrix $B$.
$p \geq 0$.

n
The number of columns of the matrices $A$ and $B$.
$n \geq 0$.

a
Array, size ($lda*n$).
On entry, the $m$-by-$n$ matrix $A$.

lda
The leading dimension of the array $a$.
$lda \geq \max(1,m)$.

b
Array, size ($ldb*n$).
On entry, the $p$-by-$n$ matrix $B$.

ldb
The leading dimension of the array $b$.
$ldb \geq \max(1,p)$.

tola, tolb
tola and tolb are the thresholds to determine the effective numerical rank of matrix $B$ and a subblock of $A$. Generally, they are set to

tola = $\max(m,n)\times\text{norm}(a)\times\text{MACHEPS}$,
tolb = $\max(p,n)\times\text{norm}(b)\times\text{MACHEPS}$.

The size of tola and tolb may affect the size of backward errors of the decomposition.

ldu
The leading dimension of the array $u$.
$ldu \geq \max(1,m)$ if $jobu = 'U' $; $ldu \geq 1$ otherwise.

ldv
The leading dimension of the array $v$.
$ldv \geq \max(1,p)$ if $jobv = 'V' $; $ldv \geq 1$ otherwise.

ldq
The leading dimension of the array $q$.
$ldq \geq \max(1,n)$ if $jobq = 'Q' $; $ldq \geq 1$ otherwise.
Output Parameters

**a**
On exit, $a$ contains the triangular (or trapezoidal) matrix described in the Description section.

**b**
On exit, $b$ contains the triangular matrix described in the Description section.

**k, l**
On exit, $k$ and $l$ specify the dimension of the subblocks described in Description section.

$k + l = \text{effective numerical rank of } (A^T,B^T)^T \text{ for real flavors or } (A^H,B^H)^H \text{ for complex flavors.}$

**u**
Array, size ($ldu*m$).
If $jobu = 'U'$, $u$ contains the orthogonal/unitary matrix $U$.
If $jobu = 'N'$, $u$ is not referenced.

**v**
Array, size ($ldv*p$).
If $jobv = 'V'$, $v$ contains the orthogonal/unitary matrix $V$.
If $jobv = 'N'$, $v$ is not referenced.

**q**
Array, size ($ldq*n$).
If $jobq = 'Q'$, $q$ contains the orthogonal/unitary matrix $Q$.
If $jobq = 'N'$, $q$ is not referenced.

Return Values
This function returns a value $info$.

$= 0$: successful exit.
$< 0$: if $info = -i$, the $i$-th argument had an illegal value.

Application Notes

The subroutine uses LAPACK subroutine ?geqp3 for the QR factorization with column pivoting to detect the effective numerical rank of the $A$ matrix. It may be replaced by a better rank determination strategy.

?ggsvp3 replaces the deprecated subroutine ?ggsvp.

?ggsvd3
Computes generalized SVD.

Include Files
• mkl.h

Description
?ggsvd3 computes the generalized singular value decomposition (GSVD) of an \( m \)-by-\( n \) real or complex matrix \( A \) and \( p \)-by-\( n \) real or complex matrix \( B \):
\[
U^T A Q = D_1 \begin{pmatrix} 0 & R \end{pmatrix}, \quad V^T B Q = D_2 \begin{pmatrix} 0 & R \end{pmatrix}
\]
for real flavors
or
\[
U^H A Q = D_1 \begin{pmatrix} 0 & R \end{pmatrix}, \quad V^H B Q = D_2 \begin{pmatrix} 0 & R \end{pmatrix}
\]
for complex flavors
where \( U, V \) and \( Q \) are orthogonal/unitary matrices.
Let \( k+l \) be the effective numerical rank of the matrix \((A^T B^T)^T\) for real flavors or the matrix \((A^H B^H)^H\) for complex flavors, then \( R \) is a \((k+l)\)-by-\((k+l)\) nonsingular upper triangular matrix, \( D_1 \) and \( D_2 \) are \( m \)-by-\((k+l)\) and \( p \)-by-\((k+l)\) "diagonal" matrices and of the following structures, respectively:

If \( m-k-l \geq 0 \),
\[
D_1 = \begin{pmatrix} k & l \\
K & L \\
\end{pmatrix}
\begin{pmatrix} I & 0 \\
0 & C \\
\end{pmatrix}
\begin{pmatrix} m-k-l & 0 \\
0 & 0 \\
\end{pmatrix}
\begin{pmatrix} k & l \\
K & L \\
\end{pmatrix}
\]
\[
D_2 = \begin{pmatrix} l & 0 \\
p-l & 0 \\
\end{pmatrix}
\begin{pmatrix} 0 & S \\
0 & 0 \\
\end{pmatrix}
\begin{pmatrix} 0 & R \\
0 & 0 \\
\end{pmatrix}
\begin{pmatrix} 0 & R \end{pmatrix}
\]
\[
= k \begin{pmatrix} 0 & R_{11} & R_{12} \\
0 & 0 & R_{22} \\
\end{pmatrix}
\]
where
\[
C = \text{diag}(\alpha(k+1), \ldots, \alpha(k+l)),
\]
\[
S = \text{diag}(\beta(k+1), \ldots, \beta(k+l)),
\]
\[
C^2 + S^2 = I.
\]
If \( m-k-l < 0 \),
\[ D_1 = \begin{bmatrix} \frac{k}{m-k} & \frac{k + l - m}{m-k} \\ \frac{1}{0} & C \end{bmatrix} \]

\[ D_2 = \begin{bmatrix} \frac{m - k}{k + l - m} & 0 & \frac{l}{m - k} \\ \frac{0}{0} & S \end{bmatrix} \]

\[
\begin{pmatrix} 0 \\ R \end{pmatrix} = \begin{bmatrix} k & 0 & R_{11} & R_{12} & R_{13} \\ m - k & 0 & R_{22} & R_{23} \\ k + l - m & 0 & 0 & R_{33} \end{bmatrix}
\]

where

\[ C = \text{diag}(\alpha(k + 1), \ldots, \alpha(m)), \]

\[ S = \text{diag}(\beta(k + 1), \ldots, \beta(m)), \]

\[ C^2 + S^2 = I. \]

The routine computes \( C, S, R, \) and optionally the orthogonal/unitary transformation matrices \( U, V \) and \( Q \).

In particular, if \( B \) is an \( n \)-by-\( n \) nonsingular matrix, then the GSVD of \( A \) and \( B \) implicitly gives the SVD of \( A^*\text{inv}(B) \):

\[ A^*\text{inv}(B) = U^*(D_1^*\text{inv}(D_2))*V^T \]

for real flavors

or

\[ A^*\text{inv}(B) = U^*(D_1^*\text{inv}(D_2))*V^H \]

for complex flavors.

If \((A^T,B^T)^T\) for real flavors or \((A^H,B^H)^H\) for complex flavors has orthonormal columns, then the GSVD of \( A \) and \( B \) is also equal to the CS decomposition of \( A \) and \( B \). Furthermore, the GSVD can be used to derive the solution of the eigenvalue problem:

\[ A^T*AX = \lambda^* B^T*BX \]

for real flavors

or

\[ A^H*AX = \lambda^* B^H*BX \]

for complex flavors.

In some literature, the GSVD of \( A \) and \( B \) is presented in the form

\[ U^*A*X = (0 \ D_1), \ V^*B*X = (0 \ D_2) \]

for real \((A, B)\)

or

\[ U^H*A*X = (0 \ D_1), \ V^H*B*X = (0 \ D_2) \]

for complex \((A, B)\)

where \( U \) and \( V \) are orthogonal and \( X \) is nonsingular, \( D_1 \) and \( D_2 \) are "diagonal". The former GSVD form can be converted to the latter form by taking the nonsingular matrix \( X \) as

\[ X = Q* \begin{bmatrix} I & 0 \\ 0 & \text{inv}(R) \end{bmatrix} \]

**Input Parameters**

- **matrix_layout**: Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **jobu**:
  - = ‘U’: Orthogonal/unitary matrix \( U \) is computed;
  - = ‘N’: \( U \) is not computed.
jobv
= 'V': Orthogonal/unitary matrix V is computed;
= 'N': V is not computed.

jobq
= 'Q': Orthogonal/unitary matrix Q is computed;
= 'N': Q is not computed.

m
The number of rows of the matrix A.
\( m \geq 0 \).

n
The number of columns of the matrices A and B.
\( n \geq 0 \).

p
The number of rows of the matrix B.
\( p \geq 0 \).

a
Array, size \((lda*n)\).
On entry, the \( m \)-by-\( n \) matrix A.

lda
The leading dimension of the array a.
\( lda \geq \max(1,m) \).

b
Array, size \((ldb*n)\).
On entry, the \( p \)-by-\( n \) matrix B.

ldb
The leading dimension of the array b.
\( ldb \geq \max(1,p) \).

ldu
The leading dimension of the array u.
\( ldu \geq \max(1,m) \) if jobu = 'U'; \( ldu \geq 1 \) otherwise.

ldv
The leading dimension of the array v.
\( ldv \geq \max(1,p) \) if jobv = 'V'; \( ldv \geq 1 \) otherwise.

ldq
The leading dimension of the array q.
\( ldq \geq \max(1,n) \) if jobq = 'Q'; \( ldq \geq 1 \) otherwise.

iwork
Array, size \((n)\).

Output Parameters

k, l
On exit, \( k \) and \( l \) specify the dimension of the subblocks described in the Description section.
\[ k + l \text{ is effective numerical rank of } (A^T,B^T)^T \text{ for real flavors or } (A^H,B^H)^H \text{ for complex flavors}. \]

a
On exit, \( a \) contains the triangular matrix \( R \), or part of \( R \).
If \( m-k-l \geq 0 \), \( R \) is stored in the elements of array \( a \) corresponding to \( A_1: \\
\phantom{=} k + l,n - k - l + 1:n. \]
If \( m - k - l < 0 \), \[
\begin{bmatrix}
R_{11} & R_{12} & R_{13} \\
0 & R_{22} & R_{23}
\end{bmatrix}
\] is stored in the elements of array \( a \) corresponding to \( A(1:m, n - k - l + 1:n) \), and \( R_{33} \) is stored in the elements of array \( a \) corresponding to \( A(m - k + 1:1, n + m - k - l + 1:n) \) on exit.

On exit, \( b \) contains part of the triangular matrix \( R \) if \( m - k - l < 0 \). See Description for details.

- **alpha**: Array, size \((n)\)
  
  On exit, \( \alpha \) and \( \beta \) contain the generalized singular value pairs of \( a \) and \( b \):
  
  \[
  \alpha[0: k - 1] = 1, \\
  \beta[0: k - 1] = 0,
  \]
  
  and if \( m - k - l \geq 0 \),
  
  \[
  \alpha[k:k + l - 1] = C, \\
  \beta[k:k + l - 1] = S,
  \]
  
  or if \( m - k - l < 0 \),
  
  \[
  \alpha[k:m - 1] = C, \alpha[m: k + l - 1] = 0 \\
  \beta[k: m - 1] = S, \beta[m: k + l - 1] = 1
  \]
  
  and
  
  \[
  \alpha[k + l: n - 1] = 0 \\
  \beta[k + l : n - 1] = 0
  \]

- **u**: Array, size \((ldu*m)\).
  
  If \( jobu = 'U' \), \( u \) contains the \( m \)-by-\( m \) orthogonal/unitary matrix \( U \).
  If \( jobu = 'N' \), \( u \) is not referenced.

- **v**: Array, size \((ldv*p)\).
  
  If \( jobv = 'V' \), \( v \) contains the \( p \)-by-\( p \) orthogonal/unitary matrix \( V \).
  If \( jobv = 'N' \), \( v \) is not referenced.

- **q**: Array, size \((ldq*n)\).
  
  If \( jobq = 'Q' \), \( q \) contains the \( n \)-by-\( n \) orthogonal/unitary matrix \( Q \).
  If \( jobq = 'N' \), \( q \) is not referenced.

- **iwork**: On exit, \( iwork \) stores the sorting information. More precisely, the following loop uses \( iwork \) to sort \( \alpha \):
  
  ```
  for (i = k; i<min(m,k+l); i++) {
      swap (alpha[i], alpha[iwork[i] - 1]);
  }
  ```

  such that \( \alpha[0] \geq \alpha[1] \geq ... \geq \alpha[n-1] \).
Return Values

This function returns a value info.

= 0: successful exit.
< 0: if info = -i, the i-th argument had an illegal value.
> 0: if info = 1, the Jacobi-type procedure failed to converge.

For further details, see subroutine ?tgsja.

Application Notes

?ggsvd3 replaces the deprecated subroutine ?gsvd.

?tgsja

Computes the generalized SVD of two upper triangular or trapezoidal matrices.

Include Files

• mkl.h

Description

The routine computes the generalized singular value decomposition (GSVD) of two real/complex upper triangular (or trapezoidal) matrices A and B. On entry, it is assumed that matrices A and B have the following forms, which may be obtained by the preprocessing subroutine ggsvp from a general m-by-n matrix A and p-by-n matrix B:
where the \( k \)-by-\( k \) matrix \( A_{12} \) and \( l \)-by-\( l \) matrix \( B_{13} \) are nonsingular upper triangular; \( A_{23} \) is \( l \)-by-\( l \) upper triangular if \( m-k-l \geq 0 \), otherwise \( A_{23} \) is \((m-k)\)-by-\( l \) upper trapezoidal.

On exit,
\[
U^*A^*Q = D_1^*(0 R), \quad V^*B^*Q = D_2^*(0 R),
\]
where \( U, V \) and \( Q \) are orthogonal/unitary matrices, \( R \) is a nonsingular upper triangular matrix, and \( D_1 \) and \( D_2 \) are "diagonal" matrices, which are of the following structures:

If \( m-k-l \geq 0 \),
\[
D_1 = \begin{pmatrix} k & l \\ \end{pmatrix}, \quad D_2 = \begin{pmatrix} 0 & S \\ \end{pmatrix}
\]

where
\[
C = \text{diag}(\alpha[k], \ldots, \alpha[k+l-1])
\]
\[
S = \text{diag}(\beta[k], \ldots, \beta[k+l-1])
\]
\[ C^2 + S^2 = I \]

\( R \) is stored in \( a(1:k+l, n-k-l+1:n) \) on exit.

If \( m-k-l < 0 \),

\[
\begin{bmatrix}
  k & m-k & k+1-m \\
  m-k & C & 0 \\
\end{bmatrix}
\]

\[
D_2 = \begin{bmatrix}
  m-k & S & 0 \\
  k+l-m & 0 & 0 \\
  p-l & 0 & 0 \\
\end{bmatrix}
\]

\[
(0 \ P) = \begin{bmatrix}
  k & 0 & R_{11} & R_{12} & R_{13} \\
  m-k & 0 & R_{22} & R_{23} \\
  k+l-m & 0 & 0 & 0 & R_{33} \\
\end{bmatrix}
\]

where

\[
C = \text{diag}(\alpha[k], \ldots, \alpha[m-1]),
\]

\[
S = \text{diag}(\beta[k], \ldots, \beta[m-1]),
\]

\[ C^2 + S^2 = I \]

\[
\begin{pmatrix}
  R_{11} & R_{12} & R_{13} \\
  0 & R_{22} & R_{23} \\
\end{pmatrix}
\]

On exit, \( (0 \ P) \) is stored in \( a(1:m, n-k-l+1:n) \) and \( R_{33} \) is stored in \( b(m-k+1:l, n+m-k-l+1:n) \).

The computation of the orthogonal/unitary transformation matrices \( U, V \) or \( Q \) is optional. These matrices may either be formed explicitly, or they may be postmultiplied into input matrices \( U_1, V_1, \) or \( Q_1 \).

**Input Parameters**

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **jobu**
  Must be 'U', 'I', or 'N'.
  - If \( \text{jobu} = 'U' \), \( u \) must contain an orthogonal/unitary matrix \( U_1 \) on entry.
  - If \( \text{jobu} = 'I' \), \( u \) is initialized to the unit matrix.
  - If \( \text{jobu} = 'N' \), \( u \) is not computed.

- **jobv**
  Must be 'V', 'I', or 'N'.
  - If \( \text{jobv} = 'V' \), \( v \) must contain an orthogonal/unitary matrix \( V_1 \) on entry.
  - If \( \text{jobv} = 'I' \), \( v \) is initialized to the unit matrix.
If \( \textit{jobv} = 'N' \), \( v \) is not computed.

\textbf{jobq}

Must be 'Q', 'I', or 'N'.

If \( \textit{jobq} = 'Q' \), \( q \) must contain an orthogonal/unitary matrix \( Q_1 \) on entry.

If \( \textit{jobq} = 'I' \), \( q \) is initialized to the unit matrix.

If \( \textit{jobq} = 'N' \), \( q \) is not computed.

\textbf{m}

The number of rows of the matrix \( A \) (\( m \geq 0 \)).

\textbf{p}

The number of rows of the matrix \( B \) (\( p \geq 0 \)).

\textbf{n}

The number of columns of the matrices \( A \) and \( B \) (\( n \geq 0 \)).

\textbf{k, l}

Specify the subblocks in the input matrices \( A \) and \( B \), whose GSVD is computed.

\textbf{a, b, u, v, q}

Arrays:

\( a \) (size at least \( \max(1, \text{lda} \times n) \) for column major layout and \( \max(1, \text{lda} \times m) \) for row major layout) contains the \( m \)-by-\( n \) matrix \( A \).

\( b \) (size at least \( \max(1, \text{ldb} \times n) \) for column major layout and \( \max(1, \text{ldb} \times p) \) for row major layout) contains the \( p \)-by-\( n \) matrix \( B \).

If \( \textit{jobu} = 'U' \), \( u \) (size \( \max(1, \text{ldu} \times m) \)) must contain a matrix \( U_1 \) (usually the orthogonal/unitary matrix returned by \(?\text{ggsvp}\)).

If \( \textit{jobv} = 'V' \), \( v \) (size \( \max(1, \text{ldv} \times p) \)) must contain a matrix \( V_1 \) (usually the orthogonal/unitary matrix returned by \(?\text{ggsvp}\)).

If \( \textit{jobq} = 'Q' \), \( q \) (size \( \max(1, \text{ldq} \times n) \)) must contain a matrix \( Q_1 \) (usually the orthogonal/unitary matrix returned by \(?\text{ggsvp}\)).

\textbf{lda}

The leading dimension of \( a \); at least \( \max(1, \text{i} \times m) \) for column major layout and \( \max(1, \text{i} \times n) \) for row major layout.

\textbf{ldb}

The leading dimension of \( b \); at least \( \max(1, \text{i} \times p) \) for column major layout and \( \max(1, \text{i} \times n) \) for row major layout.

\textbf{ldu}

The leading dimension of the array \( u \).

\( \text{ldu} \geq \max(1, \text{i}) \) if \( \textit{jobu} = 'U'; \text{ldu} \geq 1 \) otherwise.

\textbf{ldv}

The leading dimension of the array \( v \).

\( \text{ldv} \geq \max(1, \text{i}) \) if \( \textit{jobv} = 'V'; \text{ldv} \geq 1 \) otherwise.

\textbf{ldq}

The leading dimension of the array \( q \).

\( \text{ldq} \geq \max(1, \text{i}) \) if \( \textit{jobq} = 'Q'; \text{ldq} \geq 1 \) otherwise.

\textbf{tola, tolb}

tola and tolb are the convergence criteria for the Jacobi-Kogbetliantz iteration procedure. Generally, they are the same as used in \(?\text{ggsvp}\):

\( \text{tola} = \max(\text{m}, \text{n}) \times |A| \times \text{MACHEPS}, \)

\( \text{tolb} = \max(\text{p}, \text{n}) \times |B| \times \text{MACHEPS}. \)
Output Parameters

\( a \)

On exit, \( a(n-k+1:n, 1:\min(k+l, m)) \) contains the triangular matrix \( R \) or part of \( R \).

\( b \)

On exit, if necessary, \( b(m-k+1: l, n+m-k-l+1: n) \) contains a part of \( R \).

\( \alpha, \beta \)

Arrays, size at least \( \max(1,n) \). Contain the generalized singular value pairs of \( A \) and \( B \):

\[
\alpha(1:k) = 1, \\
\beta(1:k) = 0, \\
\text{and if } m-k-l \geq 0, \\
\alpha(k+1:k+l) = \text{diag}(C), \\
\beta(k+1:k+l) = \text{diag}(S), \\
or if m-k-l < 0, \\
\alpha(k+1:m) = \text{diag}(C), \alpha(m+1:k+l) = 0 \\
\beta(k+1:m) = \text{diag}(S), \\
\beta(m+1:k+l) = 1.
\]

Furthermore, if \( k+l < n \),

\[
\alpha(k+l+1:n) = 0 \text{ and} \\
\beta(k+l+1:n) = 0.
\]

\( u \)

If \( \text{jobu} = 'I' \), \( u \) contains the orthogonal/unitary matrix \( U \).

If \( \text{jobu} = 'U' \), \( u \) contains the product \( U_1 * U \).

If \( \text{jobu} = 'N' \), \( u \) is not referenced.

\( v \)

If \( \text{jobv} = 'I' \), \( v \) contains the orthogonal/unitary matrix \( U \).

If \( \text{jobv} = 'V' \), \( v \) contains the product \( V_1 * V \).

If \( \text{jobv} = 'N' \), \( v \) is not referenced.

\( q \)

If \( \text{jobq} = 'I' \), \( q \) contains the orthogonal/unitary matrix \( U \).

If \( \text{jobq} = 'Q' \), \( q \) contains the product \( Q_1 * Q \).

If \( \text{jobq} = 'N' \), \( q \) is not referenced.

\( ncycle \)

The number of cycles required for convergence.

Return Values

This function returns a value \( \text{info} \).

If \( \text{info} = 0 \), the execution is successful.

If \( \text{info} = -i \), the \( i \)-th parameter had an illegal value.

If \( \text{info} = 1 \), the procedure does not converge after \( \text{MAXIT} \) cycles.
Cosine-Sine Decomposition: LAPACK Computational Routines

This section describes LAPACK computational routines for computing the *cosine-sine decomposition* (CS decomposition) of a partitioned unitary/orthogonal matrix. The algorithm computes a complete 2-by-2 CS decomposition, which requires simultaneous diagonalization of all the four blocks of a unitary/orthogonal matrix partitioned into a 2-by-2 block structure.

The computation has the following phases:

1. The matrix is reduced to a bidiagonal block form.
2. The blocks are simultaneously diagonalized using techniques from the bidiagonal SVD algorithms.

Table "Computational Routines for Cosine-Sine Decomposition (CSD)" lists LAPACK routines that perform CS decomposition of matrices.

S & | & C & 0 & 0 \\
0 & 0 & 0 & I \\
\end{pmatrix} \begin{pmatrix}
    v_1 \\
v_2 \\
\end{pmatrix}^H
\]

respectively.

\( x \) is \( m \)-by-\( m \) with the top-left block \( p \)-by-\( q \). Note that \( q \) must not be larger than \( p, m-p, \) or \( m-q \). If \( q \) is not the smallest index, \( x \) must be transposed and/or permuted in constant time using the \( \text{trans} \) option. See ?orcsd/?uncsd for details.

The bidiagonal matrices \( b_{11}, b_{12}, b_{21}, \) and \( b_{22} \) are represented implicitly by angles \( \text{theta}(1:q) \) and \( \text{phi}(1:q-1) \).

The orthogonal/unitary matrices \( u_1, u_2, v_{1t}, \) and \( v_{2t} \) are input/output. The input matrices are pre- or post-multiplied by the appropriate singular vector matrices.

Input Parameters

\text{matrix\_layout} \hspace{2cm} \text{Specifies whether matrix storage layout is row major (LAPACK\_ROW\_MAJOR) or column major (LAPACK\_COL\_MAJOR).}

\text{jobu1} \hspace{2cm} \text{If equals Y, then } u_1 \text{ is updated. Otherwise, } u_1 \text{ is not updated.}

\text{jobu2} \hspace{2cm} \text{If equals Y, then } u_2 \text{ is updated. Otherwise, } u_2 \text{ is not updated.}

\text{jobv1t} \hspace{2cm} \text{If equals Y, then } v_{1t} \text{ is updated. Otherwise, } v_{1t} \text{ is not updated.}

\text{jobv2t} \hspace{2cm} \text{If equals Y, then } v_{2t} \text{ is updated. Otherwise, } v_{2t} \text{ is not updated.}

\text{trans} \hspace{2cm} \text{If } \text{trans} = 'T', \text{ then } x, u_1, u_2, v_{1t}, v_{2t} \text{ are stored in row-major order. Otherwise, } x, u_1, u_2, v_{1t}, v_{2t} \text{ are stored in column-major order.}

\text{m} \hspace{2cm} \text{The number of rows and columns of the orthogonal/unitary matrix } X \text{ in bidiagonal-block form.}
p

The number of rows in the top-left block of \( x \). \( 0 \leq p \leq m \).

q

The number of columns in the top-left block of \( x \). \( 0 \leq q \leq \min(p, m-p, m-q) \).

theta

Array, size \( q \).

On entry, the angles \( \theta[0], ..., \theta[q-1] \) that, along with \( \phi[0], ..., \phi[q-2] \), define the matrix in bidiagonal-block form as returned by ordbdb/unbdb.

phi

Array, size \( q-1 \).

The angles \( \phi[0], ..., \phi[q-2] \) that, along with \( \theta[0], ..., \theta[q-1] \), define the matrix in bidiagonal-block form as returned by ordbdb/unbdb.

u1

Array, size at least \( \max(1, ldu1 \times p) \).

On entry, a \( p \times p \) matrix.

ldu1

The leading dimension of the array \( u_1 \), \( ldu1 \leq \max(1, p) \).

u2

Array, size \( \max(1, ldu2 \times (m-p)) \).

On entry, an \( (m-p) \times (m-p) \) matrix.

ldu2

The leading dimension of the array \( u_2 \), \( ldu2 \leq \max(1, m-p) \).

v1t

Array, size \( \max(1, ldv1t \times q) \).

On entry, a \( q \times q \) matrix.

ldv1t

The leading dimension of the array \( v_{1t} \), \( ldv1t \leq \max(1, q) \).

v2t

Array, size.

On entry, an \( (m-q) \times (m-q) \) matrix.

ldv2t

The leading dimension of the array \( v_{2t} \), \( ldv2t \leq \max(1, m-q) \).

Output Parameters

theta

On exit, the angles whose cosines and sines define the diagonal blocks in the CS decomposition.

u1

On exit, \( u_1 \) is postmultiplied by the left singular vector matrix common to \([ \begin{bmatrix} b_{11} & 0 \end{bmatrix} \]) and \([ \begin{bmatrix} b_{12} & 0 & 0 \end{bmatrix} ; 0 & -I & 0 \] \).

u2

On exit, \( u_2 \) is postmultiplied by the left singular vector matrix common to \([ \begin{bmatrix} b_{21} & 0 \end{bmatrix} \]) and \([ \begin{bmatrix} b_{22} & 0 & 0 \end{bmatrix} ; 0 & 0 & I \] \).

v1t

Array, size \( q \).

On exit, \( v_{1t} \) is premultiplied by the transpose of the right singular vector matrix common to \([ \begin{bmatrix} 0 \end{bmatrix} ] \) and \([ \begin{bmatrix} b_{11} \end{bmatrix} ; 0 \] \).

v2t

On exit, \( v_{2t} \) is premultiplied by the transpose of the right singular vector matrix common to \([ \begin{bmatrix} b_{12} & 0 & 0 \end{bmatrix} ; 0 & -I & 0 \] \) and \([ \begin{bmatrix} b_{22} & 0 & 0 \end{bmatrix} ; 0 & 0 & I \] \).

b11d

Array, size \( q \).
When \( \text{bbcsd} \) converges, \( b11d \) contains the cosines of \( \theta[0], \ldots, \theta[q-1] \). If \( \text{bbcsd} \) fails to converge, \( b11d \) contains the diagonal of the partially reduced top left block.

\( b11e \)
Array, size \( q-1 \).
When \( \text{bbcsd} \) converges, \( b11e \) contains zeros. If \( \text{bbcsd} \) fails to converge, \( b11e \) contains the superdiagonal of the partially reduced top left block.

\( b12d \)
Array, size \( q \).
When \( \text{bbcsd} \) converges, \( b12d \) contains the negative sines of \( \theta[0], \ldots, \theta[q-1] \). If \( \text{bbcsd} \) fails to converge, \( b12d \) contains the diagonal of the partially reduced top right block.

\( b12e \)
Array, size \( q-1 \).
When \( \text{bbcsd} \) converges, \( b12e \) contains zeros. If \( \text{bbcsd} \) fails to converge, \( b12e \) contains the superdiagonal of the partially reduced top right block.

**Return Values**

This function returns a value \( \text{info} \).

- If \( \text{info}=0 \), the execution is successful.
- If \( \text{info} = -i \), the \( i \)-th parameter had an illegal value.
- If \( \text{info} > 0 \) and if \( \text{bbcsd} \) did not converge, \( \text{info} \) specifies the number of nonzero entries in \( \phi \), and \( b11d, b11e, \) etc. contain the partially reduced matrix.

Description
The routines ?orbdb/?unbdb simultaneously bidiagonalizes the blocks of an m-by-m partitioned orthogonal
matrix $X$:

$$X = \begin{pmatrix} x_{11} & x_{12} \\ x_{21} & x_{22} \end{pmatrix} = \begin{pmatrix} p_1 & | \\ | & p_2 \end{pmatrix} \begin{pmatrix} b_{11} | b_{12} & 0 & 0 \\ 0 & 0 & -I & 0 \\ b_{21} | b_{22} & 0 & 0 \\ 0 & 0 & 0 & I \end{pmatrix} \begin{pmatrix} q_1 & | \\ | & q_2 \end{pmatrix}^T$$

or unitary matrix:

$$X = \begin{pmatrix} x_{11} & x_{12} \\ x_{21} & x_{22} \end{pmatrix} = \begin{pmatrix} p_1 & | \\ | & p_2 \end{pmatrix} \begin{pmatrix} b_{11} | b_{12} & 0 & 0 \\ 0 & 0 & -I & 0 \\ b_{21} | b_{22} & 0 & 0 \\ 0 & 0 & 0 & I \end{pmatrix} \begin{pmatrix} q_1 & | \\ | & q_2 \end{pmatrix}^H$$

$x_{11}$ is p-by-q. $q$ must not be larger than $p$, $m-p$, or $m-q$. Otherwise, $X$ must be transposed and/or permuted
in constant time using the trans and signs options.

The orthogonal/unitary matrices $p_1, p_2, q_1$, and $q_2$ are p-by-p, (m-p)-by-(m-p), q-by-q, (m-q)-by-(m-q),
respectively. They are represented implicitly by Housholder vectors.

The bidiagonal matrices $b_{11}, b_{12}, b_{21}$, and $b_{22}$ are q-by-q bidiagonal matrices represented implicitly by angles
$\text{theta}[0], \ldots, \text{theta}[\text{q}-1]$ and $\text{phi}[0], \ldots, \text{phi}[\text{q}-2]$. $b_{11}$ and $b_{12}$ are upper bidiagonal, while $b_{21}$ and
$b_{22}$ are lower bidiagonal. Every entry in each bidiagonal band is a product of a sine or cosine of $\text{theta}$ with a
sine or cosine of $\phi$. See [Sutton09] for details.

$p_1, p_2, q_1$, and $q_2$ are represented as products of elementary reflectors.

Input Parameters

`matrix_layout` 
Specifies whether matrix storage layout is row major (`LAPACK_ROW_MAJOR`) or column major (`LAPACK_COL_MAJOR`).

`trans` 
= 'T': $X, u_1, u_2, v_1^t, v_2^t$ are stored in row-major order.
otherwise $X, u_1, u_2, v_1^t, v_2^t$ are stored in column-major order.

`signs` 
= 'O': The lower-left block is made nonpositive (the "other" convention).
otherwise The upper-right block is made nonpositive (the "default" convention).
m

The number of rows and columns of the matrix X.

p

The number of rows in x_{11} and x_{12}. \( 0 \leq p \leq m \).

q

The number of columns in x_{11} and x_{21}. \( 0 \leq q \leq \min(p, m-p, m-q) \).

x_{11}

Array, size (size \( \max(1, ldx_{11} \times q) \) for column major layout and \( \max(1, ldx_{11} \times p) \) for row major layout).

On entry, the top-left block of the orthogonal/unitary matrix to be reduced.

ldx_{11}

The leading dimension of the array X_{11}. If \( \text{trans} = 'T' \), \( ldx_{11} \geq p \) for column major layout and \( ldx_{11} \geq q \) for row major layout. Otherwise, \( ldx_{11} \geq q \).

x_{12}

Array, size (size \( \max(1, ldx_{12} \times (m-q)) \) for column major layout and \( \max(1, ldx_{12} \times p) \) for row major layout).

On entry, the top-right block of the orthogonal/unitary matrix to be reduced.

ldx_{12}

The leading dimension of the array X_{12}. If \( \text{trans} = 'N' \), \( ldx_{12} \geq p \) for column major layout and \( ldx_{12} \geq m-q \) for row major layout. Otherwise, \( ldx_{12} \geq m-q \).

x_{21}

Array, size (size \( \max(1, ldx_{21} \times q) \) for column major layout and \( \max(1, ldx_{21} \times (m-p)) \) for row major layout).

On entry, the bottom-left block of the orthogonal/unitary matrix to be reduced.

ldx_{21}

The leading dimension of the array X_{21}. If \( \text{trans} = 'N' \), \( ldx_{21} \geq m-p \) for column major layout and \( ldx_{21} \geq q \) for row major layout. Otherwise, \( ldx_{21} \geq q \).

x_{22}

Array, size (size \( \max(1, ldx_{22} \times (m-q)) \) for column major layout and \( \max(1, ldx_{22} \times (m-p)) \) for row major layout).

On entry, the bottom-right block of the orthogonal/unitary matrix to be reduced.

ldx_{22}

The leading dimension of the array X_{22}. If \( \text{trans} = 'N' \), \( ldx_{22} \geq m-p \) for column major layout and \( ldx_{22} \geq m-q \) for row major layout. Otherwise, \( ldx_{22} \geq m-q \).

**Output Parameters**

x_{11}

On exit, the form depends on \( \text{trans} \): 

If \( \text{trans}= 'N' \), 
the columns of the lower triangle of x_{11} specify reflectors for p_{1}, the rows of the upper triangle of x_{11}(1:q - 1, q:q - 1) specify reflectors for q_{1}

otherwise

\( \text{trans}= 'T' \),
the rows of the upper triangle of x_{11} specify reflectors for p_{1}, the columns of the lower triangle of x_{11}(1:q - 1, q:q - 1) specify reflectors for q_{1}

x_{12}

On exit, the form depends on \( \text{trans} \):
If \( \text{trans}='N' \), the columns of the upper triangle of \( x_{12} \) specify the first \( p \) reflectors for \( q_2 \)

otherwise \( \text{trans}='T' \), the columns of the lower triangle of \( x_{12} \) specify the first \( p \) reflectors for \( q_2 \)

\( x_{21} \)

On exit, the form depends on \( \text{trans} \):

If \( \text{trans}='N' \), the columns of the lower triangle of \( x_{21} \) specify the reflectors for \( p_2 \)

otherwise \( \text{trans}='T' \), the columns of the upper triangle of \( x_{21} \) specify the reflectors for \( p_2 \)

\( x_{22} \)

On exit, the form depends on \( \text{trans} \):

If \( \text{trans}='N' \), the rows of the upper triangle of \( x_{22}(q+1:m-p,p+1:m-q) \) specify the last \( m-p-q \) reflectors for \( q_2 \)

otherwise \( \text{trans}='T' \), the columns of the lower triangle of \( x_{22}(p+1:m-q,q+1:m-p) \) specify the last \( m-p-q \) reflectors for \( p_2 \)

\( \theta \)

Array, size \( q \). The entries of bidiagonal blocks \( b_{11}, b_{12}, b_{21}, \) and \( b_{22} \) can be computed from the angles \( \theta \) and \( \phi \). See the Description section for details.

\( \phi \)

Array, size \( q-1 \). The entries of bidiagonal blocks \( b_{11}, b_{12}, b_{21}, \) and \( b_{22} \) can be computed from the angles \( \theta \) and \( \phi \). See the Description section for details.

\( \text{taup}_1 \)

Array, size \( p \).

Scalar factors of the elementary reflectors that define \( p_1 \).

\( \text{taup}_2 \)

Array, size \( m-p \).

Scalar factors of the elementary reflectors that define \( p_2 \).

\( \text{tauq}_1 \)

Array, size \( q \).

Scalar factors of the elementary reflectors that define \( q_1 \).

\( \text{tauq}_2 \)

Array, size \( m-q \).

Scalar factors of the elementary reflectors that define \( q_2 \).

Return Values

This function returns a value \( \text{info} \).

If \( \text{info}=0 \), the execution is successful.

If \( \text{info} = -i \), the \( i \)-th parameter had an illegal value.

LAPACK Least Squares and Eigenvalue Problem Driver Routines

Each of the LAPACK driver routines solves a complete problem. To arrive at the solution, driver routines typically call a sequence of appropriate computational routines.

Driver routines are described in the following sections:
Linear Least Squares (LLS) Problems
Generalized LLS Problems
Symmetric Eigenproblems
Nonsymmetric Eigenproblems
Singular Value Decomposition
Cosine-Sine Decomposition
Generalized Symmetric Definite Eigenproblems
Generalized Nonsymmetric Eigenproblems

Linear Least Squares (LLS) Problems: LAPACK Driver Routines

This section describes LAPACK driver routines used for solving linear least squares problems. Table "Driver Routines for Solving LLS Problems" lists all such routines.

?gels

Uses QR or LQ factorization to solve a overdetermined or underdetermined linear system with full rank matrix.

Syntax

```c
lapack_int LAPACKE_sgels (int matrix_layout, char trans, lapack_int m, lapack_int n, lapack_int nrhs, float* a, lapack_int lda, float* b, lapack_int ldb);

lapack_int LAPACKE_dgels (int matrix_layout, char trans, lapack_int m, lapack_int n, lapack_int nrhs, double* a, lapack_int lda, double* b, lapack_int ldb);

lapack_int LAPACKE_cgels (int matrix_layout, char trans, lapack_int m, lapack_int n, lapack_int nrhs, lapack_complex_float* a, lapack_int lda, lapack_complex_float* b, lapack_int ldb);

lapack_int LAPACKE_zgels (int matrix_layout, char trans, lapack_int m, lapack_int n, lapack_int nrhs, lapack_complex_double* a, lapack_int lda, lapack_complex_double* b, lapack_int ldb);
```
Include Files

- mkl.h

Description

The routine solves overdetermined or underdetermined real/complex linear systems involving an \( m\)-by-\( n\) matrix \( A \), or its transpose/conjugate-transpose, using a QR or LQ factorization of \( A \). It is assumed that \( A \) has full rank.

The following options are provided:

1. If \( \text{trans} = 'N' \) and \( m \geq n \): find the least squares solution of an overdetermined system, that is, solve the least squares problem
   \[
   \minimize \|b - A^*x\|_2
   \]
2. If \( \text{trans} = 'N' \) and \( m < n \): find the minimum norm solution of an underdetermined system \( A^*X = B \).
3. If \( \text{trans} = 'T' \) or \( 'C' \) and \( m \geq n \): find the minimum norm solution of an undetermined system \( A^H*X = B \).
4. If \( \text{trans} = 'T' \) or \( 'C' \) and \( m < n \): find the least squares solution of an overdetermined system, that is, solve the least squares problem
   \[
   \minimize \|b - A^Hx\|_2
   \]

Several right hand side vectors \( b \) and solution vectors \( x \) can be handled in a single call; they are formed by the columns of the right hand side matrix \( B \) and the solution matrix \( X \) (when coefficient matrix is \( A \), \( B \) is \( m\)-by-\( nrhs \) and \( X \) is \( n\)-by-\( nrhs \); if the coefficient matrix is \( A^T \) or \( A^H \), \( B \) is \( n\)-by-\( nrhs \) and \( X \) is \( m\)-by-\( nrhs \)).

Input Parameters

- \textit{matrix_layout} specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- \textit{trans} must be \('N'\), \('T'\), or \('C'\).
  - If \( \text{trans} = 'N' \), the linear system involves matrix \( A \);
  - If \( \text{trans} = 'T' \), the linear system involves the transposed matrix \( A^T \) (for real flavors only);
  - If \( \text{trans} = 'C' \), the linear system involves the conjugate-transposed matrix \( A^H \) (for complex flavors only).
- \textit{m} the number of rows of the matrix \( A \) (\( m \geq 0 \)).
- \textit{n} the number of columns of the matrix \( A \) (\( n \geq 0 \)).
- \textit{nrhs} the number of right-hand sides; the number of columns in \( B \) (\( nrhs \geq 0 \)).
- \textit{a, b} arrays:
  - \( a \) (size max(1, \( lda\)*\( n \)) for column major layout and max(1, \( lda\)*\( m \)) for row major layout) contains the \( m\)-by-\( n \) matrix \( A \).
  - \( b \) (size max(1, \( ldb\)*\( nrhs \)) for column major layout and max(1, \( ldb\)*max(\( m \), \( n \)) for row major layout) contains the matrix \( B \) of right hand side vectors.
- \textit{lda} the leading dimension of \( a \); at least max(1, \( m \)) for column major layout and at least max(1, \( n \)) for row major layout.
The leading dimension of $b$; must be at least \( \max(1, m, n) \) for column major layout if \( \text{trans} = \text{'N'} \) and at least \( \max(1, n) \) if \( \text{trans} = \text{'T'} \) and at least \( \max(1, \text{nrhs}) \) for row major layout regardless of the value of \( \text{trans} \).

Output Parameters

$a$

On exit, overwritten by the factorization data as follows:
- If \( m \geq n \), array \( a \) contains the details of the QR factorization of the matrix \( A \) as returned by \( \text{gesqr} \);
- If \( m < n \), array \( a \) contains the details of the LQ factorization of the matrix \( A \) as returned by \( \text{gelsq} \).

If \( \text{info} = 0 \), \( b \) overwritten by the solution vectors, stored columnwise:
- If \( \text{trans} = \text{'N'} \) and \( m \geq n \), rows 1 to \( n \) of \( b \) contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of modulus of elements \( n+1 \) to \( m \) in that column;
- If \( \text{trans} = \text{'N'} \) and \( m < n \), rows 1 to \( n \) of \( b \) contain the minimum norm solution vectors;
- If \( \text{trans} = \text{'T'} \) or \( \text{'C'} \) and \( m \geq n \), rows 1 to \( m \) of \( b \) contain the minimum norm solution vectors;
- If \( \text{trans} = \text{'T'} \) or \( \text{'C'} \) and \( m < n \), rows 1 to \( m \) of \( b \) contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of modulus of elements \( m+1 \) to \( n \) in that column.

Return Values

This function returns a value \( \text{info} \).
- If \( \text{info} = 0 \), the execution is successful.
- If \( \text{info} = -i \), the \( i \)-th parameter had an illegal value.
- If \( \text{info} = i \), the \( i \)-th diagonal element of the triangular factor of \( A \) is zero, so that \( A \) does not have full rank; the least squares solution could not be computed.

??gelsy

Computes the minimum-norm solution to a linear least squares problem using a complete orthogonal factorization of \( A \).

Syntax

For single precision:

```
lapack_int LAPACKE_sgelsy( int matrix_layout, lapack_int m, lapack_int n, lapack_int nrhs, float* a, lapack_int lda, float* b, lapack_int ldb, lapack_int* jpvt, float rcond, lapack_int* rank );
```

For double precision:

```
lapack_int LAPACKE_dgelsy( int matrix_layout, lapack_int m, lapack_int n, lapack_int nrhs, double* a, lapack_int lda, double* b, lapack_int ldb, lapack_int* jpvt, double rcond, lapack_int* rank );
```

For complex single precision:

```
lapack_int LAPACKE_cgelsy( int matrix_layout, lapack_int m, lapack_int n, lapack_int nrhs, lapack_complex_float* a, lapack_int lda, lapack_complex_float* b, lapack_int ldb, lapack_int* jpvt, float rcond, lapack_int* rank );
```
lapack_int LAPACKE_zgelsy( int matrix_layout, lapack_int m, lapack_int n, lapack_int nrhs, lapack_complex_double* a, lapack_int lda, lapack_complex_double* b, lapack_int ldb, lapack_int* jpvt, double rcond, lapack_int* rank );

**Include Files**
- mkl.h

**Description**
The ?gelsy routine computes the minimum-norm solution to a real/complex linear least squares problem:

\[
\text{minimize } \|b - Ax\|_2
\]

using a complete orthogonal factorization of \( A \). \( A \) is an \( m \)-by-\( n \) matrix which may be rank-deficient. Several right hand side vectors \( b \) and solution vectors \( x \) can be handled in a single call; they are stored as the columns of the \( m \)-by-\( nrhs \) right hand side matrix \( B \) and the \( n \)-by-\( nrhs \) solution matrix \( X \).

The routine first computes a \( QR \) factorization with column pivoting:

\[
AP = Q \begin{pmatrix} R_{11} & R_{12} \\ 0 & R_{22} \end{pmatrix}
\]

with \( R_{11} \) defined as the largest leading submatrix whose estimated condition number is less than \( 1/rcond \). The order of \( R_{11} \), \( \text{rank} \), is the effective rank of \( A \). Then, \( R_{22} \) is considered to be negligible, and \( R_{12} \) is annihilated by orthogonal/unitary transformations from the right, arriving at the complete orthogonal factorization:

\[
AP = Q \begin{pmatrix} T_{11} & 0 \\ 0 & 0 \end{pmatrix} Z
\]

The minimum-norm solution is then

\[
X = PZ^T \begin{pmatrix} T_{11}^{-1}Q_1^T B \\ 0 \end{pmatrix}
\]

for real flavors and

\[
X = PZ^H \begin{pmatrix} T_{11}^{-1}Q_1^H B \\ 0 \end{pmatrix}
\]

for complex flavors,

where \( Q_1 \) consists of the first \( \text{rank} \) columns of \( Q \).

The ?gelsy routine is identical to the original deprecated ?gelsx routine except for the following differences:
- The call to the subroutine ?geqpf has been substituted by the call to the subroutine ?geqp3, which is a BLAS-3 version of the \( QR \) factorization with column pivoting.
- The matrix \( B \) (the right hand side) is updated with BLAS-3.
- The permutation of the matrix \( B \) (the right hand side) is faster and more simple.

**Input Parameters**

*matrix_layout* Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
The number of rows of the matrix $A$ ($m \geq 0$).

The number of columns of the matrix $A$ ($n \geq 0$).

The number of right-hand sides; the number of columns in $B$ ($nrhs \geq 0$).

Arrays:

- $a$ (size $max(1, lda*n)$ for column major layout and $max(1, lda*m)$ for row major layout) contains the $m$-by-$n$ matrix $A$.
- $b$ (size $max(1, ldb*nrhs)$ for column major layout and $max(1, ldb*max(m, n))$ for row major layout) contains the $m$-by-$nrhs$ right hand side matrix $B$.

The leading dimension of $a$; at least $max(1, m)$ for column major layout and $max(1, n)$ for row major layout.

The leading dimension of $b$; must be at least $max(1, m, n)$ for column major layout and at least $max(1, nrhs)$ for row major layout.

Array, size at least $max(1, n)$.

On entry, if $jpvt[i - 1] \neq 0$, the $i$-th column of $A$ is permuted to the front of $AP$, otherwise the $i$-th column of $A$ is a free column.

$rcond$ is used to determine the effective rank of $A$, which is defined as the order of the largest leading triangular submatrix $R_{11}$ in the $QR$ factorization with pivoting of $A$, whose estimated condition number $< 1/rcond$.

Output Parameters

- $a$ On exit, overwritten by the details of the complete orthogonal factorization of $A$.
- $b$ Overwritten by the $n$-by-$nrhs$ solution matrix $X$.
- $jpvt$ On exit, if $jpvt[i - 1] = k$, then the $i$-th column of $AP$ was the $k$-th column of $A$.
- $rank$ The effective rank of $A$, that is, the order of the submatrix $R_{11}$. This is the same as the order of the submatrix $T_{11}$ in the complete orthogonal factorization of $A$.

Return Values

This function returns a value $info$.

If $info = 0$, the execution is successful.

If $info = -i$, the $i$-th parameter had an illegal value.

$\texttt{?gelss}$

Computes the minimum-norm solution to a linear least squares problem using the singular value decomposition of $A$. 
Syntax

```c
lapack_int LAPACKE_sgelss(int matrix_layout, lapack_int m, lapack_int n, lapack_int nrhs, float* a, lapack_int lda, float* b, lapack_int ldb, float* s, float rcond, lapack_int* rank);

lapack_int LAPACKE_dgelss(int matrix_layout, lapack_int m, lapack_int n, lapack_int nrhs, double* a, lapack_int lda, double* b, lapack_int ldb, double* s, double rcond, lapack_int* rank);

lapack_int LAPACKE_cgelss(int matrix_layout, lapack_int m, lapack_int n, lapack_int nrhs, lapack_complex_float* a, lapack_int lda, lapack_complex_float* b, lapack_int ldb, float* s, float rcond, lapack_int* rank);

lapack_int LAPACKE_zgelss(int matrix_layout, lapack_int m, lapack_int n, lapack_int nrhs, lapack_complex_double* a, lapack_int lda, lapack_complex_double* b, lapack_int ldb, double* s, double rcond, lapack_int* rank);
```

Include Files

- mkl.h

Description

The routine computes the minimum norm solution to a real linear least squares problem:

\[
\minimize_{x} ||b - Ax||_2
\]

using the singular value decomposition (SVD) of \(A\). \(A\) is an \(m\)-by-\(n\) matrix which may be rank-deficient. Several right hand side vectors \(b\) and solution vectors \(x\) can be handled in a single call; they are stored as the columns of the \(m\)-by-\(nrhs\) right hand side matrix \(B\) and the \(n\)-by-\(nrhs\) solution matrix \(X\). The effective rank of \(A\) is determined by treating as zero those singular values which are less than \(rcond\) times the largest singular value.

Input Parameters

- `matrix_layout` Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- `m` The number of rows of the matrix \(A\) \((m \geq 0)\).
- `n` The number of columns of the matrix \(A\) \((n \geq 0)\).
- `nrhs` The number of right-hand sides; the number of columns in \(B\) \((nrhs \geq 0)\).
- `a`, `b` Arrays:
  - \(a\)(size max(1, \(lda\)*\(n\)) for column major layout and max(1, \(lda\)*\(m\)) for row major layout) contains the \(m\)-by-\(n\) matrix \(A\).
  - \(b\)(size max(1, \(ldb\)*\(nrhs\)) for column major layout and max(1, \(ldb\)*max(\(m\), \(n\))) for row major layout) contains the \(m\)-by-\(nrhs\) right hand side matrix \(B\).
- `lda` The leading dimension of \(a\); at least max(1, \(m\)) for column major layout and max(1, \(n\)) for row major layout.
ldb

The leading dimension of b; must be at least max(1, m, n) for column major layout and at least max(1, nrhs) for row major layout.

rcond

$rcond$ is used to determine the effective rank of $A$. Singular values $s(i) < rcond * s(1)$ are treated as zero.

If $rcond < 0$, machine precision is used instead.

Output Parameters

$a$

On exit, the first min(m, n) rows of $a$ are overwritten with the matrix of right singular vectors of $A$, stored row-wise.

$b$

Overwritten by the $n$-by-$nrhs$ solution matrix $X$.

If $m \geq n$ and $rank = n$, the residual sum-of-squares for the solution in the $i$-th column is given by the sum of squares of modulus of elements $n+1:m$ in that column.

$s$

Array, size at least max(1, min(m, n)). The singular values of $A$ in decreasing order. The condition number of $A$ in the 2-norm is $k_2(A) = s(1) / s(\min(m, n))$.

$rank$

The effective rank of $A$, that is, the number of singular values which are greater than $rcond * s(1)$.

Return Values

This function returns a value $info$.

If $info=0$, the execution is successful.

If $info = -i$, the $i$-th parameter had an illegal value.

If $info = i$, then the algorithm for computing the SVD failed to converge; $i$ indicates the number of off-diagonal elements of an intermediate bidiagonal form which did not converge to zero.

$\texttt{gelsd}$

Computes the minimum-norm solution to a linear least squares problem using the singular value decomposition of $A$ and a divide and conquer method.

Syntax

```c
lapack_int LAPACKE_sgelsd( int matrix_layout, lapack_int m, lapack_int n, lapack_int nrhs, float* a, lapack_int lda, float* b, lapack_int ldb, float* s, float rcond, lapack_int* rank );

lapack_int LAPACKE_dgelsd( int matrix_layout, lapack_int m, lapack_int n, lapack_int nrhs, double* a, lapack_int lda, double* b, lapack_int ldb, double* s, double rcond, lapack_int* rank );

lapack_int LAPACKE_cgelsd( int matrix_layout, lapack_int m, lapack_int n, lapack_int nrhs, lapack_complex_float* a, lapack_int lda, lapack_complex_float* b, lapack_int ldb, float* s, float rcond, lapack_int* rank );

lapack_int LAPACKE_zgelsd( int matrix_layout, lapack_int m, lapack_int n, lapack_int nrhs, lapack_complex_double* a, lapack_int lda, lapack_complex_double* b, lapack_int ldb, double* s, double rcond, lapack_int* rank );
```
Include Files

- mkl.h

Description

The routine computes the minimum-norm solution to a real linear least squares problem:

$$\min_{x} ||b - A^*x||_2$$

using the singular value decomposition (SVD) of \(A\). \(A\) is an \(m\)-by-\(n\) matrix which may be rank-deficient.

Several right hand side vectors \(b\) and solution vectors \(x\) can be handled in a single call; they are stored as the columns of the \(m\)-by-\(nrhs\) right hand side matrix \(B\) and the \(n\)-by-\(nrhs\) solution matrix \(X\).

The problem is solved in three steps:

1. Reduce the coefficient matrix \(A\) to bidiagonal form with Householder transformations, reducing the original problem into a "bidiagonal least squares problem" (BLS).
2. Solve the BLS using a divide and conquer approach.
3. Apply back all the Householder transformations to solve the original least squares problem.

The effective rank of \(A\) is determined by treating as zero those singular values which are less than \(rcond\) times the largest singular value.

Input Parameters

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- **m**
  The number of rows of the matrix \(A\) \((m \geq 0)\).
- **n**
  The number of columns of the matrix \(A\) \((n \geq 0)\).
- **nrhs**
  The number of right-hand sides; the number of columns in \(B\) \((nrhs \geq 0)\).
- **a, b**
  Arrays:
  - \(a\) (size max(1, \(lda\)*\(n\)) for column major layout and max(1, \(lda\)*\(m\)) for row major layout) contains the \(m\)-by-\(n\) matrix \(A\).
  - \(b\) (size max(1, \(ldb\)*\(nrhs\)) for column major layout and max(1, \(ldb\)*max(\(m\), \(n\))) for row major layout) contains the \(m\)-by-\(nrhs\) right hand side matrix \(B\).
- **lda**
  The leading dimension of \(a\); at least max(1, \(m\)) for column major layout and max(1, \(n\)) for row major layout.
- **ldb**
  The leading dimension of \(b\); must be at least max(1, \(m\), \(n\)) for column major layout and at least max(1, \(nrhs\)) for row major layout.
- **rcond**
  \(rcond\) is used to determine the effective rank of \(A\). Singular values \(s(i) \leq rcond \cdot s(1)\) are treated as zero. If \(rcond \leq 0\), machine precision is used instead.

Output Parameters

- **a**
  On exit, \(A\) has been overwritten.
- **b**
  Overwritten by the \(n\)-by-\(nrhs\) solution matrix \(X\).
If $m \geq n$ and $\text{rank} = n$, the residual sum-of-squares for the solution in the $i$-th column is given by the sum of squares of modulus of elements $n+1:m$ in that column.

$s$

Array, size at least $\max(1, \min(m, n))$. The singular values of $A$ in decreasing order. The condition number of $A$ in the 2-norm is $k_2(A) = s(1) / s(\min(m, n))$.

$\text{rank}$

The effective rank of $A$, that is, the number of singular values which are greater than $rcond \times s(1)$.

**Return Values**

This function returns a value $\text{info}$.

If $\text{info}=0$, the execution is successful.

If $\text{info} = -i$, the $i$-th parameter had an illegal value.

If $\text{info} = i$, then the algorithm for computing the SVD failed to converge; $i$ indicates the number of off-diagonal elements of an intermediate bidiagonal form that did not converge to zero.

**Generalized Linear Least Squares (LLS) Problems: LAPACK Driver Routines**

lapack_complex_double* c, lapack_complex_double* d, lapack_complex_double* x);
```

**Include Files**

- mkl.h
Description

The routine solves the linear equality-constrained least squares (LSE) problem:

\[ \min \| c - A^*x \|^2 \quad \text{subject to} \quad B^*x = d \]

where \( A \) is an \( m \)-by-\( n \) matrix, \( B \) is a \( p \)-by-\( n \) matrix, \( c \) is a given \( m \)-vector, and \( d \) is a given \( p \)-vector. It is assumed that \( p \leq n \leq m + p \), and

\[ \text{rank}(B) = p \quad \text{and} \quad \text{rank} \left( \begin{bmatrix} A \\ B \end{bmatrix} \right) = n. \]

These conditions ensure that the LSE problem has a unique solution, which is obtained using a generalized RQ factorization of the matrices \((B, A)\) given by

\[ B = (0 \quad R)^*Q, \quad A = Z^*T^*Q \]

Input Parameters

- **matrix_layout**: Specifies whether matrix storage layout is row major (**LAPACK_ROW_MAJOR**) or column major (**LAPACK_COL_MAJOR**).
- **m**: The number of rows of the matrix \( A \) \((m \geq 0)\).
- **n**: The number of columns of the matrices \( A \) and \( B \) \((n \geq 0)\).
- **p**: The number of rows of the matrix \( B \)
  \((0 \leq p \leq n \leq m + p)\).
- **a**, **b**, **c**, **d**: Arrays:
  - \( a \) (size \( \text{max}(1, lda*n) \) for column major layout and \( \text{max}(1, lda*m) \) for row major layout) contains the \( m \)-by-\( n \) matrix \( A \).
  - \( b \) (size \( \text{max}(1, ldb*n) \) for column major layout and \( \text{max}(1, ldb*p) \) for row major layout) contains the \( p \)-by-\( n \) matrix \( B \).
  - \( c \) size at least \( \text{max}(1, m) \), contains the right hand side vector for the least squares part of the LSE problem.
  - \( d \), size at least \( \text{max}(1, p) \), contains the right hand side vector for the constrained equation.
- **lda**: The leading dimension of \( a \); at least \( \text{max}(1, m) \) for column major layout and \( \text{max}(1, n) \) for row major layout.
- **ldb**: The leading dimension of \( b \); at least \( \text{max}(1, p) \) for column major layout and \( \text{max}(1, n) \) for row major layout.

Output Parameters

- **a**: The elements on and above the diagonal contain the \( \text{min}(m, n) \)-by-\( n \) upper trapezoidal matrix \( T \) as returned by \( ?ggrqf \).
- **x**: The solution of the LSE problem.
- **b**: On exit, the upper right triangle contains the \( p \)-by-\( p \) upper triangular matrix \( R \) as returned by \( ?ggrqf \).
On exit, \( d \) is destroyed.

On exit, the residual sum-of-squares for the solution is given by the sum of squares of elements \( n-p+1 \) to \( m \) of vector \( c \).

**Return Values**

This function returns a value \( info \).

If \( info = 0 \), the execution is successful.

If \( info = -i \), the \( i \)-th parameter had an illegal value.

If \( info = 1 \), the upper triangular factor \( R \) associated with \( B \) in the generalized RQ factorization of the pair \((B, A)\) is singular, so that \( \text{rank}(B) < p \); the least squares solution could not be computed.

If \( info = 2 \), the \((n-p)\)-by-\((n-p)\) part of the upper trapezoidal factor \( T \) associated with \( A \) in the generalized RQ factorization of the pair \((B, A)\) is singular, so that 

\[
\text{rank} \begin{pmatrix} A \\ B \end{pmatrix} < n
\]

the least squares solution could not be computed.

**?ggglm**

Solves a general Gauss-Markov linear model problem using a generalized QR factorization.

**Syntax**

```c
lapack_int LAPACKE_sggglm (int matrix_layout, lapack_int n, lapack_int m, lapack_int p,
float* a, lapack_int lda, float* b, lapack_int ldb, float* d, float* x, float* y);

lapack_int LAPACKE_dggglm (int matrix_layout, lapack_int n, lapack_int m, lapack_int p,
double* a, lapack_int lda, double* b, lapack_int ldb, double* d, double* x, double* y);

lapack_int LAPACKE_cggglm (int matrix_layout, lapack_int n, lapack_int m, lapack_int p,
lapack_complex_float* a, lapack_int lda, lapack_complex_float* b, lapack_int ldb,
lapack_complex_float* d, lapack_complex_float* x, lapack_complex_float* y);

lapack_int LAPACKE_zggglm (int matrix_layout, lapack_int n, lapack_int m, lapack_int p,
lapack_complex_double* a, lapack_int lda, lapack_complex_double* b, lapack_int ldb,
lapack_complex_double* d, lapack_complex_double* x, lapack_complex_double* y);
```

**Include Files**

- mkl.h

**Description**

The routine solves a general Gauss-Markov linear model (GLM) problem:

\[
\text{minimize}_{x} ||y||_2 \text{ subject to } d = A*x + B*y
\]

where \( A \) is an \( n \)-by-\( m \) matrix, \( B \) is an \( n \)-by-\( p \) matrix, and \( d \) is a given \( n \)-vector. It is assumed that \( m \leq n \leq m + p \), and \( \text{rank}(A) = m \) and \( \text{rank}(AB) = n \).

Under these assumptions, the constrained equation is always consistent, and there is a unique solution \( x \) and a minimal 2-norm solution \( y \), which is obtained using a generalized QR factorization of the matrices \((A, B)\) given by
In particular, if matrix $B$ is square nonsingular, then the problem GLM is equivalent to the following weighted linear least squares problem

$$\minimize_x ||B^{-1}(d-A^*x)||_2.$$ 

**Input Parameters**

$matrix\_layout$  
Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

$n$  
The number of rows of the matrices $A$ and $B$ ($n \geq 0$).

$m$  
The number of columns in $A$ ($m \geq 0$).

$p$  
The number of columns in $B$ ($p \geq n - m$).

$a$, $b$, $d$  
Arrays:

- $a$ (size max(1, $lda*m$) for column major layout and max(1, $lda*n$) for row major layout) contains the $n$-by-$m$ matrix $A$.
- $b$ (size max(1, $ldb*p$) for column major layout and max(1, $ldb*n$) for row major layout) contains the $n$-by-$p$ matrix $B$.
- $d$, size at least max(1, $n$), contains the left hand side of the GLM equation.

$lda$  
The leading dimension of $a$; at least max(1, $n$) for column major layout and max(1, $m$) for row major layout.

$ldb$  
The leading dimension of $b$; at least max(1, $n$) for column major layout and max(1, $p$) for row major layout.

**Output Parameters**

$x$, $y$  
Arrays $x$, $y$. size at least max(1, $m$) for $x$ and at least max(1, $p$) for $y$.

On exit, $x$ and $y$ are the solutions of the GLM problem.

$a$  
On exit, the upper triangular part of the array $a$ contains the $m$-by-$m$ upper triangular matrix $R$.

$b$  
On exit, if $n \leq p$, the upper right triangle contains the $n$-by-$n$ upper triangular matrix $T$ as returned by ?ggrqf; if $n > p$, the elements on and above the ($n-p$)-th subdiagonal contain the $n$-by-$p$ upper trapezoidal matrix $T$.

$d$  
On exit, $d$ is destroyed

**Return Values**

This function returns a value $info$.

If $info=0$, the execution is successful.

If $info = -i$, the $i$-th parameter had an illegal value.
If $info = 1$, the upper triangular factor $R$ associated with $A$ in the generalized QR factorization of the pair $(A, B)$ is singular, so that $\text{rank}(A) < m$; the least squares solution could not be computed.

If $info = 2$, the bottom $(n-m)$-by-$(n-m)$ part of the upper trapezoidal factor $T$ associated with $B$ in the generalized QR factorization of the pair $(A, B)$ is singular, so that $\text{rank}(AB) < n$; the least squares solution could not be computed.

syev

*Computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix.*
Syntax

lapack_int LAPACKE_ssyev (int matrix_layout, char jobz, char uplo, lapack_int n, float* a, lapack_int lda, float* w);

lapack_int LAPACKE_dsyev (int matrix_layout, char jobz, char uplo, lapack_int n, double* a, lapack_int lda, double* w);

Include Files

• mkl.h

Description

The routine computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix A. Note that for most cases of real symmetric eigenvalue problems the default choice should be syevr function as its underlying algorithm is faster and uses less workspace.

Input Parameters

matrix_layout

Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

jobz

Must be 'N' or 'V'.

If jobz = 'N', then only eigenvalues are computed.

If jobz = 'V', then eigenvalues and eigenvectors are computed.

uplo

Must be 'U' or 'L'.

If uplo = 'U', a stores the upper triangular part of A.

If uplo = 'L', a stores the lower triangular part of A.

n

The order of the matrix A (n ≥ 0).

a

a (size max(1, lda*n)) is an array containing either upper or lower triangular part of the symmetric matrix A, as specified by uplo.

lda

The leading dimension of the array a.

Must be at least max(1, n).

Output Parameters

a

On exit, if jobz = 'V', then if info = 0, array a contains the orthonormal eigenvectors of the matrix A.

If jobz = 'N', then on exit the lower triangle (if uplo = 'L') or the upper triangle (if uplo = 'U') of A, including the diagonal, is overwritten.

w

Array, size at least max(1, n).

If info = 0, contains the eigenvalues of the matrix A in ascending order.

Return Values

This function returns a value info.
If info=0, the execution is successful.

If info = -i, the i-th parameter had an illegal value.

If info = i, then the algorithm failed to converge; i indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.

**heev**

*Computes all eigenvalues and, optionally, eigenvectors of a Hermitian matrix.*

**Syntax**

lapack_int LAPACKE_cheev( int matrix_layout, char jobz, char uplo, lapack_int n, lapack_complex_float* a, lapack_int lda, float* w);

lapack_int LAPACKE_zheev( int matrix_layout, char jobz, char uplo, lapack_int n, lapack_complex_double* a, lapack_int lda, double* w);

**Include Files**

- mkl.h

**Description**

Return Values
This function returns a value info.
If info=0, the execution is successful.
If info = -i, the i-th parameter had an illegal value.
If info = i, then the algorithm failed to converge; i indicates the number of elements of an intermediate
tridiagonal form which did not converge to zero.

?syevd
Computes all eigenvalues and, optionally, all
eigenvectors of a real symmetric matrix using divide
and conquer algorithm.

Syntax

lapack_int LAPACKE_ssyevd (int matrix_layout, char jobz, char uplo, lapack_int n,
float* a, lapack_int lda, float* w);

lapack_int LAPACKE_dsyevd (int matrix_layout, char jobz, char uplo, lapack_int n,
double* a, lapack_int lda, double* w);

Include Files
• mkl.h

Description
The routine computes all the eigenvalues, and optionally all the eigenvectors, of a real symmetric matrix A.
In other words, it can compute the spectral factorization of A as: A = Z*Λ*Z^T.

Here Λ is a diagonal matrix whose diagonal elements are the eigenvalues λ_i, and Z is the orthogonal matrix
whose columns are the eigenvectors z_i. Thus,
A*z_i = λ_i*z_i for i = 1, 2, ..., n.

If the eigenvectors are requested, then this routine uses a divide and conquer algorithm to compute
eigenvalues and eigenvectors. However, if only eigenvalues are required, then it uses the Pal-Walker-Kahan
variant of the QL or QR algorithm.

Note that for most cases of real symmetric eigenvalue problems the default choice should be syevr function
as its underlying algorithm is faster and uses less workspace. ?syevd requires more workspace but is faster
in some cases, especially for large matrices.

Input Parameters

matrix_layout
Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR)
or column major (LAPACK_COL_MAJOR).

jobz
Must be 'N' or 'V'.
If jobz = 'N', then only eigenvalues are computed.
If \( jobz = 'V' \), then eigenvalues and eigenvectors are computed.

**uplo**

Must be 'U' or 'L'.

If \( uplo = 'U' \), \( a \) stores the upper triangular part of \( A \).

If \( uplo = 'L' \), \( a \) stores the lower triangular part of \( A \).

**n**

The order of the matrix \( A \) (\( n \geq 0 \)).

**a**

Array, size (\( lda, * \)).

\( a \) (size max(1, \( lda*n \))) is an array containing either upper or lower triangular part of the symmetric matrix \( A \), as specified by \( uplo \).

**lda**

The leading dimension of the array \( a \).

Must be at least max(1, \( n \)).

**Output Parameters**

**w**

Array, size at least max(1, \( n \)).

If \( info = 0 \), contains the eigenvalues of the matrix \( A \) in ascending order. See also \( info \).

**a**

If \( jobz = 'V' \), then on exit this array is overwritten by the orthogonal matrix \( Z \) which contains the eigenvectors of \( A \).

**Return Values**

This function returns a value \( info \).

If \( info = 0 \), the execution is successful.

If \( info = i, and \ jobz = 'N' \), then the algorithm failed to converge; \( i \) indicates the number of off-diagonal elements of an intermediate tridiagonal form which did not converge to zero.

If \( info = i, and \ jobz = 'V' \), then the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns \( info/(n+1) \) through \( mod(info,n+1) \).

If \( info = -i \), the \( i \)-th parameter had an illegal value.

**Application Notes**

The computed eigenvalues and eigenvectors are exact for a matrix \( A+E \) such that \( ||E||_2 = O(\varepsilon) * ||A||_2 \), where \( \varepsilon \) is the machine precision.

The complex analogue of this routine is heevd?

heevd

Computes all eigenvalues and, optionally, all eigenvectors of a complex Hermitian matrix using divide and conquer algorithm.

**Syntax**

```c
lapack_int LAPACKE_cheevd( int matrix_layout, char jobz, char uplo, lapack_int n, lapack_complex_float* a, lapack_int lda, float* w );

lapack_int LAPACKE_zheevd( int matrix_layout, char jobz, char uplo, lapack_int n, lapack_complex_double* a, lapack_int lda, double* w );
```
Include Files

- mkl.h

Description

The routine computes all the eigenvalues, and optionally all the eigenvectors, of a complex Hermitian matrix $A$. In other words, it can compute the spectral factorization of $A$ as: $A = Z^* \Lambda Z^H$.

Here $\Lambda$ is a real diagonal matrix whose diagonal elements are the eigenvalues $\lambda_i$, and $Z$ is the (complex) unitary matrix whose columns are the eigenvectors $z_i$. Thus,

$$A^* z_i = \lambda_i z_i$$

for $i = 1, 2, \ldots, n$.

If the eigenvectors are requested, then this routine uses a divide and conquer algorithm to compute eigenvalues and eigenvectors. However, if only eigenvalues are required, then it uses the Pal-Walker-Kahan variant of the $QL$ or $QR$ algorithm.

Note that for most cases of complex Hermitian eigenvalue problems the default choice should be $heevr$ function as its underlying algorithm is faster and uses less workspace. $heevr$ requires more workspace but is faster in some cases, especially for large matrices.

Input Parameters

$matrix\_layout$  
Specifies whether matrix storage layout is row major ($LAPACK\_ROW\_MAJOR$) or column major ($LAPACK\_COL\_MAJOR$).

$jobz$  
Must be 'N' or 'V'.

If $jobz = 'N'$, then only eigenvalues are computed.

If $jobz = 'V'$, then eigenvalues and eigenvectors are computed.

$uplo$  
Must be 'U' or 'L'.

If $uplo = 'U'$, $a$ stores the upper triangular part of $A$.

If $uplo = 'L'$, $a$ stores the lower triangular part of $A$.

$n$  
The order of the matrix $A$ ($n \geq 0$).

$a$  
$a$ (size $\text{max}(1, lda \times n)$) is an array containing either upper or lower triangular part of the Hermitian matrix $A$, as specified by $uplo$.

$lda$  
The leading dimension of the array $a$. Must be at least $\text{max}(1, n)$.

Output Parameters

$w$  
Array, size at least $\text{max}(1, n)$.

If $info = 0$, contains the eigenvalues of the matrix $A$ in ascending order. See also $info$.

$a$  
If $jobz = 'V'$, then on exit this array is overwritten by the unitary matrix $Z$ which contains the eigenvectors of $A$.

Return Values

This function returns a value $info$.

If $info=0$, the execution is successful.
If $info = i$, and $jobz = 'N'$, then the algorithm failed to converge; $i$ off-diagonal elements of an intermediate tridiagonal form did not converge to zero;

if $info = i$, and $jobz = 'V'$, then the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns $info/(n+1)$ through $\text{mod}(info, n+1)$.

If $info = -i$, the $i$-th parameter had an illegal value.

**Application Notes**

The computed eigenvalues and eigenvectors are exact for a matrix $A + E$ such that $||E||_2 = O(e) ||A||_2$, where $e$ is the machine precision.

The real analogue of this routine is syevd. See also hpevd for matrices held in packed storage, and hbevd for banded matrices.

**?syevx**

*Computes selected eigenvalues and, optionally, eigenvectors of a symmetric matrix.*

**Syntax**

```c
lapack_int LAPACKE_ssyevx (int matrix_layout, char jobz, char range, char uplo,
lapack_int n, float* a, lapack_int lda, float vl, float vu, lapack_int il, lapack_int
iu, float abstol, lapack_int* m, float* w, float* z, lapack_int ldz, lapack_int* ifail);
```

```c
lapack_int LAPACKE_dsyevx (int matrix_layout, char jobz, char range, char uplo,
lapack_int n, double* a, lapack_int lda, double vl, double vu, lapack_int il, lapack_int
iu, double abstol, lapack_int* m, double* w, double* z, lapack_int ldz, lapack_int* ifail);
```

**Include Files**

- mkl.h

**Description**

The routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix $A$. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Note that for most cases of real symmetric eigenvalue problems the default choice should be syevr function as its underlying algorithm is faster and uses less workspace. ?syevx is faster for a few selected eigenvalues.

**Input Parameters**

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **jobz**
  Must be 'N' or 'V'.
  If $jobz = 'N'$, then only eigenvalues are computed.
  If $jobz = 'V'$, then eigenvalues and eigenvectors are computed.

- **range**
  Must be 'A', 'V', or 'I'.
  If $range = 'A'$, all eigenvalues will be found.
If \( \text{range} = 'V' \), all eigenvalues in the half-open interval \((vl, vu]\) will be found.

If \( \text{range} = 'I' \), the eigenvalues with indices \( il \) through \( iu \) will be found.

**uplo**

Must be 'U' or 'L'.

If \( uplo = 'U' \), \( a \) stores the upper triangular part of \( A \).

If \( uplo = 'L' \), \( a \) stores the lower triangular part of \( A \).

**n**

The order of the matrix \( A \) (\( n \geq 0 \)).

\( a \) (size \( \text{max}(1, \text{lda} \times n) \)) is an array containing either upper or lower triangular part of the symmetric matrix \( A \), as specified by \( uplo \).

**lda**

The leading dimension of the array \( a \). Must be at least \( \text{max}(1, n) \).

**vl, vu**

If \( \text{range} = 'V' \), the lower and upper bounds of the interval to be searched for eigenvalues; \( vl \leq vu \). Not referenced if \( \text{range} = 'A' \) or 'I'.

**il, iu**

If \( \text{range} = 'I' \), the indices of the smallest and largest eigenvalues to be returned.

Constraints: \( 1 \leq il \leq iu \leq n \), if \( n > 0 \);

\( il = 1 \) and \( iu = 0 \), if \( n = 0 \).

Not referenced if \( \text{range} = 'A' \) or 'V'.

**abstol**

The absolute error tolerance for the eigenvalues. See Application Notes for more information.

**ldz**

The leading dimension of the output array \( z \); \( ldz \geq 1 \).

If \( \text{jobz} = 'V' \), then \( ldz \geq \text{max}(1, n) \) for column major layout and \( ldz \geq \text{max}(1, m) \) for row major layout.

### Output Parameters

**a**

On exit, the lower triangle (if \( uplo = 'L' \)) or the upper triangle (if \( uplo = 'U' \)) of \( A \), including the diagonal, is overwritten.

The total number of eigenvalues found;

\( 0 \leq m \leq n \).

If \( \text{range} = 'A', m = n \), and if \( \text{range} = 'I', m = iu-il+1 \).

**w**

Array, size at least \( \text{max}(1, n) \). The first \( m \) elements contain the selected eigenvalues of the matrix \( A \) in ascending order.

**z**

Array \( z \)(size \( \text{max}(1, ldz \times m) \) for column major layout and \( \text{max}(1, ldz \times n) \) for row major layout) contains eigenvectors.

If \( \text{jobz} = 'V' \), then if \( info = 0 \), the first \( m \) columns of \( z \) contain the orthonormal eigenvectors of the matrix \( A \) corresponding to the selected eigenvalues, with the \( i \)-th column of \( z \) holding the eigenvector associated with \( w(i) \).
If an eigenvector fails to converge, then that column of $z$ contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in `ifail`.

If `jobz` = 'N', then $z$ is not referenced.

Note: you must ensure that at least max(1, $m$) columns are supplied in the array $z$; if `range` = 'V', the exact value of $m$ is not known in advance and an upper bound must be used.

`ifail` Array, size at least max(1, $n$).

If `jobz` = 'V', then if `info` = 0, the first $m$ elements of `ifail` are zero; if `info` > 0, then `ifail` contains the indices of the eigenvectors that failed to converge.

If `jobz` = 'V', then `ifail` is not referenced.

Return Values

This function returns a value `info`.

If `info`=0, the execution is successful.

If `info` = -i, the i-th parameter had an illegal value.

If `info` = i, then i eigenvectors failed to converge; their indices are stored in the array `ifail`.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to $\text{abstol} + \epsilon \max(|a|,|b|)$, where $\epsilon$ is the machine precision.

If $\text{abstol}$ is less than or equal to zero, then $\epsilon \cdot ||T||$ is used as tolerance, where $||T||$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form. Eigenvalues are computed most accurately when $\text{abstol}$ is set to twice the underflow threshold $2\cdot\text{lamch}(\text{\'S}')$, not zero.

If this routine returns with `info` > 0, indicating that some eigenvectors did not converge, try setting $\text{abstol}$ to $2\cdot\text{lamch}(\text{\'S}')$.

`heevx`

Computes selected eigenvalues and, optionally, eigenvectors of a Hermitian matrix.

Syntax

```c
lapack_int LAPACKE_cheevx( int matrix_layout, char jobz, char range, char uplo,
                      lapack_int n, lapack_complex_float* a, lapack_int lda, float vl, float vu, lapack_int il,
                      lapack_int iu, float abstol, lapack_int* m, float* w, lapack_complex_float* z,
                      lapack_int ldz, lapack_int* ifail );

lapack_int LAPACKE_zheevx( int matrix_layout, char jobz, char range, char uplo,
                      lapack_int n, lapack_complex_double* a, lapack_int lda, double vl, double vu,
                      lapack_int il, lapack_int iu, double abstol, lapack_int* m, double* w,
                      lapack_complex_double* z, lapack_int ldz, lapack_int* ifail );
```

Include Files

- mkl.h
Description

The routine computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix $A$. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Note that for most cases of complex Hermitian eigenvalue problems the default choice should be `heevr` function as its underlying algorithm is faster and uses less workspace. `?heevx` is faster for a few selected eigenvalues.

Input Parameters

- **matrix_layout**: Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **jobz**: Must be 'N' or 'V'.
  
  If `jobz` = 'N', then only eigenvalues are computed.
  
  If `jobz` = 'V', then eigenvalues and eigenvectors are computed.

- **range**: Must be 'A', 'V', or 'I'.
  
  If `range` = 'A', all eigenvalues will be found.
  
  If `range` = 'V', all eigenvalues in the half-open interval $(vl, vu]$ will be found.
  
  If `range` = 'I', the eigenvalues with indices $il$ through $iu$ will be found.

- **uplo**: Must be 'U' or 'L'.
  
  If `uplo` = 'U', $a$ stores the upper triangular part of $A$.
  
  If `uplo` = 'L', $a$ stores the lower triangular part of $A$.

- **n**: The order of the matrix $A$ ($n \geq 0$).

- **a**: ($\text{size max}(1, \text{lda} \times n)$) is an array containing either upper or lower triangular part of the Hermitian matrix $A$, as specified by `uplo`.

- **lda**: The leading dimension of the array $a$. Must be at least $\text{max}(1, n)$.

- **vl, vu**: If `range` = 'V', the lower and upper bounds of the interval to be searched for eigenvalues; $vl \leq vu$. Not referenced if `range` = 'A' or 'I'.

- **il, iu**: If `range` = 'I', the indices of the smallest and largest eigenvalues to be returned. Constraints:
  
  $1 \leq il \leq n$, if $n > 0$; $il = 1$ and $iu = 0$, if $n = 0$. Not referenced if `range` = 'A' or 'V'.

- **abstol**: The leading dimension of the output array $z$; $ldz \geq 1$.

- **ldz**: The leading dimension of the output array $z$; $ldz \geq 1$ for column major layout and $lda \geq \text{max}(1, m)$ for row major layout.
Output Parameters

- **a**: On exit, the lower triangle (if uplo = 'L') or the upper triangle (if uplo = 'U') of A, including the diagonal, is overwritten.

- **m**: The total number of eigenvalues found; 0 ≤ m ≤ n.
  If range = 'A', m = n, and if range = 'I', m = il - ii + 1.

- **w**: Array, size max(1, n). The first m elements contain the selected eigenvalues of the matrix A in ascending order.

- **z**: Array z(size max(1, ldz*m) for column major layout and max(1, ldz*n) for row major layout) contains eigenvectors.
  If jobz = 'V', then if info = 0, the first m columns of z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of z holding the eigenvector associated with w(i).
  If an eigenvector fails to converge, then that column of z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in ifail.
  If jobz = 'N', then z is not referenced.

- **ifail**: Array, size at least max(1, n).
  If jobz = 'V', then if info = 0, the first m elements of ifail are zero; if info > 0, then ifail contains the indices of the eigenvectors that failed to converge.
  If jobz = 'V', then ifail is not referenced.

Return Values

This function returns a value info.

- If info=0, the execution is successful.
- If info = -i, the i-th parameter had an illegal value.
- If info = i, then i eigenvectors failed to converge; their indices are stored in the array ifail.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to abstol+ε*max(|a|,|b|), where ε is the machine precision.

If abstol is less than or equal to zero, then ε*||T|| will be used in its place, where ||T|| is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form. Eigenvalues will be computed most accurately when abstol is set to twice the underflow threshold 2*?lamch('S'), not zero.

If this routine returns with info > 0, indicating that some eigenvectors did not converge, try setting abstol to 2*?lamch('S').

?syevr
Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix using the Relatively Robust Representations.
Syntax

```c
lapack_int LAPACKE_ssyevr (int matrix_layout, char jobz, char range, char uplo,
            lapack_int n, float* a, lapack_int lda, float vl, float vu, lapack_int il, lapack_int iu,

            lapack_int n, double* a, lapack_int lda, double vl, double vu, lapack_int il, lapack_int iu,
            double abstol, lapack_int* m, double* w, double* z, lapack_int ldz, lapack_int* isuppz);
```

Include Files

- mkl.h

Description

The routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix \(A\). Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

The routine first reduces the matrix \(A\) to tridiagonal form \(T\). Then, whenever possible, \(?syevr\) calls \(stemr\) to compute the eigenspectrum using Relatively Robust Representations. \(stemr\) computes eigenvalues by the \(dqds\) algorithm, while orthogonal eigenvectors are computed from various “good” \(L*D*L^T\) representations (also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows. For the each unreduced block of \(T\):

- \(a\). Compute \(T - \sigma I = L*D*L^T\), so that \(L\) and \(D\) define all the wanted eigenvalues to high relative accuracy. This means that small relative changes in the entries of \(D\) and \(L\) cause only small relative changes in the eigenvalues and eigenvectors. The standard (unfactored) representation of the tridiagonal matrix \(T\) does not have this property in general.
- \(b\). Compute the eigenvalues to suitable accuracy. If the eigenvectors are desired, the algorithm attains full accuracy of the computed eigenvalues only right before the corresponding vectors have to be computed, see Steps c) and d).
- \(c\). For each cluster of close eigenvalues, select a new shift close to the cluster, find a new factorization, and refine the shifted eigenvalues to suitable accuracy.
- \(d\). For each eigenvalue with a large enough relative separation, compute the corresponding eigenvector by forming a rank revealing twisted factorization. Go back to Step c) for any clusters that remain.

The desired accuracy of the output can be specified by the input parameter \(abstol\).

The routine \(?syevr\) calls \(stemr\) when the full spectrum is requested on machines that conform to the IEEE-754 floating point standard. \(?syevr\) calls \(stebz\) and \(stein\) on non-IEEE machines and when partial spectrum requests are made.

Normal execution of \(?dsyevr\) may create NaNs and infinities and may abort due to a floating point exception in environments that do not handle NaNs and infinities in the IEEE standard default manner.

Note that \(?syevr\) is preferable for most cases of real symmetric eigenvalue problems as its underlying algorithm is fast and uses less workspace.

Input Parameters

- \(matrix_layout\) Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- \(jobz\) Must be ‘N’ or ‘V’.
If \( \text{jobz} = 'N' \), then only eigenvalues are computed.
If \( \text{jobz} = 'V' \), then eigenvalues and eigenvectors are computed.

**range**
Must be 'A' or 'V' or 'I'.
If \( \text{range} = 'A' \), the routine computes all eigenvalues.
If \( \text{range} = 'V' \), the routine computes eigenvalues \( w[i] \) in the half-open interval:
\( vl < w[i] \leq vu \).
If \( \text{range} = 'I' \), the routine computes eigenvalues with indices \( il \) to \( iu \).
For \( \text{range} = 'V' \) or 'I' and \( iu-il < n-1 \), \text{sstebz/dstebz} and \text{sstein/dstein} are called.

**uplo**
Must be 'U' or 'L'.
If \( \text{uplo} = 'U' \), \( a \) stores the upper triangular part of \( A \).
If \( \text{uplo} = 'L' \), \( a \) stores the lower triangular part of \( A \).

**n**
The order of the matrix \( A \) (\( n \geq 0 \)).

**a**
\( a \) (size max(1, \( lda* n \))) is an array containing either upper or lower triangular part of the symmetric matrix \( A \), as specified by \( \text{uplo} \).

**lda**
The leading dimension of the array \( a \). Must be at least \( \max(1, n) \).

**vl, vu**
If \( \text{range} = 'V' \), the lower and upper bounds of the interval to be searched for eigenvalues.
Constraint: \( vl < vu \).
If \( \text{range} = 'A' \) or 'I', \( vl \) and \( vu \) are not referenced.

**il, iu**
If \( \text{range} = 'I' \), the indices in ascending order of the smallest and largest eigenvalues to be returned.
Constraint:
\( 1 \leq il \leq iu \leq n \), if \( n > 0 \);
\( il=1 \) and \( iu=0 \), if \( n = 0 \).
If \( \text{range} = 'A' \) or 'V', \( il \) and \( iu \) are not referenced.

**abstol**
If \( \text{jobz} = 'V' \), the eigenvalues and eigenvectors output have residual norms bounded by \( \text{abstol} \), and the dot products between different eigenvectors are bounded by \( \text{abstol} \).
If \( \text{abstol} < n * \text{eps} * ||T|| \), then \( n * \text{eps} * ||T|| \) is used instead, where \( \text{eps} \) is the machine precision, and \( ||T|| \) is the 1-norm of the matrix \( T \). The eigenvalues are computed to an accuracy of \( \text{eps} * ||T|| \) irrespective of \( \text{abstol} \).
If high relative accuracy is important, set \( \text{abstol} \) to ?lamch('S').

**ldz**
The leading dimension of the output array \( z \).
Constraints:
\( ldz \geq 1 \) if \( \text{jobz} = 'N' \) and
\[ ldz \geq \max(1, n) \] for column major layout and \[ ldz \geq \max(1, m) \] for row major layout if \( jobz = 'V' \).

**Output Parameters**

\( a \)

On exit, the lower triangle (if \( uplo = 'L' \)) or the upper triangle (if \( uplo = 'U' \)) of \( A \), including the diagonal, is overwritten.

\( m \)

The total number of eigenvalues found, \( 0 \leq m \leq n \).

If \( range = 'A' \), \( m = n \), if \( range = 'I' \), \( m = iu - il + 1 \), and if \( range = 'V' \) the exact value of \( m \) is not known in advance.

\( w, z \)

Arrays:

- \( w \), size at least \( \max(1, n) \), contains the selected eigenvalues in ascending order, stored in \( w[0] \) to \( w[m-1] \);
- \( z \) (size \( \max(1, ldz \times m) \) for column major layout and \( \max(1, ldz \times n) \) for row major layout).

If \( jobz = 'V' \), then if \( info = 0 \), the first \( m \) columns of \( z \) contain the orthonormal eigenvectors of the matrix \( A \) corresponding to the selected eigenvalues, with the \( i \)-th column of \( z \) holding the eigenvector associated with \( w[i-1] \).

If \( jobz = 'N' \), then \( z \) is not referenced.

\( isuppz \)

Array, size at least \( 2 \times \max(1, m) \).

The support of the eigenvectors in \( z \), i.e., the indices indicating the nonzero elements in \( z \). The \( i \)-th eigenvector is nonzero only in elements \( isuppz[2i - 2] \) through \( isuppz[2i - 1] \). Referenced only if eigenvectors are needed (\( jobz = 'V' \)) and all eigenvalues are needed, that is, \( range = 'A' \) or \( range = 'I' \) and \( il = 1 \) and \( iu = n \).

**Return Values**

This function returns a value \( info \).

If \( info = 0 \), the execution is successful.

If \( info = -i \), the \( i \)-th parameter had an illegal value.

If \( info = i \), an internal error has occurred.

**Application Notes**

\texttt{heevr}

*Computes selected eigenvalues and, optionally, eigenvectors of a Hermitian matrix using the Relatively Robust Representations.*

**Syntax**

```c
lapack_int LAPACKE_cheevr( int matrix_layout, char jobz, char range, char uplo,
lapack_int n, lapack_complex_float* a, lapack_int lda, float vl, float vu, lapack_int il, lapack_int iu, float abstol, lapack_int* m, float* w, lapack_complex_float* z, lapack_int ldz, lapack_int* isuppz );
```
The routine computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix $A$. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

The routine first reduces the matrix $A$ to tridiagonal form $T$ with a call to `hetrd`. Then, whenever possible, `heevr` calls `stegr` to compute the eigenspectrum using Relatively Robust Representations. `stegr` computes eigenvalues by the dqds algorithm, while orthogonal eigenvectors are computed from various "good" $L*D*L^T$ representations (also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows. For each unreduced block (submatrix) of $T$:

a. Compute $T - \sigma I = L*D*L^T$, so that $L$ and $D$ define all the wanted eigenvalues to high relative accuracy. This means that small relative changes in the entries of $D$ and $L$ cause only small relative changes in the eigenvalues and eigenvectors. The standard (unfactored) representation of the tridiagonal matrix $T$ does not have this property in general.

b. Compute the eigenvalues to suitable accuracy. If the eigenvectors are desired, the algorithm attains full accuracy of the computed eigenvalues only right before the corresponding vectors have to be computed, see Steps c) and d).

c. For each cluster of close eigenvalues, select a new shift close to the cluster, find a new factorization, and refine the shifted eigenvalues to suitable accuracy.

d. For each eigenvalue with a large enough relative separation, compute the corresponding eigenvector by forming a rank revealing twisted factorization. Go back to Step c) for any clusters that remain.

The desired accuracy of the output can be specified by the input parameter `abstol`.

The routine `heevr` calls `stemr` when the full spectrum is requested on machines which conform to the IEEE-754 floating point standard, or `stebz` and `stein` on non-IEEE machines and when partial spectrum requests are made.

Note that the routine `heevr` is preferable for most cases of complex Hermitian eigenvalue problems as its underlying algorithm is fast and uses less workspace.

### Input Parameters

- **matrix_layout**: Specifies whether matrix storage layout is row major (`LAPACK_ROW_MAJOR`) or column major (`LAPACK_COL_MAJOR`).
- **jobz**: Must be `'N'` or `'V'`. If `jobz = 'N'`, then only eigenvalues are computed. If `jobz = 'V'`, then eigenvalues and eigenvectors are computed.
- **range**: Must be `'A'` or `'V'` or `'I'`. If `range = 'A'`, the routine computes all eigenvalues. If `range = 'V'`, the routine computes eigenvalues $\lambda(i)$ in the half-open interval: $vl < \lambda(i) \leq vu$. 

Include Files

- `mkl.h`
If \( \text{range} = 'I' \), the routine computes eigenvalues with indices \( il \) to \( iu \).

For \( \text{range} = 'V' \) or \( 'I' \), \text{sstebz/dstebz} and \text{cstein/zstein} are called.

**uplo**

Must be \( 'U' \) or \( 'L' \).

If \( \text{uplo} = 'U' \), \( a \) stores the upper triangular part of \( A \).

If \( \text{uplo} = 'L' \), \( a \) stores the lower triangular part of \( A \).

**n**

The order of the matrix \( A \) (\( n \geq 0 \)).

**a**

\( a \) (size max(1, \( lda \times n \))) is an array containing either upper or lower triangular part of the Hermitian matrix \( A \), as specified by \( \text{uplo} \).

**lda**

The leading dimension of the array \( a \).

Must be at least max(1, \( n \)).

**vl, vu**

If \( \text{range} = 'V' \), the lower and upper bounds of the interval to be searched for eigenvalues.

Constraint: \( vl < vu \).

If \( \text{range} = 'A' \) or \( 'I' \), \( vl \) and \( vu \) are not referenced.

**il, iu**

If \( \text{range} = 'I' \), the indices in ascending order of the smallest and largest eigenvalues to be returned.

Constraint: \( 1 \leq il \leq iu \leq n \), if \( n > 0 \); \( il=1 \) and \( iu=0 \) if \( n = 0 \).

If \( \text{range} = 'A' \) or \( 'V' \), \( il \) and \( iu \) are not referenced.

**abstol**

The absolute error tolerance to which each eigenvalue/eigenvector is required.

If \( \text{jobz} = 'V' \), the eigenvalues and eigenvectors output have residual norms bounded by \( \text{abstol} \), and the dot products between different eigenvectors are bounded by \( \text{abstol} \).

If \( \text{abstol} < n \times \text{eps} \times ||T|| \), then \( n \times \text{eps} \times ||T|| \) is used instead, where \( \text{eps} \) is the machine precision, and \( ||T|| \) is the 1-norm of the matrix \( T \). The eigenvalues are computed to an accuracy of \( \text{eps} \times ||T|| \) irrespective of \( \text{abstol} \).

If high relative accuracy is important, set \( \text{abstol} \) to \( ?\text{lamch}('S') \).

**ldz**

The leading dimension of the output array \( z \). Constraints:

\( ldz \geq 1 \) if \( \text{jobz} = 'N' \);

\( ldz \geq \max(1, n) \) for column major layout and \( ldz \geq \max(1, m) \) for row major layout if \( \text{jobz} = 'V' \).

**Output Parameters**

\( a \)

On exit, the lower triangle (if \( \text{uplo} = 'L' \)) or the upper triangle (if \( \text{uplo} = 'U' \)) of \( A \), including the diagonal, is overwritten.

\( m \)

The total number of eigenvalues found,

\( 0 \leq m \leq n \).
If range = 'A', m = n, if range = 'I', m = il-iu+1, and if range = 'V' the exact value of m is not known in advance.

w

Array, size at least max(1, n), contains the selected eigenvalues in ascending order, stored in w[0] to w[m-1].

z

Array z(size max(1, ldz*m) for column major layout and max(1, ldz*n) for row major layout).

If jobz = 'V', then if info = 0, the first m columns of z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of z holding the eigenvector associated with w[i-1].

If jobz = 'N', then z is not referenced.

isuppz

Array, size at least 2 *max(1, m).

The support of the eigenvectors in z, i.e., the indices indicating the nonzero elements in z. The i-th eigenvector is nonzero only in elements isuppz[2i-2] through isuppz[2i-1]. Referenced only if eigenvectors are needed (jobz = 'V') and all eigenvalues are needed, that is, range = 'A' or range = 'I' and il = 1 and iu = n.

Return Values

This function returns a value info.

If info=0, the execution is successful.

If info = -i, the i-th parameter had an illegal value.

If info = i, an internal error has occurred.

Application Notes

Normal execution of ?stemr may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not handle NaNs and infinities in the IEEE standard default manner.

For more details, see ?stemr and these references:

?spev
Computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix in packed storage.

Syntax

```c
lapack_int LAPACKE_sspev (int matrix_layout, char jobz, char uplo, lapack_int n, float* ap, float* w, float* z, lapack_int ldz);
```

```c
lapack_int LAPACKE_dspev (int matrix_layout, char jobz, char uplo, lapack_int n, double* ap, double* w, double* z, lapack_int ldz);
```
Include Files

- mkl.h

Description

The routine computes all the eigenvalues and, optionally, eigenvectors of a real symmetric matrix \( A \) in packed storage.

Input Parameters

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **jobz**
  Must be 'N' or 'V'.
  - If job = 'N', then only eigenvalues are computed.
  - If job = 'V', then eigenvalues and eigenvectors are computed.

- **uplo**
  Must be 'U' or 'L'.
  - If uplo = 'U', \( ap \) stores the packed upper triangular part of \( A \).
  - If uplo = 'L', \( ap \) stores the packed lower triangular part of \( A \).

- **n**
  The order of the matrix \( A \) (\( n \geq 0 \)).

- **ap**
  Array \( ap \) contains the packed upper or lower triangle of symmetric matrix \( A \), as specified by \( uplo \).
  The size of \( ap \) must be at least \( \max(1, n*(n+1)/2) \).

- **ldz**
  The leading dimension of the output array \( z \). Constraints:
  - if jobz = 'N', then \( ldz \geq 1 \);
  - if jobz = 'V', then \( ldz \geq \max(1, n) \).

Output Parameters

- **w, z**
  Arrays:
  - \( w \), size at least \( \max(1, n) \).
    - If info = 0, \( w \) contains the eigenvalues of the matrix \( A \) in ascending order.
    - \( z \) (size \( \max(1, ldz*n) \)).
    - If jobz = 'V', then if info = 0, \( z \) contains the orthonormal eigenvectors of the matrix \( A \), with the \( i \)-th column of \( z \) holding the eigenvector associated with \( w[i - 1] \).
    - If jobz = 'N', then \( z \) is not referenced.

- **ap**
  On exit, this array is overwritten by the values generated during the reduction to tridiagonal form. The elements of the diagonal and the off-diagonal of the tridiagonal matrix overwrite the corresponding elements of \( A \).

Return Values

This function returns a value info.
If $info=0$, the execution is successful.

If $info = -i$, the $i$-th parameter had an illegal value.

If $info = i$, then the algorithm failed to converge; $i$ indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.

$hpev$

*Computes all eigenvalues and, optionally, eigenvectors of a Hermitian matrix in packed storage.*

**Syntax**

```c
lapack_int LAPACKE_chpev( int matrix_layout, char jobz, char uplo, lapack_int n, lapack_complex_float* ap, float* w, lapack_complex_float* z, lapack_int ldz );
```

```c
lapack_int LAPACKE_zhpev( int matrix_layout, char jobz, char uplo, lapack_int n, lapack_complex_double* ap, double* w, lapack_complex_double* z, lapack_int ldz );
```

**Include Files**

- mkl.h

**Description**

The routine computes all the eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix $A$ in packed storage.

**Input Parameters**

- $matrix_layout$
  
  Specifies whether matrix storage layout is row major ($\text{LAPACK\_ROW\_MAJOR}$) or column major ($\text{LAPACK\_COL\_MAJOR}$).

- $jobz$
  
  Must be 'N' or 'V'.

  If $job = 'N'$, then only eigenvalues are computed.

  If $job = 'V'$, then eigenvalues and eigenvectors are computed.

- $uplo$
  
  Must be 'U' or 'L'.

  If $uplo = 'U'$, $ap$ stores the packed upper triangular part of $A$.

  If $uplo = 'L'$, $ap$ stores the packed lower triangular part of $A$.

- $n$
  
  The order of the matrix $A$ ($n \geq 0$).

- $ap$
  
  Array $ap$ contains the packed upper or lower triangle of Hermitian matrix $A$, as specified by $uplo$.

  The size of $ap$ must be at least max$(1, n^{*}(n+1)/2)$.

- $ldz$
  
  The leading dimension of the output array $z$.

  Constraints:

  if $jobz = 'N'$, then $ldz \geq 1$;

  if $jobz = 'V'$, then $ldz \geq \text{max}(1, n)$.
Output Parameters

\( w \)

Array, size at least \( \max(1, n) \).
If \( \text{info} = 0 \), \( w \) contains the eigenvalues of the matrix \( A \) in ascending order.

\( z \)

Array \( z \) (size at least \( \max(1, \text{ldz} \times n) \)).
If \( \text{jobz} = 'V' \), then if \( \text{info} = 0 \), \( z \) contains the orthonormal eigenvectors of the matrix \( A \), with the \( i \)-th column of \( z \) holding the eigenvector associated with \( w[i - 1] \).
If \( \text{jobz} = 'N' \), then \( z \) is not referenced.

\( \text{ap} \)

On exit, this array is overwritten by the values generated during the reduction to tridiagonal form. The elements of the diagonal and the off-diagonal of the tridiagonal matrix overwrite the corresponding elements of \( A \).

Return Values

This function returns a value \( \text{info} \).
If \( \text{info} = 0 \), the execution is successful.
If \( \text{info} = -i \), the \( i \)-th parameter had an illegal value.
If \( \text{info} = i \), then the algorithm failed to converge; \( i \) indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.

\( \text{?spevd} \)

Uses divide and conquer algorithm to compute all eigenvalues and (optionally) all eigenvectors of a real symmetric matrix held in packed storage.

Syntax

```c
lapack_int LAPACKE_sspevd (int matrix_layout, char jobz, char uplo, lapack_int n, float* ap, float* w, float* z, lapack_int ldz);
lapack_int LAPACKE_dspevd (int matrix_layout, char jobz, char uplo, lapack_int n, double* ap, double* w, double* z, lapack_int ldz);
```

Include Files

- mkl.h

Description

The routine computes all the eigenvalues, and optionally all the eigenvectors, of a real symmetric matrix \( A \) (held in packed storage). In other words, it can compute the spectral factorization of \( A \) as:

\[ A = Z^*\Lambda Z^T. \]

Here \( \Lambda \) is a diagonal matrix whose diagonal elements are the eigenvalues \( \lambda_i \), and \( Z \) is the orthogonal matrix whose columns are the eigenvectors \( z_i \). Thus,

\[ A^*z_i = \lambda_i^*z_i \text{ for } i = 1, 2, \ldots, n. \]

If the eigenvectors are requested, then this routine uses a divide and conquer algorithm to compute eigenvalues and eigenvectors. However, if only eigenvalues are required, then it uses the Pal-Walker-Kahan variant of the \(QL \) or \(QR \) algorithm.
Input Parameters

**matrix_layout**
Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

**jobz**
Must be 'N' or 'V'.
If jobz = 'N', then only eigenvalues are computed.
If jobz = 'V', then eigenvalues and eigenvectors are computed.

**uplo**
Must be 'U' or 'L'.
If uplo = 'U', ap stores the packed upper triangular part of A.
If uplo = 'L', ap stores the packed lower triangular part of A.

**n**
The order of the matrix A (n ≥ 0).

**ap**
ap contains the packed upper or lower triangle of symmetric matrix A, as specified by uplo.
The dimension of ap must be max(1, n*(n+1)/2)

**ldz**
The leading dimension of the output array z.
Constraints:
if jobz = 'N', then ldz ≥ 1;
if jobz = 'V', then ldz ≥ max(1, n).

Output Parameters

**w, z**
Arrays:
w, size at least max(1, n).
If info = 0, contains the eigenvalues of the matrix A in ascending order. See also info.
z (size max(1, ldz*n)).
If jobz = 'V', then this array is overwritten by the orthogonal matrix Z which contains the eigenvectors of A. If jobz = 'N', then z is not referenced.

**ap**
On exit, this array is overwritten by the values generated during the reduction to tridiagonal form. The elements of the diagonal and the off-diagonal of the tridiagonal matrix overwrite the corresponding elements of A.

Return Values

This function returns a value info.
If info=0, the execution is successful.
If info = i, then the algorithm failed to converge; i indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.
If info = -i, the i-th parameter had an illegal value.
Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix $A+E$ such that $||E||_2 = O(\varepsilon) * ||A||_2$, where $\varepsilon$ is the machine precision.

The complex analogue of this routine is hpevd.

See also syevd for matrices held in full storage, and sbevd for banded matrices.

?hpevd

Uses divide and conquer algorithm to compute all eigenvalues and, optionally, all eigenvectors of a complex Hermitian matrix held in packed storage.

Syntax

```c
lapack_int LAPACKE_chpevd( int matrix_layout, char jobz, char uplo, lapack_int n,
lapack_complex_float* ap, float* w, lapack_complex_float* z, lapack_int ldz );
```

```c
lapack_int LAPACKE_zhpevd( int matrix_layout, char jobz, char uplo, lapack_int n,
lapack_complex_double* ap, double* w, lapack_complex_double* z, lapack_int ldz );
```

Include Files

- mkl.h

Description

The routine computes all the eigenvalues, and optionally all the eigenvectors, of a complex Hermitian matrix $A$ (held in packed storage). In other words, it can compute the spectral factorization of $A$ as: $A = Z \Lambda Z^H$.

Here $\Lambda$ is a real diagonal matrix whose diagonal elements are the eigenvalues $\lambda_i$, and $Z$ is the (complex) unitary matrix whose columns are the eigenvectors $z_i$. Thus,

$A z_i = \lambda_i z_i$ for $i = 1, 2, \ldots, n$.

If the eigenvectors are requested, then this routine uses a divide and conquer algorithm to compute eigenvalues and eigenvectors. However, if only eigenvalues are required, then it uses the Pal-Walker-Kahan variant of the QL or QR algorithm.

Input Parameters

- `matrix_layout` specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- `jobz` must be 'N' or 'V'.
  - If `jobz` = 'N', then only eigenvalues are computed.
  - If `jobz` = 'V', then eigenvalues and eigenvectors are computed.
- `uplo` must be 'U' or 'L'.
  - If `uplo` = 'U', `ap` stores the packed upper triangular part of $A$.
  - If `uplo` = 'L', `ap` stores the packed lower triangular part of $A$.
- `n` - the order of the matrix $A$ ($n \geq 0$).
- `ap` - contains the packed upper or lower triangle of Hermitian matrix $A$, as specified by `uplo`. 
The dimension of \( ap \) must be at least \( \max(1, n^* (n+1)/2) \).

\( ldz \)

The leading dimension of the output array \( z \).

Constraints:
- If \( jobz = 'N' \), then \( ldz \geq 1 \);
- If \( jobz = 'V' \), then \( ldz \geq \max(1, n) \).

Output Parameters

\( w \)

Array, size at least \( \max(1, n) \).
- If \( info = 0 \), contains the eigenvalues of the matrix \( A \) in ascending order.
- See also \( info \).

\( z \)

Array, size 1 if \( jobz = 'N' \) and \( \max(1, ldz*n) \) if \( jobz = 'V' \).
- If \( jobz = 'V' \), then this array is overwritten by the unitary matrix \( Z \) which contains the eigenvectors of \( A \).
- If \( jobz = 'N' \), then \( z \) is not referenced.

\( ap \)

On exit, this array is overwritten by the values generated during the reduction to tridiagonal form. The elements of the diagonal and the off-diagonal of the tridiagonal matrix overwrite the corresponding elements of \( A \).

Return Values

This function returns a value \( info \).
- If \( info=0 \), the execution is successful.
- If \( info = -i \), the \( i \)-th parameter had an illegal value.
- If \( info = i \), then the algorithm failed to converge; \( i \) indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.

Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix \( A + E \) such that \( ||E||_2 = O(\epsilon) * ||A||_2 \), where \( \epsilon \) is the machine precision.

The real analogue of this routine is \( \text{spevd} \).

See also \( \text{heevd} \) for matrices held in full storage, and \( \text{hbevd} \) for banded matrices.

\( ? \text{spevx} \)

\text{Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix in packed storage.}

\textbf{Syntax}

```c
lapack_int LAPACKE_sspevx (int matrix_layout, char jobz, char range, char uplo,
  lapack_int n, float* ap, float vl, float vu, lapack_int il, lapack_int iu, float abstol,
  lapack_int* m, float* w, float* z, lapack_int ldz, lapack_int* ifail);
```

```c
lapack_int LAPACKE_dspevx (int matrix_layout, char jobz, char range, char uplo,
  lapack_int n, double* ap, double vl, double vu, lapack_int il, lapack_int iu, double abstol,
  lapack_int* m, double* w, double* z, lapack_int ldz, lapack_int* ifail);
```
Include Files
• mkl.h

Description
The routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix \( A \) in packed storage. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

- **matrix_layout**: Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- **jobz**: Must be 'N' or 'V'.
  - If \( job = 'N' \), then only eigenvalues are computed.
  - If \( job = 'V' \), then eigenvalues and eigenvectors are computed.
- **range**: Must be 'A' or 'V' or 'I'.
  - If \( range = 'A' \), the routine computes all eigenvalues.
  - If \( range = 'V' \), the routine computes eigenvalues \( w[i] \) in the half-open interval: \( vl < w[i] \leq vu \).
  - If \( range = 'I' \), the routine computes eigenvalues with indices \( il \) to \( iu \).
- **uplo**: Must be 'U' or 'L'.
  - If \( uplo = 'U' \), \( ap \) stores the packed upper triangular part of \( A \).
  - If \( uplo = 'L' \), \( ap \) stores the packed lower triangular part of \( A \).
- **n**: The order of the matrix \( A \) (\( n \geq 0 \)).
- **ap**: Array \( ap \) contains the packed upper or lower triangle of the symmetric matrix \( A \), as specified by \( uplo \).
  - The size of \( ap \) must be at least \( \max(1, n^*(n+1)/2) \).
- **vl, vu**: If \( range = 'V' \), the lower and upper bounds of the interval to be searched for eigenvalues.
  - Constraint: \( vl < vu \).
  - If \( range = 'A' \) or 'I', \( vl \) and \( vu \) are not referenced.
- **il, iu**: If \( range = 'I' \), the indices in ascending order of the smallest and largest eigenvalues to be returned.
  - Constraint: \( 1 \leq il \leq iu \leq n \), if \( n > 0 \); \( il = 1 \) and \( iu = 0 \) if \( n = 0 \).
  - If \( range = 'A' \) or 'V', \( il \) and \( iu \) are not referenced.
- **abstol**: The absolute error tolerance to which each eigenvalue is required. See Application notes for details on error tolerance.
- **ldz**: The leading dimension of the output array \( z \).
Constraints:

if \( \text{jobz} = 'N' \), then \( ldz \geq 1 \);

if \( \text{jobz} = 'V' \), then \( ldz \geq \max(1, n) \) for column major layout and \( ldz \geq \max(1, m) \) for row major layout.

Output Parameters

\( \text{ap} \)

On exit, this array is overwritten by the values generated during the reduction to tridiagonal form. The elements of the diagonal and the off-diagonal of the tridiagonal matrix overwrite the corresponding elements of \( A \).

The total number of eigenvalues found,

\( 0 \leq m \leq n \). If range = 'A', \( m = n \), if range = 'I', \( m = iu - il + 1 \), and if range = 'V' the exact value of \( m \) is not known in advance..

\( w, z \) Arrays:

\( w \), size at least \( \max(1, n) \).

If info = 0, contains the selected eigenvalues of the matrix \( A \) in ascending order.

\( z \)(size \( \max(1, ldz*m) \) for column major layout and \( \max(1, ldz*n) \) for row major layout).

If \( \text{jobz} = 'V' \), then if info = 0, the first \( m \) columns of \( z \) contain the orthonormal eigenvectors of the matrix \( A \) corresponding to the selected eigenvalues, with the \( i \)-th column of \( z \) holding the eigenvector associated with \( w[i - 1] \).

If an eigenvector fails to converge, then that column of \( z \) contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in ifail.

If \( \text{jobz} = 'N' \), then \( z \) is not referenced.

\( \text{ifail} \)

Array, size at least \( \max(1, n) \).

If \( \text{jobz} = 'V' \), then if info = 0, the first \( m \) elements of \( \text{ifail} \) are zero; if info > 0, the \( \text{ifail} \) contains the indices the eigenvectors that failed to converge.

If \( \text{jobz} = 'N' \), then \( \text{ifail} \) is not referenced.

Return Values

This function returns a value info.

If info=0, the execution is successful.

If info = -i, the \( i \)-th parameter had an illegal value.

If info = i, then \( i \) eigenvectors failed to converge; their indices are stored in the array ifail.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to \( abstol + \varepsilon \max(|a|,|b|) \), where \( \varepsilon \) is the machine precision.
If $\text{abstol}$ is less than or equal to zero, then $\epsilon \|T\|_1$ will be used in its place, where $T$ is the tridiagonal matrix obtained by reducing $A$ to tridiagonal form. Eigenvalues will be computed most accurately when $\text{abstol}$ is set to twice the underflow threshold $2^*\text{?lamch}('S')$, not zero.

If this routine returns with $\text{info} > 0$, indicating that some eigenvectors did not converge, try setting $\text{abstol}$ to $2^*\text{?lamch}('S$).

$hpevx$

*Computes selected eigenvalues and, optionally, eigenvectors of a Hermitian matrix in packed storage.*

**Syntax**

```c
lapack_int LAPACKE_chpevx( int matrix_layout, char jobz, char range, char uplo,
    lapack_int n, lapack_complex_float* ap, float vl, float vu, lapack_int il, lapack_int iu,
    float abstol, lapack_int* m, float* w, lapack_complex_float* z, lapack_int ldz,
    lapack_int* ifail );

lapack_int LAPACKE_zhpevx( int matrix_layout, char jobz, char range, char uplo,
    lapack_int n, lapack_complex_double* ap, double vl, double vu, lapack_int il, lapack_int iu,
    double abstol, lapack_int* m, double* w, lapack_complex_double* z, lapack_int ldz,
    lapack_int* ifail );
```

**Include Files**

- mkl.h

**Description**

The routine computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix $A$ in packed storage. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

**Input Parameters**

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **jobz**
  Must be 'N' or 'V'.

  - If $\text{job} = 'N'$, then only eigenvalues are computed.
  - If $\text{job} = 'V'$, then eigenvalues and eigenvectors are computed.

- **range**
  Must be 'A' or 'V' or 'I'.

  - If $\text{range} = 'A'$, the routine computes all eigenvalues.
  - If $\text{range} = 'V'$, the routine computes eigenvalues $w[i]$ in the half-open interval: $vl < w[i] \leq vu$.
  - If $\text{range} = 'I'$, the routine computes eigenvalues with indices $\text{il}$ to $\text{iu}$.

- **uplo**
  Must be 'U' or 'L'.

  - If $\text{uplo} = 'U'$, $ap$ stores the packed upper triangular part of $A$.
  - If $\text{uplo} = 'L'$, $ap$ stores the packed lower triangular part of $A$.

- **n**
  The order of the matrix $A (n \geq 0)$.
Array \textit{ap} contains the packed upper or lower triangle of the Hermitian matrix \textit{A}, as specified by \textit{uplo}.

The size of \textit{ap} must be at least \( \max(1, n^* (n+1)/2) \).

If \textit{range} = 'V', the lower and upper bounds of the interval to be searched for eigenvalues.

Constraint: \( vl<vu \).

If \textit{range} = 'A' or 'I', \textit{vl} and \textit{vu} are not referenced.

If \textit{range} = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned.

Constraint: \( 1 \leq il \leq iu \leq n \), if \( n > 0 \); \( il=1 \) and \( iu=0 \) if \( n = 0 \).

If \textit{range} = 'A' or 'V', \textit{il} and \textit{iu} are not referenced.

The absolute error tolerance to which each eigenvalue is required. See \textit{Application notes} for details on error tolerance.

The leading dimension of the output array \textit{z}.

Constraints:

\begin{align*}
\text{if } \textit{jobz} = 'N', & \text{ then } \textit{ldz} \geq 1; \\
\text{if } \textit{jobz} = 'V', & \text{ then } \textit{ldz} \geq \max(1, n) \text{ for column major layout and } \textit{ldz} \geq \max(1, m) \text{ for row major layout.}
\end{align*}

Output Parameters

On exit, this array is overwritten by the values generated during the reduction to tridiagonal form. The elements of the diagonal and the off-diagonal of the tridiagonal matrix overwrite the corresponding elements of \textit{A}.

The total number of eigenvalues found, \( 0 \leq m \leq n \).

Array, size at least \( \max(1, n) \).

If \textit{info} = 0, contains the selected eigenvalues of the matrix \textit{A} in ascending order.

Array \textit{z}(size \( \max(1, \textit{ldz} \times m) \) for column major layout and \( \max(1, \textit{ldz} \times n) \) for row major layout).

If \textit{jobz} = 'V', then if \textit{info} = 0, the first \( m \) columns of \textit{z} contain the orthonormal eigenvectors of the matrix \textit{A} corresponding to the selected eigenvalues, with the \( i \)-th column of \textit{z} holding the eigenvector associated with \textit{w}(\textit{i}).

If an eigenvector fails to converge, then that column of \textit{z} contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in \textit{ifail}.

If \textit{jobz} = 'N', then \textit{z} is not referenced.
ifail

Array, size at least max(1, n).

If jobz = 'V', then if info = 0, the first \( m \) elements of ifail are zero; if info > 0, the ifail contains the indices the eigenvectors that failed to converge.

If jobz = 'N', then ifail is not referenced.

Return Values

This function returns a value info.

If info=0, the execution is successful.

If info = -i, the \( i \)-th parameter had an illegal value.

If info = i, then \( i \) eigenvectors failed to converge; their indices are stored in the array ifail.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval \([a,b]\) of width less than or equal to \( abstol + \epsilon \max(|a|,|b|) \), where \( \epsilon \) is the machine precision.

If abstol is less than or equal to zero, then \( \epsilon \times |T| \) will be used in its place, where \( T \) is the tridiagonal matrix obtained by reducing A to tridiagonal form. Eigenvalues will be computed most accurately when abstol is set to twice the underflow threshold \( 2 \times \text{lamch}'(S)' \), not zero.

If this routine returns with info > 0, indicating that some eigenvectors did not converge, try setting abstol to \( 2 \times \text{lamch}'(S)' \).

?sbev

Computes all eigenvalues and, optionally, eigenvectors of a real symmetric band matrix.

Syntax

```c
lapack_int LAPACKE_ssbev (int matrix_layout, char jobz, char uplo, lapack_int n, lapack_int kd, float* ab, lapack_int ldab, float* w, float* z, lapack_int ldz);
lapack_int LAPACKE_dsbev (int matrix_layout, char jobz, char uplo, lapack_int n, lapack_int kd, double* ab, lapack_int ldab, double* w, double* z, lapack_int ldz);
```

Include Files

- mkl.h

Description

The routine computes all eigenvalues and, optionally, eigenvectors of a real symmetric band matrix \( A \).

Input Parameters

matrix_layout

Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

jobz

Must be 'N' or 'V'.

If jobz = 'N', then only eigenvalues are computed.

If jobz = 'V', then eigenvalues and eigenvectors are computed.
**uplo**
Must be 'U' or 'L'.
If uplo = 'U', ab stores the upper triangular part of A.
If uplo = 'L', ab stores the lower triangular part of A.

**n**
The order of the matrix A (n ≥ 0).

**kd**
The number of super- or sub-diagonals in A (kd ≥ 0).

**ab**
(a size at least max(1, ldab * n) for column major layout and at least max(1, ldab * (kd + 1)) for row major layout) is an array containing either upper or lower triangular part of the symmetric matrix A (as specified by uplo) in band storage format.

**ldab**
The leading dimension of ab; must be at least kd +1 for column major layout and n for row major layout.

**ldz**
The leading dimension of the output array z.
Constraints:
if jobz = 'N', then ldz ≥ 1;
if jobz = 'V', then ldz ≥ max(1, n).

**Output Parameters**

**w, z**
Arrays:
w, size at least max(1, n).
If info = 0, contains the eigenvalues of the matrix A in ascending order.
z(size max(1, ldz * n)).
If jobz = 'V', then if info = 0, z contains the orthonormal eigenvectors of the matrix A, with the i-th column of z holding the eigenvector associated with w[i - 1].
If jobz = 'N', then z is not referenced.

**ab**
On exit, this array is overwritten by the values generated during the reduction to tridiagonal form (see the description of ?sbtrd).

**Return Values**
This function returns a value info.
If info = 0, the execution is successful.
If info = -i, the i-th parameter had an illegal value.

**?hbev**
Computes all eigenvalues and, optionally, eigenvectors of a Hermitian band matrix.
Syntax

```c
lapack_int LAPACKE_chbev( int matrix_layout, char jobz, char uplo, lapack_int n,
lapack_int kd, lapack_complex_float* ab, lapack_int ldab, float* w,
lapack_complex_float* z, lapack_int ldz );
```

```c
lapack_int LAPACKE_zhbev( int matrix_layout, char jobz, char uplo, lapack_int n,
lapack_int kd, lapack_complex_double* ab, lapack_int ldab, double* w,
lapack_complex_double* z, lapack_int ldz );
```

Include Files

- mkl.h

Description

The routine computes all eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix \( A \).

Input Parameters

- `matrix_layout` Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- `jobz` Must be 'N' or 'V'.
  - If `jobz` = 'N', then only eigenvalues are computed.
  - If `jobz` = 'V', then eigenvalues and eigenvectors are computed.
- `uplo` Must be 'U' or 'L'.
  - If `uplo` = 'U', `ab` stores the upper triangular part of \( A \).
  - If `uplo` = 'L', `ab` stores the lower triangular part of \( A \).
- `n` The order of the matrix \( A \) (\( n \geq 0 \)).
- `kd` The number of super- or sub-diagonals in \( A \) (\( kd \geq 0 \)).
- `ab` (size at least max(1, \( ldab * n \)) for column major layout and at least max(1, \( ldab * (kd + 1) \)) for row major layout) is an array containing either upper or lower triangular part of the Hermitian matrix \( A \) (as specified by `uplo`) in band storage format.
- `ldab` The leading dimension of `ab`; must be at least \( kd + 1 \) for column major layout and \( n \) for row major layout.
- `ldz` The leading dimension of the output array `z`.

Constraints:

- If `jobz` = 'N', then `ldz` ≥ 1;
- If `jobz` = 'V', then `ldz` ≥ max(1, \( n \)).

Output Parameters

- `w` Array, size at least max(1, \( n \)).
  - If `info` = 0, contains the eigenvalues in ascending order.
Array $z$ with size $\max(1, ldz*n)$.

If $jobz = 'V'$, then if $info = 0$, $z$ contains the orthonormal eigenvectors of the matrix $A$, with the $i$-th column of $z$ holding the eigenvector associated with $\lambda_{i-1}$.

If $jobz = 'N'$, then $z$ is not referenced.

On exit, this array is overwritten by the values generated during the reduction to tridiagonal form (see the description of $\text{hbtrd}$).

Return Values
This function returns a value $info$.

If $info = 0$, the execution is successful.

If $info = -i$, the $i$-th parameter had an illegal value.

If $info = i$, then the algorithm failed to converge; $i$ indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.

$sbevd$

Computes all eigenvalues and, optionally, all eigenvectors of a real symmetric band matrix using divide and conquer algorithm.

Syntax

```c
lapack_int LAPACKE_ssbenvd (int matrix_layout, char jobz, char uplo, lapack_int n, lapack_int kd, float* ab, lapack_int ldab, float* w, float* z, lapack_int ldz);
```

```c
lapack_int LAPACKE_dsbevd (int matrix_layout, char jobz, char uplo, lapack_int n, lapack_int kd, double* ab, lapack_int ldab, double* w, double* z, lapack_int ldz);
```

Include Files

- mkl.h

Description

The routine computes all the eigenvalues, and optionally all the eigenvectors, of a real symmetric band matrix $A$. In other words, it can compute the spectral factorization of $A$ as:

$$A = Z^T \Lambda Z$$

Here $\Lambda$ is a diagonal matrix whose diagonal elements are the eigenvalues $\lambda_i$, and $Z$ is the orthogonal matrix whose columns are the eigenvectors $z_i$. Thus,

$$A^T z_i = \lambda_i z_i$$

for $i = 1, 2, \ldots, n$.

If the eigenvectors are requested, then this routine uses a divide and conquer algorithm to compute eigenvalues and eigenvectors. However, if only eigenvalues are required, then it uses the Pal-Walker-Kahan variant of the $QL$ or $QR$ algorithm.

Input Parameters

- **matrix_layout**
  
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **jobz**
  
  Must be 'N' or 'V'.

If `jobz = 'N'`, then only eigenvalues are computed.
If `jobz = 'V'`, then eigenvalues and eigenvectors are computed.

`uplo` must be 'U' or 'L'.
If `uplo = 'U'`, `ab` stores the upper triangular part of `A`.
If `uplo = 'L'`, `ab` stores the lower triangular part of `A`.

`n` is the order of the matrix `A` (`n` ≥ 0).

`kd` is the number of super- or sub-diagonals in `A` (`kd` ≥ 0).

`ab` is an array containing either upper or lower triangular part of the symmetric matrix `A` (as specified by `uplo`) in band storage format.

`ldab` is the leading dimension of `ab`; must be at least `kd`+1 for column major layout and `n` for row major layout.

`ldz` is the leading dimension of the output array `z`.

Constraints:
- if `jobz = 'N'`, then `ldz` ≥ 1;
- if `jobz = 'V'`, then `ldz` ≥ max(1, `n`).

**Output Parameters**

`w`, `z` are arrays:

- `w`, size at least max(1, `n`).
  If `info = 0`, contains the eigenvalues of the matrix `A` in ascending order.
  See also `info`.
- `z` (size max(1, `ldz`*`n` if `job = 'V'` and at least 1 if `job = 'N'`)).
  If `job = 'V'`, then this array is overwritten by the orthogonal matrix `Z` which contains the eigenvectors of `A`. The `i`-th column of `Z` contains the eigenvector which corresponds to the eigenvalue `w[i - 1].`
  If `job = 'N'`, then `z` is not referenced.

`ab` is overwritten by the values generated during the reduction to tridiagonal form.

**Return Values**

This function returns a value `info`.

- If `info=0`, the execution is successful.
- If `info = i`, then the algorithm failed to converge; `i` indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.
- If `info = -i`, the `i`-th parameter had an illegal value.
Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix $A+E$ such that $||E||_2 = O(\epsilon) * ||A||_2$, where $\epsilon$ is the machine precision.

The complex analogue of this routine is hbevd.

See also syevd for matrices held in full storage, and spevd for matrices held in packed storage.

*?hbevd*

*Computes all eigenvalues and, optionally, all eigenvectors of a complex Hermitian band matrix using divide and conquer algorithm.*

**Syntax**

```c
lapack_int LAPACKE_chbevd( int matrix_layout, char jobz, char uplo, lapack_int n, lapack_int kd, lapack_complex_float* ab, lapack_int ldab, float* w, lapack_complex_float* z, lapack_int ldz);

lapack_int LAPACKE_zhbevd( int matrix_layout, char jobz, char uplo, lapack_int n, lapack_int kd, lapack_complex_double* ab, lapack_int ldab, double* w, lapack_complex_double* z, lapack_int ldz);
```

**Include Files**

- mkl.h

**Description**

The routine computes all the eigenvalues, and optionally all the eigenvectors, of a complex Hermitian band matrix $A$. In other words, it can compute the spectral factorization of $A$ as: $A = Z^{*} \Lambda Z^{H}$.

Here $\Lambda$ is a real diagonal matrix whose diagonal elements are the eigenvalues $\lambda_i$, and $Z$ is the (complex) unitary matrix whose columns are the eigenvectors $z_i$. Thus, $A z_i = \lambda_i z_i$ for $i = 1, 2, \ldots, n$.

If the eigenvectors are requested, then this routine uses a divide and conquer algorithm to compute eigenvalues and eigenvectors. However, if only eigenvalues are required, then it uses the Pal-Walker-Kahan variant of the QL or QR algorithm.

**Input Parameters**

- `matrix_layout`
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- `jobz`
  Must be 'N' or 'V'.
  
  If `jobz` = 'N', then only eigenvalues are computed.
  
  If `jobz` = 'V', then eigenvalues and eigenvectors are computed.

- `uplo`
  Must be 'U' or 'L'.
  
  If `uplo` = 'U', $ab$ stores the upper triangular part of $A$.
  
  If `uplo` = 'L', $ab$ stores the lower triangular part of $A$.

- `n`
  The order of the matrix $A$ ($n \geq 0$).

- `kd`
  The number of super- or sub-diagonals in $A$.
(kd≥ 0).

**ab**

ab (size at least max(1, ldab*n) for column major layout and at least max(1, ldab*(kd + 1)) for row major layout) is an array containing either upper or lower triangular part of the Hermitian matrix A (as specified by uplo) in band storage format.

**ldab**

The leading dimension of ab; must be at least kd+1 for column major layout and n for row major layout.

**ldz**

The leading dimension of the output array z.

Constraints:

if jobz = 'N', then ldz≥ 1;
if jobz = 'V', then ldz≥ max(1, n).

**Output Parameters**

**w**

Array, size at least max(1, n).
If info = 0, contains the eigenvalues of the matrix A in ascending order. See also info.

**z**

Array, size max(1, ldz*n) if job = 'V' and at least 1 if job = 'N'.
If jobz = 'V', then this array is overwritten by the unitary matrix Z which contains the eigenvectors of A. The i-th column of Z contains the eigenvector which corresponds to the eigenvalue w[i - 1].
If jobz = 'N', then z is not referenced.

**ab**

On exit, this array is overwritten by the values generated during the reduction to tridiagonal form.

**Return Values**

This function returns a value info.
If info=0, the execution is successful.
If info = -i, the i-th parameter had an illegal value.

**Application Notes**

The computed eigenvalues and eigenvectors are exact for a matrix $A + E$ such that $||E||_2 = O(\varepsilon) ||A||_2$, where $\varepsilon$ is the machine precision.

The real analogue of this routine is sbevd.
See also heevd for matrices held in full storage, and hpevd for matrices held in packed storage.

?sbevx

*Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric band matrix.*
Syntax
lapack_int LAPACKE_ssbevx (int matrix_layout, char jobz, char range, char uplo,
lapack_int n, lapack_int kd, float* ab, lapack_int ldab, float* q, lapack_int ldq, float
vl, float vu, lapack_int il, lapack_int iu, float abstol, lapack_int* m, float* w,
float* z, lapack_int ldz, lapack_int* ifail);

apack_int LAPACKE_dsbevx (int matrix_layout, char jobz, char range, char uplo,
lapack_int n, lapack_int kd, double* ab, lapack_int ldab, double* q, lapack_int ldq,
double vl, double vu, lapack_int il, lapack_int iu, double abstol, lapack_int* m,
double* w, double* z, lapack_int ldz, lapack_int* ifail);

Include Files
• mkl.h

Description
The routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric band matrix $A$. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **jobz**
  Must be 'N' or 'V'.
  If jobz = 'N', then only eigenvalues are computed.
  If jobz = 'V', then eigenvalues and eigenvectors are computed.

- **range**
  Must be 'A' or 'V' or 'I'.
  If range = 'A', the routine computes all eigenvalues.
  If range = 'V', the routine computes eigenvalues $w[i]$ in the half-open interval: vl < w[i] ≤ vu.
  If range = 'I', the routine computes eigenvalues with indices in range il to iu.

- **uplo**
  Must be 'U' or 'L'.
  If uplo = 'U', ab stores the upper triangular part of $A$.
  If uplo = 'L', ab stores the lower triangular part of $A$.

- **n**
  The order of the matrix $A$ ($n ≥ 0$).

- **kd**
  The number of super- or sub-diagonals in $A$ ($kd ≥ 0$).

- **ab**
  Arrays:
  Array ab (size at least max(1, ldab*n) for column major layout and at least max(1, ldab*(kd + 1)) for row major layout) contains either upper or lower triangular part of the symmetric matrix $A$ (as specified by uplo) in band storage format.
ldab

The leading dimension of \( ab \); must be at least \( kd +1 \) for column major layout and \( n \) for row major layout.

vl, vu

If range = 'V', the lower and upper bounds of the interval to be searched for eigenvalues.

Constraint: \( vl < vu \).

If range = 'A' or 'I', vl and vu are not referenced.

il, iu

If range = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned.

Constraint: \( 1 \leq il \leq iu \leq n \), if \( n > 0 \); \( il = 1 \) and \( iu = 0 \) if \( n = 0 \).

If range = 'A' or 'V', il and iu are not referenced.

abstol

The absolute error tolerance to which each eigenvalue is required. See Application notes for details on error tolerance.

ldq, ldz

The leading dimensions of the output arrays \( q \) and \( z \), respectively.

Constraints:

\( ldq \geq 1, \ ldz \geq 1 \);

If jobz = 'V', then \( ldq \geq \max(1, n) \) and \( ldz \geq \max(1, n) \) for column major layout and \( ldz \geq \max(1, m) \) for row major layout.

Output Parameters

q

Array, size \( \max(1, \ ldz * n) \).

If jobz = 'V', the \( n \)-by-\( n \) orthogonal matrix is used in the reduction to tridiagonal form.

If jobz = 'N', the array \( q \) is not referenced.

m

The total number of eigenvalues found, \( 0 \leq m \leq n \).

If range = 'A', \( m = n \), if range = 'I', \( m = iu-il+1 \), and if range = 'V', the exact value of \( m \) is not known in advance.

w, z

Arrays:

\( w \), size at least \( \max(1, n) \). The first \( m \) elements of \( w \) contain the selected eigenvalues of the matrix \( A \) in ascending order.

\( z \), size at least \( \max(1, \ ldz * m) \) for column major layout and \( \max(1, \ ldz * n) \) for row major layout.

If jobz = 'V', then if info = 0, the first \( m \) columns of \( z \) contain the orthonormal eigenvectors of the matrix \( A \) corresponding to the selected eigenvalues, with the \( i \)-th column of \( z \) holding the eigenvector associated with \( w[i-1] \).

If an eigenvector fails to converge, then that column of \( z \) contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in ifail.

If jobz = 'N', then \( z \) is not referenced.
On exit, this array is overwritten by the values generated during the reduction to tridiagonal form.

Array, size at least max(1, n).

If jobz = 'V', then if info = 0, the first m elements of ifail are zero; if info > 0, the ifail contains the indices the eigenvectors that failed to converge.

If jobz = 'N', then ifail is not referenced.

This function returns a value info.

If info=0, the execution is successful.

If info = -i, the i-th parameter had an illegal value.

If info = i, then i eigenvectors failed to converge; their indices are stored in the array ifail.

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to abstol+ε*max(|a|,|b|), where ε is the machine precision.

If abstol is less than or equal to zero, then ε*||T||1 is used as tolerance, where T is the tridiagonal matrix obtained by reducing A to tridiagonal form. Eigenvalues will be computed most accurately when abstol is set to twice the underflow threshold 2*?lamch('S'), not zero.

If this routine returns with info > 0, indicating that some eigenvectors did not converge, try setting abstol to 2*?lamch('S').

Computes selected eigenvalues and, optionally, eigenvectors of a Hermitian band matrix.

The routine computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.
**Input Parameters**

**matrix_layout**
Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

**jobz**
Must be 'N' or 'V'.
If job = 'N', then only eigenvalues are computed.
If job = 'V', then eigenvalues and eigenvectors are computed.

**range**
Must be 'A' or 'V' or 'I'.
If range = 'A', the routine computes all eigenvalues.
If range = 'V', the routine computes eigenvalues \( w[i] \) in the half-open interval: \( vl < w[i] \leq vu \).
If range = 'I', the routine computes eigenvalues with indices \( il \) to \( iu \).

**uplo**
Must be 'U' or 'L'.
If uplo = 'U', \( ab \) stores the upper triangular part of \( A \).
If uplo = 'L', \( ab \) stores the lower triangular part of \( A \).

**n**
The order of the matrix \( A \) (\( n \geq 0 \)).

**kd**
The number of super- or sub-diagonals in \( A \) (\( kd \geq 0 \)).

**ab**
\( ab \) (size at least max(1, \( ldab \times n \)) for column major layout and at least max(1, \( ldab \times (kd + 1) \)) for row major layout) is an array containing either upper or lower triangular part of the Hermitian matrix \( A \) (as specified by \( uplo \)) in band storage format.

**ldab**
The leading dimension of \( ab \); must be at least \( kd + 1 \) for column major layout and \( n \) for row major layout.

**vl, vu**
If range = 'V', the lower and upper bounds of the interval to be searched for eigenvalues.
Constraint: \( vl < vu \).
If range = 'A' or 'I', \( vl \) and \( vu \) are not referenced.

**il, iu**
If range = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned.
Constraint: \( 1 \leq il \leq iu \leq n \), if \( n > 0 \); \( il = 1 \) and \( iu = 0 \) if \( n = 0 \).
If range = 'A' or 'V', \( il \) and \( iu \) are not referenced.

**abstol**
The absolute error tolerance to which each eigenvalue is required. See Application notes for details on error tolerance.

**ldq, ldz**
The leading dimensions of the output arrays \( q \) and \( z \), respectively.
Constraints:
\( ldq \geq 1, \ ldz \geq 1; \)
If \( \text{jobz} = 'V' \), then \( ldq \geq \max(1, n) \) and \( ldz \geq \max(1, n) \) for column major layout and \( ldz \geq \max(1, m) \) for row major layout.

**Output Parameters**

- **q**: Array, size \( \max(1, ldz*n) \).
  - If \( \text{jobz} = 'V' \), the \( n \)-by-\( n \) unitary matrix is used in the reduction to tridiagonal form.
  - If \( \text{jobz} = 'N' \), the array \( q \) is not referenced.

- **m**: The total number of eigenvalues found, \( 0 \leq m \leq n \).
  - If \( \text{range} = 'A' \), \( m = n \); if \( \text{range} = 'I' \), \( m = iu-ii+1 \); and if \( \text{range} = 'V' \), the exact value of \( m \) is not known in advance.

- **w**: Array, size at least \( \max(1, n) \). The first \( m \) elements contain the selected eigenvalues of the matrix \( A \) in ascending order.

- **z**: Array \( z(\text{size at least} \ max(1, ldz*m) \text{ for column major layout and} \ max(1, ldz*n) \text{ for row major layout}) \).
  - If \( \text{jobz} = 'V' \), then if \( info = 0 \), the first \( m \) columns of \( z \) contain the orthonormal eigenvectors of the matrix \( A \) corresponding to the selected eigenvalues, with the \( i \)-th column of \( z \) holding the eigenvector associated with \( w[i-1] \).
  - If an eigenvector fails to converge, then that column of \( z \) contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in \( \text{ifail} \).
  - If \( \text{jobz} = 'N' \), then \( z \) is not referenced.

- **ab**: On exit, this array is overwritten by the values generated during the reduction to tridiagonal form.
  - If \( \text{uplo} = 'U' \), the first superdiagonal and the diagonal of the tridiagonal matrix \( T \) are returned in rows \( kd \) and \( kd+1 \) of \( ab \), and if \( \text{uplo} = 'L' \), the diagonal and first subdiagonal of \( T \) are returned in the first two rows of \( ab \).

- **ifail**: Array, size at least \( \max(1, n) \).
  - If \( \text{jobz} = 'V' \), then if \( info = 0 \), the first \( m \) elements of \( \text{ifail} \) are zero; if \( info > 0 \), the \( \text{ifail} \) contains the indices of the eigenvectors that failed to converge.
  - If \( \text{jobz} = 'N' \), then \( \text{ifail} \) is not referenced.

**Return Values**

This function returns a value \( info \).

- If \( info = 0 \), the execution is successful.
- If \( info = -i \), the \( i \)-th parameter had an illegal value.
- If \( info = i \), then \( i \) eigenvectors failed to converge; their indices are stored in the array \( \text{ifail} \).
Application Notes
An approximate eigenvalue is accepted as converged when it is determined to lie in an interval \([a,b]\) of width less than or equal to \(abstol + \varepsilon \max( |a|, |b| )\), where \(\varepsilon\) is the machine precision.

If \(abstol\) is less than or equal to zero, then \(\varepsilon \|T\|_1\) will be used in its place, where \(T\) is the tridiagonal matrix obtained by reducing \(A\) to tridiagonal form. Eigenvalues will be computed most accurately when \(abstol\) is set to twice the underflow threshold \(2\times\text{?lamch('S')}\), not zero.

If this routine returns with \(info > 0\), indicating that some eigenvectors did not converge, try setting \(abstol\) to \(2\times\text{?lamch('S')}\).

\texttt{?stev}
\textit{Computes all eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix.}

**Syntax**

```c
lapack_int LAPACKE_sstev (int matrix_layout, char jobz, lapack_int n, float* d, float* e, float* z, lapack_int ldz);

lapack_int LAPACKE_dstev (int matrix_layout, char jobz, lapack_int n, double* d, double* e, double* z, lapack_int ldz);
```

**Include Files**

- mkl.h

**Description**
The routine computes all eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix \(A\).

**Input Parameters**

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **jobz**
  Must be 'N' or 'V'.
  - If \(jobz = 'N'\), then only eigenvalues are computed.
  - If \(jobz = 'V'\), then eigenvalues and eigenvectors are computed.

- **n**
  The order of the matrix \(A\) (\(n \geq 0\)).

- **d, e**
  Arrays:
  - Array \(d\) contains the \(n\) diagonal elements of the tridiagonal matrix \(A\).
  - The size of \(d\) must be at least \(\max(1, n)\).
  - Array \(e\) contains the \(n-1\) subdiagonal elements of the tridiagonal matrix \(A\).
  - The size of \(e\) must be at least \(\max(1, n)\). The \(n\)-th element of this array is used as workspace.

- **ldz**
  The leading dimension of the output array \(z\); \(ldz \geq 1\). If \(jobz = 'V'\) then \(ldz \geq \max(1, n)\).
Output Parameters

\( d \)

On exit, if \( info = 0 \), contains the eigenvalues of the matrix \( A \) in ascending order.

\( z \)

Array, size (size max(1, \( ldz*n \))).

If \( jobz = 'V' \), then if \( info = 0 \), \( z \) contains the orthonormal eigenvectors of the matrix \( A \), with the \( i \)-th column of \( z \) holding the eigenvector associated with the eigenvalue returned in \( d[i - 1] \).

If \( job = 'N' \), then \( z \) is not referenced.

\( e \)

On exit, this array is overwritten with intermediate results.

Return Values

This function returns a value \( info \).

If \( info = 0 \), the execution is successful.

If \( info = -i \), the \( i \)-th parameter had an illegal value.

If \( info = i \), then the algorithm failed to converge; \( i \) elements of \( e \) did not converge to zero.

### ?stevd

Computes all eigenvalues and, optionally, all eigenvectors of a real symmetric tridiagonal matrix using divide and conquer algorithm.

#### Syntax

```c
lapack_int LAPACKE_sstevd (int matrix_layout, char jobz, lapack_int n, float* d, float* e, float* z, lapack_int ldz);
```

```c
lapack_int LAPACKE_dstevd (int matrix_layout, char jobz, lapack_int n, double* d, double* e, double* z, lapack_int ldz);
```

#### Include Files

- mkl.h

#### Description

The routine computes all the eigenvalues, and optionally all the eigenvectors, of a real symmetric tridiagonal matrix \( T \). In other words, the routine can compute the spectral factorization of \( T \) as: \( T = Z*\Lambda*Z^T \).

Here \( \Lambda \) is a diagonal matrix whose diagonal elements are the eigenvalues \( \lambda_i \), and \( Z \) is the orthogonal matrix whose columns are the eigenvectors \( z_i \). Thus, \( T*z_i = \lambda_i*z_i \) for \( i = 1, 2, \ldots, n \).

If the eigenvectors are requested, then this routine uses a divide and conquer algorithm to compute eigenvalues and eigenvectors. However, if only eigenvalues are required, then it uses the Pal-Walker-Kahan variant of the QL or QR algorithm.

There is no complex analogue of this routine.
Input Parameters

**matrix_layout**
Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

**jobz**
Must be 'N' or 'V'.
If jobz = 'N', then only eigenvalues are computed.
If jobz = 'V', then eigenvalues and eigenvectors are computed.

**n**
The order of the matrix $T$ ($n \geq 0$).

**d, e**
Arrays:
d contains the $n$ diagonal elements of the tridiagonal matrix $T$.
The dimension of $d$ must be at least max(1, $n$).
e contains the $n$-1 off-diagonal elements of $T$.
The dimension of $e$ must be at least max(1, $n$). The $n$-th element of this array is used as workspace.

**ldz**
The leading dimension of the output array $z$. Constraints:
$ldz \geq 1$ if job = 'N';
$ldz \geq \text{max}(1, n)$ if job = 'V'.

Output Parameters

**d**
On exit, if info = 0, contains the eigenvalues of the matrix $T$ in ascending order.
See also info.

**z**
Array, size max(1, ldz*$n$) if jobz = 'V' and 1 if jobz = 'N'.
If jobz = 'V', then this array is overwritten by the orthogonal matrix $Z$ which contains the eigenvectors of $T$.
If jobz = 'N', then $z$ is not referenced.

**e**
On exit, this array is overwritten with intermediate results.

Return Values

This function returns a value info.
If info=0, the execution is successful.
If info = i, then the algorithm failed to converge; $i$ indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.
If info = -i, the $i$-th parameter had an illegal value.

Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix $T+E$ such that $||E||_2 = O(\varepsilon)*||T||_2$, where $\varepsilon$ is the machine precision.
If $\lambda_i$ is an exact eigenvalue, and $\mu_i$ is the corresponding computed value, then
$|\mu_i - \lambda_i| \leq c(n) \varepsilon^* ||T||_2$
where \( c(n) \) is a modestly increasing function of \( n \).

If \( z_i \) is the corresponding exact eigenvector, and \( w_i \) is the corresponding computed vector, then the angle \( \theta(z_i, w_i) \) between them is bounded as follows:

\[
\theta(z_i, w_i) \leq c(n)^* \varepsilon^* \|T\|_2 / \min_{i \neq j} |\lambda_i - \lambda_j|.
\]

Thus the accuracy of a computed eigenvector depends on the gap between its eigenvalue and all the other eigenvalues.

\textbf{?stevx}

Computes selected eigenvalues and eigenvectors of a real symmetric tridiagonal matrix.

\textbf{Syntax}

```c

lapack_int LAPACKE_sstevx (int matrix_layout, char jobz, char range, lapack_int n,
float* d, float* e, float vl, float vu, lapack_int il, lapack_int iu, float abstol,
lapack_int* m, float* w, float* z, lapack_int ldz, lapack_int* ifail);

lapack_int LAPACKE_dstevx (int matrix_layout, char jobz, char range, lapack_int n,
double* d, double* e, double vl, double vu, lapack_int il, lapack_int iu, double abstol,
lapack_int* m, double* w, double* z, lapack_int ldz, lapack_int* ifail);
```

\textbf{Include Files}

- mkl.h

\textbf{Description}

The routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix \( A \). Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

\textbf{Input Parameters}

\textit{matrix_layout} Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

\textit{jobz} Must be 'N' or 'V'.

If \textit{job} = 'N', then only eigenvalues are computed.

If \textit{job} = 'V', then eigenvalues and eigenvectors are computed.

\textit{range} Must be 'A' or 'V' or 'I'.

If \textit{range} = 'A', the routine computes all eigenvalues.

If \textit{range} = 'V', the routine computes eigenvalues \( w[i] \) in the half-open interval: \( vl < w[i] \leq vu \).

If \textit{range} = 'I', the routine computes eigenvalues with indices \( il \) to \( iu \).

\textit{n} The order of the matrix \( A \) (\( n \geq 0 \)).

\textit{d, e} Arrays:

\( d \) contains the \( n \) diagonal elements of the tridiagonal matrix \( A \).

The dimension of \( d \) must be at least \( \max(1, n) \).
\( e \) contains the \( n-1 \) subdiagonal elements of \( A \).

The dimension of \( e \) must be at least \( \max(1, n-1) \). The \( n \)-th element of this array is used as workspace.

\( vl, vu \)

If \( \text{range} = 'V' \), the lower and upper bounds of the interval to be searched for eigenvalues.

Constraint: \( vl < vu \).

If \( \text{range} = 'A' \) or \( 'I' \), \( vl \) and \( vu \) are not referenced.

\( il, iu \)

If \( \text{range} = 'I' \), the indices in ascending order of the smallest and largest eigenvalues to be returned.

Constraint: \( 1 \leq il \leq iu \leq n \), if \( n > 0 \); \( il = 1 \) and \( iu = 0 \) if \( n = 0 \).

If \( \text{range} = 'A' \) or \( 'V' \), \( il \) and \( iu \) are not referenced.

\( abstol \)

\( ldz \)

The leading dimensions of the output array \( z \); \( ldz \geq 1 \). If \( \text{jobz} = 'V' \), then \( ldz \geq \max(1, n) \) for column major layout and \( ldz \geq \max(1, m) \) for row major layout.

**Output Parameters**

\( m \)

The total number of eigenvalues found,

\( 0 \leq m \leq n \).

If \( \text{range} = 'A' \), \( m = n \), if \( \text{range} = 'I' \), \( m = iu-il+1 \), and if \( \text{range} = 'V' \) the exact value of \( m \) is unknown.

\( w, z \)

Arrays:

- \( w \), size at least \( \max(1, n) \).
- The first \( m \) elements of \( w \) contain the selected eigenvalues of the matrix \( A \) in ascending order.
- \( z \) (size at least \( \max(1, ldz*m) \) for column major layout and \( \max(1, ldz*n) \) for row major layout).

If \( \text{jobz} = 'V' \), then if \( \text{info} = 0 \), the first \( m \) columns of \( z \) contain the orthonormal eigenvectors of the matrix \( A \) corresponding to the selected eigenvalues, with the \( i \)-th column of \( z \) holding the eigenvector associated with \( w[i-1] \).

If an eigenvector fails to converge, then that column of \( z \) contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in \( \text{ifail} \).

If \( \text{jobz} = 'N' \), then \( z \) is not referenced.

\( d, e \)

On exit, these arrays may be multiplied by a constant factor chosen to avoid overflow or underflow in computing the eigenvalues.

\( \text{ifail} \)

Array, size at least \( \max(1, n) \).
If $jobz = 'V'$, then if $info = 0$, the first $m$ elements of $ifail$ are zero; if $info > 0$, the $ifail$ contains the indices of the eigenvectors that failed to converge.

If $jobz = 'N'$, then $ifail$ is not referenced.

Return Values

This function returns a value $info$.

If $info=0$, the execution is successful.

If $info = -i$, the $i$-th parameter had an illegal value.

If $info = i$, then $i$ eigenvectors failed to converge; their indices are stored in the array $ifail$.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a, b]$ of width less than or equal to $abstol + \varepsilon \max(|a|, |b|)$, where $\varepsilon$ is the machine precision.

If $abstol$ is less than or equal to zero, then $\varepsilon |A|_1$ is used instead. Eigenvalues are computed most accurately when $abstol$ is set to twice the underflow threshold $2^* \text{?lamch}(\text'S')$, not zero.

If this routine returns with $info > 0$, indicating that some eigenvectors did not converge, set $abstol$ to $2^* \text{?lamch}(\text'S')$.

\textit{?stevr}

Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix using the Relatively Robust Representations.

Syntax

```c
lapack_int LAPACKE_sstevr (int matrix_layout, char jobz, char range, lapack_int n, float* d, float* e, float vl, float vu, lapack_int il, lapack_int iu, float abstol, lapack_int* m, float* w, float* z, lapack_int ldz, lapack_int* isuppz);

lapack_int LAPACKE_dstevr (int matrix_layout, char jobz, char range, lapack_int n, double* d, double* e, double vl, double vu, lapack_int il, lapack_int iu, double abstol, lapack_int* m, double* w, double* z, lapack_int ldz, lapack_int* isuppz);
```

Include Files

- mkl.h

Description

The routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix $T$. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Whenever possible, the routine calls stemr to compute the eigenspectrum using Relatively Robust Representations. steqr computes eigenvalues by the dqds algorithm, while orthogonal eigenvectors are computed from various "good" $L^*D^*L^T$ representations (also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows. For the $i$-th unreduced block of $T$:

a. Compute $T - \sigma_i = L_i^*D_i^*L_i^T$, such that $L_i^*D_i^*L_i^T$ is a relatively robust representation.

b. Compute the eigenvalues, $\lambda_j$, of $L_i^*D_i^*L_i^T$ to high relative accuracy by the dqds algorithm.
c. If there is a cluster of close eigenvalues, "choose" \( \sigma_i \) close to the cluster, and go to Step (a).

d. Given the approximate eigenvalue \( \lambda_j \) of \( \tilde{L}_i \tilde{D}_i \tilde{L}_i^T \), compute the corresponding eigenvector by forming a rank-revealing twisted factorization.

The desired accuracy of the output can be specified by the input parameter \( \text{abstol} \). The routine \( \text{?stevr} \) calls \( \text{stemr} \) when the full spectrum is requested on machines which conform to the IEEE-754 floating point standard. \( \text{?stevr} \) calls \( \text{stebz} \) and \( \text{stein} \) on non-IEEE machines and when partial spectrum requests are made.

### Input Parameters

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **jobz**
  Must be 'N' or 'V'.

  - If \( \text{jobz} = 'N' \), then only eigenvalues are computed.
  - If \( \text{jobz} = 'V' \), then eigenvalues and eigenvectors are computed.

- **range**
  Must be 'A' or 'V' or 'I'.

  - If \( \text{range} = 'A' \), the routine computes all eigenvalues.
  - If \( \text{range} = 'V' \), the routine computes eigenvalues \( w[i] \) in the half-open interval:
    \( vl < w[i] \leq vu \).
  - If \( \text{range} = 'I' \), the routine computes eigenvalues with indices \( il \) to \( iu \).

  For \( \text{range} = 'V' \) or 'I' and \( iu-il < n-1 \), \( \text{stebz/dstebz} \) and \( \text{sstein/dstein} \) are called.

- **n**
  The order of the matrix \( T (n \geq 0) \).

- **d, e**
  Arrays:

  - \( d \) contains the \( n \) diagonal elements of the tridiagonal matrix \( T \).
  - \( e \) contains the \( n-1 \) subdiagonal elements of \( A \).

  The dimension of \( d \) must be at least \( \max(1, n) \).

  The dimension of \( e \) must be at least \( \max(1, n-1) \). The \( n \)-th element of this array is used as workspace.

- **vl, vu**
  If \( \text{range} = 'V' \), the lower and upper bounds of the interval to be searched for eigenvalues.

  Constraint: \( vl < vu \).

  If \( \text{range} = 'A' \) or 'I', \( vl \) and \( vu \) are not referenced.

- **il, iu**
  If \( \text{range} = 'I' \), the indices in ascending order of the smallest and largest eigenvalues to be returned.

  Constraint: \( 1 \leq il\leq iu \leq n \), if \( n > 0 \); \( il=1 \) and \( iu=0 \) if \( n = 0 \).

  If \( \text{range} = 'A' \) or 'V', \( il \) and \( iu \) are not referenced.

- **abstol**
  The absolute error tolerance to which each eigenvalue/eigenvector is required.
If \( \text{jobz} = \text{'V'} \), the eigenvalues and eigenvectors output have residual norms bounded by \( \text{abstol} \), and the dot products between different eigenvectors are bounded by \( \text{abstol} \). If \( \text{abstol} < n \cdot \text{eps} \cdot \|T\| \), then \( n \cdot \text{eps} \cdot \|T\| \) will be used in its place, where \( \text{eps} \) is the machine precision, and \( \|T\| \) is the 1-norm of the matrix \( T \). The eigenvalues are computed to an accuracy of \( \text{eps} \cdot \|T\| \) irrespective of \( \text{abstol} \). If high relative accuracy is important, set \( \text{abstol} \) to \( ?\text{lamch}\text{('S')} \).

\( \text{ldz} \)

The leading dimension of the output array \( z \).

Constraints:

- \( \text{ldz} \geq 1 \) if \( \text{jobz} = \text{'N'} \);
- \( \text{ldz} \geq \text{max}(1, n) \) for column major layout and \( \text{ldz} \geq \text{max}(1, m) \) for row major layout if \( \text{jobz} = \text{'V'} \).

\textbf{Output Parameters}

\( m \)

The total number of eigenvalues found,

\( 0 \leq m \leq n \). If \( \text{range} = \text{'A'} \), \( m = n \); if \( \text{range} = \text{'I'} \), \( m = iu-il+1 \), and if \( \text{range} = \text{'V'} \) the exact value of \( m \) is unknown.

\( w, z \)

Arrays:

- \( w \), size at least \( \text{max}(1, n) \).
- The first \( m \) elements of \( w \) contain the selected eigenvalues of the matrix \( T \) in ascending order.
- \( z \), size at least \( \text{max}(1, \text{ldz}\cdot m) \) for column major layout and \( \text{max}(1, \text{ldz}\cdot n) \) for row major layout.

If \( \text{jobz} = \text{'V'} \), then if \( \text{info} = 0 \), the first \( m \) columns of \( z \) contain the orthonormal eigenvectors of the matrix \( T \) corresponding to the selected eigenvalues, with the \( i \)-th column of \( z \) holding the eigenvector associated with \( w[i-1] \).

If \( \text{jobz} = \text{'N'} \), then \( z \) is not referenced.

\( d, e \)

On exit, these arrays may be multiplied by a constant factor chosen to avoid overflow or underflow in computing the eigenvalues.

\( \text{isuppz} \)

Array, size at least \( 2 \cdot \text{max}(1, m) \).

The support of the eigenvectors in \( z \), i.e., the indices indicating the nonzero elements in \( z \). The \( i \)-th eigenvector is nonzero only in elements \( \text{isuppz}[2i-2] \) through \( \text{isuppz}[2i-1] \).

Implemented only for \( \text{range} = \text{'A'} \) or \( \text{'I'} \) and \( iu-il = n-1 \).

\textbf{Return Values}

This function returns a value \( \text{info} \). If \( \text{info}=0 \), the execution is successful.

If \( \text{info} = -i \), the \( i \)-th parameter had an illegal value.

If \( \text{info} = i \), an internal error has occurred.
Application Notes

Normal execution of the routine ?stegr may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not handle NaNs and infinities in the IEEE standard default manner.

Nonsymmetric Eigenvalue Problems: LAPACK Driver Routines

This section describes LAPACK driver routines used for solving nonsymmetric eigenproblems. See also computational routines that can be called to solve these problems. Table "Driver Routines for Solving Nonsymmetric Eigenproblems" lists all such driver routines.

Driver Routines for Solving Nonsymmetric Eigenproblems

?gees

*Computes the eigenvalues and Schur factorization of a general matrix, and orders the factorization so that selected eigenvalues are at the top left of the Schur form.*

Syntax

```c
lapack_int LAPACKE_sgees( int matrix_layout, char jobvs, char sort, LAPACK_S_SELECT2 select, lapack_int n, float* a, lapack_int lda, lapack_int* sdim, float* wr, float* wi, float* vs, lapack_int ldvs );

lapack_int LAPACKE_dgees( int matrix_layout, char jobvs, char sort, LAPACK_D_SELECT2 select, lapack_int n, double* a, lapack_int lda, lapack_int* sdim, double* wr, double* wi, double* vs, lapack_int ldvs );

lapack_int LAPACKE_cgees( int matrix_layout, char jobvs, char sort, LAPACK_C_SELECT1 select, lapack_int n, lapack_complex_float* a, lapack_int lda, lapack_int* sdim, lapack_complex_float* w, lapack_complex_float* vs, lapack_int ldvs );

lapack_int LAPACKE_zgees( int matrix_layout, char jobvs, char sort, LAPACK_Z_SELECT1 select, lapack_int n, lapack_complex_double* a, lapack_int lda, lapack_int* sdim, lapack_complex_double* w, lapack_complex_double* vs, lapack_int ldvs );
```

Include Files

- mkl.h

Description

The routine computes for an n-by-n real/complex nonsymmetric matrix A, the eigenvalues, the real Schur form T, and, optionally, the matrix of Schur vectors Z. This gives the Schur factorization $A = Z^* T Z^H$. 
Optionally, it also orders the eigenvalues on the diagonal of the real-Schur/Schur form so that selected eigenvalues are at the top left. The leading columns of $Z$ then form an orthonormal basis for the invariant subspace corresponding to the selected eigenvalues.

A real matrix is in real-Schur form if it is upper quasi-triangular with 1-by-1 and 2-by-2 blocks. 2-by-2 blocks will be standardized in the form

$$
\begin{pmatrix}
    a & b \\
    c & a
\end{pmatrix}
$$

where $b^*c < 0$. The eigenvalues of such a block are $a \pm i\sqrt{bc}$.

A complex matrix is in Schur form if it is upper triangular.

**Input Parameters**

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **jobvs**
  Must be 'N' or 'V'.
  - If jobvs = 'N', then Schur vectors are not computed.
  - If jobvs = 'V', then Schur vectors are computed.

- **sort**
  Must be 'N' or 'S'. Specifies whether or not to order the eigenvalues on the diagonal of the Schur form.
  - If sort = 'N', then eigenvalues are not ordered.
  - If sort = 'S', eigenvalues are ordered (see select).

- **select**
  If sort = 'S', select is used to select eigenvalues to sort to the top left of the Schur form.
  - If sort = 'N', select is not referenced.

For real flavors:
An eigenvalue $wr[j]+\sqrt{-1}*wi[j]$ is selected if select($wr[j], wi[j]$) is true; that is, if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected.

For complex flavors:
An eigenvalue $w[j]$ is selected if select($w[j]$) is true.

Note that a selected complex eigenvalue may no longer satisfy select($wr[j], wi[j]$) = 1 after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned); in this case info may be set to $n+2$ (see info below).

- **n**
  The order of the matrix $A$ ($n \geq 0$).

- **a**
  Arrays:
  - $a$ (size at least max(1, lda*$_n$)) is an array containing the $n$-by-$n$ matrix $A$.

- **lda**
  The leading dimension of the array $a$. Must be at least max(1, $n$).

- **ldvs**
  The leading dimension of the output array vs. Constraints:
ldvs ≥ 1;
ldvs ≥ max(1, n) if jobvs = 'V'.

Output Parameters

a
On exit, this array is overwritten by the real-Schur/Schur form T.

sdim
If sort = 'N', sdim = 0.
If sort = 'S', sdim is equal to the number of eigenvalues (after sorting) for which select is true.
Note that for real flavors complex conjugate pairs for which select is true for either eigenvalue count as 2.

wr, wi
Arrays, size at least max (1, n) each. Contain the real and imaginary parts, respectively, of the computed eigenvalues, in the same order that they appear on the diagonal of the output real-Schur form T. Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having positive imaginary part first.

w
Array, size at least max(1, n). Contains the computed eigenvalues. The eigenvalues are stored in the same order as they appear on the diagonal of the output Schur form T.

vs
Array vs (size at least max(1, ldvs*n)).
If jobvs = 'V', vs contains the orthogonal/unitary matrix Z of Schur vectors.
If jobvs = 'N', vs is not referenced.

Return Values

This function returns a value info.
If info=0, the execution is successful.
If info = -i, the i-th parameter had an illegal value.
If info = i, and
i ≤ n:
the QR algorithm failed to compute all the eigenvalues; elements 1:ilo-1 and i+1:n of wr and wi (for real flavors) or w (for complex flavors) contain those eigenvalues which have converged; if jobvs = 'V', vs contains the matrix which reduces A to its partially converged Schur form;
i = n+1:
the eigenvalues could not be reordered because some eigenvalues were too close to separate (the problem is very ill-conditioned);
i = n+2:
after reordering, round-off changed values of some complex eigenvalues so that leading eigenvalues in the Schur form no longer satisfy select = 1. This could also be caused by underflow due to scaling.
?geesx

Computes the eigenvalues and Schur factorization of a general matrix, orders the factorization and computes reciprocal condition numbers.

Syntax

```c
lapack_int LAPACKE_sgeesx( int matrix_layout, char jobvs, char sort, LAPACK_S_SELECT2 select, char sense, lapack_int n, float* a, lapack_int lda, lapack_int* sdim, float* wr, float* wi, float* vs, lapack_int ldvs, float* rconde, float* rcondv );
```

```c
lapack_int LAPACKE_dgeesx( int matrix_layout, char jobvs, char sort, LAPACK_D_SELECT2 select, char sense, lapack_int n, double* a, lapack_int lda, lapack_int* sdim, double* wr, double* wi, double* vs, lapack_int ldvs, double* rconde, double* rcondv );
```

```c
lapack_int LAPACKE_cgeesx( int matrix_layout, char jobvs, char sort, LAPACK_C_SELECT1 select, char sense, lapack_int n, lapack_complex_float* a, lapack_int lda, lapack_int* sdim, lapack_complex_float* w, lapack_complex_float* vs, lapack_int ldvs, float* rconde, float* rcondv );
```

```c
lapack_int LAPACKE_zgeesx( int matrix_layout, char jobvs, char sort, LAPACK_Z_SELECT1 select, char sense, lapack_int n, lapack_complex_double* a, lapack_int lda, lapack_int* sdim, lapack_complex_double* w, lapack_complex_double* vs, lapack_int ldvs, double* rconde, double* rcondv );
```

Include Files

- mkl.h

Description

The routine computes for an n-by-n real/complex nonsymmetric matrix A, the eigenvalues, the real-Schur/Schur form T, and, optionally, the matrix of Schur vectors Z. This gives the Schur factorization $A = Z \cdot T \cdot Z^H$.

Optionally, it also orders the eigenvalues on the diagonal of the real-Schur/Schur form so that selected eigenvalues are at the top left; computes a reciprocal condition number for the average of the selected eigenvalues (rconde); and computes a reciprocal condition number for the right invariant subspace corresponding to the selected eigenvalues (rcondv). The leading columns of Z form an orthonormal basis for this invariant subspace.

For further explanation of the reciprocal condition numbers rconde and rcondv, see [LUG], Section 4.10 (where these quantities are called s and sep respectively).

A real matrix is in real-Schur form if it is upper quasi-triangular with 1-by-1 and 2-by-2 blocks. 2-by-2 blocks will be standardized in the form

$$
\begin{pmatrix}
    a & b \\
    c & a
\end{pmatrix}
$$

where $b \cdot c < 0$. The eigenvalues of such a block are $a \pm i \sqrt{bc}$.

A complex matrix is in Schur form if it is upper triangular.

Input Parameters

matrix_layout Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
**jobvs**

Must be 'N' or 'V'.

If jobvs = 'N', then Schur vectors are not computed.

If jobvs = 'V', then Schur vectors are computed.

**sort**

Must be 'N' or 'S'. Specifies whether or not to order the eigenvalues on the diagonal of the Schur form.

If sort = 'N', then eigenvalues are not ordered.

If sort = 'S', eigenvalues are ordered (see select).

**select**

If sort = 'S', select is used to select eigenvalues to sort to the top left of the Schur form.

If sort = 'N', select is not referenced.

*For real flavors:*

An eigenvalue \( wr[j] + \sqrt{-1} * wi[j] \) is selected if \( \text{select}(wr[j], wi[j]) \) is true; that is, if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected.

*For complex flavors:*

An eigenvalue \( w[j] \) is selected if \( \text{select}(w[j]) \) is true.

Note that a selected complex eigenvalue may no longer satisfy \( \text{select}(wr[j], wi[j]) = 1 \) after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned); in this case info may be set to \( n + 2 \) (see info below).

**sense**

Must be 'N', 'E', 'V', or 'B'. Determines which reciprocal condition number are computed.

If sense = 'N', none are computed;

If sense = 'E', computed for average of selected eigenvalues only;

If sense = 'V', computed for selected right invariant subspace only;

If sense = 'B', computed for both.

If sense is 'E', 'V', or 'B', then sort must equal 'S'.

**n**

The order of the matrix \( A \) (\( n \geq 0 \)).

**a**

Arrays:

\( a \) (size at least \( \max(1, lda* n) \)) is an array containing the \( n \)-by-\( n \) matrix \( A \).

**lda**

The leading dimension of the array \( a \). Must be at least \( \max(1, n) \).

**ldvs**

The leading dimension of the output array \( vs \). Constraints:

\( ldvs \geq 1 \);

\( ldvs \geq \max(1, n) \) if jobvs = 'V'.

**Output Parameters**

**a**

On exit, this array is overwritten by the real-Schur/Schur form \( T \).

**sdim**

If sort = 'N', \( sdim = 0 \).
If \( \text{sort} = 'S' \), \( sdim \) is equal to the number of eigenvalues (after sorting) for which \( \text{select} \) is true.

Note that for real flavors complex conjugate pairs for which \( \text{select} \) is true for either eigenvalue count as 2.

\( wr, wi \) Arrays, size at least \( \max(1, n) \) each. Contain the real and imaginary parts, respectively, of the computed eigenvalues, in the same order that they appear on the diagonal of the output real-Schur form \( T \). Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having positive imaginary part first.

\( w \) Array, size at least \( \max(1, n) \). Contains the computed eigenvalues. The eigenvalues are stored in the same order as they appear on the diagonal of the output Schur form \( T \).

\( vs \) Array \( vs \) (size at least \( \max(1, \text{ldvs} \times n) \))

If \( \text{jobvs} = 'V' \), \( vs \) contains the orthogonal/unitary matrix \( Z \) of Schur vectors.

If \( \text{jobvs} = 'N' \), \( vs \) is not referenced.

\( rconde, rcondv \)

If \( \text{sense} = 'E' \) or \( 'B' \), \( rconde \) contains the reciprocal condition number for the average of the selected eigenvalues.

If \( \text{sense} = 'N' \) or \( 'V' \), \( rconde \) is not referenced.

If \( \text{sense} = 'V' \) or \( 'B' \), \( rcondv \) contains the reciprocal condition number for the selected right invariant subspace.

If \( \text{sense} = 'N' \) or \( 'E' \), \( rcondv \) is not referenced.

**Return Values**

This function returns a value \( \text{info} \).

If \( \text{info}=0 \), the execution is successful.

If \( \text{info} = -i \), the \( i \)-th parameter had an illegal value.

If \( \text{info} = i \), and

\( i \leq n \):

the QR algorithm failed to compute all the eigenvalues; elements \( 1:ilo-1 \) and \( i+1:n \) of \( wr \) and \( wi \) (for real flavors) or \( w \) (for complex flavors) contain those eigenvalues which have converged; if \( \text{jobvs} = 'V' \), \( vs \) contains the transformation which reduces \( A \) to its partially converged Schur form;

\( i = n+1 \):

the eigenvalues could not be reordered because some eigenvalues were too close to separate (the problem is very ill-conditioned);

\( i = n+2 \):

after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Schur form no longer satisfy \( \text{select} = 1 \). This could also be caused by underflow due to scaling.

Include Files

• mkl.h

Description

The routine computes for an n-by-n real/complex nonsymmetric matrix A, the eigenvalues and, optionally, 
the left and/or right eigenvectors. The right eigenvector v of A satisfies

A*v = \lambda*v

where \lambda is its eigenvalue.

The left eigenvector u of A satisfies

u^H*A = \lambda*u^H

where u^H denotes the conjugate transpose of u. The computed eigenvectors are normalized to have 
Euclidean norm equal to 1 and largest component real.

Input Parameters

matrix_layout 

Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) 
or column major (LAPACK_COL_MAJOR).

jobvl 

Must be 'N' or 'V'.

If jobvl = 'N', then left eigenvectors of A are not computed.

If jobvl = 'V', then left eigenvectors of A are computed.

jobvr 

Must be 'N' or 'V'.

If jobvr = 'N', then right eigenvectors of A are not computed.

If jobvr = 'V', then right eigenvectors of A are computed.

n 

The order of the matrix A (n ≥ 0).

a (size at least max(1, lda*n)) is an array containing the n-by-n matrix A.

lda 

The leading dimension of the array a. Must be at least max(1, n).

ldvl, ldvr 

The leading dimensions of the output arrays vl and vr, respectively.
Constraints:

\[ ldvl \geq 1; \quad ldvr \geq 1. \]

If \( jobvl = 'V' \), \( ldvl \geq \max(1, n) \);

If \( jobvr = 'V' \), \( ldvr \geq \max(1, n) \).

**Output Parameters**

\( a \)

On exit, this array is overwritten.

\( wr, wi \)

Arrays, size at least \( \max(1, n) \) each.

Contain the real and imaginary parts, respectively, of the computed eigenvalues. Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having positive imaginary part first.

\( w \)

Array, size at least \( \max(1, n) \).

Contains the computed eigenvalues.

\( vl, vr \)

Arrays:

- \( vl \) (size at least \( \max(1, ldvl*n) \)).
  
  If \( jobvl = 'N' \), \( vl \) is not referenced.

  **For real flavors:**
  
  If the \( j \)-th eigenvalue is real, the \( i \)-th component of the \( j \)-th eigenvector \( u_j \) is stored in \( vl[(i - 1) + (j - 1)*ldvl] \) for column major layout and in \( vl[(i - 1)*ldvl + (j - 1)] \) for row major layout.

  If the \( j \)-th and \((j+1)\)-st eigenvalues form a complex conjugate pair, then for \( i = \sqrt{-1} \), the \( k \)-th component of the \( j \)-th eigenvector \( u_j \) is stored in \( vl[(k - 1) + (j - 1)*ldvl] + i*vl[(k - 1) + (j + 1)*ldvl] \) for column major layout and as \( vl[(k - 1)*ldvl + (j - 1)] + i*vl[(k-1)*ldvl + j] \) for row major layout.

  Similarly, the \( k \)-th component of vector \( (j+1)u_{j+1} \) is stored in \( vl[(k - 1) + (j - 1)*ldvl] - i*vl[(k - 1) + (j + 1)*ldvl] \) for column major layout and as \( vl[(k - 1)*ldvl + (j - 1)] - i*vl[(k-1)*ldvl + j] \) for row major layout.

- \( vr \) (size at least \( \max(1, ldvr*n) \)).
  
  If \( jobvr = 'N' \), \( vr \) is not referenced.

  **For complex flavors:**
  
  The \( i \)-th component of the \( j \)-th eigenvector \( u_j \) is stored in \( vl[(i - 1) + (j - 1)*ldvl] \) for column major layout and in \( vl[(i - 1)*ldvl + (j - 1)] \) for row major layout.

  If the \( j \)-th eigenvalue is real, then the \( i \)-th component of the \( j \)-th eigenvector \( v_j \) is stored in \( vr[(i - 1) + (j - 1)*ldvr] \) for column major layout and in \( vr[(i - 1)*ldvr + (j - 1)] \) for row major layout.

  If the \( j \)-th and \((j+1)\)-st eigenvalues form a complex conjugate pair, then for \( i = \sqrt{-1} \), the \( k \)-th component of the \( j \)-th eigenvector \( v_j \) is stored in \( vr[(k - 1) + (j - 1)*ldvr] + i*vr[(k - 1) + (j + 1)*ldvr] \) for column major layout and as \( vr[(k - 1)*ldvr + (j - 1)] + i*vr[(k-1)*ldvr + j] \) for row major layout.
Similarly, the $k$-th component of vector $j + 1$ $v_{j+1}$ is $vr[(k - 1) + (j - 1)*ldvr] - i*vr[(k - 1) + j*ldvr]$ for column major layout and as $vr[(k - 1)*ldvr + (j - 1)] - i*vr[(k - 1)*ldvr + j]$ for row major layout.

For complex flavors:

The $i$-th component of the $j$-th eigenvector $v_j$ is stored in $vr[(i - 1) + (j - 1)*ldvr]$ for column major layout and in $vr[(i - 1)*ldvr + (j - 1)]$ for row major layout.

Return Values

This function returns a value $info$.

If $info=0$, the execution is successful.

If $info = -i$, the $i$-th parameter had an illegal value.

If $info = i$, the QR algorithm failed to compute all the eigenvalues, and no eigenvectors have been computed; elements $i+1:n$ of $wr$ and $wi$ (for real flavors) or $w$ (for complex flavors) contain those eigenvalues which have converged.

?geevx

Computes the eigenvalues and left and right eigenvectors of a general matrix, with preliminary matrix balancing, and computes reciprocal condition numbers for the eigenvalues and right eigenvectors.

Syntax

```c

```

Include Files

- mkl.h

Description
The routine computes for an \( n \times n \) real/complex nonsymmetric matrix \( A \), the eigenvalues and, optionally, the left and/or right eigenvectors.

Optionally also, it computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (\( \text{ilo, ihi, scale, and abnrms} \)), reciprocal condition numbers for the eigenvalues (\( \text{rconde} \)), and reciprocal condition numbers for the right eigenvectors (\( \text{rconde}_v \)).

The right eigenvector \( v \) of \( A \) satisfies
\[
A v = \lambda v
\]
where \( \lambda \) is its eigenvalue.

The left eigenvector \( u \) of \( A \) satisfies
\[
u^H A = \lambda u^H
\]
where \( u^T \) denotes the conjugate transpose of \( u \). The computed eigenvectors are normalized to have Euclidean norm equal to 1 and largest component real.

Balancing a matrix means permuting the rows and columns to make it more nearly upper triangular, and applying a diagonal similarity transformation \( D^* A D^{-1} \), where \( D \) is a diagonal matrix, to make its rows and columns closer in norm and the condition numbers of its eigenvalues and eigenvectors smaller. The computed reciprocal condition numbers correspond to the balanced matrix. Permuting rows and columns will not change the condition numbers in exact arithmetic) but diagonal scaling will. For further explanation of balancing, see [LUG], Section 4.10.

**Input Parameters**

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **balanc**
  Must be 'N', 'P', 'S', or 'B'. Indicates how the input matrix should be diagonally scaled and/or permuted to improve the conditioning of its eigenvalues.
  - If \( \text{balanc} = 'N' \), do not diagonally scale or permute;
  - If \( \text{balanc} = 'P' \), perform permutations to make the matrix more nearly upper triangular. Do not diagonally scale;
  - If \( \text{balanc} = 'S' \), diagonally scale the matrix, i.e. replace \( A \) by \( D^* A D^{-1} \), where \( D \) is a diagonal matrix chosen to make the rows and columns of \( A \) more equal in norm. Do not permute;
  - If \( \text{balanc} = 'B' \), both diagonally scale and permute \( A \).

  Computed reciprocal condition numbers will be for the matrix after balancing and/or permuting. Permuting does not change condition numbers (in exact arithmetic), but balancing does.

- **jobvl**
  Must be 'N' or 'V'.
  - If \( \text{jobvl} = 'N' \), left eigenvectors of \( A \) are not computed;
  - If \( \text{jobvl} = 'V' \), left eigenvectors of \( A \) are computed.
  - If \( \text{sense} = 'E' \) or 'B', then \( \text{jobvl} \) must be 'V'.

- **jobvr**
  Must be 'N' or 'V'.
  - If \( \text{jobvr} = 'N' \), right eigenvectors of \( A \) are not computed;
  - If \( \text{jobvr} = 'V' \), right eigenvectors of \( A \) are computed.
If \( \text{sense} = 'E' \) or \'B', then \( \text{jobvr} \) must be \'V'.

\( \text{sense} \)

Must be \'N', \'E', \'V', \) or \'B'. Determines which reciprocal condition number are computed.

If \( \text{sense} = 'N' \), none are computed;
If \( \text{sense} = 'E' \), computed for eigenvalues only;
If \( \text{sense} = 'V' \), computed for right eigenvectors only;
If \( \text{sense} = 'B' \), computed for eigenvalues and right eigenvectors.

If \( \text{sense} \) is \'E' or \'B', both left and right eigenvectors must also be computed (\( \text{jobvl} = 'V' \) and \( \text{jobvr} = 'V' \)).

\( n \)
The order of the matrix \( A (n\geq 0) \).

\( a \)
Arrays:
\( a \) (size at least \( \max(1, lda*n) \)) is an array containing the \( n \)-by-\( n \) matrix \( A \).

\( lda \)
The leading dimension of the array \( a \). Must be at least \( \max(1, n) \).

\( ldvl, ldvr \)
The leading dimensions of the output arrays \( vl \) and \( vr \), respectively.

Constraints:
\( ldvl \geq 1; ldvr \geq 1. \)

If \( \text{jobvl} = 'V' \), \( ldvl \geq \max(1, n) \);
If \( \text{jobvr} = 'V' \), \( ldvr \geq \max(1, n) \).

Output Parameters

\( a \)
On exit, this array is overwritten.
If \( \text{jobvl} = 'V' \) or \( \text{jobvr} = 'V' \), it contains the real-Schur/Schur form of the balanced version of the input matrix \( A \).

\( wr, wi \)
Arrays, size at least \( \max(1, n) \) each. Contain the real and imaginary parts, respectively, of the computed eigenvalues. Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having positive imaginary part first.

\( w \)
Array, size at least \( \max(1, n) \). Contains the computed eigenvalues.

\( vl, vr \)
Arrays:
\( vl \) (size at least \( \max(1, ldvl*n) \)).
If \( \text{jobvl} = 'N' \), \( vl \) is not referenced.

For real flavors:
If the \( j \)-th eigenvalue is real, the \( i \)-th component of the \( j \)-th eigenvector \( u_j \) is stored in \( vl[(i-1)+(j-1)*ldvl] \) for column major layout and in \( vl[(i-1)*ldvl + (j-1)] \) for row major layout..

If the \( j \)-th and \( (j+1) \)-st eigenvalues form a complex conjugate pair, then for \( i = \sqrt{-1} \), the \( k \)-th component of the \( j \)-th eigenvector \( u_j \) is \( vl[(k-1)+(j-1)*ldvl] + i*vl[(k-1)+(j-1)*ldvl] \) for column major layout and as \( vl[(k-1)*ldvl + (j-1)] + i*vl[(k-1)*ldvl + j] \) for row major layout.
Similarly, the $k$-th component of vector $(j+1) u_{j+1}$ is $vl[(k - 1) + (j - 1)*ldvl] - i*vl[(k - 1) + j*ldvl]$ for column major layout and as $vl[(k - 1)*ldvl + (j - 1)] - i*vl[(k - 1)*ldvl + j]$ for row major layout.

For complex flavors:
The $i$-th component of the $j$-th eigenvector $u_j$ is stored in $vl[(i - 1) + (j - 1)*ldvl]$ for column major layout and in $vl[(i - 1)*ldvl + (j - 1)]$ for row major layout.

For real flavors:
If the $j$-th eigenvalue is real, then the $i$-th component of $j$-th eigenvector $v_j$ is stored in $vr[(i - 1) + (j - 1)*ldvr]$ for column major layout and in $vr[(i - 1)*ldvr + (j - 1)]$ for row major layout.

For complex flavors:
The $i$-th component of the $j$-th eigenvector $v_j$ is stored in $vr[(i - 1) + (j - 1)*ldvr]$ for column major layout and in $vr[(i - 1)*ldvr + (j - 1)]$ for row major layout.

For complex flavors:
The $i$-th component of the $j$-th eigenvector $v_j$ is stored in $vr[(i - 1) + (j - 1)*ldvr]$ for column major layout and in $vr[(i - 1)*ldvr + (j - 1)]$ for row major layout.

$i_l o, i_h i$

$i_l o$ and $i_h i$ are integer values determined when $A$ was balanced.

The balanced $A(i,j) = 0$ if $i > j$ and $j = 1, \ldots, i_l o - 1$ or $i = i_h i + 1, \ldots, n$.

If $b a l a n c = ' N ' o r ' S ' , i_l o = 1$ and $i_h i = n$.

$s c a l e$

Array, size at least max(1, $n$). Details of the permutations and scaling factors applied when balancing $A$.

If $P[j - 1]$ is the index of the row and column interchanged with row and column $J$, and $D[j - 1]$ is the scaling factor applied to row and column $J$, then

$s c a l e[j - 1] = P[j - 1], f o r j = 1, \ldots, i_l o - 1$

$= D[j - 1], f o r j = i_l o, \ldots, i_h i$

$= P[j - 1] f o r j = i_h i + 1, \ldots, n$.

The order in which the interchanges are made is $n$ to $i_h i + 1$, then 1 to $i_l o - 1$.

$a b n r m$

The one-norm of the balanced matrix (the maximum of the sum of absolute values of elements of any column).

$r c o n d _ e, r c o n d _ v$

Arrays, size at least max(1, $n$) each.

$r c o n d _ e[j - 1]$ is the reciprocal condition number of the $j$-th eigenvalue.
\[ r\text{condv}[j - 1] \] is the reciprocal condition number of the \( j \)-th right eigenvector.

**Return Values**

This function returns a value \( info \).

- If \( info=0 \), the execution is successful.
- If \( info = -i \), the \( i \)-th parameter had an illegal value.
- If \( info = i \), the QR algorithm failed to compute all the eigenvalues, and no eigenvectors or condition numbers have been computed; elements 1:ilo-1 and i+1:n of \( wr \) and \( wi \) (for real flavors) or \( w \) (for complex flavors) contain eigenvalues which have converged.

Include Files

- mkl.h

Description

The routine computes the singular value decomposition (SVD) of a real/complex m-by-n matrix A, optionally computing the left and/or right singular vectors. The SVD is written as

\[ A = U \Sigma V^T \] for real routines

\[ A = U \Sigma V^H \] for complex routines

where \( \Sigma \) is an \( m \times n \) matrix which is zero except for its \( \min(m,n) \) diagonal elements, \( U \) is an \( m \times m \) orthogonal/unitary matrix, and \( V \) is an \( n \times n \) orthogonal/unitary matrix. The diagonal elements of \( \Sigma \) are the singular values of \( A \); they are real and non-negative, and are returned in descending order. The first \( \min(m, n) \) columns of \( U \) and \( V \) are the left and right singular vectors of \( A \).

The routine returns \( V^T \) (for real flavors) or \( V^H \) (for complex flavors), not \( V \).

Input Parameters

- **matrix_layout**: Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **jobu**: Must be 'A', 'S', 'O', or 'N'. Specifies options for computing all or part of the matrix \( U \).
  - If \( jobu = 'A' \), all \( m \) columns of \( U \) are returned in the array \( u \);
  - if \( jobu = 'S' \), the first \( \min(m, n) \) columns of \( U \) (the left singular vectors) are returned in the array \( u \);
  - if \( jobu = 'O' \), the first \( \min(m, n) \) columns of \( U \) (the left singular vectors) are overwritten on the array \( a \);
  - if \( jobu = 'N' \), no columns of \( U \) (no left singular vectors) are computed.

- **jobvt**: Must be 'A', 'S', 'O', or 'N'. Specifies options for computing all or part of the matrix \( V^T/V^H \).
  - If \( jobvt = 'A' \), all \( n \) rows of \( V^T/V^H \) are returned in the array \( vt \);
  - if \( jobvt = 'S' \), the first \( \min(m, n) \) rows of \( V^T/V^H \) (the right singular vectors) are returned in the array \( vt \);
  - if \( jobvt = 'O' \), the first \( \min(m, n) \) rows of \( V^T/V^H \) (the right singular vectors) are overwritten on the array \( a \);
  - if \( jobvt = 'N' \), no rows of \( V^T/V^H \) (no right singular vectors) are computed.

- **m**: The number of rows of the matrix \( A \) (\( m \geq 0 \)).

- **n**: The number of columns in \( A \) (\( n \geq 0 \)).

Arrays:
A (size at least \(\max(1, lda*n)\) for column major layout and \(\max(1, lda*m)\) for row major layout) is an array containing the \(m\)-by-\(n\) matrix \(A\).

**lda**

The leading dimension of the array \(a\).

Must be at least \(\max(1, m)\) for column major layout and at least \(\max(1, n)\) for row major layout.

**ldu, ldvt**

The leading dimensions of the output arrays \(u\) and \(vt\), respectively.

**Constraints:**

\(ldu \geq 1; ldvt \geq 1\).

If \(jobu = 'A'\), \(ldu \geq m\); 

If \(jobu = 'S'\), \(ldu \geq m\) for column major layout and \(ldu \geq \min(m, n)\) for row major layout;

If \(jobvt = 'A'\), \(ldvt \geq n\); 

If \(jobvt = 'S'\), \(ldvt \geq \min(m, n)\) for column major layout and \(ldvt \geq n\) for row major layout.

**Output Parameters**

**\(a\)**

On exit,

If \(jobu = 'O'\), \(a\) is overwritten with the first \(\min(m, n)\) columns of \(U\) (the left singular vectors stored columnwise);

If \(jobvt = 'O'\), \(a\) is overwritten with the first \(\min(m, n)\) rows of \(V^T/V^H\) (the right singular vectors stored rowwise);

If \(jobu \neq 'O' \text{ and } jobvt \neq 'O'\), the contents of \(a\) are destroyed.

**\(s\)**

Array, size at least \(\max(1, \min(m, n))\). Contains the singular values of \(A\) sorted so that \(s[i] \geq s[i + 1]\).

**Arrays:**

Array \(u\) minimum size:

<table>
<thead>
<tr>

<td>(jobu = 'A')</td>
<td>(\max(1, ldu*m))</td>
<td>(\max(1, ldu*m))</td>
</tr>
<tr>
<td>(jobu = 'S')</td>
<td>(\max(1, ldu*\min(m, n)))</td>
<td>(\max(1, ldu*m))</td>
</tr>
</tbody>
</table>

If \(jobu = 'A'\), \(u\) contains the \(m\)-by-\(m\) orthogonal/unitary matrix \(U\).

If \(jobu = 'S'\), \(u\) contains the first \(\min(m, n)\) columns of \(U\) (the left singular vectors stored column-wise).

If \(jobu = 'N' \text{ or } 'O'\), \(u\) is not referenced.

Array \(v\) minimum size:

<table>
<thead>
<tr>
<th></th>
<th>Column major layout</th>
<th>Row major layout</th>
</tr>
</thead>
<tbody>
<tr>
<td>(jobvt = 'A')</td>
<td>(\max(1, ldvt*n))</td>
<td>(\max(1, ldvt*n))</td>
</tr>
</tbody>
</table>
If \( \text{jobvt} = 'A' \), \( vt \) contains the \( n \)-by-\( n \) orthogonal/unitary matrix \( V^T/V^H \).

If \( \text{jobvt} = 'S' \), \( vt \) contains the first \( \min(m, n) \) rows of \( V^T/V^H \) (the right singular vectors stored row-wise).

If \( \text{jobvt} = 'N' \) or 'O', \( vt \) is not referenced.

If \( ?bdsqr \) does not converge (indicated by the return value \( \text{info} > 0 \)), on exit \( \text{superb}(0:\min(m,n)-2) \) contains the unconverged superdiagonal elements of an upper bidiagonal matrix \( B \) whose diagonal is in \( s \) (not necessarily sorted). \( B \) satisfies \( A = u*B*V^T \) (real flavors) or \( A = u*B*V^H \) (complex flavors), so it has the same singular values as \( A \), and singular vectors related by \( u \) and \( vt \).

**Return Values**

This function returns a value \( \text{info} \).

If \( \text{info} = 0 \), the execution is successful.

If \( \text{info} = -i \), the \( i \)-th parameter had an illegal value.

If \( \text{info} = i \), then if \( ?bdsqr \) did not converge, \( i \) specifies how many superdiagonals of the intermediate bidiagonal form \( B \) did not converge to zero (see the description of the \( \text{superb} \) parameter for details).

**?gesdd**

*Computes the singular value decomposition of a general rectangular matrix using a divide and conquer method.*

**Syntax**

```c
lapack_int LAPACKE_sgesdd( int matrix_layout, char jobz, lapack_int m, lapack_int n,
float* a, lapack_int lda, float* s, float* u, lapack_int ldu, float* vt, lapack_int ldvt );

lapack_int LAPACKE_dgesdd( int matrix_layout, char jobz, lapack_int m, lapack_int n,
double* a, lapack_int lda, double* s, double* u, lapack_int ldu, double* vt, lapack_int ldvt );

lapack_int LAPACKE_cgesdd( int matrix_layout, char jobz, lapack_int m, lapack_int n,
lapack_complex_float* a, lapack_int lda, float* s, lapack_complex_float* u, lapack_int ldu, lapack_complex_float* vt, lapack_int ldvt );

lapack_int LAPACKE_zgesdd( int matrix_layout, char jobz, lapack_int m, lapack_int n,
lapack_complex_double* a, lapack_int lda, double* s, lapack_complex_double* u, lapack_int ldu, lapack_complex_double* vt, lapack_int ldvt );
```

**Include Files**

- mkl.h

**Description**
The routine computes the singular value decomposition (SVD) of a real/complex \( m \)-by-\( n \) matrix \( A \), optionally computing the left and/or right singular vectors. If singular vectors are desired, it uses a divide-and-conquer algorithm. The SVD is written

\[
A = U^* \Sigma V^T \quad \text{for real routines,}
\]

\[
A = U^* \Sigma V^H \quad \text{for complex routines,}
\]

where \( \Sigma \) is an \( m \)-by-\( n \) matrix which is zero except for its \( \min(m,n) \) diagonal elements, \( U \) is an \( m \)-by-\( m \) orthogonal/unitary matrix, and \( V \) is an \( n \)-by-\( n \) orthogonal/unitary matrix. The diagonal elements of \( \Sigma \) are the singular values of \( A \); they are real and non-negative, and are returned in descending order. The first \( \min(m,n) \) columns of \( U \) and \( V \) are the left and right singular vectors of \( A \).

Note that the routine returns \( v^t = V^T \) (for real flavors) or \( v^t = V^H \) (for complex flavors), not \( V \).

**Input Parameters**

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **jobz**
  Must be 'A', 'S', 'O', or 'N'.

  Specifies options for computing all or part of the matrices \( U \) and \( V \).

  If \( \text{jobz} = \text{'A'} \), all \( m \) columns of \( U \) and all \( n \) rows of \( V^T \) or \( V^H \) are returned in the arrays \( u \) and \( v^t \);

  if \( \text{jobz} = \text{'S'} \), the first \( \min(m,n) \) columns of \( U \) and the first \( \min(m,n) \) rows of \( V^T \) or \( V^H \) are returned in the arrays \( u \) and \( v^t \);

  if \( \text{jobz} = \text{'O'} \), then

  if \( m \geq n \), the first \( n \) columns of \( U \) are overwritten in the array \( a \) and all rows of \( V^T \) or \( V^H \) are returned in the array \( v^t \);

  if \( m < n \), all columns of \( U \) are returned in the array \( u \) and the first \( m \) rows of \( V^T \) or \( V^H \) are overwritten in the array \( a \);

  if \( \text{jobz} = \text{'N'} \), no columns of \( U \) or rows of \( V^T \) or \( V^H \) are computed.

- **m**
  The number of rows of the matrix \( A \) (\( m \geq 0 \)).

- **n**
  The number of columns in \( A \) (\( n \geq 0 \)).

- **a**
  \( \text{a(size max(1, lda*n))} \) for column major layout and \( \text{max(1, lda*m)} \) for row major layout) is an array containing the \( m \)-by-\( n \) matrix \( A \).

- **lda**
  The leading dimension of the array \( a \). Must be at least \( \text{max(1, m)} \) for column major layout and at least \( \text{max(1, n)} \) for row major layout.

- **ldu, ldvt**
  The leading dimensions of the output arrays \( u \) and \( v^t \), respectively.

  The minimum size of \( ldu \) is

<table>
<thead>
<tr>
<th>( \text{jobz} )</th>
<th>( m \geq n )</th>
<th>( m &lt; n )</th>
</tr>
</thead>
<tbody>
<tr>
<td>'N'</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>'A'</td>
<td>( m )</td>
<td>( m )</td>
</tr>
<tr>
<td>'S'</td>
<td>( m ) for column major layout; ( n ) for row major layout</td>
<td>( m ) for column major layout; ( n ) for row major layout</td>
</tr>
</tbody>
</table>
Output Parameters

On exit:

If jobz = 'O', then if m ≥ n, a is overwritten with the first n columns of U (the left singular vectors, stored columnwise). If m < n, a is overwritten with the first m rows of Vᵀ (the right singular vectors, stored rowwise);

If jobz≠'O', the contents of a are destroyed.

Array, size at least max(1, min(m, n)). Contains the singular values of A sorted so that s(i) ≥ s(i+1).

Arrays:

Array u is of size:

<table>
<thead>
<tr>
<th>jobz</th>
<th>m≥n</th>
<th>m &lt; n</th>
</tr>
</thead>
<tbody>
<tr>
<td>'N'</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>'A'</td>
<td>max(1, ldu*m)</td>
<td>max(1, ldu*m)</td>
</tr>
<tr>
<td>'S'</td>
<td>max(1, ldu<em>n) for column major layout; max(1, ldu</em>m) for row major layout</td>
<td>max(1, ldu*m)</td>
</tr>
<tr>
<td>'O'</td>
<td>1</td>
<td>max(1, ldu*m)</td>
</tr>
</tbody>
</table>

If jobz = 'A' or jobz = 'O' and m < n, u contains the m-by-m orthogonal/unitary matrix U.

If jobz = 'S', u contains the first min(m, n) columns of U (the left singular vectors, stored columnwise).

If jobz = 'O' and m≥n, or jobz = 'N', u is not referenced.

Array vt is of size:
<table>
<thead>
<tr>
<th>jobz</th>
<th>( m \geq n )</th>
<th>( m &lt; n )</th>
</tr>
</thead>
<tbody>
<tr>
<td>'N'</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>'A'</td>
<td>( \max(1, \text{ldvt}*n) )</td>
<td>( \max(1, \text{ldvt}*n) )</td>
</tr>
<tr>
<td>'S'</td>
<td>( \max(1, \text{ldvt}*n) )</td>
<td>( \max(1, \text{ldvt}*n) ) for column major layout; ( \max(1, \text{ldvt}*m) ) for row major layout;</td>
</tr>
<tr>
<td>'O'</td>
<td>( \max(1, \text{ldvt}*n) )</td>
<td>1</td>
</tr>
</tbody>
</table>

If \( \text{jobz} = 'A' \) or \( \text{jobz} = 'O' \) and \( m \geq n \), \( \text{vt} \) contains the \( n \)-by-\( n \) orthogonal/unitary matrix \( V^T \).

If \( \text{jobz} = 'S' \), \( \text{vt} \) contains the first \( \min(m, n) \) rows of \( V^T \) (the right singular vectors, stored rowwise).

If \( \text{jobz} = 'O' \) and \( m < n \), or \( \text{jobz} = 'N' \), \( \text{vt} \) is not referenced.

**Return Values**

This function returns a value \( \text{info} \).

If \( \text{info} = 0 \), the execution is successful.

If \( \text{info} = -i \), the \( i \)-th parameter had an illegal value.

If \( \text{info} = i \), then \( \text{?bdsdc} \) did not converge, updating process failed.

**?gejsv**

*Computes the singular value decomposition using a preconditioned Jacobi SVD method.*

**Syntax**

```c
lapack_int LAPACKE_sgejsv (int matrix_layout, char joba, char jobu, char jobv, char jobr, char jobt, char jobp, lapack_int m, lapack_int n, float * a, lapack_int lda, float * sva, float * u, lapack_int ldu, float * v, lapack_int ldv, float * stat, lapack_int * istat);

lapack_int LAPACKE_dgejsv (int matrix_layout, char joba, char jobu, char jobv, char jobr, char jobt, char jobp, lapack_int m, lapack_int n, double * a, lapack_int lda, double * sva, double * u, lapack_int ldu, double * v, lapack_int ldv, double * stat, lapack_int * istat);

lapack_int LAPACKE_cgejsv (int matrix_layout, char joba, char jobu, char jobv, char jobr, char jobt, char jobp, lapack_int m, lapack_int n, lapack_complex_float * a, lapack_int lda, float * sva, lapack_complex_float * u, lapack_int ldu, lapack_complex_float * v, lapack_int ldv, float * stat, lapack_int * istat);

lapack_int LAPACKE_zgejsv (int matrix_layout, char joba, char jobu, char jobv, char jobr, char jobt, char jobp, lapack_int m, lapack_int n, lapack_complex_double * a, lapack_int lda, double * sva, lapack_complex_double * u, lapack_int ldu, lapack_complex_double * v, lapack_int ldv, double * stat, lapack_int * istat);
```

- mkl.h

Description

The routine computes the singular value decomposition (SVD) of a real/complex $m$-by-$n$ matrix $A$, where $m \geq n$.

The SVD is written as

$$ A = U \Sigma V^T $$

for real routines

$$ A = U \Sigma V^H $$

for complex routines

where $\Sigma$ is an $m$-by-$n$ matrix which is zero except for its $n$ diagonal elements, $U$ is an $m$-by-$n$ (or $m$-by-$m$) orthonormal matrix, and $V$ is an $n$-by-$n$ orthogonal matrix. The diagonal elements of $\Sigma$ are the singular values of $A$; the columns of $U$ and $V$ are the left and right singular vectors of $A$, respectively. The matrices $U$ and $V$ are computed and stored in the arrays $u$ and $v$, respectively. The diagonal of $\Sigma$ is computed and stored in the array $sva$.

The ?gejsv routine can sometimes compute tiny singular values and their singular vectors much more accurately than other SVD routines.

The routine implements a preconditioned Jacobi SVD algorithm. It uses ?geqp3, ?geqrf, and ?gelqf as preprocessors and preconditioners. Optionally, an additional row pivoting can be used as a preprocessor, which in some cases results in much higher accuracy. An example is matrix $A$ with the structure $A = D1 \times C \times D2$, where $D1, D2$ are arbitrarily ill-conditioned diagonal matrices and $C$ is a well-conditioned matrix. In that case, complete pivoting in the first QR factorizations provides accuracy dependent on the condition number of $C$, and independent of $D1, D2$. Such higher accuracy is not completely understood theoretically, but it works well in practice.

If $A$ can be written as $A = B \times D$, with well-conditioned $B$ and some diagonal $D$, then the high accuracy is guaranteed, both theoretically and in software, independent of $D$. For more details see [Drmac08-1], [Drmac08-2].

The computational range for the singular values can be the full range ($\text{UNDERFLOW,OVERFLOW}$), provided that the machine arithmetic and the BLAS and LAPACK routines called by ?gejsv are implemented to work in that range. If that is not the case, the restriction for safe computation with the singular values in the range of normalized IEEE numbers is that the spectral condition number $\kappa(A) = \sigma_{\text{max}}(A)/\sigma_{\text{min}}(A)$ does not overflow. This code (?gejsv) is best used in this restricted range, meaning that singular values of magnitude below $||A||_2 / \text{slamch('O')} \text{ (for single precision) or } ||A||_2 / \text{dlamch('O')} \text{ (for double precision)}$ are returned as zeros. See jobr for details on this.

This implementation is slower than the one described in [Drmac08-1], [Drmac08-2] due to replacement of some non-LAPACK components, and because the choice of some tuning parameters in the iterative part (?gesvj) is left to the implementer on a particular machine.

The rank revealing QR factorization (in this code: ?geqp3) should be implemented as in [Drmac08-3].

If $m$ is much larger than $n$, it is obvious that the initial QRF with column pivoting can be preprocessed by the QRF without pivoting. That well known trick is not used in ?gejsv because in some cases heavy row weighting can be treated with complete pivoting. The overhead in cases $m$ much larger than $n$ is then only due to pivoting, but the benefits in accuracy have prevailed. You can incorporate this extra QRF step easily and also improve data movement (matrix transpose, matrix copy, matrix transposed copy) - this implementation of ?gejsv uses only the simplest, naive data movement.
Input Parameters

\textbf{matrix_layout}

Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

\textbf{joba}

Must be 'C', 'E', 'F', 'G', 'A', or 'R'.

Specifies the level of accuracy:

If \textit{joba} = 'C', high relative accuracy is achieved if \( A = B \cdot D \) with well-conditioned \( B \) and arbitrary diagonal matrix \( D \). The accuracy cannot be spoiled by column scaling. The accuracy of the computed output depends on the condition of \( B \), and the procedure aims at the best theoretical accuracy. The relative error \( \max_{i=1:N} |d \cdot \sigma_i| / \sigma_i \) is bounded by \( f(M,N) \cdot \text{epsilon} \cdot \text{cond}(B) \), independent of \( D \). The input matrix is preprocessed with the QRF with column pivoting. This initial preprocessing and preconditioning by a rank revealing QR factorization is common for all values of \textit{joba}. Additional actions are specified as follows:

If \textit{joba} = 'E', computation as with 'C' with an additional estimate of the condition number of \( B \). It provides a realistic error bound.

If \textit{joba} = 'F', accuracy higher than in the 'C' option is achieved, if \( A = D_1 \cdot C \cdot D_2 \) with ill-conditioned diagonal scalings \( D_1, D_2 \), and a well-conditioned matrix \( C \). This option is advisable, if the structure of the input matrix is not known and relative accuracy is desirable. The input matrix \( A \) is preprocessed with QR factorization with full (row and column) pivoting.

If \textit{joba} = 'G', computation as with 'F' with an additional estimate of the condition number of \( B \), where \( A = B \cdot D \). If \( A \) has heavily weighted rows, using this condition number gives too pessimistic error bound.

If \textit{joba} = 'A', small singular values are the noise and the matrix is treated as numerically rank deficient. The error in the computed singular values is bounded by \( f(m,n) \cdot \text{epsilon} \cdot ||A|| \). The computed SVD \( A = U \cdot S \cdot V^\top \) (for real flavors) or \( A = U \cdot S \cdot V^\ast \) (for complex flavors) restores \( A \) up to \( f(m,n) \cdot \text{epsilon} \cdot ||A|| \). This enables the procedure to set all singular values below \( \text{epsilon} \cdot ||A|| \) to zero.

If \textit{joba} = 'R', the procedure is similar to the 'A' option. Rank revealing property of the initial QR factorization is used to reveal (using triangular factor) a gap \( \sigma_{r+1} < \text{epsilon} \cdot \sigma_r \), in which case the numerical rank is declared to be \( r \). The SVD is computed with absolute error bounds, but more accurately than with 'A'.
jobu

Must be 'U', 'F', 'W', or 'N'.

Specifies whether to compute the columns of the matrix $U$:

If $jobu = 'U'$, $n$ columns of $U$ are returned in the array $u$.

If $jobu = 'F'$, a full set of $m$ left singular vectors is returned in the array $u$.

If $jobu = 'W'$, $u$ may be used as workspace of length $m \times n$. See the description of $u$.

If $jobu = 'N'$, $u$ is not computed.

jobv

Must be 'V', 'J', 'W', or 'N'.

Specifies whether to compute the matrix $V$:

If $jobv = 'V'$, $n$ columns of $V$ are returned in the array $v$; Jacobi rotations are not explicitly accumulated.

If $jobv = 'J'$, $n$ columns of $V$ are returned in the array $v$ but they are computed as the product of Jacobi rotations. This option is allowed only if $jobu \neq 'N'$.

If $jobv = 'W'$, $v$ may be used as workspace of length $n \times n$. See the description of $v$.

If $jobv = 'N'$, $v$ is not computed.

jobr

Must be 'N' or 'R'.

Specifies the range for the singular values. If small positive singular values are outside the specified range, they may be set to zero. If $A$ is scaled so that the largest singular value of the scaled matrix is around $\sqrt{\text{big}}$, $\text{big} = \text{lamch('O')}$, the function can remove columns of $A$ whose norm in the scaled matrix is less than $\sqrt{\text{lamch('S')}}$ (for $jobr = 'R'$), or less than $\text{small} = \text{lamch('S')}/\text{lamch('E')}$.

If $jobr = 'N'$, the function does not remove small columns of the scaled matrix. This option assumes that BLAS and QR factorizations and triangular solvers are implemented to work in that range. If the condition of $A$ is greater than $\text{big}$, use $\text{gesvj}$.

If $jobr = 'R'$, restricted range for singular values of the scaled matrix $A$ is $[\sqrt{\text{lamch('S')}}, \sqrt{\text{big}}]$, roughly as described above. This option is recommended.

For computing the singular values in the full range $[\text{lamch('S')}, \text{big}]$, use $\text{gesvj}$.

jobt

Must be 'T' or 'N'.

If the matrix is square, the procedure may determine to use a transposed $A$ if $A^T$ (for real flavors) or $A^H$ (for complex flavors) seems to be better with respect to convergence. If the matrix is not square, $jobt$ is ignored.

The decision is based on two values of entropy over the adjoint orbit of $A^T * A$ (for real flavors) or $A^H * A$ (for complex flavors). See the descriptions of $\text{stat}[5]$ and $\text{stat}[6]$. 
If \( jobt = 'T' \), the function performs transposition if the entropy test indicates possibly faster convergence of the Jacobi process, if \( A \) is taken as input. If \( A \) is replaced with \( A^T \) or \( A^H \), the row pivoting is included automatically.

If \( jobt = 'N' \), the functions attempts no speculations. This option can be used to compute only the singular values, or the full SVD \((u, sigma, and v)\). For only one set of singular vectors \((u or v)\), the caller should provide both \( u \) and \( v \), as one of the arrays is used as workspace if the matrix \( A \) is transposed. The implementer can easily remove this constraint and make the code more complicated. See the descriptions of \( u \) and \( v \).

**Caution**
The \( jobt = 'T' \) option is experimental and its effect might not be the same in subsequent releases. Consider using the \( jobt = 'N' \) instead.

\[ \text{jobp} \]

Must be \( 'P' \) or \( 'N' \).

Enables structured perturbations of denormalized numbers. This option should be active if the denormals are poorly implemented, causing slow computation, especially in cases of fast convergence. For details, see [Drmac08-1], [Drmac08-2]. For simplicity, such perturbations are included only when the full SVD or only the singular values are requested. You can add the perturbation for the cases of computing one set of singular vectors.

If \( jobp = 'P' \), the function introduces perturbation.

If \( jobp = 'N' \), the function introduces no perturbation.

\[ m \]

The number of rows of the input matrix \( A \); \( m \geq 0 \).

\[ n \]

The number of columns in the input matrix \( A \); \( m \geq n \geq 0 \).

\[ a, u, v \]

Array \( a(\text{size } lda \times n \text{ for column major layout and } lda \times m \text{ for row major layout}) \) is an array containing the \( m \)-by-\( n \) matrix \( A \).

\( u \) is a workspace array, its size for column major layout is \( ldu \times n \) for \( jobu = 'U' \) or \( 'W' \) and \( ldu \times m \) for \( jobu = 'F' \); for row major layout its size is at least \( ldu \times m \). When \( jobt = 'T' \) and \( m = n \), \( u \) must be provided even though \( jobu = 'N' \).

\( v \) is a workspace array, its size is \( ldv \times n \). When \( jobt = 'T' \) and \( m = n \), \( v \) must be provided even though \( jobv = 'N' \).

\[ lda \]

The leading dimension of the array \( a \). Must be at least \( \max(1, m) \) for column major layout and at least \( \max(1, n) \) for row major layout.

\[ sva \]

\( sva \) is a workspace array, its size is \( n \).

\[ ldu \]

The leading dimension of the array \( u \); \( ldu \geq 1 \).

\[ jobu = 'U' \text{ or 'F' or 'W', } ldu \geq m \text{ for column major layout; for row major layout if } jobu = 'U' \text{ or } jobu = 'W', ldu \geq n \text{ and if } jobu = 'F', ldu \geq m \).

\[ ldv \]

The leading dimension of the array \( v \); \( ldv \geq 1 \).
jobv = 'V' or 'J' or 'W', ldv≥n.

cwork is a workspace array of size \( \max(2, \text{lwork}) \).

rwork is an array of size at least \( \max(7, \text{lrwork}) \) for real flavors and at least \( \max(7, \text{lwork}) \) for complex flavors.

Output Parameters

sva

On exit:

For \( \text{stat}[0]/\text{stat}[1] = 1 \): the singular values of \( A \). During the computation \( \text{sva} \) contains Euclidean column norms of the iterated matrices in the array \( a \).

For \( \text{stat}[0]\ne\text{stat}[1] \): the singular values of \( A \) are \((\text{stat}[0]/\text{stat}[1]) * \text{sva}[0:n-1]\). This factored form is used if \( \text{sigma}_\text{max}(A) \) overflows or if small singular values have been saved from underflow by scaling the input matrix \( A \).

jobr = 'R', some of the singular values may be returned as exact zeros obtained by 'setting to zero' because they are below the numerical rank threshold or are denormalized numbers.

u

On exit:

If \( \text{jobu} = 'U' \), contains the \( m \)-by-\( n \) matrix of the left singular vectors.

If \( \text{jobu} = 'F' \), contains the \( m \)-by-\( m \) matrix of the left singular vectors, including an orthonormal basis of the orthogonal complement of the range of \( A \).

If \( \text{jobu} = 'W' \) and \( \text{jobv} = 'V' \), \( \text{jobt} = 'T' \), and \( m = n \), then \( u \) is used as workspace if the procedure replaces \( A \) with \( A^T \) (for real flavors) or \( A^H \) (for complex flavors). In that case, \( v \) is computed in \( u \) as left singular vectors of \( A^T \) or \( A^H \) and copied back to the \( v \) array. This 'W' option is just a reminder to the caller that in this case \( u \) is reserved as workspace of length \( n*n \).

If \( \text{jobu} = 'N' \), \( u \) is not referenced.

v

On exit:

If \( \text{jobv} = 'V' \) or 'J', contains the \( n \)-by-\( n \) matrix of the right singular vectors.

If \( \text{jobv} = 'W' \) and \( \text{jobu} = 'U' \), \( \text{jobt} = 'T' \), and \( m = n \), then \( v \) is used as workspace if the procedure replaces \( A \) with \( A^T \) (for real flavors) or \( A^H \) (for complex flavors). In that case, \( u \) is computed in \( v \) as right singular vectors of \( A^T \) or \( A^H \) and copied back to the \( u \) array. This 'W' option is just a reminder to the caller that in this case \( v \) is reserved as workspace of length \( n*n \).

If \( \text{jobv} = 'N' \), \( v \) is not referenced.

stat

On exit,

\( \text{stat}[0] = \text{scale} = \text{stat}[1]/\text{stat}[0] \) is the scaling factor such that \( \text{scale}*\text{sva}(1:n) \) are the computed singular values of \( A \). See the description of \( \text{sva} \).
stat[1] = see the description of stat[0].

stat[2] = *sconda* is an estimate for the condition number of column equilibrated A. If joba = 'E' or 'G', *sconda* is an estimate of $\sqrt{|| (R^T \ast R)^{-1} ||_1}$. It is computed using ?pocon. It holds $n^{-1/4} \ast sconda \leq || R^{-1} ||_2 \leq n^{-1/4} + sconda$, where R is the triangular factor from the QRF of A. However, if R is truncated and the numerical rank is determined to be strictly smaller than n, *sconda* is returned as -1, indicating that the smallest singular values might be lost.

If full SVD is needed, the following two condition numbers are useful for the analysis of the algorithm. They are provided for a user who is familiar with the details of the method.

stat[3] = an estimate of the scaled condition number of the triangular factor in the first QR factorization.

stat[4] = an estimate of the scaled condition number of the triangular factor in the second QR factorization.

The following two parameters are computed if jobt = 'T'. They are provided for a user who is familiar with the details of the method.

stat[5] = the entropy of $A^T \ast A$ :: this is the Shannon entropy of $\text{diag}(A^T \ast A) / \text{Trace}(A^T \ast A)$ taken as point in the probability simplex.

stat[6] = the entropy of $A \ast A^{**}t$.

*istat*

On exit,

*istat[0] =* the numerical rank determined after the initial QR factorization with pivoting. See the descriptions of joba and jobr.

*istat[1] =* the number of the computed nonzero singular value.

*istat[2] =* if nonzero, a warning message. If *istat[2] = 1*, some of the column norms of A were denormalized floats. The requested high accuracy is not warranted by the data.

For complex flavors, *istat[3] = 1* or -1. If *istat[3] = 1*, then the procedure used $A^H$ to do the job as specified by the *job* parameters.

**Return Values**

This function returns a value *info*.

If *info=0*, the execution is successful.

If *info = -i*, the *i*-th parameter had an illegal value.

If *info > 0*, the function did not converge in the maximal number of sweeps. The computed values may be inaccurate.

**Description**

The routine computes the singular value decomposition (SVD) of a real or complex $m$-by-$n$ matrix $A$, where $m \geq n$.

The SVD of $A$ is written as

$$ A = U \Sigma V^T $$ for real flavors, or

$$ A = U \Sigma V^H $$ for complex flavors,

where $\Sigma$ is an $m$-by-$n$ diagonal matrix, $U$ is an $m$-by-$n$ orthonormal matrix, and $V$ is an $n$-by-$n$ orthogonal/unitary matrix. The diagonal elements of $\Sigma$ are the singular values of $A$; the columns of $U$ and $V$ are the left and right singular vectors of $A$, respectively. The matrices $U$ and $V$ are computed and stored in the arrays $u$ and $v$, respectively. The diagonal of $\Sigma$ is computed and stored in the array $sva$.

The `gesvj` routine can sometimes compute tiny singular values and their singular vectors much more accurately than other SVD routines.

The $n$-by-$n$ orthogonal matrix $V$ is obtained as a product of Jacobi plane rotations. The rotations are implemented as fast scaled rotations of Anda and Park [AndaPark94]. In the case of underflow of the Jacobi angle, a modified Jacobi transformation of Drmac ([Drmac08-4]) is used. Pivot strategy uses column interchanges of de Rijk ([deRijk98]). The relative accuracy of the computed singular values and the accuracy of the computed singular vectors (in angle metric) is as guaranteed by the theory of Demmel and Veselic [Demmel92]. The condition number that determines the accuracy in the full rank case is essentially

$$ (\min_i d_i) \cdot \kappa(A \cdot D) $$

where $\kappa(.)$ is the spectral condition number. The best performance of this Jacobi SVD procedure is achieved if used in an accelerated version of Drmac and Veselic [Drmac08-1], [Drmac08-2].
The computational range for the nonzero singular values is the machine number interval \((\text{UNDERFLOW}, \text{OVERFLOW})\). In extreme cases, even denormalized singular values can be computed with the corresponding gradual loss of accurate digit.

**Input Parameters**

**matrix_layout**

Specifies whether matrix storage layout is row major (LAPACK\_ROW\_MAJOR) or column major (LAPACK\_COL\_MAJOR).

**joba**

Must be 'L', 'U' or 'G'.

Specifies the structure of A:

If joba = 'L', the input matrix A is lower triangular.

If joba = 'U', the input matrix A is upper triangular.

If joba = 'G', the input matrix A is a general \(m\)-by-\(n\), \(m \geq n\).

**jobu**

Must be 'U', 'C' or 'N'.

Specifies whether to compute the left singular vectors (columns of \(U\)):

If jobu = 'U', the left singular vectors corresponding to the nonzero singular values are computed and returned in the leading columns of A. See more details in the description of \(a\). The default numerical orthogonality threshold is set to approximately \(\text{TOL}=\text{CTOL} \times \text{EPS}\), \(\text{CTOL} = \sqrt{m}\), \(\text{EPS} = \text{?lamch('E')}\)

If jobu = 'C', analogous to jobu = 'U', except that you can control the level of numerical orthogonality of the computed left singular vectors. TOL can be set to \(\text{TOL} = \text{CTOL} \times \text{EPS}\), where \text{CTOL} is given on input in the array \text{stat}. No \text{CTOL} smaller than ONE is allowed. \text{CTOL} greater than \(1 / \text{EPS}\) is meaningless. The option 'C' can be used if \(m \times \text{EPS}\) is satisfactory orthogonality of the computed left singular vectors, so \text{CTOL} = m could save a few sweeps of Jacobi rotations. See the descriptions of \(a\) and \text{stat}[0].

If jobu = 'N', \(u\) is not computed. However, see the description of \(a\).

**jobv**

Must be 'V', 'A' or 'N'.

Specifies whether to compute the right singular vectors, that is, the matrix \(V\):

If jobv = 'V', the matrix \(V\) is computed and returned in the array \(v\).

If jobv = 'A', the Jacobi rotations are applied to the \(mv\)-by-\(n\) array \(v\). In other words, the right singular vector matrix \(V\) is not computed explicitly, instead it is applied to an \(mv\)-by-\(n\) matrix initially stored in the first \(mv\) rows of \(V\).

If jobv = 'N', the matrix \(V\) is not computed and the array \(v\) is not referenced.

**m**

The number of rows of the input matrix A.

\(1 / \text{lamch('E')} > m \geq 0\) for sgsvj.

\(1 / \text{dlamch('E')} > m \geq 0\) for dgesvj.

**n**

The number of columns in the input matrix A; \(m \geq n \geq 0\).
Array $a$ (size at least $lda*n$ for column major layout and $lda*m$ for row major layout) is an array containing the $m$-by-$n$ matrix $A$.

Array $v$ (size at least $\max(1, ldv*n)$) contains, if $jobv = 'A$' the $mv$-by-$n$ matrix to be post-multiplied by Jacobi rotations.

The leading dimension of the array $a$. Must be at least $\max(1, m)$ for column major layout and at least $\max(1, n)$ for row major layout.

If $jobv = 'A$', the product of Jacobi rotations in $?gesvj$ is applied to the first $mv$ rows of $v$. See the description of $jobv$. $0 \leq mv \leq ldv$.

The leading dimension of the array $v$; $ldv \geq 1$.

$jobv = 'V$', $ldv \geq \max(1, n)$.

$jobv = 'A$', $ldv \geq \max(1, mv)$ for column major layout and $ldv \geq \max(1, n)$ for row major layout.

Array size 6. If $jobu = 'C$', $stat[0] = CTOL$, where $CTOL$ defines the threshold for convergence. The process stops if all columns of $A$ are mutually orthogonal up to $CTOL*EPS$, where $EPS = \?lamch('E')$. It is required that $CTOL \geq 1 -$ that is, it is not allowed to force the routine to obtain orthogonality below $\varepsilon$.

Output Parameters

On exit:

If $jobu = 'U$' or $jobu = 'C$':

- if $info = 0$, the leading columns of $A$ contain left singular vectors corresponding to the computed singular values of $a$ that are above the underflow threshold $\?lamch('S')$, that is, non-zero singular values. The number of the computed non-zero singular values is returned in $stat[1]$. Also see the descriptions of $sva$ and $stat$. The computed columns of $u$ are mutually numerically orthogonal up to approximately $TOL = \sqrt{m} \cdot EPS$ (default); or $TOL = CTOL \cdot EPS$ $jobu = 'C$, see the description of $jobu$.

- if $info > 0$, the procedure $?gesvj$ did not converge in the given number of iterations (sweeps). In that case, the computed columns of $u$ may not be orthogonal up to $TOL$. The output $u$ (stored in $a$), $sigma$ (given by the computed singular values in $sva(1:n)$) and $v$ is still a decomposition of the input matrix $A$ in the sense that the residual $||A-scale*U*sigma*V^T||_2 / ||A||_2$ for real flavors or $||A-scale*U*sigma*V^H||_2 / ||A||_2$ for complex flavors (where $scale = stat[0]$) is small.

If $jobu = 'N$':

- if $info = 0$, note that the left singular vectors are 'for free' in the one-sided Jacobi SVD algorithm. However, if only the singular values are needed, the level of numerical orthogonality of $u$ is not an issue and iterations are stopped when the columns of the iterated matrix are numerically orthogonal up to approximately $m \cdot EPS$. Thus, on exit, $a$ contains the columns of $u$ scaled with the corresponding singular values.
• if info > 0, the procedure ?gesvj did not converge in the given number of iterations (sweeps).

**sva**

Array size n.

If info = 0, depending on the value scale = stat[0], where scale is the scaling factor:

• if scale = 1, sva[0:n - 1] contains the computed singular values of a.
• if scale ≠ 1, the singular values of a are scale*sva(1:n), and this factored representation is due to the fact that some of the singular values of a might underflow or overflow.

If info > 0, the procedure ?gesvj did not converge in the given number of iterations (sweeps) and scale*sva(1:n) may not be accurate.

**v**

On exit:

If jobv = 'V', contains the n-by-n matrix of the right singular vectors.

If jobv = 'A', then v contains the product of the computed right singular vector matrix and the initial matrix in the array v.

If jobv = 'N', v is not referenced.

**stat**

On exit,

stat[0] = scale is the scaling factor such that scale*sva(1:n) are the computed singular values of A. See the description of sva.

stat[1] is the number of the computed nonzero singular values.

stat[2] is the number of the computed singular values that are larger than the underflow threshold.

stat[3] is the number of sweeps of Jacobi rotations needed for numerical convergence.

stat[4] = \max_{i ≠ j} |\cos(A(:,i),A(:,j))| in the last sweep. This is useful information in cases when ?gesvj did not converge, as it can be used to estimate whether the output is still useful and for post festum analysis.

stat[5] is the largest absolute value over all sines of the Jacobi rotation angles in the last sweep. It can be useful in a post festum analysis.

**Return Values**

This function returns a value info.

If info=0, the execution is successful.

If info = -i, the i-th parameter had an illegal value.

If info > 0, the function did not converge in the maximal number (30) of sweeps. The output may still be useful. See the description of stat.

Include Files

- mkl.h

Description

This routine is deprecated; use ggsvd3.

The routine computes the generalized singular value decomposition (GSVD) of an \( m \)-by-\( n \) real/complex matrix \( A \) and \( p \)-by-\( n \) real/complex matrix \( B \):

\[
U^*A*Q = D_1*(0 \ R), \quad V^*B*Q = D_2*(0 \ R),
\]

where \( U, V \) and \( Q \) are orthogonal/unitary matrices and \( U', V' \) mean transpose/conjugate transpose of \( U \) and \( V \) respectively.

Let \( k+l \) be the effective numerical rank of the matrix \((A', B')\), then \( R \) is a \((k+l)\)-by-\((k+l)\) nonsingular upper triangular matrix, \( D_1 \) and \( D_2 \) are \( m\)-by-\((k+l)\) and \( p\)-by-\((k+l)\) "diagonal" matrices and of the following structures, respectively:

If \( m-k-l \geq 0 \),
where

\[ C = \text{diag}(\alpha[k], \ldots, \alpha[k + l - 1]) \]

\[ S = \text{diag}(\beta[k], \ldots, \beta[k + l - 1]) \]

\[ C^2 + S^2 = I \]

Nonzero element \( r_{ij} (1 \leq i \leq n) \) of \( R \) is stored in \( a[(i - 1) + (n - k - l + j - 1)*\text{lda}] \) for column major layout and in \( a[(i - 1)*\text{lda} + (n - k - l + j - 1)] \) for row major layout.

If \( m-k-l < 0 \),

\[ D_1 = \begin{pmatrix} k & m-k & 0 & 0 \\ m-k & 0 & C & 0 \\ 0 & C & 0 \\ 0 & 0 & 0 \end{pmatrix} \]

\[ D_2 = \begin{pmatrix} k & m-k & k+l-m \\ m-k & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \]

\[ D_3 = \begin{pmatrix} k & m-k & k+l-m \\ n-k-l & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \]

\[ (0 \ R) = \begin{pmatrix} k & 0 & R_{11} & R_{12} \\ m-k & 0 & R_{21} & R_{22} \\ k+l-m & 0 & R_{31} & R_{32} \end{pmatrix} \]

where

\[ C = \text{diag}(\alpha[k], \ldots, \alpha(m)) \]

\[ S = \text{diag}(\beta[k], \ldots, \beta(m-1)) \]
On exit, the location of nonzero element \( r_{ij} \) of \( R \) depends on the value of \( i \). For \( i \leq m \) this element is stored in \( a[(i - 1) + (n - k - 1 + j - 1)*lda] \) for column major layout and in \( a[(i - 1)*lda + (n - k - 1 + j - 1)] \) for row major layout. For \( m < i \leq k + l \) it is stored in \( b[(i - k - 1) + (n - k - 1 + j - 1)*ldb] \) for column major layout and in \( b[(i - k - 1)*ldb + (n - k - 1 + j - 1)] \) for row major layout.

The routine computes \( C, S, R \), and optionally the orthogonal/unitary transformation matrices \( U, V \) and \( Q \).

In particular, if \( B \) is an \( n \times n \) nonsingular matrix, then the GSVD of \( A \) and \( B \) implicitly gives the SVD of \( A^*B^{-1} \):

\[
A^*B^{-1} = U^*(D_1*D_2^{-1})*V'.
\]

If \( (A', B')' \) has orthonormal columns, then the GSVD of \( A \) and \( B \) is also equal to the CS decomposition of \( A \) and \( B \). Furthermore, the GSVD can be used to derive the solution of the eigenvalue problem:

\[
A'^*A^*x = \lambda*B'^*B^*x.
\]

**Input Parameters**

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **jobu**
  Must be 'U' or 'N'.
  - If \( jobu = 'U' \), orthogonal/unitary matrix \( U \) is computed.
  - If \( jobu = 'N' \), \( U \) is not computed.

- **jobv**
  Must be 'V' or 'N'.
  - If \( jobv = 'V' \), orthogonal/unitary matrix \( V \) is computed.
  - If \( jobv = 'N' \), \( V \) is not computed.

- **jobq**
  Must be 'Q' or 'N'.
  - If \( jobq = 'Q' \), orthogonal/unitary matrix \( Q \) is computed.
  - If \( jobq = 'N' \), \( Q \) is not computed.

- **m**
  The number of rows of the matrix \( A \) \((m \geq 0)\).

- **n**
  The number of columns of the matrices \( A \) and \( B \) \((n \geq 0)\).

- **p**
  The number of rows of the matrix \( B \) \((p \geq 0)\).

- **a, b**
  Arrays:
  - \( a \) (size at least \( \max(1, \text{lda}\times n) \)) for column major layout and \( \max(1, \text{lda}\times m) \) for row major layout) contains the \( m \times n \) matrix \( A \).
  - \( b \) (size at least \( \max(1, \text{ldb}\times n) \)) for column major layout and \( \max(1, \text{ldb}\times p) \) for row major layout) contains the \( p \times n \) matrix \( B \).

- **lda**
  The leading dimension of \( a \); at least \( \max(1, m) \) for column major layout and \( \max(1, n) \) for row major layout.

- **ldb**
  The leading dimension of \( b \); at least \( \max(1, p) \) for column major layout and \( \max(1, n) \) for row major layout.

- **ldu**
  The leading dimension of the array \( u \).
ldu \geq \max(1, m) \text{ if } jobu = 'U'; \ ldu \geq 1 \text{ otherwise.}

\text{The leading dimension of the array } v .

ldv \geq \max(1, p) \text{ if } jobv = 'V'; \ ldv \geq 1 \text{ otherwise.}

ldq \geq \max(1, n) \text{ if } jobq = 'Q'; \ ldq \geq 1 \text{ otherwise.}

\textbf{Output Parameters}

\textit{k, l}

On exit, \(k\) and \(l\) specify the dimension of the subblocks. The sum \(k+l\) is equal to the effective numerical rank of \((A', B')\).

\textit{a}

On exit, \(a\) contains the triangular matrix \(R\) or part of \(R\).

\textit{b}

On exit, \(b\) contains part of the triangular matrix \(R\) if \(m-k-l < 0\).

\textit{alpha, beta}

Arrays, size at least max(1, \(n\)) each.

Contain the generalized singular value pairs of \(A\) and \(B\):

\[ \alpha(1:k) = 1, \]
\[ \beta(1:k) = 0, \]
\[ \text{and if } m-k-l \geq 0, \]
\[ \alpha(k+1:k+l) = c, \]
\[ \beta(k+1:k+l) = s, \]
\[ \text{or if } m-k-l < 0, \]
\[ \alpha(k+1:m) = c, \alpha(m+1:k+l) = 0 \]
\[ \beta(k+1:m) = s, \beta(m+1:k+l) = 1 \]

and

\[ \alpha(k+l+1:n) = 0 \]
\[ \beta(k+l+1:n) = 0. \]

\textit{u, v, q}

Arrays:

\(u\), size at least max(1, \(ldu*m\)).

If \(jobu = 'U'\), \(u\) contains the \(m\)-by-\(m\) orthogonal/unitary matrix \(U\).

If \(jobu = 'N'\), \(u\) is not referenced.

\(v\), size at least max(1, \(ldv*p\)).

If \(jobv = 'V'\), \(v\) contains the \(p\)-by-\(p\) orthogonal/unitary matrix \(V\).

If \(jobv = 'N'\), \(v\) is not referenced.

\(q\), size at least max(1, \(ldq*n\)).

If \(jobq = 'Q'\), \(q\) contains the \(n\)-by-\(n\) orthogonal/unitary matrix \(Q\).

If \(jobq = 'N'\), \(q\) is not referenced.

\textit{iwork}

On exit, \(iwork\) stores the sorting information.
Return Values

This function returns a value info.

If info=0, the execution is successful.

If info = -i, the i-th parameter had an illegal value.

If info = 1, the Jacobi-type procedure failed to converge. For further details, see subroutine tgsja.

Include Files

• mkl.h

Description

?gesvdx computes the singular value decomposition (SVD) of a real or complex m-by-n matrix A, optionally computing the left and right singular vectors. The SVD is written

\[ A = U \times \Sigma \times \text{transpose}(V) \]

where \( \Sigma \) is an \( m \)-by-\( n \) matrix which is zero except for its \( \min(m,n) \) diagonal elements, \( U \) is an \( m \)-by-\( m \) matrix, and \( V \) is an \( n \)-by-\( n \) matrix. The matrices \( U \) and \( V \) are orthogonal for real \( A \), and unitary for complex \( A \). The diagonal elements of \( \Sigma \) are the singular values of \( A \); they are real and non-negative, and are returned in descending order. The first \( \min(m,n) \) columns of \( U \) and \( V \) are the left and right singular vectors of \( A \).

?gesvdx uses an eigenvalue problem for obtaining the SVD, which allows for the computation of a subset of singular values and vectors. See ?bdsvx for details.

Note that the routine returns \( V^T \), not \( V \).
**Input Parameters**

**matrix_layout**
Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

**jobu**
Specifies options for computing all or part of the matrix $U$:
- 'V': the first min($m,n$) columns of $U$ (the left singular vectors) or as specified by range are returned in the array $u$;
- 'N': no columns of $U$ (no left singular vectors) are computed.

**jobvt**
Specifies options for computing all or part of the matrix $V^T$:
- 'V': the first min($m,n$) rows of $V^T$ (the right singular vectors) or as specified by range are returned in the array $vt$;
- 'N': no rows of $V^T$ (no right singular vectors) are computed.

**range**
- 'A': find all singular values.
- 'V': all singular values in the half-open interval $(vl,vu]$ are found.
- 'I': the $il$-th through $iu$-th singular values are found.

**m**
The number of rows of the input matrix $A$. $m \geq 0$.

**n**
The number of columns of the input matrix $A$. $n \geq 0$.

**a**
Array, size $lda*n$
On entry, the $m$-by-$n$ matrix $A$.

**lda**
The leading dimension of the array $a$.
$lda \geq \max(1,m)$.

**vl**
$vl \geq 0$.

**vu**
If range='V', the lower and upper bounds of the interval to be searched for singular values. $vu > vl$. Not referenced if range = 'A' or 'I'.

**il**

**iu**
If range='I', the indices (in ascending order) of the smallest and largest singular values to be returned. $1 \leq il \leq iu \leq \min(m,n)$, if $\min(m,n) > 0$. Not referenced if range = 'A' or 'V'.

**ldu**
The leading dimension of the array $u$. $ldu \geq 1$; if jobu = 'V', $ldu \geq m$.

**ldvt**
The leading dimension of the array $vt$. $ldvt \geq 1$; if jobvt = 'V', $ldvt \geq ns$ (see above).

**Output Parameters**

**a**
On exit, the contents of $a$ are destroyed.

**ns**
The total number of singular values found,
$0 \leq ns \leq \min(m,n)$.
If range = 'A', $ns = \min(m,n)$; if range = 'I', $ns = iu - il + 1$. 

The singular values of $A$, sorted so that $s[i] \geq s[i + 1]$.

**Return Values**

This function returns a value $info$.

$= 0$: successful exit.

$< 0$: if $info = -i$, the $i$-th argument had an illegal value.

$> 0$: if $info = i$, then $i$ eigenvectors failed to converge in ?bdsdx/?stevx. if $info = n*2 + 1$, an internal error occurred in ?bdsdx.

?bdsdx

Computes the SVD of a bidiagonal matrix.

**Syntax**

```c
lapack_int LAPACKE_sbdsvdx (int matrix_layout, char uplo, char jobz, char range,
lapack_int n, float * d, float * e, float vl, float vu, lapack_int il, lapack_int iu,
lapack_int * ns, float * s, float * z, lapack_int ldz, lapack_int * superb);

lapack_int LAPACKE_dbdsvdx (int matrix_layout, char uplo, char jobz, char range,
lapack_int n, double * d, double * e, double vl, double vu, lapack_int il, lapack_int iu,
lapack_int * ns, double * s, double * z, lapack_int ldz, lapack_int * superb);
```

**Include Files**

- mkl.h
Description

?bdsvdx computes the singular value decomposition (SVD) of a real n-by-n (upper or lower) bidiagonal matrix $B$, $B = U * S * V^T$, where $S$ is a diagonal matrix with non-negative diagonal elements (the singular values of $B$), and $U$ and $V$ are orthogonal matrices of left and right singular vectors, respectively.

Given an upper bidiagonal $B$ with diagonal $d = [d_1d_2 \ldots d_n]$ and superdiagonal $e = [e_1e_2 \ldots e_{n-1}]$, ?bdsvdx computes the singular value decomposition of $B$ through the eigenvalues and eigenvectors of the $n*2$-by-$n*2$ tridiagonal matrix

$$TGK = \begin{pmatrix} 0 & d_1 \\ d_1 & 0 & e_1 \\ & d_2 & \ddots & \vdots \\ & e_1 & \ddots & \ddots \\ \end{pmatrix}$$

If $(s,u,v)$ is a singular triplet of $B$ with $||u|| = ||v|| = 1$, then $(\pm s, q)$, $||q|| = 1$, are eigenpairs of TGK, with

$$q = P * \left( \frac{u' \pm v'}{\sqrt{2}} \right) = \left( \frac{v_1 u_1 u_2 u_3 \cdots v_n u_n}{\sqrt{2}} \right),$$

and

$$P = \left( e_{n+1} e_1 e_{n+2} e_2 \cdots \right).$$

Given a TGK matrix, one can either

1. compute $-s$, $-v$ and change signs so that the singular values (and corresponding vectors) are already in descending order (as in ?gesvd/?gesdd) or
2. compute $s$, $v$ and reorder the values (and corresponding vectors).

Input Parameters

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **uplo**
  = 'U': $B$ is upper bidiagonal;
  = 'L': $B$ is lower bidiagonal.

- **jobz**
  = 'N': Compute singular values only;
  = 'V': Compute singular values and singular vectors.

- **range**
  = 'A': Find all singular values.
  = 'V': all singular values in the half-open interval $[vl,vu]$ are found.
  = 'I': the $il$-th through $iu$-th singular values are found.

- **n**
  The order of the bidiagonal matrix.
  $n \geq 0$.

- **d**
  Array, size $n$.
  The $n$ diagonal elements of the bidiagonal matrix $B$.

- **e**
  Array, size $(\text{max}(1,n-1))$
  The $(n-1)$ superdiagonal elements of the bidiagonal matrix $B$ in elements 1 to $n-1$. 
If range='V', the lower and upper bounds of the interval to be searched for singular values. vu > vl.
Not referenced if range = 'A' or 'I'.
If range='I', the indices (in ascending order) of the smallest and largest singular values to be returned.
1 ≤ il ≤ iu ≤ min(m,n), if min(m,n) > 0.
Not referenced if range = 'A' or 'V'.
The leading dimension of the array z.
ldz ≥ 1, and if jobz = 'V', ldz ≥ max(2,n*2).

Output Parameters

ns
The total number of singular values found. 0 ≤ ns ≤ n.
If range = 'A', ns = n, and if range = 'I', ns = iu - il + 1.
s
Array, size (n)
The first ns elements contain the selected singular values in ascending order.
z
Array, size 2*n*k
If jobz = 'V', then if info = 0 the first ns columns of z contain the singular vectors of the matrix B corresponding to the selected singular values, with U in rows 1 to n and V in rows n+1 to n*2, i.e.
\[ z = \begin{bmatrix} U \\ V \end{bmatrix} \]
If jobz = 'N', then z is not referenced.

NOTE
Make sure that at least k = ns+1 columns are supplied in the array z; if range = 'V', the exact value of ns is not known in advance and an upper bound must be used.

superb
Array, size (12*n).
If jobz = 'V', then if info = 0, the first ns elements of iwork are zero. If info > 0, then iwork contains the indices of the eigenvectors that failed to converge in ?stevx.

Return Values
This function returns a value info.
= 0: successful exit.
< 0: if info = -i, the i-th argument had an illegal value.
> 0:
if info = i, then i eigenvectors failed to converge in ?stevx. The indices of the eigenvectors (as returned by ?stevx) are stored in the array iwork.

if info = n*2 + 1, an internal error occurred.

**Cosine-Sine Decomposition: LAPACK Driver Routines**

This section describes LAPACK driver routines for computing the cosine-sine decomposition (CS decomposition). You can also call the corresponding computational routines to perform the same task.

The computation has the following phases:

1. The matrix is reduced to a bidiagonal block form.
2. The blocks are simultaneously diagonalized using techniques from the bidiagonal SVD algorithms.

Table "Driver Routines for Cosine-Sine Decomposition (CSD)" lists LAPACK routines that perform CS decomposition of matrices.

Include Files
• mkl.h

Description
The routines ?orcsd/?uncsd compute the CS decomposition of an \(m\)-by-\(m\) partitioned orthogonal matrix \(X\):

\[
X = \begin{pmatrix}
    x_{11} & x_{12} \\
    x_{21} & x_{22}
\end{pmatrix} =
\begin{pmatrix}
    u_1 \mid u_2
\end{pmatrix}
\begin{pmatrix}
    I & 0 & 0 & 0 & 0 \\
    0 & C & 0 & -S & 0 \\
    0 & 0 & 0 & 0 & -I \\
    0 & 0 & 0 & I & 0 \\
    0 & S & 0 & 0 & C \\
    0 & 0 & I & 0 & 0
\end{pmatrix}
\begin{pmatrix}
    v_1 \mid v_2
\end{pmatrix}
\]

or unitary matrix:

\[
X = \begin{pmatrix}
    x_{11} & x_{12} \\
    x_{21} & x_{22}
\end{pmatrix} =
\begin{pmatrix}
    u_1 \mid u_2
\end{pmatrix}
\begin{pmatrix}
    I & 0 & 0 & 0 & 0 \\
    0 & C & 0 & -S & 0 \\
    0 & 0 & 0 & 0 & -I \\
    0 & 0 & 0 & I & 0 \\
    0 & S & 0 & 0 & C \\
    0 & 0 & I & 0 & 0
\end{pmatrix}
\begin{pmatrix}
    v_1 \mid v_2
\end{pmatrix}
\]

\(x_{11}\) is \(p\)-by-\(q\). The orthogonal/unitary matrices \(u_1, u_2, v_1,\) and \(v_2\) are \(p\)-by-\(p\), \((m-p)\)-by-\((m-p)\), \(q\)-by-\(q\), \((m-q)\)-by-\((m-q)\), respectively. \(C\) and \(S\) are \(r\)-by-\(r\) nonnegative diagonal matrices satisfying \(C^2 + S^2 = I\), in which \(r = \min(p, m-p, q, m-q)\).

Input Parameters

\(\text{matrix\_layout}\)

- Specifies whether matrix storage layout is row major (\text{LAPACK\_ROW\_MAJOR}) or column major (\text{LAPACK\_COL\_MAJOR}).

\(\text{jobu1}\)

- If equals \(Y\), then \(u_1\) is computed. Otherwise, \(u_1\) is not computed.

\(\text{jobu2}\)

- If equals \(Y\), then \(u_2\) is computed. Otherwise, \(u_2\) is not computed.

\(\text{jobv1t}\)

- If equals \(Y\), then \(v_1^t\) is computed. Otherwise, \(v_1^t\) is not computed.

\(\text{jobv2t}\)

- If equals \(Y\), then \(v_2^t\) is computed. Otherwise, \(v_2^t\) is not computed.

\(\text{trans}\)

\(= \text{’T’}: \)

- \(x, u_1, u_2, v_1^t, v_2^t\) are stored in row-major order.

\(\text{otherwise}\)

- \(x, u_1, u_2, v_1^t, v_2^t\) are stored in column-major order.

\(\text{signs}\)

\(= \text{’O’}: \)

- The lower-left block is made nonpositive (the "other" convention).
otherwise The upper-right block is made nonpositive (the "default" convention).

$m$
The number of rows and columns of the matrix $X$.

$p$
The number of rows in $x_{11}$ and $x_{12}$. $0 \leq p \leq m$.

$q$
The number of columns in $x_{11}$ and $x_{21}$. $0 \leq q \leq m$.

$x_{11}, x_{12}, x_{21}, x_{22}$ Arrays of size $x_{11}(ldx_{11}, q)$, $x_{12}(ldx_{12}, m - q)$, $x_{21}(ldx_{21}, q)$, and $x_{22}(ldx_{22}, m - q)$.

Contain the parts of the orthogonal/unitary matrix whose CSD is desired.

$ldx_{11}, ldx_{12}, ldx_{21}, ldx_{22}$ The leading dimensions of the parts of array $X$. $ldx_{11} \geq \max(1, p)$, $ldx_{12} \geq \max(1, q)$, $ldx_{21} \geq \max(1, m - p)$, $ldx_{22} \geq \max(1, m - q)$.

$ldu_1$ The leading dimension of the array $u_1$. If $jobu_1 = 'Y'$, $ldu_1 \geq \max(1, p)$.

$ldu_2$ The leading dimension of the array $u_2$. If $jobu_2 = 'Y'$, $ldu_2 \geq \max(1, m - p)$.

$ldv_1t$ The leading dimension of the array $v_1t$. If $jobv_1t = 'Y'$, $ldv_1t \geq \max(1, q)$.

$ldv_2t$ The leading dimension of the array $v_2t$. If $jobv_2t = 'Y'$, $ldv_2t \geq \max(1, m - q)$.

Output Parameters

$theta$ Array, size $r$, in which $r = \min(p, m-p, q, m-q)$. $C = \text{diag}(\cos(\theta[0]), ..., \cos(\theta[r-1]))$, and $S = \text{diag}(\sin(\theta[0]), ..., \sin(\theta[r-1]))$.

$u_1$ Array, size at least $\max(1, ldu_1*p)$.

If $jobu_1 = 'Y'$, $u_1$ contains the $p$-by-$p$ orthogonal/unitary matrix $u_1$.

$u_2$ Array, size at least $\max(1, ldu_2*(m - p))$.

If $jobu_2 = 'Y'$, $u_2$ contains the $(m-p)$-by-$(m-p)$ orthogonal/unitary matrix $u_2$.

$v_1t$ Array, size at least $\max(1, ldv_1t*q)$.

If $jobv_1t = 'Y'$, $v_1t$ contains the $q$-by-$q$ orthogonal matrix $v_1^T$ or unitary matrix $v_1^H$.

$v_2t$ Array, size at least $\max(1, ldv_2t*(m - q))$.

If $jobv_2t = 'Y'$, $v_2t$ contains the $(m-q)$-by-$(m-q)$ orthogonal matrix $v_2^T$ or unitary matrix $v_2^H$.

Return Values

This function returns a value $info$.

If $info=0$, the execution is successful.

If $info = -i$, the $i$-th parameter had an illegal value.
> 0: ?orcsd/?uncsd did not converge.

```
Include Files

- mkl.h

Description

The routine computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form

\[ A^*x = \lambda^*B^*x, \quad A^*B^*x = \lambda^*x, \quad \text{or} \quad B^*A^*x = \lambda^*x. \]

Here \( A \) and \( B \) are assumed to be symmetric and \( B \) is also positive definite.

Input Parameters

- **matrix_layout**
  
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **itype**
  
  Must be 1 or 2 or 3.

  Specifies the problem type to be solved:

  - if \( itype = 1 \), the problem type is \( A^*x = \lambda^*B^*x \);
  - if \( itype = 2 \), the problem type is \( A^*B^*x = \lambda^*x \);
  - if \( itype = 3 \), the problem type is \( B^*A^*x = \lambda^*x \).

- **jobz**
  
  Must be 'N' or 'V'.

  If \( jobz = 'N' \), then compute eigenvalues only.

  If \( jobz = 'V' \), then compute eigenvalues and eigenvectors.

- **uplo**
  
  Must be 'U' or 'L'.

  If \( uplo = 'U' \), arrays \( a \) and \( b \) store the upper triangles of \( A \) and \( B \);

  If \( uplo = 'L' \), arrays \( a \) and \( b \) store the lower triangles of \( A \) and \( B \).

- **n**
  
  The order of the matrices \( A \) and \( B \) (\( n \geq 0 \)).

- **a, b**
  
  Arrays:

  - \( a \) (size at least max(1, lda*n)) contains the upper or lower triangle of the symmetric matrix \( A \), as specified by \( uplo \).
  
  - \( b \) (size at least max(1, ldb*n)) contains the upper or lower triangle of the symmetric positive definite matrix \( B \), as specified by \( uplo \).

- **lda**
  
  The leading dimension of \( a \); at least max(1, n).

- **ldb**
  
  The leading dimension of \( b \); at least max(1, n).

Output Parameters

- **a**
  
  On exit, if \( jobz = 'V' \), then if \( info = 0 \), \( a \) contains the matrix \( Z \) of eigenvectors. The eigenvectors are normalized as follows:

  - if \( itype = 1 \) or 2, \( Z^*B^*Z = I \);
  - if \( itype = 3 \), \( Z^*\text{inv}(B)^*Z = I \);
If jobz = 'N', then on exit the upper triangle (if uplo = 'U') or the lower triangle (if uplo = 'L') of A, including the diagonal, is destroyed.

On exit, if info≤n, the part of b containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization B = U^T U or B = L*L^T.

Array, size at least max(1, n).
If info = 0, contains the eigenvalues in ascending order.

Return Values
This function returns a value info.
If info=0, the execution is successful.
If info = -i, the i-th parameter had an illegal value.
If info > 0, spotrf/dpotrf or ssyev/dsyev returned an error code:
If info = i≤n, ssyev/dsyev failed to converge, and i off-diagonal elements of an intermediate tridiagonal did not converge to zero;
If info = n + i, for 1 ≤i≤n, then the leading minor of order i of B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

?hegv
Computes all eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian positive-definite eigenproblem.

Syntax
lapack_int LAPACKE_chegv( int matrix_layout, lapack_int itype, char jobz, char uplo,
lapack_int n, lapack_complex_float* a, lapack_int lda, lapack_complex_float* b,
lapack_int ldb, float* w );
lapack_int LAPACKE_zhegv( int matrix_layout, lapack_int itype, char jobz, char uplo,
lapack_int n, lapack_complex_double* a, lapack_int lda, lapack_complex_double* b,
lapack_int ldb, double* w );

Include Files
• mkl.h

Description
The routine computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian positive-definite eigenproblem, of the form
A*x = λ*B*x,  A*B*x = λ*x, or B*A*x = λ*x.

Here A and B are assumed to be Hermitian and B is also positive definite.

Input Parameters
matrix_layout       Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
itype

Must be 1 or 2 or 3. Specifies the problem type to be solved:
if itype = 1, the problem type is $A*x = \lambda*B*x$;
if itype = 2, the problem type is $A*B*x = \lambda*x$;
if itype = 3, the problem type is $B*A*x = \lambda*x$.

jobz

Must be 'N' or 'V'.
If jobz = 'N', then compute eigenvalues only.
If jobz = 'V', then compute eigenvalues and eigenvectors.

uplo

Must be 'U' or 'L'.
If uplo = 'U', arrays $a$ and $b$ store the upper triangles of $A$ and $B$;
If uplo = 'L', arrays $a$ and $b$ store the lower triangles of $A$ and $B$.

n

The order of the matrices $A$ and $B$ ($n \geq 0$).

$a, b$

Arrays:
a (size at least max(1, lda*n)) contains the upper or lower triangle of the
Hermitian matrix $A$, as specified by uplo.
b (size at least max(1, ldb*n)) contains the upper or lower triangle of the
Hermitian positive definite matrix $B$, as specified by uplo.

lda

The leading dimension of $a$; at least max(1, $n$).

ldb

The leading dimension of $b$; at least max(1, $n$).

Output Parameters

$a$

On exit, if jobz = 'V', then if info = 0, $a$ contains the matrix $Z$ of
eigenvectors. The eigenvectors are normalized as follows:
if itype = 1 or 2, $Z^H*B*Z = I$;
if itype = 3, $Z^H*inv(B)*Z = I$;
If jobz = 'N', then on exit the upper triangle (if uplo = 'U') or the
lower triangle (if uplo = 'L') of $A$, including the diagonal, is destroyed.

$b$

On exit, if info<=n, the part of $b$ containing the matrix is overwritten by the
triangular factor $U$ or $L$ from the Cholesky factorization $B = U^H*U$ or $B =
L*L^H$.

w

Array, size at least max(1, $n$).
If info = 0, contains the eigenvalues in ascending order.

Return Values

This function returns a value info.
If info=0, the execution is successful.
If info=-i, the i-th parameter had an illegal value.
If info > 0, cpotrf/zpotrf or cheev/zheev return an error code:
If $info = i\leq n$, cheev/zheev fails to converge, and $i$ off-diagonal elements of an intermediate tridiagonal do not converge to zero;

If $info = n + i$, for $1 \leq i \leq n$, then the leading minor of order $i$ of $B$ is not positive-definite. The factorization of $B$ can not be completed and no eigenvalues or eigenvectors are computed.

?sygvd
Computes all eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem using a divide and conquer method.

Syntax

```c
lapack_int LAPACKE_ssygvd(int matrix_layout, lapack_int itype, char jobz, char uplo, lapack_int n, float* a, lapack_int lda, float* b, lapack_int ldb, float* w);

lapack_int LAPACKE_dsygvd(int matrix_layout, lapack_int itype, char jobz, char uplo, lapack_int n, double* a, lapack_int lda, double* b, lapack_int ldb, double* w);
```

Include Files

- mkl.h

Description

The routine computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form

$$A^*x = \lambda*B^*x, \quad A^*B^*x = \lambda*x, \quad \text{or} \quad B^*A^*x = \lambda*x.$$ 

Here $A$ and $B$ are assumed to be symmetric and $B$ is also positive definite.

It uses a divide and conquer algorithm.

Input Parameters

- **matrix_layout**
  - Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **itype**
  - Must be 1, 2, or 3. Specifies the problem type to be solved:
    - If $itype = 1$, the problem type is $A^*x = \lambda B^*x$;
    - If $itype = 2$, the problem type is $A^*B^*x = \lambda x$;
    - If $itype = 3$, the problem type is $B^*A^*x = \lambda x$.

- **jobz**
  - Must be 'N' or 'V'.
    - If $jobz = 'N'$, then compute eigenvalues only.
    - If $jobz = 'V'$, then compute eigenvalues and eigenvectors.

- **uplo**
  - Must be 'U' or 'L'.
    - If $uplo = 'U'$, arrays $a$ and $b$ store the upper triangles of $A$ and $B$;
    - If $uplo = 'L'$, arrays $a$ and $b$ store the lower triangles of $A$ and $B$.

- **n**
  - The order of the matrices $A$ and $B$ ($n \geq 0$).

- **a, b**
  - Arrays:
\( a \) (size at least \( \text{lda}*n \)) contains the upper or lower triangle of the symmetric matrix \( A \), as specified by \( \text{uplo} \).

\( b \) (size at least \( \text{ldb}*n \)) contains the upper or lower triangle of the symmetric positive definite matrix \( B \), as specified by \( \text{uplo} \).

Output Parameters

\( a \)

On exit, if \( \text{jobz} = 'V' \), then if \( \text{info} = 0 \), \( a \) contains the matrix \( Z \) of eigenvectors. The eigenvectors are normalized as follows:

- If \( \text{itype} = 1 \) or \( 2 \), \( Z^T*B*Z = I \);
- If \( \text{itype} = 3 \), \( Z^T*\text{inv}(B)*Z = I \);

If \( \text{jobz} = 'N' \), then on exit the upper triangle (if \( \text{uplo} = 'U' \)) or the lower triangle (if \( \text{uplo} = 'L' \)) of \( A \), including the diagonal, is destroyed.

\( b \)

On exit, if \( \text{info} \leq n \), the part of \( b \) containing the matrix is overwritten by the triangular factor \( U \) or \( L \) from the Cholesky factorization \( B = U^T*U \) or \( B = L*L^T \).

\( w \)

Array, size at least \( \text{max}(1, n) \).

If \( \text{info} = 0 \), contains the eigenvalues in ascending order.

Return Values

This function returns a value \( \text{info} \).

If \( \text{info} = 0 \), the execution is successful.

If \( \text{info} = -i \), the \( i \)-th parameter had an illegal value.

If \( \text{info} > 0 \), an error code is returned as specified below.

- For \( \text{info} \leq n \):
  - If \( \text{info} = i \) and \( \text{jobz} = 'N' \), then the algorithm failed to converge; \( i \) off-diagonal elements of an intermediate tridiagonal form did not converge to zero.
  - If \( \text{jobz} = 'V' \), then the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns \( \text{info}/(n+1) \) through \( \text{mod}(\text{info},n+1) \).

- For \( \text{info} > n \):
  - If \( \text{info} = n + i \), for \( 1 \leq i \leq n \), then the leading minor of order \( i \) of \( B \) is not positive-definite. The factorization of \( B \) could not be completed and no eigenvalues or eigenvectors were computed.

?hegvd

Computes all eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem using a divide and conquer method.

Syntax

\[
\text{lapack_int LAPACKE_chegvd( int matrix_layout, int itype, char jobz, char uplo, int n, lapack_complex_float* a, int lda, lapack_complex_float* b, int ldb, float* w );}
\]
lapack_int LAPACKE_zhegvd( int matrix_layout, lapack_int itype, char jobz, char uplo,
lapack_int n, lapack_complex_double* a, lapack_int lda, lapack_complex_double* b,
lapack_int ldb, double* w );

**Include Files**

- mkl.h

**Description**

The routine computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian positive-definite eigenproblem, of the form

\[ A\mathbf{x} = \lambda B\mathbf{x}, \quad A^*B\mathbf{x} = \lambda\mathbf{x}, \text{ or } B^*A\mathbf{x} = \lambda\mathbf{x}. \]

Here \( A \) and \( B \) are assumed to be Hermitian and \( B \) is also positive definite.

It uses a divide and conquer algorithm.

**Input Parameters**

- **matrix_layout**
  
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **itype**
  
  Must be 1 or 2 or 3. Specifies the problem type to be solved:
  
  - if \( \text{itype} = 1 \), the problem type is \( A\mathbf{x} = \lambda B\mathbf{x} \);
  - if \( \text{itype} = 2 \), the problem type is \( A^*B\mathbf{x} = \lambda\mathbf{x} \);
  - if \( \text{itype} = 3 \), the problem type is \( B^*A\mathbf{x} = \lambda\mathbf{x} \).

- **jobz**
  
  Must be 'N' or 'V'.
  
  - If \( \text{jobz} = 'N' \), then compute eigenvalues only.
  - If \( \text{jobz} = 'V' \), then compute eigenvalues and eigenvectors.

- **uplo**
  
  Must be 'U' or 'L'.
  
  - If \( \text{uplo} = 'U' \), arrays \( a \) and \( b \) store the upper triangles of \( A \) and \( B \);
  - If \( \text{uplo} = 'L' \), arrays \( a \) and \( b \) store the lower triangles of \( A \) and \( B \).

- **n**
  
  The order of the matrices \( A \) and \( B \) (n\geq 0).

- **a, b**
  
  Arrays:
  
  - \( a \) (size at least \( \max(1, lda*n) \)) contains the upper or lower triangle of the Hermitian matrix \( A \), as specified by \( \text{uplo} \).
  - \( b \) (size at least \( \max(1, ldb*n) \)) contains the upper or lower triangle of the Hermitian positive definite matrix \( B \), as specified by \( \text{uplo} \).

- **lda**
  
  The leading dimension of \( a \); at least \( \max(1, n) \).

  The leading dimension of \( b \); at least \( \max(1, n) \).

**Output Parameters**

- **a**
  
  On exit, if \( \text{jobz} = 'V' \), then if \( \text{info} = 0 \), \( a \) contains the matrix \( Z \) of eigenvectors. The eigenvectors are normalized as follows:
  
  - if \( \text{itype} = 1 \) or 2, \( Z^*BZ = I \);
if \( i_{\text{type}} = 3 \), \( Z^H \text{inv}(B) Z = I \);

If \( \text{jobz} = 'N' \), then on exit the upper triangle (if \( \text{uplo} = 'U' \)) or the lower triangle (if \( \text{uplo} = 'L' \)) of \( A \), including the diagonal, is destroyed.

On exit, if \( \text{info} \leq n \), the part of \( b \) containing the matrix is overwritten by the triangular factor \( U \) or \( L \) from the Cholesky factorization \( B = U^H U \) or \( B = L^H L \).

Array, size at least \( \max(1, n) \).

If \( \text{info} = 0 \), contains the eigenvalues in ascending order.

Return Values
This function returns a value \( \text{info} \).

If \( \text{info} = 0 \), the execution is successful.

If \( \text{info} = -i \), the \( i \)-th parameter had an illegal value.

If \( \text{info} = i \), and \( \text{jobz} = 'N' \), then the algorithm failed to converge; \( i \)-off-diagonal elements of an intermediate tridiagonal form did not converge to zero;

if \( \text{info} = i \), and \( \text{jobz} = 'V' \), then the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns \( \text{info}/(n+1) \) through \( \text{mod}(\text{info}, n+1) \).

If \( \text{info} = n + i \), for \( 1 \leq i \leq n \), then the leading minor of order \( i \) of \( B \) is not positive-definite. The factorization of \( B \) could not be completed and no eigenvalues or eigenvectors were computed.

sygvx
Computes selected eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem.

Syntax

```c
#include <mkl.h>

lapack_int LAPACKE_ssygvx (int matrix_layout, lapack_int itype, char jobz, char range, char uplo, lapack_int n, float* a, lapack_int lda, float* b, lapack_int ldb, float vl, float vu, lapack_int il, lapack_int iu, float abstol, lapack_int* m, float* w, float* z, lapack_int ldz, lapack_int* ifail);

lapack_int LAPACKE_dsygvx (int matrix_layout, lapack_int itype, char jobz, char range, char uplo, lapack_int n, double* a, lapack_int lda, double* b, lapack_int ldb, double vl, double vu, lapack_int il, lapack_int iu, double abstol, lapack_int* m, double* w, double* z, lapack_int ldz, lapack_int* ifail);
```

Include Files

- mkl.h

Description
The routine computes selected eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form

\[ A^* x = \lambda^* B^* x, \quad A^* B^* x = \lambda^* x, \quad \text{or} \quad B^* A^* x = \lambda^* x. \]

Here \( A \) and \( B \) are assumed to be symmetric and \( B \) is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.
Input Parameters

**matrix_layout**
Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

**itype**
Must be 1 or 2 or 3. Specifies the problem type to be solved:
if itype = 1, the problem type is $A*x = \lambda*B*x$;
if itype = 2, the problem type is $A*B*x = \lambda*x$;
if itype = 3, the problem type is $B*A*x = \lambda*x$.

**jobz**
Must be 'N' or 'V'.
If jobz = 'N', then compute eigenvalues only.
If jobz = 'V', then compute eigenvalues and eigenvectors.

**range**
Must be 'A' or 'V' or 'I'.
If range = 'A', the routine computes all eigenvalues.
If range = 'V', the routine computes eigenvalues $w[i]$ in the half-open interval:
$vl < w[i] \leq vu$.
If range = 'I', the routine computes eigenvalues with indices $il$ to $iu$.

**uplo**
Must be 'U' or 'L'.
If uplo = 'U', arrays a and b store the upper triangles of $A$ and $B$;
If uplo = 'L', arrays a and b store the lower triangles of $A$ and $B$.

**n**
The order of the matrices $A$ and $B$ ($n \geq 0$).

**a, b**
Arrays:
a (size at least max(1, lda*n)) contains the upper or lower triangle of the
symmetric matrix $A$, as specified by uplo.
b (size at least max(1, ldb*n)) contains the upper or lower triangle of the
symmetric positive definite matrix $B$, as specified by uplo.

**lda**
The leading dimension of a; at least max(1, n).

**ldb**
The leading dimension of b; at least max(1, n).

**vl, vu**
If range = 'V', the lower and upper bounds of the interval to be searched
for eigenvalues.
Constraint: $vl < vu$.
If range = 'A' or 'I', vl and vu are not referenced.

**il, iu**
If range = 'I', the indices in ascending order of the smallest and largest
eigenvalues to be returned.
Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$
if $n = 0$.
If range = 'A' or 'V', il and iu are not referenced.
The leading dimension of the output array `z`. Constraints:
\[ ldz \geq 1; \text{if } jobz = 'V', ldz \geq \max(1, n) \text{ for column major layout and } ldz \geq \max(1, m) \text{ for row major layout.} \]

**Output Parameters**

- **a**: On exit, the upper triangle (if `uplo = 'U'`) or the lower triangle (if `uplo = 'L'`) of `A`, including the diagonal, is overwritten.

- **b**: On exit, if `info \leq n`, the part of `b` containing the matrix is overwritten by the triangular factor `U` or `L` from the Cholesky factorization `B = U^T * U` or `B = L * L^T`.

- **m**: The total number of eigenvalues found, \[ 0 \leq m \leq n. \text{ If } range = 'A', m = n, \text{ and if } range = 'I', m = iu - il + 1. \]

- **w, z**: Arrays:
  - `w`, size at least \( \max(1, n) \).
  - The first \( m \) elements of `w` contain the selected eigenvalues in ascending order.
  - `z` (size at least \( \max(1, ldz * m) \) for column major layout and \( \max(1, ldz * n) \) for row major layout).
  - If `jobz = 'V'`, then if `info = 0`, the first \( m \) columns of `z` contain the orthonormal eigenvectors of the matrix `A` corresponding to the selected eigenvalues, with the \( i \)-th column of `z` holding the eigenvector associated with \( w[i - 1] \). The eigenvectors are normalized as follows:
    - if `itype = 1` or `2`, \( Z^T * B * Z = I \);
    - if `itype = 3`, \( Z^T * \text{inv}(B) * Z = I \);
  - If `jobz = 'N'`, then `z` is not referenced.

- **ifail**: Array, size at least \( \max(1, n) \).
  - If `jobz = 'V'`, then if `info = 0`, the first \( m \) elements of `ifail` are zero; if `info > 0`, the `ifail` contains the indices of the eigenvectors that failed to converge.
  - If `jobz = 'N'`, then `ifail` is not referenced.

**Return Values**

This function returns a value `info`.
If info=0, the execution is successful.

If info = -i, the i-th parameter had an illegal value.

If info > 0, spotrf/dpotrf and ssyevx/dsyevx returned an error code:

If info = i ≤ n, ssyevx/dsyevx failed to converge, and i eigenvectors failed to converge. Their indices are stored in the array ifail;

If info = n + i, for 1 ≤ i ≤ n, then the leading minor of order i of B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Application Notes
An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to abstol+ε*max(|a|,|b|), where ε is the machine precision.

If abstol is less than or equal to zero, then ε*||T||_1 is used as tolerance, where T is the tridiagonal matrix obtained by reducing C to tridiagonal form, where C is the symmetric matrix of the standard symmetric problem to which the generalized problem is transformed. Eigenvalues will be computed most accurately when abstol is set to twice the underflow threshold 2*?lamch('S'), not zero.

If this routine returns with info > 0, indicating that some eigenvectors did not converge, set abstol to 2*?lamch('S').

?hegvx
Computes selected eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian positive-definite eigenproblem.

Syntax

lapack_int LAPACKE_chegvx( int matrix_layout, lapack_int itype, char jobz, char range, char uplo, lapack_int n, lapack_complex_float* a, lapack_int lda, lapack_complex_float* b, lapack_int ldb, float vl, float vu, lapack_int il, lapack_int iu, float abstol, lapack_int* m, float* w, lapack_complex_float* z, lapack_int ldz, lapack_int* ifail );

lapack_int LAPACKE_zhegvx( int matrix_layout, lapack_int itype, char jobz, char range, char uplo, lapack_int n, lapack_complex_double* a, lapack_int lda, lapack_complex_double* b, lapack_int ldb, double vl, double vu, lapack_int il, lapack_int iu, double abstol, lapack_int* m, double* w, lapack_complex_double* z, lapack_int ldz, lapack_int* ifail );

Include Files
• mkl.h

Description
The routine computes selected eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian positive-definite eigenproblem, of the form

A*x = λ*B*x,  A*B*x = λ*x, or B*A*x = λ*x.

Here A and B are assumed to be Hermitian and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.
Input Parameters

**matrix_layout**

Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

**itype**

Must be 1 or 2 or 3. Specifies the problem type to be solved:

- if itype = 1, the problem type is $A*x = \lambda*B*x$;
- if itype = 2, the problem type is $A*B*x = \lambda*x$;
- if itype = 3, the problem type is $B*A*x = \lambda*x$.

**jobz**

Must be 'N' or 'V'.

- If jobz = 'N', then compute eigenvalues only.
- If jobz = 'V', then compute eigenvalues and eigenvectors.

**range**

Must be 'A' or 'V' or 'I'.

- If range = 'A', the routine computes all eigenvalues.
- If range = 'V', the routine computes eigenvalues $w[i]$ in the half-open interval:
  $vl < w[i] \leq vu$.
- If range = 'I', the routine computes eigenvalues with indices $il$ to $iu$.

**uplo**

Must be 'U' or 'L'.

- If uplo = 'U', arrays a and b store the upper triangles of A and B;
- If uplo = 'L', arrays a and b store the lower triangles of A and B.

**n**

The order of the matrices $A$ and $B$ ($n \geq 0$).

**a**, **b**

Arrays:

- a (size at least max(1, lda*n)) contains the upper or lower triangle of the Hermitian matrix $A$, as specified by uplo.
- b (size at least max(1, ldb*n)) contains the upper or lower triangle of the Hermitian positive definite matrix $B$, as specified by uplo.

**lda**

The leading dimension of a; at least max(1, n).

**ldb**

The leading dimension of b; at least max(1, n).

**vl**, **vu**

If range = 'V', the lower and upper bounds of the interval to be searched for eigenvalues.

Constraint: $vl < vu$.

If range = 'A' or 'I', vl and vu are not referenced.

**il**, **iu**

If range = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned.

Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$ if $n = 0$.

If range = 'A' or 'V', il and iu are not referenced.
**abstol**

The absolute error tolerance for the eigenvalues. See Application Notes for more information.

**ldz**

The leading dimension of the output array z. Constraints:

\[ ldz \geq 1; \text{if } jobz = 'V', ldz \geq \max(1, n) \text{ for column major layout and } ldz \geq \max(1, m) \text{ for row major layout.} \]

### Output Parameters

**a**

On exit, the upper triangle (if uplo = 'U') or the lower triangle (if uplo = 'L') of A, including the diagonal, is overwritten.

**b**

On exit, if info\(\leq n\), the part of b containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization \( B = U^H \) or \( B = L \). The total number of eigenvalues found,

\[ 0 \leq m \leq n. \text{ If range = 'A', } m = n, \text{ and if range = 'I', } m = iu-il+1. \]

**w**

Array, size at least \( \max(1, n) \).

The first \( m \) elements of w contain the selected eigenvalues in ascending order.

**z**

Array z(size at least \( \max(1, ldz*m) \) for column major layout and \( \max(1, ldz*n) \) for row major layout).

If jobz = 'V', then if info = 0, the first \( m \) columns of z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the \( i \)-th column of z holding the eigenvector associated with \( w[i-1] \). The eigenvectors are normalized as follows:

- If itype = 1 or 2, \( Z^H*B*Z = I \);
- If itype = 3, \( Z^H*inv(B)*Z = I \);

If jobz = 'N', then z is not referenced.

If an eigenvector fails to converge, then that column of z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in ifail.

Note: you must ensure that at least \( \max(1,m) \) columns are supplied in the array z; if range = 'V', the exact value of m is not known in advance and an upper bound must be used.

**ifail**

Array, size at least \( \max(1, n) \).

If jobz = 'V', then if info = 0, the first \( m \) elements of ifail are zero; if info > 0, the ifail contains the indices of the eigenvectors that failed to converge.

If jobz = 'N', then ifail is not referenced.

### Return Values

This function returns a value \( \text{info} \).
If \( \text{info}=0 \), the execution is successful.

If \( \text{info} = -i \), the \( i \)-th parameter had an illegal value.

If \( \text{info} > 0 \), \text{cpotrf}/\text{zpotrf} \) and \( \text{cheevx}/\text{zheevx} \) returned an error code:

If \( \text{info} = i \leq n \), \text{cheevx}/\text{zheevx} failed to converge, and \( i \) eigenvectors failed to converge. Their indices are stored in the array \( \text{ifail} \);

If \( \text{info} = n + i \), for \( 1 \leq i \leq n \), then the leading minor of order \( i \) of \( B \) is not positive-definite. The factorization of \( B \) could not be completed and no eigenvalues or eigenvectors were computed.

**Application Notes**

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval \([a,b]\) of width less than or equal to \( \text{abstol}+\varepsilon \times \max(|a|,|b|) \), where \( \varepsilon \) is the machine precision.

If \( \text{abstol} \) is less than or equal to zero, then \( \varepsilon \times \|T\|_1 \) will be used in its place, where \( T \) is the tridiagonal matrix obtained by reducing \( C \) to tridiagonal form, where \( C \) is the symmetric matrix of the standard symmetric problem to which the generalized problem is transformed. Eigenvalues will be computed most accurately when \( \text{abstol} \) is set to twice the underflow threshold \( 2 \times \text{?lamch}('S') \), not zero.

If this routine returns with \( \text{info} > 0 \), indicating that some eigenvectors did not converge, try setting \( \text{abstol} \) to \( 2 \times \text{?lamch}('S') \).

**?spgv**

Computes all eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem with matrices in packed storage.

**Syntax**

```c
lapack_int LAPACK_sspgv (int matrix_layout, lapack_int itype, char jobz, char uplo, lapack_int n, float* ap, float* bp, float* w, float* z, lapack_int ldz);
lapack_int LAPACK_dspgv (int matrix_layout, lapack_int itype, char jobz, char uplo, lapack_int n, double* ap, double* bp, double* w, double* z, lapack_int ldz);
```

**Include Files**

- mkl.h

**Description**

The routine computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form

\[
A^* x = \lambda^* B^* x, \quad A^* B^* x = \lambda^* x, \quad \text{or} \quad B^* A^* x = \lambda^* x.
\]

Here \( A \) and \( B \) are assumed to be symmetric, stored in packed format, and \( B \) is also positive definite.

**Input Parameters**

- **matrix_layout**
  - Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **itype**
  - Must be 1 or 2 or 3. Specifies the problem type to be solved:
    - if \( \text{itype} = 1 \), the problem type is \( A^* x = \lambda^* B^* x \);
    - if \( \text{itype} = 2 \), the problem type is \( A^* B^* x = \lambda^* x \);
if $i_{\text{type}} = 3$, the problem type is $B^*A^*x = \lambda x$.

jobz

Must be 'N' or 'V'.
If jobz = 'N', then compute eigenvalues only.
If jobz = 'V', then compute eigenvalues and eigenvectors.

uplo

Must be 'U' or 'L'.
If uplo = 'U', arrays $ap$ and $bp$ store the upper triangles of $A$ and $B$;
If uplo = 'L', arrays $ap$ and $bp$ store the lower triangles of $A$ and $B$.

$n$

The order of the matrices $A$ and $B$ ($n \geq 0$).

$ap, bp$

Arrays:
$ap$ contains the packed upper or lower triangle of the symmetric matrix $A$,
as specified by uplo.
The dimension of $ap$ must be at least max(1, $n * (n+1)/2$).
$bp$ contains the packed upper or lower triangle of the symmetric matrix $B$,
as specified by uplo.
The dimension of $bp$ must be at least max(1, $n * (n+1)/2$).

$ldz$

The leading dimension of the output array $z$; $ldz \geq 1$. If jobz = 'V', $ldz \geq$
max(1, $n$).

Output Parameters

$ap$

On exit, the contents of $ap$ are overwritten.

$bp$

On exit, contains the triangular factor $U$ or $L$ from the Cholesky factorization
$B = U^T U$ or $B = L L^T$, in the same storage format as $B$.

$w, z$

Arrays:
$w$, size at least max(1, $n$).
If info = 0, contains the eigenvalues in ascending order.
$z$ (size max(1, $ldz * n$)).
If jobz = 'V', then if info = 0, $z$ contains the matrix $Z$ of eigenvectors.
The eigenvectors are normalized as follows:
if $i_{\text{type}} = 1$ or $2$, $Z^T B^* Z = I$;
if $i_{\text{type}} = 3$, $Z^T \text{inv}(B) * Z = I$;
If jobz = 'N', then $z$ is not referenced.

Return Values

This function returns a value info.
If info=0, the execution is successful.
If info = -i, the $i$-th parameter had an illegal value.
If info > 0, $\text{spptrf/dpptrf}$ and $\text{sspev/dspev}$ returned an error code:
If $info = i \leq n$, sspev/dspev failed to converge, and $i$ off-diagonal elements of an intermediate tridiagonal
did not converge to zero;

If $info = n + i$, for $1 \leq i \leq n$, then the leading minor of order $i$ of $B$ is not positive-definite. The factorization
of $B$ could not be completed and no eigenvalues or eigenvectors were computed.

?hpgv
Computes all eigenvalues and, optionally,
eigenvectors of a complex generalized Hermitian
positive-definite eigenproblem with matrices in packed
storage.

Syntax

lapack_int LAPACKE_chpgv( int matrix_layout, lapack_int itype, char jobz, char uplo,
lapack_int n, lapack_complex_float* ap, lapack_complex_float* bp, float* w,
lapack_complex_float* z, lapack_int ldz );

lapack_int LAPACKE_zhpgv( int matrix_layout, lapack_int itype, char jobz, char uplo,
lapack_int n, lapack_complex_double* ap, lapack_complex_double* bp, double* w,
lapack_complex_double* z, lapack_int ldz );

Include Files
• mkl.h

Description
The routine computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized
Hermitian positive-definite eigenproblem, of the form

$A^*x = \lambda B^*x$, $A^*B^*x = \lambda x$, or $B^*A^*x = \lambda x$.

Here $A$ and $B$ are assumed to be Hermitian, stored in packed format, and $B$ is also positive definite.

Input Parameters

$matrix_layout$ Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR)
or column major (LAPACK_COL_MAJOR).

$itype$ Must be 1 or 2 or 3. Specifies the problem type to be solved:
if $itype = 1$, the problem type is $A^*x = \lambda B^*x$;
if $itype = 2$, the problem type is $A^*B^*x = \lambda x$;
if $itype = 3$, the problem type is $B^*A^*x = \lambda x$.

$jobz$ Must be 'N' or 'V'.
If $jobz = 'N'$, then compute eigenvalues only.
If $jobz = 'V'$, then compute eigenvalues and eigenvectors.

$uplo$ Must be 'U' or 'L'.
If $uplo = 'U'$, arrays $ap$ and $bp$ store the upper triangles of $A$ and $B$;
If $uplo = 'L'$, arrays $ap$ and $bp$ store the lower triangles of $A$ and $B$.

$n$ The order of the matrices $A$ and $B$ ($n \geq 0$).
Arrays:
ap contains the packed upper or lower triangle of the Hermitian matrix \( A \), as specified by \( uplo \).

The dimension of \( ap \) must be at least \( \max(1, n*(n+1)/2) \).

\( bp \) contains the packed upper or lower triangle of the Hermitian matrix \( B \), as specified by \( uplo \).

The dimension of \( bp \) must be at least \( \max(1, n*(n+1)/2) \).

\( ldz \):

The leading dimension of the output array \( z \); \( ldz \geq 1 \). If \( jobz = 'V' \), \( ldz \geq \max(1, n) \).

Output Parameters

\( ap \):

On exit, the contents of \( ap \) are overwritten.

\( bp \):

On exit, contains the triangular factor \( U \) or \( L \) from the Cholesky factorization \( B = U^H \cdot U \) or \( B = L \cdot L^H \), in the same storage format as \( B \).

\( w \):

Array, size at least \( \max(1, n) \).

If \( info = 0 \), contains the eigenvalues in ascending order.

\( z \):

Array \( z \) (size \( \max(1, ldz * n) \)).

If \( jobz = 'V' \), then if \( info = 0 \), \( z \) contains the matrix \( Z \) of eigenvectors.
The eigenvectors are normalized as follows:

- If \( itype = 1 \) or \( 2 \), \( Z^H \cdot B \cdot Z = I \);
- If \( itype = 3 \), \( Z^H \cdot inv(B) \cdot Z = I \);
- If \( jobz = 'N' \), then \( z \) is not referenced.

Return Values

This function returns a value \( info \).

If \( info = 0 \), the execution is successful.

If \( info = -i \), the \( i \)-th parameter had an illegal value.

If \( info > 0 \), \( cpptrf/zpttrf \) and \( chpev/zhpev \) returned an error code:

If \( info = i \leq n \), \( chpev/zhpev \) failed to converge, and \( i \) off-diagonal elements of an intermediate tridiagonal did not converge to zero;

If \( info = n + i \), for \( 1 \leq i \leq n \), then the leading minor of order \( i \) of \( B \) is not positive-definite. The factorization of \( B \) could not be completed and no eigenvalues or eigenvectors were computed.

\( ? \)spgvd

Computes all eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem with matrices in packed storage using a divide and conquer method.

Syntax

```c
lapack_int LAPACKE_sspgvd (int matrix_layout, lapack_int itype, char jobz, char uplo, lapack_int n, float* ap, float* bp, float* w, float* z, lapack_int ldz);
```
lapack_int LAPACKE_dspgvd (int matrix_layout, lapack_int itype, char jobz, char uplo, lapack_int n, double* ap, double* bp, double* w, double* z, lapack_int ldz);

**Include Files**
- mkl.h

**Description**

The routine computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form

\[ A^* x = \lambda^* B^* x, \quad A^* B^* x = \lambda^* x, \quad \text{or} \quad B^* A^* x = \lambda^* x. \]

Here \( A \) and \( B \) are assumed to be symmetric, stored in packed format, and \( B \) is also positive definite.

If eigenvectors are desired, it uses a divide and conquer algorithm.

**Input Parameters**

- **matrix_layout**
  Specifies whether matrix storage layout is row major (`LAPACK_ROW_MAJOR`) or column major (`LAPACK_COL_MAJOR`).

- **itype**
  Must be 1 or 2 or 3. Specifies the problem type to be solved:
  - if `itype = 1`, the problem type is \( A^* x = \lambda^* B^* x \);
  - if `itype = 2`, the problem type is \( A^* B^* x = \lambda^* x \);
  - if `itype = 3`, the problem type is \( B^* A^* x = \lambda^* x \).

- **jobz**
  Must be `'N'` or `'V'`.
  - If `jobz = 'N'`, then compute eigenvalues only.
  - If `jobz = 'V'`, then compute eigenvalues and eigenvectors.

- **uplo**
  Must be `'U'` or `'L'`.
  - If `uplo = 'U'`, arrays `ap` and `bp` store the upper triangles of \( A \) and \( B \);
  - If `uplo = 'L'`, arrays `ap` and `bp` store the lower triangles of \( A \) and \( B \).

- **n**
  The order of the matrices \( A \) and \( B \) (\( n \geq 0 \)).

- **ap, bp**
  Arrays:
  - `ap` contains the packed upper or lower triangle of the symmetric matrix \( A \), as specified by `uplo`.
  - `bp` contains the packed upper or lower triangle of the symmetric matrix \( B \), as specified by `uplo`.

  The dimension of `ap` must be at least \( \max(1, n(n+1)/2) \).
  The dimension of `bp` must be at least \( \max(1, n(n+1)/2) \).

- **ldz**
  The leading dimension of the output array `z`; `ldz` \( \geq 1 \). If `jobz = 'V'`, `ldz` \( \geq \max(1, n) \).

**Output Parameters**

- **ap**
  On exit, the contents of `ap` are overwritten.
On exit, contains the triangular factor $U$ or $L$ from the Cholesky factorization
$B = U^T U$ or $B = L^T L$, in the same storage format as $B$.

Arrays:

$w$, size at least max(1, $n$).
If $info = 0$, contains the eigenvalues in ascending order.
$z$ (size at least max(1, $ldz*n$)).
If $jobz = 'V$', then if $info = 0$, $z$ contains the matrix $Z$ of eigenvectors.
The eigenvectors are normalized as follows:
if $itype = 1$ or $2$, $Z^T B^* Z = I$;
if $itype = 3$, $Z^T \text{inv}(B)^* Z = I$;
If $jobz = 'N$', then $z$ is not referenced.

Return Values

This function returns a value $info$.
If $info=0$, the execution is successful.
If $info = -i$, the $i$-th parameter had an illegal value.
If $info > 0$, spptrf/dptrf and sspevd/dspevd returned an error code:
If $info = i \leq n$, sspevd/dspevd failed to converge, and $i$ off-diagonal elements of an intermediate tridiagonal
did not converge to zero;
If $info = n + i$, for $1 \leq i \leq n$, then the leading minor of order $i$ of $B$ is not positive-definite. The factorization
of $B$ could not be completed and no eigenvalues or eigenvectors were computed.

?hpgvd
Computes all eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian positive-definite eigenproblem with matrices in packed storage using a divide and conquer method.

Syntax

lapack_int LAPACKE_chpgvd( int matrix_layout, lapack_int itype, char jobz, char uplo,
lapack_int n, lapack_complex_float* ap, lapack_complex_float* bp, float* w,
lapack_complex_float* z, lapack_int ldz);

lapack_int LAPACKE_zhpgvd( int matrix_layout, lapack_int itype, char jobz, char uplo,

lapack_complex_double* z, lapack_int ldz);

Include Files

- mkl.h

Description

The routine computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian positive-definite eigenproblem, of the form

$A^* x = \lambda^* B^* x$, $A^* B^* x = \lambda^* x$, or $B^* A^* x = \lambda^* x$.

Here $A$ and $B$ are assumed to be Hermitian, stored in packed format, and $B$ is also positive definite.
If eigenvectors are desired, it uses a divide and conquer algorithm.

**Input Parameters**

**matrix_layout**

Specifies whether matrix storage layout is row major (**LAPACK_ROW_MAJOR**) or column major (**LAPACK_COL_MAJOR**).

**itype**

Must be 1 or 2 or 3. Specifies the problem type to be solved:

- If itype = 1, the problem type is $A*x = \lambda*B*x$;
- If itype = 2, the problem type is $A*B*x = \lambda*x$;
- If itype = 3, the problem type is $B*A*x = \lambda*B*x$.

**jobz**

Must be 'N' or 'V'.

- If jobz = 'N', then compute eigenvalues only.
- If jobz = 'V', then compute eigenvalues and eigenvectors.

**uplo**

Must be 'U' or 'L'.

- If uplo = 'U', arrays $ap$ and $bp$ store the upper triangles of $A$ and $B$;
- If uplo = 'L', arrays $ap$ and $bp$ store the lower triangles of $A$ and $B$.

**n**

The order of the matrices $A$ and $B$ ($n \geq 0$).

**ap, bp**

Arrays:

- $ap$ contains the packed upper or lower triangle of the Hermitian matrix $A$, as specified by uplo.
  - The dimension of $ap$ must be at least max(1, $n*(n+1)/2$).
- $bp$ contains the packed upper or lower triangle of the Hermitian matrix $B$, as specified by uplo.
  - The dimension of $bp$ must be at least max(1, $n*(n+1)/2$).

**ldz**

The leading dimension of the output array $z$; $ldz \geq 1$. If jobz = 'V', $ldz \geq \max(1, n)$.

**Output Parameters**

**ap**

On exit, the contents of $ap$ are overwritten.

**bp**

On exit, contains the triangular factor $U$ or $L$ from the Cholesky factorization $B = U^H*U$ or $B = L*L^H$, in the same storage format as $B$.

**w**

Array, size at least max(1, $n$).

- If info = 0, contains the eigenvalues in ascending order.

**z**

Array $z$ (size at least max(1, $ldz*n$)).

- If jobz = 'V', then if info = 0, $z$ contains the matrix $Z$ of eigenvectors. The eigenvectors are normalized as follows:
  - if itype = 1 or 2, $Z^H*B*Z = I$;
  - if itype = 3, $Z^H*inv(B)*Z = I$;
- If jobz = 'N', then $z$ is not referenced.
Return Values

This function returns a value info.

If info=0, the execution is successful.

If info = -i, the i-th parameter had an illegal value.

If info > 0, cppyf/zpptrf and chpevd/zhpevd returned an error code:

If info = i≤n, chpevd/zhpevd failed to converge, and i off-diagonal elements of an intermediate tridiagonal did not converge to zero;

If info = n + i, for 1 ≤i≤n, then the leading minor of order i of B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

?spgvx

Computes selected eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem with matrices in packed storage.

Syntax

lapack_int LAPACKE_sspgvx (int matrix_layout, lapack_int itype, char jobz, char range, char uplo, lapack_int n, float* ap, float* bp, float vl, float vu, lapack_int il, lapack_int iu, float abstol, lapack_int* m, float* w, float* z, lapack_int ldz, lapack_int* ifail);

lapack_int LAPACKE_dspgvx (int matrix_layout, lapack_int itype, char jobz, char range, char uplo, lapack_int n, double* ap, double* bp, double vl, double vu, lapack_int il, lapack_int iu, double abstol, lapack_int* m, double* w, double* z, lapack_int ldz, lapack_int* ifail);

Include Files

- mkl.h

Description

The routine computes selected eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form

\[ A*x = \lambda*B*x, \quad A*B*x = \lambda*x, \quad \text{or} \quad B*A*x = \lambda*x. \]

Here A and B are assumed to be symmetric, stored in packed format, and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

matrix_layout

Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

itype

Must be 1 or 2 or 3. Specifies the problem type to be solved:

if itype = 1, the problem type is \( A*x = \lambda*B*x \);

if itype = 2, the problem type is \( A*B*x = \lambda*x \);

if itype = 3, the problem type is \( B*A*x = \lambda*x \).

jobz

Must be 'N' or 'V'.

If $jobz = 'N'$, then compute eigenvalues only.
If $jobz = 'V'$, then compute eigenvalues and eigenvectors.

$range$  
Must be 'A' or 'V' or 'I'.
If $range = 'A'$, the routine computes all eigenvalues.
If $range = 'V'$, the routine computes eigenvalues $w[i]$ in the half-open interval:
$vl < w[i] \leq vu$.
If $range = 'I'$, the routine computes eigenvalues with indices $il$ to $iu$.

$uplo$  
Must be 'U' or 'L'.
If $uplo = 'U'$, arrays $ap$ and $bp$ store the upper triangles of $A$ and $B$;
If $uplo = 'L'$, arrays $ap$ and $bp$ store the lower triangles of $A$ and $B$.

$n$  
The order of the matrices $A$ and $B$ ($n \geq 0$).

$ap$, $bp$  
Arrays:
$ap$ contains the packed upper or lower triangle of the symmetric matrix $A$, as specified by $uplo$.
The size of $ap$ must be at least $\max(1, n^*(n+1)/2)$.
$bp$ contains the packed upper or lower triangle of the symmetric matrix $B$, as specified by $uplo$.
The size of $bp$ must be at least $\max(1, n^*(n+1)/2)$.

$vl$, $vu$  
If $range = 'V'$, the lower and upper bounds of the interval to be searched for eigenvalues.
Constraint: $vl < vu$.
If $range = 'A'$ or 'I', $vl$ and $vu$ are not referenced.

$il$, $iu$  
If $range = 'I'$, the indices in ascending order of the smallest and largest eigenvalues to be returned.
Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il = 1$ and $iu = 0$ if $n = 0$.
If $range = 'A'$ or 'V', $il$ and $iu$ are not referenced.

$abstol$  
The absolute error tolerance for the eigenvalues. See Application Notes for more information.

$ldz$  
The leading dimension of the output array $z$. Constraints:
$ldz \geq 1$; if $jobz = 'V'$, $ldz \geq \max(1, n)$ for column major layout and $ldz \geq \max(1, m)$ for row major layout.

Output Parameters

$ap$  
On exit, the contents of $ap$ are overwritten.
On exit, contains the triangular factor $U$ or $L$ from the Cholesky factorization $B = U^T U$ or $B = L^T L^T$, in the same storage format as $B$.

The total number of eigenvalues found, $0 \leq m \leq n$. If range = 'A', $m = n$, and if range = 'I', $m = iu-il+1$.

Arrays:
$w$, size at least max(1, $n$).
If info = 0, contains the eigenvalues in ascending order.
$z$ (size at least max(1, ldz* $m$) for column major layout and max(1, ldz* $n$) for row major layout).
If jobz = 'V', then if info = 0, the first $m$ columns of $z$ contain the orthonormal eigenvectors of the matrix $A$ corresponding to the selected eigenvalues, with the $i$-th column of $z$ holding the eigenvector associated with $w(i)$. The eigenvectors are normalized as follows:
if itype = 1 or 2, $Z^T B Z = I$;
if itype = 3, $Z^T \text{inv}(B) Z = I$;
If jobz = 'N', then $z$ is not referenced.
If an eigenvector fails to converge, then that column of $z$ contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in ifail.

Note: you must ensure that at least max(1, $m$) columns are supplied in the array $z$; if range = 'V', the exact value of $m$ is not known in advance and an upper bound must be used.

$\text{ifail}$
Array, size at least max(1, $n$).
If jobz = 'V', then if info = 0, the first $m$ elements of $\text{ifail}$ are zero; if info > 0, the $\text{ifail}$ contains the indices of the eigenvectors that failed to converge.
If jobz = 'N', then $\text{ifail}$ is not referenced.

**Return Values**
This function returns a value info.
If info=0, the execution is successful.
If info = -i, the $i$-th parameter had an illegal value.
If info > 0, spptrf/dpptrf and sspevx/dspevx returned an error code:
If info = $i$≤$n$, sspevx/dspevx failed to converge, and $i$ eigenvectors failed to converge. Their indices are stored in the array ifail;
If info = $n + i$, for 1 ≤$i$≤$n$, then the leading minor of order $i$ of $B$ is not positive-definite. The factorization of $B$ could not be completed and no eigenvalues or eigenvectors were computed.
Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval \([a,b]\) of width less than or equal to \(\text{abstol} + \varepsilon \max(|a|,|b|)\), where \(\varepsilon\) is the machine precision.

If \(\text{abstol}\) is less than or equal to zero, then \(\varepsilon \|T\|_1\) is used instead, where \(T\) is the tridiagonal matrix obtained by reducing \(A\) to tridiagonal form. Eigenvalues are computed most accurately when \(\text{abstol}\) is set to twice the underflow threshold \(2^{*}\text{lamch}'S'\), not zero.

If this routine returns with \(\text{info} > 0\), indicating that some eigenvectors did not converge, set \(\text{abstol}\) to \(2^{*}\text{lamch}'S'\).

\(\text{chpgvx}\)

Computes selected eigenvalues and, optionally, eigenvectors of a generalized Hermitian positive-definite eigenproblem with matrices in packed storage.

Syntax

```
lapack_int LAPACKE_chpgvx( int matrix_layout, lapack_int itype, char jobz, char range,    char uplo, lapack_int n, lapack_complex_float* ap, lapack_complex_float* bp, float vl,    float vu, lapack_int il, lapack_int iu, float abstol, lapack_int* m, float* w,    lapack_complex_float* z, lapack_int ldz, lapack_int* ifail );
```

```
lapack_int LAPACKE_zhpgvx( int matrix_layout, lapack_int itype, char jobz, char range,    char uplo, lapack_int n, lapack_complex_double* ap, lapack_complex_double* bp, double vl,    double vu, lapack_int il, lapack_int iu, double abstol, lapack_int* m, double* w,    lapack_complex_double* z, lapack_int ldz, lapack_int* ifail );
```

Include Files

- \(\text{mkl.h}\)

Description

The routine computes selected eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian positive-definite eigenproblem, of the form

\[ A^*x = \lambda^*B^*x, \quad A^*B^*x = \lambda^*x, \quad \text{or} \quad B^*A^*x = \lambda^*x. \]

Here \(A\) and \(B\) are assumed to be Hermitian, stored in packed format, and \(B\) is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **itype**
  Must be 1 or 2 or 3. Specifies the problem type to be solved:
  - if \(\text{itype} = 1\), the problem type is \(A^*x = \lambda^*B^*x\);
  - if \(\text{itype} = 2\), the problem type is \(A^*B^*x = \lambda^*x\);
  - if \(\text{itype} = 3\), the problem type is \(B^*A^*x = \lambda^*x\).

- **jobz**
  Must be ‘N’ or ‘V’.
  - If \(\text{jobz} = 'N'\), then compute eigenvalues only.
If \( \text{jobz} = 'V' \), then compute eigenvalues and eigenvectors.

**range**

Must be 'A' or 'V' or 'I'.

If \( \text{range} = 'A' \), the routine computes all eigenvalues.

If \( \text{range} = 'V' \), the routine computes eigenvalues \( w[i] \) in the half-open interval:

\[ vl < w[i] \leq vu. \]

If \( \text{range} = 'I' \), the routine computes eigenvalues with indices \( il \) to \( iu \).

**uplo**

Must be 'U' or 'L'.

If \( \text{uplo} = 'U' \), arrays \( ap \) and \( bp \) store the upper triangles of \( A \) and \( B \);

If \( \text{uplo} = 'L' \), arrays \( ap \) and \( bp \) store the lower triangles of \( A \) and \( B \).

**n**

The order of the matrices \( A \) and \( B \) (\( n \geq 0 \)).

**ap, bp**

Arrays:

\( ap \) contains the packed upper or lower triangle of the Hermitian matrix \( A \), as specified by \( \text{uplo} \).

The dimension of \( ap \) must be at least \( \max(1, n*(n+1)/2) \).

\( bp \) contains the packed upper or lower triangle of the Hermitian matrix \( B \), as specified by \( \text{uplo} \).

The dimension of \( bp \) must be at least \( \max(1, n*(n+1)/2) \).

**vl, vu**

If \( \text{range} = 'V' \), the lower and upper bounds of the interval to be searched for eigenvalues.

Constraint: \( vl < vu \).

If \( \text{range} = 'A' \) or 'I', \( vl \) and \( vu \) are not referenced.

**il, iu**

If \( \text{range} = 'I' \), the indices in ascending order of the smallest and largest eigenvalues to be returned.

Constraint: \( 1 \leq il \leq iu \leq n \), if \( n > 0 \); \( il=1 \) and \( iu=0 \) if \( n = 0 \).

If \( \text{range} = 'A' \) or 'V', \( il \) and \( iu \) are not referenced.

**abstol**

The absolute error tolerance for the eigenvalues.

See Application Notes for more information.

**ldz**

The leading dimension of the output array \( z \); \( ldz \geq 1 \). If \( \text{jobz} = 'V' \), \( ldz \geq \max(1, n) \) for column major layout and \( ldz \geq \max(1, m) \) for row major layout.

### Output Parameters

**ap**

On exit, the contents of \( ap \) are overwritten.

**bp**

On exit, contains the triangular factor \( U \) or \( L \) from the Cholesky factorization \( B = U^H U \) or \( B = L L^H \), in the same storage format as \( B \).
The total number of eigenvalues found, $0 \leq m \leq n$. If \textit{range} = 'A', $m = n$, and if \textit{range} = 'I', $m = \text{iu} - \text{il} + 1$.

$w$

Array, size at least $\max(1, n)$.
If \textit{info} = 0, contains the eigenvalues in ascending order.

$z$

Array $z$(size at least $\max(1, \text{ldz}*m)$ for column major layout and $\max(1, \text{ldz}*n)$ for row major layout).
If \textit{jobz} = 'V', then if \textit{info} = 0, the first $m$ columns of $z$ contain the orthonormal eigenvectors of the matrix $A$ corresponding to the selected eigenvalues, with the $i$-th column of $z$ holding the eigenvector associated with $w(i)$. The eigenvectors are normalized as follows:

- If $\text{itype} = 1$ or $2$, $Z^H B^H Z = I$;
- If $\text{itype} = 3$, $Z^H \text{inv}(B) Z = I$;
If \textit{jobz} = 'N', then $z$ is not referenced.

If an eigenvector fails to converge, then that column of $z$ contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in \textit{ifail}.

Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array $z$; if \textit{range} = 'V', the exact value of $m$ is not known in advance and an upper bound must be used.

$\textit{ifail}$

Array, size at least $\max(1, n)$.
If \textit{jobz} = 'V', then if \textit{info} = 0, the first $m$ elements of \textit{ifail} are zero; if \textit{info} > 0, the \textit{ifail} contains the indices of the eigenvectors that failed to converge.
If \textit{jobz} = 'N', then \textit{ifail} is not referenced.

Return Values
This function returns a value \textit{info}.
If \textit{info} = 0, the execution is successful.
If \textit{info} = -i, the $i$-th parameter had an illegal value.
If \textit{info} > 0, \texttt{cpptrf/zpptrf} and \texttt{chpevx/zhpevx} returned an error code:
If \textit{info} = $i \leq n$, \texttt{chpevx/zhpevx} failed to converge, and $i$ eigenvectors failed to converge. Their indices are stored in the array \textit{ifail};
If \textit{info} = $n + i$, for $1 \leq i \leq n$, then the leading minor of order $i$ of $B$ is not positive-definite. The factorization of $B$ could not be completed and no eigenvalues or eigenvectors were computed.

Application Notes
An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to $\text{abstol} + \varepsilon \max(|a|,|b|)$, where $\varepsilon$ is the machine precision.
If $\text{abstol}$ is less than or equal to zero, then $\varepsilon \|T\|_1$ is used as tolerance, where $T$ is the tridiagonal matrix obtained by reducing $A$ to tridiagonal form. Eigenvalues will be computed most accurately when $\text{abstol}$ is set to twice the underflow threshold $2*\text{?lamch('S')}$, not zero.
If this routine returns with \( \text{info} > 0 \), indicating that some eigenvectors did not converge, try setting \( \text{abstol} \) to \( 2^*?\text{lamch}(\text{'S'}) \).

\( \text{?sbgv} \)

_Computes all eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem with banded matrices._

**Syntax**

```c
lapack_int LAPACKE_ssbgv (int matrix_layout, char jobz, char uplo, lapack_int n, lapack_int ka, lapack_int kb, float* ab, lapack_int ldab, float* bb, lapack_int ldbb, float* w, float* z, lapack_int ldz);
```

```c
lapack_int LAPACKE_dsbgv (int matrix_layout, char jobz, char uplo, lapack_int n, lapack_int ka, lapack_int kb, double* ab, lapack_int ldab, double* bb, lapack_int ldbb, double* w, double* z, lapack_int ldz);
```

**Include Files**

- mkl.h

**Description**

The routine computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form \( A^*x = \lambda B^*x \). Here \( A \) and \( B \) are assumed to be symmetric and banded, and \( B \) is also positive definite.

**Input Parameters**

- `matrix_layout`
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- `jobz`
  Must be 'N' or 'V'.
  
  If `jobz` = 'N', then compute eigenvalues only.
  
  If `jobz` = 'V', then compute eigenvalues and eigenvectors.

- `uplo`
  Must be 'U' or 'L'.

  If `uplo` = 'U', arrays `ab` and `bb` store the upper triangles of \( A \) and \( B \);

  If `uplo` = 'L', arrays `ab` and `bb` store the lower triangles of \( A \) and \( B \).

- `n`
  The order of the matrices \( A \) and \( B \) (\( n \geq 0 \)).

- `ka`
  The number of super- or sub-diagonals in \( A \) (\( ka \geq 0 \)).

- `kb`
  The number of super- or sub-diagonals in \( B \) (\( kb \geq 0 \)).

- `ab, bb`
  Arrays:

  \( ab \) (size at least max(1, \( ldab^*n \)) for column major layout and max(1, \( ldab^*(ka + 1) \)) for row major layout) is an array containing either upper or lower triangular part of the symmetric matrix \( A \) (as specified by `uplo`) in band storage format.
$bb$ (size at least max(1, $ldbb*\text{n}$) for column major layout and max(1, $ldbb*(kb + 1)$) for row major layout) is an array containing either upper or lower triangular part of the symmetric matrix $B$ (as specified by $\text{uplo}$) in band storage format.

$ldab$

The leading dimension of the array $ab$; must be at least $ka+1$ for column major layout and at least max(1, $n$) for row major layout.

$ldbb$

The leading dimension of the array $bb$; must be at least $kb+1$ for column major layout and at least max(1, $n$) for row major layout.

$ldz$

The leading dimension of the output array $z$; $ldz \geq 1$. If $jobz = 'V'$, $ldz \geq \text{max}(1, n)$.

**Output Parameters**

$ab$

On exit, the contents of $ab$ are overwritten.

$bb$

On exit, contains the factor $S$ from the split Cholesky factorization $B = S^T*S$, as returned by $\text{pbstf/pbstf}$.

$w$, $z$

Arrays:

$w$, size at least max(1, $n$).

If $info = 0$, contains the eigenvalues in ascending order.

$z$ (size at least max(1, $ldz*n$)).

If $jobz = 'V'$, then if $info = 0$, $z$ contains the matrix $Z$ of eigenvectors, with the $i$-th column of $z$ holding the eigenvector associated with $w(i)$. The eigenvectors are normalized so that $Z^T*B*Z = I$.

If $jobz = 'N'$, then $z$ is not referenced.

**Return Values**

This function returns a value $info$.

If $info=0$, the execution is successful.

If $info = -i$, the $i$-th parameter had an illegal value.

If $info > 0$, and

if $i \leq n$, the algorithm failed to converge, and $i$ off-diagonal elements of an intermediate tridiagonal did not converge to zero;

if $info = n + i$, for $1 \leq i \leq n$, then $\text{pbstf/pbstf}$ returned $info = i$ and $B$ is not positive-definite. The factorization of $B$ could not be completed and no eigenvalues or eigenvectors were computed.

**?hbgv**

Computes all eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian positive-definite eigenproblem with banded matrices.
Syntax

```c
lapack_int LAPACKE_chbgv( int matrix_layout, char jobz, char uplo, lapack_int n,
  lapack_int ka, lapack_int kb, lapack_complex_float* ab, lapack_int ldab,
  lapack_complex_float* bb, lapack_int ldbb, float* w, lapack_complex_float* z,
  lapack_int ldz );

lapack_int LAPACKE_zhbgv( int matrix_layout, char jobz, char uplo, lapack_int n,
  lapack_int ka, lapack_int kb, lapack_complex_double* ab, lapack_int ldab,
  lapack_complex_double* bb, lapack_int ldbb, double* w, lapack_complex_double* z,
  lapack_int ldz );
```

Include Files

- mkl.h

Description

The routine computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian positive-definite banded eigenproblem, of the form $A^*x = \lambda^*B^*x$. Here $A$ and $B$ are Hermitian and banded matrices, and matrix $B$ is also positive definite.

Input Parameters

- **matrix_layout**: Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- **jobz**: Must be 'N' or 'V'.
  - If `jobz` = 'N', then compute eigenvalues only.
  - If `jobz` = 'V', then compute eigenvalues and eigenvectors.
- **uplo**: Must be 'U' or 'L'.
  - If `uplo` = 'U', arrays `ab` and `bb` store the upper triangles of $A$ and $B$.
  - If `uplo` = 'L', arrays `ab` and `bb` store the lower triangles of $A$ and $B$.
- **n**: The order of the matrices $A$ and $B$ ($n \geq 0$).
- **ka**: The number of super- or sub-diagonals in $A$ ($ka \geq 0$).
- **kb**: The number of super- or sub-diagonals in $B$ ($kb \geq 0$).
- **ab, bb**: Arrays:
  - `ab` (size at least max(1, ldab*n) for column major layout and max(1, ldab*(ka + 1)) for row major layout) is an array containing either upper or lower triangular part of the Hermitian matrix $A$ (as specified by `uplo`) in band storage format.
  - `bb` (size at least max(1, ldbb*n) for column major layout and max(1, ldbb*(kb + 1)) for row major layout) is an array containing either upper or lower triangular part of the Hermitian matrix $B$ (as specified by `uplo`) in band storage format.
- **ldab**: The leading dimension of the array `ab`; must be at least `ka+1` for column major layout and at least max(1, `n` for row major layout.)
ldbb

The leading dimension of the array \( bb \); must be at least \( kb+1 \) for column major layout and at least \( \max(1, n) \) for row major layout.

ldz

The leading dimension of the output array \( z \); \( ldz \geq 1 \). If \( jobz = 'V' \), \( ldz \geq \max(1, n) \).

Output Parameters

\( ab \)

On exit, the contents of \( ab \) are overwritten.

\( bb \)

On exit, contains the factor \( S \) from the split Cholesky factorization \( B = S^H S \), as returned by \( \text{pbstf/pbstf} \).

\( w \)

Array, size at least \( \max(1, n) \).

If \( info = 0 \), contains the eigenvalues in ascending order.

\( z \)

Array \( z \) (size at least \( \max(1, ldz*n) \)).

If \( jobz = 'V' \), then if \( info = 0 \), \( z \) contains the matrix \( Z \) of eigenvectors, with the \( i \)-th column of \( z \) holding the eigenvector associated with \( w(i) \). The eigenvectors are normalized so that \( Z^H B Z = I \).

If \( jobz = 'N' \), then \( z \) is not referenced.

Return Values

This function returns a value \( info \).

If \( info = 0 \), the execution is successful.

If \( info = -i \), the \( i \)-th parameter had an illegal value.

If \( info > 0 \), and

if \( i \leq n \), the algorithm failed to converge, and \( i \) off-diagonal elements of an intermediate tridiagonal did not converge to zero;

if \( info = n + i \), for \( 1 \leq i \leq n \), then \( \text{pbstf/pbstf} \) returned \( info = i \) and \( B \) is not positive-definite. The factorization of \( B \) could not be completed and no eigenvalues or eigenvectors were computed.

?sbgvd

Computes all eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem with banded matrices. If eigenvectors are desired, it uses a divide and conquer method.

Syntax

```c
lapack_int LAPACKE_ssbgvd (int matrix_layout, char jobz, char uplo, lapack_int n, lapack_int ka, lapack_int kb, float* ab, lapack_int ldab, float* bb, lapack_int ldbb, float* w, float* z, lapack_int ldz);
```

```c
lapack_int LAPACKE_dsbgvd (int matrix_layout, char jobz, char uplo, lapack_int n, lapack_int ka, lapack_int kb, double* ab, lapack_int ldab, double* bb, lapack_int ldbb, double* w, double* z, lapack_int ldz);
```

```

Include Files

- \texttt{mkl.h}

Description

The routine computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian positive-definite banded eigenproblem, of the form \( A^* x = \lambda^* B^* x \). Here \( A \) and \( B \) are assumed to be Hermitian and banded, and \( B \) is also positive definite.

If eigenvectors are desired, it uses a divide and conquer algorithm.
**Input Parameters**

*matrix_layout*  
Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

*jobz*  
Must be 'N' or 'V'.
- If *jobz* = 'N', then compute eigenvalues only.
- If *jobz* = 'V', then compute eigenvalues and eigenvectors.

*uplo*  
Must be 'U' or 'L'.
- If *uplo* = 'U', arrays *ab* and *bb* store the upper triangles of *A* and *B*.
- If *uplo* = 'L', arrays *ab* and *bb* store the lower triangles of *A* and *B*.

*n*  
The order of the matrices *A* and *B* (*n* ≥ 0).

*ka*  
The number of super- or sub-diagonals in *A* (*ka* ≥ 0).

*kb*  
The number of super- or sub-diagonals in *B* (*kb* ≥ 0).

*ab*, *bb*  
Arrays:
- *ab* (size at least max(1, *ldab* *n*) for column major layout and max(1, *ldab*(*ka* + 1)) for row major layout) is an array containing either upper or lower triangular part of the Hermitian matrix *A* (as specified by *uplo*) in band storage format.
- *bb* (size at least max(1, *ldbb* *n*) for column major layout and max(1, *ldbb*(*kb* + 1)) for row major layout) is an array containing either upper or lower triangular part of the Hermitian matrix *B* (as specified by *uplo*) in band storage format.

*ldab*  
The leading dimension of the array *ab*; must be at least *ka*+1.

*ldbb*  
The leading dimension of the array *bb*; must be at least *kb*+1.

*ldz*  
The leading dimension of the output array *z*; *ldz* ≥ 1. If *jobz* = 'V', *ldz* ≥ max(1, *n*).

**Output Parameters**

*ab*  
On exit, the contents of *ab* are overwritten.

*bb*  
On exit, contains the factor *S* from the split Cholesky factorization *B* = *S*H*S*, as returned by *pbstf/pbstf*.

*w*  
Array, size at least max(1, *n*).
- If *info* = 0, contains the eigenvalues in ascending order.
- If *jobz* = 'V', then if *info* = 0, *z* contains the matrix *Z* of eigenvectors, with the *i*-th column of *z* holding the eigenvector associated with *w*(*i*). The eigenvectors are normalized so that *Z*H*B*Z = I.
- If *jobz* = 'N', then *z* is not referenced.
Return Values
This function returns a value info.

If info=0, the execution is successful.

If info = -i, the i-th parameter had an illegal value.

If info > 0, and

if info = n + i, for 1 ≤ i ≤ n, then pbstf/pbstf returned info = i and B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

?sbgvx
Computes selected eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem with banded matrices.

Syntax
lapack_int LAPACKE_ssbgvx (int matrix_layout, char jobz, char range, char uplo,

lapack_int iu, double abstol, lapack_int* m, double* w, double* z, lapack_int ldz, 
lapack_int* ifail);

Include Files
• mkl.h

Description
The routine computes selected eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form \( A x = \lambda B x \). Here \( A \) and \( B \) are assumed to be symmetric and banded, and \( B \) is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either all eigenvalues, a range of values or a range of indices for the desired eigenvalues.

Input Parameters

matrix_layout
Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

jobz
Must be 'N' or 'V'.

If jobz = 'N', then compute eigenvalues only.

If jobz = 'V', then compute eigenvalues and eigenvectors.

range
Must be 'A' or 'V' or 'I'.

If range = 'A', the routine computes all eigenvalues.
If range = 'V', the routine computes eigenvalues \( w[i] \) in the half-open interval: 
\[ vl < w[i] \leq vu. \]

If range = 'I', the routine computes eigenvalues in range \( il \) to \( iu \).

\( uplo \) Must be 'U' or 'L'.

If \( uplo = 'U' \), arrays \( ab \) and \( bb \) store the upper triangles of \( A \) and \( B \);

If \( uplo = 'L' \), arrays \( ab \) and \( bb \) store the lower triangles of \( A \) and \( B \).

\( n \) The order of the matrices \( A \) and \( B \) \((n \geq 0)\).

\( ka \) The number of super- or sub-diagonals in \( A \)
\((ka \geq 0)\).

\( kb \) The number of super- or sub-diagonals in \( B \) \((kb \geq 0)\).

\( ab, bb \) Arrays:

\( ab \) (size at least max(1, \( ldab \times n \)) for column major layout and max(1, \( ldab \times (ka + 1) \)) for row major layout) is an array containing either upper or lower triangular part of the symmetric matrix \( A \) (as specified by \( uplo \)) in band storage format.

\( bb \) (size at least max(1, \( ldbb \times n \)) for column major layout and max(1, \( ldbb \times (kb + 1) \)) for row major layout) is an array containing either upper or lower triangular part of the symmetric matrix \( B \) (as specified by \( uplo \)) in band storage format.

\( ldab \) The leading dimension of the array \( ab \); must be at least \( ka+1 \) for column major layout and at least max(1, \( n \)) for row major layout.

\( ldbb \) The leading dimension of the array \( bb \); must be at least \( kb+1 \) for column major layout and at least max(1, \( n \)) for row major layout.

\( vl, vu \) If range = 'V', the lower and upper bounds of the interval to be searched for eigenvalues.

Constraint: \( vl < vu \).

If range = 'A' or 'I', \( vl \) and \( vu \) are not referenced.

\( il, iu \) If range = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned.

Constraint: 1 \( \leq il \leq iu \leq n \), if \( n > 0 \); \( il=1 \) and \( iu=0 \) if \( n = 0 \).

If range = 'A' or 'V', \( il \) and \( iu \) are not referenced.

\( abstol \) The absolute error tolerance for the eigenvalues. See Application Notes for more information.

\( ldz \) The leading dimension of the output array \( z \); \( ldz \geq 1 \). If jobz = 'V', \( ldz \geq \max(1, n) \).

\( ldq \) The leading dimension of the output array \( q \); \( ldq < 1 \).
If $jobz = 'V'$, $ldq < \max(1, n)$.

**Output Parameters**

**ab**

On exit, the contents of $ab$ are overwritten.

**bb**

On exit, contains the factor $S$ from the split Cholesky factorization $B = S^T*S$, as returned by pbstf/pbstf.

**m**

The total number of eigenvalues found,$0 \leq m \leq n$. If $range = 'A'$, $m = n$, and if $range = 'I'$, $m = il-1+iu$.

**w, z, q**

Arrays:

- $w$, size at least $\max(1, n)$.
  - If $info = 0$, contains the eigenvalues in ascending order.
  - If $jobz = 'V'$, then $z$ contains the matrix $Z$ of eigenvectors, with the $i$-th column of $z$ holding the eigenvector associated with $w(i)$. The eigenvectors are normalized so that $Z^T*B*Z = I$.
  - If $jobz = 'N'$, then $z$ is not referenced.

- $q$ (size $\max(1, ldq*n)$).
  - If $jobz = 'V'$, then $q$ contains the $n$-by-$n$ matrix used in the reduction of $A*x = \lambda*B*x$ to standard form, that is, $C*x = \lambda*B*x$ and consequently $C$ to tridiagonal form.
  - If $jobz = 'N'$, then $q$ is not referenced.

**ifail**

Array, size $m$.

- If $jobz = 'V'$, then if $info = 0$, the first $m$ elements of $ifail$ are zero; if $info > 0$, the $ifail$ contains the indices of the eigenvectors that failed to converge.
- If $jobz = 'N'$, then $ifail$ is not referenced.

**Return Values**

This function returns a value $info$.

- If $info=0$, the execution is successful.
- If $info = -i$, the $i$-th parameter had an illegal value.
- If $info > 0$, and
  - if $i \leq n$, the algorithm failed to converge, and $i$ off-diagonal elements of an intermediate tridiagonal did not converge to zero;
  - if $info = n + i$, for $1 \leq i \leq n$, then pbstf/pbstf returned $info = i$ and $B$ is not positive-definite. The factorization of $B$ could not be completed and no eigenvalues or eigenvectors were computed.
Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval \([a,b]\) of width less than or equal to \(abstol+\varepsilon\max(|a|,|b|)\), where \(\varepsilon\) is the machine precision.

If \(abstol\) is less than or equal to zero, then \(\varepsilon\cdot||T||_1\) is used as tolerance, where \(T\) is the tridiagonal matrix obtained by reducing \(A\) to tridiagonal form. Eigenvalues will be computed most accurately when \(abstol\) is set to twice the underflow threshold \(2\cdot\text{lamch('S')}\), not zero.

If this routine returns with \(info > 0\), indicating that some eigenvectors did not converge, try setting \(abstol\) to \(2\cdot\text{lamch('S')}\).

\(\text{?hbgvx}\)

Computes selected eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian positive-definite eigenproblem with banded matrices.

Syntax

```c
lapack_int LAPACKE_chbgvx( int matrix_layout, char jobz, char range, char uplo,
                        lapack_int n, lapack_int ka, lapack_int kb, lapack_complex_float* ab, lapack_int ldab,
                        lapack_complex_float* bb, lapack_int ldbb, lapack_complex_float* q, lapack_int ldq,
                        float vl, float vu, lapack_int il, lapack_int iu, float abstol, lapack_int* m, float* w,
                        lapack_complex_float* z, lapack_int ldz, lapack_int* ifail);

lapack_int LAPACKE_zhbgvx( int matrix_layout, char jobz, char range, char uplo,
                        lapack_int n, lapack_int ka, lapack_int kb, lapack_complex_double* ab, lapack_int ldab,
                        lapack_complex_double* bb, lapack_int ldbb, lapack_complex_double* q, lapack_int ldq,
                        double vl, double vu, lapack_int il, lapack_int iu, double abstol, lapack_int* m, double* w,
                        lapack_complex_double* z, lapack_int ldz, lapack_int* ifail );
```

Include Files

- mkl.h

Description

The routine computes selected eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian positive-definite banded eigenproblem, of the form \(A^*x = \lambda^*B^*x\). Here \(A\) and \(B\) are assumed to be Hermitian and banded, and \(B\) is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either all eigenvalues, a range of values or a range of indices for the desired eigenvalues.

Input Parameters

- `matrix_layout` Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- `jobz` Must be 'N' or 'V'.
  - If `jobz` = 'N', then compute eigenvalues only.
  - If `jobz` = 'V', then compute eigenvalues and eigenvectors.
- `range` Must be 'A' or 'V' or 'I'.
  - If `range` = 'A', the routine computes all eigenvalues.
  - If `range` = 'V', the routine computes eigenvalues \(\omega[k]\) in the half-open interval:
If \( \text{range} = 'I' \), the routine computes eigenvalues with indices \( il \) to \( iu \).

**uplo**

Must be 'U' or 'L'.

If \( \text{uplo} = 'U' \), arrays \( ab \) and \( bb \) store the upper triangles of \( A \) and \( B \);

If \( \text{uplo} = 'L' \), arrays \( ab \) and \( bb \) store the lower triangles of \( A \) and \( B \).

**n**

The order of the matrices \( A \) and \( B \) (\( n \geq 0 \)).

**ka**

The number of super- or sub-diagonals in \( A \) (\( ka \geq 0 \)).

**kb**

The number of super- or sub-diagonals in \( B \) (\( kb \geq 0 \)).

**ab, bb**

Arrays:

\( ab \) (size at least \( \max(1, \text{ldab} \times n) \) for column major layout and \( \max(1, \text{ldab} \times (ka + 1)) \) for row major layout) is an array containing either upper or lower triangular part of the Hermitian matrix \( A \) (as specified by \( \text{uplo} \)) in band storage format.

\( bb \) (size at least \( \max(1, \text{ldbb} \times n) \) for column major layout and \( \max(1, \text{ldbb} \times (kb + 1)) \) for row major layout) is an array containing either upper or lower triangular part of the Hermitian matrix \( B \) (as specified by \( \text{uplo} \)) in band storage format.

**ldab**

The leading dimension of the array \( ab \); must be at least \( ka + 1 \) for column major layout and at least \( \max(1, n) \) for row major layout.

**ldbb**

The leading dimension of the array \( bb \); must be at least \( kb + 1 \) for column major layout and at least \( \max(1, n) \) for row major layout.

**vl, vu**

If \( \text{range} = 'V' \), the lower and upper bounds of the interval to be searched for eigenvalues.

Constraint: \( vl < vu \).

If \( \text{range} = 'A' \) or 'I', \( vl \) and \( vu \) are not referenced.

**il, iu**

If \( \text{range} = 'I' \), the indices in ascending order of the smallest and largest eigenvalues to be returned.

Constraint: \( 1 \leq il \leq iu \leq n \), if \( n > 0 \); \( il = 1 \) and \( iu = 0 \) if \( n = 0 \).

If \( \text{range} = 'A' \) or 'V', \( il \) and \( iu \) are not referenced.

**abstol**

The absolute error tolerance for the eigenvalues. See Application Notes for more information.

**ldz**

The leading dimension of the output array \( z \); \( ldz \geq 1 \). If \( \text{jobz} = 'V' \), \( ldz \geq \max(1, n) \) for column major layout and at least \( \max(1, n) \) for row major layout.

**ldq**

The leading dimension of the output array \( q \); \( ldq \geq 1 \). If \( \text{jobz} = 'V' \), \( ldq \geq \max(1, n) \).
Output Parameters

**ab**
On exit, the contents of *ab* are overwritten.

**bb**
On exit, contains the factor *S* from the split Cholesky factorization *B* = *S*H*S*, as returned by **pbstf**.

**m**
The total number of eigenvalues found,
0 ≤ *m* ≤ *n*. If **range** = 'A', *m* = *n*, and if **range** = 'I',
m = *iu*-il+1.

**w**
Array *w*, size at least max(1, *n*).
If **info** = 0, contains the eigenvalues in ascending order.

**z, q**
Arrays:

*z* (size max(1, ldz* *m*) for column major layout and max(1, ldz* *n*) for row major layout).

If **jobz** = 'V', then if **info** = 0, *z* contains the matrix *Z* of eigenvectors, with the *i*-th column of *z* holding the eigenvector associated with *w*[ *i* - 1]. The eigenvectors are normalized so that *Z*H *B*H *Z* = I.

If **jobz** = 'N', then *z* is not referenced.

*q* (size max(1, ldq* *n*)).

If **jobz** = 'V', then *q* contains the *n*-by-*n* matrix used in the reduction of

*Ax* = *λBx* to standard form, that is, *Cx* = *λx* and consequently *C* to tridiagonal form.

If **jobz** = 'N', then *q* is not referenced.

**ifail**
Array, size at least max(1, *n*).

If **jobz** = 'V', then if **info** = 0, the first *m* elements of *ifail* are zero; if **info** > 0, the *ifail* contains the indices of the eigenvectors that failed to converge.

If **jobz** = 'N', then *ifail* is not referenced.

Return Values
This function returns a value **info**.

If **info** = 0, the execution is successful.

If **info** = *i*, the *i*-th parameter had an illegal value.

If **info** > 0, and

if **info** ≤ *n*, the algorithm failed to converge, and *i* off-diagonal elements of an intermediate tridiagonal did not converge to zero;

if **info** = *n* + *i*, for 1 ≤ *i* ≤ *n*, then **pbstf** returned **info** = *i* and *B* is not positive-definite. The factorization of *B* could not be completed and no eigenvalues or eigenvectors were computed.

Application Notes
An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width
less than or equal to **abstol**+ε*max(|a|,|b|), where ε is the machine precision.
If $abstol$ is less than or equal to zero, then $\epsilon||T||_1$ will be used in its place, where $T$ is the tridiagonal matrix obtained by reducing $A$ to tridiagonal form. Eigenvalues will be computed most accurately when $abstol$ is set to twice the underflow threshold $2*:\text{lamch}(\text{'S'})$, not zero.

If this routine returns with $info > 0$, indicating that some eigenvectors did not converge, try setting $abstol$ to $2*:\text{lamch}(\text{'S'})$.

**Generalized Nonsymmetric Eigenvalue Problems: LAPACK Driver Routines**

This section describes LAPACK driver routines used for solving generalized nonsymmetric eigenproblems. See also computational routines that can be called to solve these problems. Table "Driver Routines for Solving Generalized Nonsymmetric Eigenproblems" lists all such driver routines.

Description

The \texttt{?gges} routine computes the generalized eigenvalues, the generalized real/complex Schur form \((S,T)\), optionally, the left and/or right matrices of Schur vectors \((vsl\) and \(vsr\)) for a pair of \(n\)-by-\(n\) real/complex nonsymmetric matrices \((A,B)\). This gives the generalized Schur factorization

\[
(A,B) = (vsl*S*vsl^H, vsl*T*vsl^H)
\]

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix \(S\) and the upper triangular matrix \(T\). The leading columns of \(vsl\) and \(vsr\) then form an orthonormal/unitary basis for the corresponding left and right eigenspaces (deflating subspaces).

If only the generalized eigenvalues are needed, use the driver \texttt{ggev} instead, which is faster.

A generalized eigenvalue for a pair of matrices \((A,B)\) is a scalar \(w\) or a ratio \(\alpha / \beta = w\), such that \(A - w*B\) is singular. It is usually represented as the pair \((\alpha, \beta)\), as there is a reasonable interpretation for \(\beta=0\) or for both being zero. A pair of matrices \((S,T)\) is in the generalized real Schur form if \(T\) is upper triangular with non-negative diagonal and \(S\) is block upper triangular with 1-by-1 and 2-by-2 blocks. 1-by-1 blocks correspond to real generalized eigenvalues, while 2-by-2 blocks of \(S\) are "standardized" by making the corresponding elements of \(T\) have the form:

\[
\begin{pmatrix}
\alpha & 0 \\
0 & \beta
\end{pmatrix}
\]

and the pair of corresponding 2-by-2 blocks in \(S\) and \(T\) will have a complex conjugate pair of generalized eigenvalues. A pair of matrices \((S,T)\) is in generalized complex Schur form if \(S\) and \(T\) are upper triangular and, in addition, the diagonal of \(T\) are non-negative real numbers.

The \texttt{?gges} routine replaces the deprecated \texttt{?gegs} routine.

Input Parameters

\texttt{matrix_layout}

Specifies whether matrix storage layout is row major (LAPACK\_ROW\_MAJOR) or column major (LAPACK\_COL\_MAJOR).

\texttt{jobvsl}

Must be \texttt{'N'} or \texttt{'V'}.

- If \texttt{jobvsl = 'N'}, then the left Schur vectors are not computed.
- If \texttt{jobvsl = 'V'}, then the left Schur vectors are computed.

\texttt{jobvsr}

Must be \texttt{'N'} or \texttt{'V'}.

- If \texttt{jobvsr = 'N'}, then the right Schur vectors are not computed.
- If \texttt{jobvsr = 'V'}, then the right Schur vectors are computed.

\texttt{sort}

Must be \texttt{'N'} or \texttt{'S'}. Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form.

- If \texttt{sort = 'N'}, then eigenvalues are not ordered.
- If \texttt{sort = 'S'}, eigenvalues are ordered (see \texttt{select}).
The `select` parameter is a pointer to a function returning a value of `lapack_logical` type. For different flavors the function has different arguments:

- **LAPACKE_sgges**: `lapack_logical (*LAPACK_S_SELECT3) (const float*, const float*, const float* );`
- **LAPACKE_dgges**: `lapack_logical (*LAPACK_D_SELECT3) (const double*, const double*, const double* );`
- **LAPACKE_cgges**: `lapack_logical (*LAPACK_C_SELECT2) (const lapack_complex_float*, const lapack_complex_float* );`
- **LAPACKE_zgges**: `lapack_logical (*LAPACK_Z_SELECT2) (const lapack_complex_double*, const lapack_complex_double* );`

If `sort = 'S'`, `select` is used to select eigenvalues to sort to the top left of the Schur form.

If `sort = 'N'`, `select` is not referenced.

For real flavors:

An eigenvalue `(alphar[j] + alphai[j])/beta[j]` is selected if `select(alphar[j], alphai[j], beta[j])` is true; that is, if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected.

Note that in the ill-conditioned case, a selected complex eigenvalue may no longer satisfy `select(alphar[j], alphai[j], beta[j]) = 1` after ordering. In this case `info` is set to `n+2`.

For complex flavors:

An eigenvalue `alpha[j] / beta[j]` is selected if `select(alpha[j], beta[j])` is true.

Note that a selected complex eigenvalue may no longer satisfy `select(alpha[j], beta[j]) = 1` after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned); in this case `info` is set to `n+2` (see `info` below).

The order of the matrices `A`, `B`, `vsl`, and `vsr` (`n≥ 0`).

**Arrays:**

- `a` (size at least `max(1, lda*n)`) is an array containing the `n`-by-`n` matrix `A` (first of the pair of matrices).
- `b` (size at least `max(1, ldb*n)`) is an array containing the `n`-by-`n` matrix `B` (second of the pair of matrices).

The leading dimension of the array `a`. Must be at least `max(1, n)`.

The leading dimension of the array `b`. Must be at least `max(1, n)`.

The leading dimensions of the output matrices `vsl` and `vsr`, respectively. Constraints:

- `ldvs1≥ 1. If jobvsl = 'V', ldvs1≥ max(1, n)`.
- `ldvsr≥ 1. If jobvsr = 'V', ldvsr≥ max(1, n)`.
Output Parameters

- **a**: On exit, this array has been overwritten by its generalized Schur form $S$.

- **b**: On exit, this array has been overwritten by its generalized Schur form $T$.

- **sdim**: If $\text{sort} = 'N'$, $sdim = 0$.

  If $\text{sort} = 'S'$, $sdim$ is equal to the number of eigenvalues (after sorting) for which $\text{select}$ is true.

  Note that for real flavors complex conjugate pairs for which $\text{select}$ is true for either eigenvalue count as 2.

- **alphar, alphai**: Arrays, size at least $\max(1, n)$ each. Contain values that form generalized eigenvalues in real flavors.

  See $\beta$.

- **alpha**: Array, size at least $\max(1, n)$. Contain values that form generalized eigenvalues in complex flavors. See $\beta$.

- **beta**: Array, size at least $\max(1, n)$.

  For real flavors:

  On exit, $(\text{alphar}[j] + \text{alphai}[j]i)/\text{beta}[j], j=0,\ldots, n-1$, will be the generalized eigenvalues.

  $\text{alphar}[j] + \text{alphai}[j]i$ and $\text{beta}[j], j=0,\ldots, n-1$ are the diagonals of the complex Schur form $(S, T)$ that would result if the 2-by-2 diagonal blocks of the real generalized Schur form of $(A, B)$ were further reduced to triangular form using complex unitary transformations. If alphai[j] is zero, then the $j$-th eigenvalue is real; if positive, then the $j$-th and $(j+1)$-st eigenvalues are a complex conjugate pair, with alphai[j+1] negative.

  For complex flavors:

  On exit, $\text{alpha}[j]/\text{beta}[j], j=0,\ldots, n-1$, will be the generalized eigenvalues. $\text{alpha}[j]$ and $\text{beta}[j], j=0,\ldots, n-1$ are the diagonals of the complex Schur form $(S, T)$ output by cgges/zgges. The $\text{beta}[j]$ will be non-negative real.

  See also Application Notes below.

- **vsl, vsr**: Arrays:

  $vsl$ (size at least $\max(1, ldvsl*n)$).

  If $\text{jobvsl} = 'V'$, this array will contain the left Schur vectors.

  If $\text{jobvsl} = 'N'$, $vsl$ is not referenced.

  $vsr$ (size at least $\max(1, ldvsr*n)$).

  If $\text{jobvsr} = 'V'$, this array will contain the right Schur vectors.

  If $\text{jobvsr} = 'N'$, $vsr$ is not referenced.

Return Values

This function returns a value $\text{info}$.

If $\text{info} = 0$, the execution is successful.

If $\text{info} = -i$, the $i$-th parameter had an illegal value.
If info = i, and 

\( i \leq n \):

the QZ iteration failed. \((A, B)\) is not in Schur form, but \(\alpha_{l, j}, \alpha_{r, j}\) (for real flavors), or \(\alpha_{j}\) (for complex flavors), and \(\beta_{j}, j = info, \ldots, n - 1\) should be correct.

\( i > n \): errors that usually indicate LAPACK problems:

\( i = n+1 \): other than QZ iteration failed in \(rgeqz\);

\( i = n+2 \): after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the generalized Schur form no longer satisfy \(\text{select} = 1\). This could also be caused due to scaling;

\( i = n+3 \): reordering failed in \(tgsen\).

**Application Notes**

The quotients \(\alpha_{l, j}/\beta_{j}\) and \(\alpha_{r, j}/\beta_{j}\) may easily over- or underflow, and \(\beta_{j}\) may even be zero. Thus, you should avoid simply computing the ratio. However, \(\alpha_{l}\) and \(\alpha_{r}\) will be always less than and usually comparable with \(\text{norm}(A)\) in magnitude, and \(\beta\) always less than and usually comparable with \(\text{norm}(B)\).

**?ggesx**

Computes the generalized eigenvalues, Schur form, and, optionally, the left and/or right matrices of Schur vectors.

**Syntax**

```c
lapack_int LAPACK_sggesx( int matrix_layout, char jobvsl, char jobvsr, char sort,
LAPACK_S_SELECT3 select, char sense, lapack_int n, float* a, lapack_int lda, float* b,

lapack_complex_double* b, lapack_int ldb, lapack_int* sdim, lapack_complex_double* alpha,
lapack_complex_double* beta, lapack_complex_double* vsl, lapack_int ldvsl,
lapack_complex_double* vsr, lapack_int ldvsl, double* rconde, double* rcondv );
```

**Include Files**

- mkl.h

**Description**
The routine computes for a pair of \( n \times n \) real/complex nonsymmetric matrices \((A, B)\), the generalized eigenvalues, the generalized real/complex Schur form \((S, T)\), optionally, the left and/or right matrices of Schur vectors \( (vsl \text{ and } vsr) \). This gives the generalized Schur factorization

\[
(A, B) = (vsl \cdot S \cdot vsr^H, \; vsl \cdot T \cdot vsr^H)
\]

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix \( S \) and the upper triangular matrix \( T \); computes a reciprocal condition number for the average of the selected eigenvalues \((rconde)\); and computes a reciprocal condition number for the right and left deflating subspaces corresponding to the selected eigenvalues \((rcondv)\). The leading columns of \( vsl \) and \( vsr \) then form an orthonormal/unitary basis for the corresponding left and right eigenspaces (deflating subspaces).

A generalized eigenvalue for a pair of matrices \((A, B)\) is a scalar \( w \) or a ratio \( \alpha / \beta = w \), such that \( A - w \cdot B \) is singular. It is usually represented as the pair \((\alpha, \beta)\), as there is a reasonable interpretation for \( \beta = 0 \) or for both being zero. A pair of matrices \((S, T)\) is in generalized real Schur form if \( T \) is upper triangular with non-negative diagonal and \( S \) is block upper triangular with 1-by-1 and 2-by-2 blocks. 1-by-1 blocks correspond to real generalized eigenvalues, while 2-by-2 blocks of \( S \) will be "standardized" by making the corresponding elements of \( T \) have the form:

\[
\begin{pmatrix}
\alpha & 0 \\
0 & \beta
\end{pmatrix}
\]

and the pair of corresponding 2-by-2 blocks in \( S \) and \( T \) will have a complex conjugate pair of generalized eigenvalues. A pair of matrices \((S, T)\) is in generalized complex Schur form if \( S \) and \( T \) are upper triangular and, in addition, the diagonal of \( T \) are non-negative real numbers.

**Input Parameters**

- **matrix_layout**
  Specifies whether matrix storage layout is row major \((\text{LAPACK\_ROW\_MAJOR})\) or column major \((\text{LAPACK\_COL\_MAJOR})\).

- **jobvsl**
  Must be \('N' \text{ or } 'V'\).
  - If \( \text{jobvsl} = 'N' \), then the left Schur vectors are not computed.
  - If \( \text{jobvsl} = 'V' \), then the left Schur vectors are computed.

- **jobvsr**
  Must be \('N' \text{ or } 'V'\).
  - If \( \text{jobvsr} = 'N' \), then the right Schur vectors are not computed.
  - If \( \text{jobvsr} = 'V' \), then the right Schur vectors are computed.

- **sort**
  Must be \('N' \text{ or } 'S'\). Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form.
  - If \( \text{sort} = 'N' \), then eigenvalues are not ordered.
  - If \( \text{sort} = 'S' \), eigenvalues are ordered (see \( \text{select} \)).

- **select**
  The \( \text{select} \) parameter is a pointer to a function returning a value of \( \text{lapack\_logical} \) type. For different flavors the function has different arguments:
  - \( \text{LAPACKE\_sggesx}: \text{lapack\_logical} \left( \ast \text{LAPACK\_S\_SELECT3} \right) \left( \text{const float*, const float*, const float* } \right) \);
  - \( \text{LAPACKE\_dggesx}: \text{lapack\_logical} \left( \ast \text{LAPACK\_D\_SELECT3} \right) \left( \text{const double*, const double*, const double* } \right) \);
LAPACKE_cggesx: `lapack_logical (*LAPACK_C_SELECT2) (const lapack_complex_float*, const lapack_complex_float* );`

LAPACKE_zggesx: `lapack_logical (*LAPACK_Z_SELECT2) (const lapack_complex_double*, const lapack_complex_double* );`

If `sort = 'S'`, `select` is used to select eigenvalues to sort to the top left of the Schur form.

If `sort = 'N'`, `select` is not referenced.

For real flavors:

An eigenvalue \( (\text{alphar}[j] + \text{alphai}[j])/\text{beta}[j] \) is selected if `select(\text{alphar}[j], \text{alphai}[j], \text{beta}[j])` is true; that is, if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected.

Note that in the ill-conditioned case, a selected complex eigenvalue may no longer satisfy `select(\text{alphar}[j], \text{alphai}[j], \text{beta}[j]) = 1` after ordering. In this case `info` is set to `n+2`.

For complex flavors:

An eigenvalue \( \alpha[j]/\beta[j] \) is selected if `select(\alpha[j], \beta[j])` is true.

Note that a selected complex eigenvalue may no longer satisfy `select(\alpha[j], \beta[j]) = 1` after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned); in this case `info` is set to `n+2` (see `info` below).

**sense**

Must be 'N', 'E', 'V', or 'B'. Determines which reciprocal condition number are computed.

If `sense = 'N'`, none are computed;

If `sense = 'E'`, computed for average of selected eigenvalues only;

If `sense = 'V'`, computed for selected deflating subspaces only;

If `sense = 'B'`, computed for both.

If `sense` is 'E', 'V', or 'B', then `sort` must equal 'S'.

**n**

The order of the matrices \( A, B, vsl, \) and \( vsr (n \geq 0) \).

**a, b**

Arrays:

\( a \) (size at least max(1, lda*n)) is an array containing the \( n \)-by-\( n \) matrix \( A \) (first of the pair of matrices).

\( b \) (size at least max(1, ldb*n)) is an array containing the \( n \)-by-\( n \) matrix \( B \) (second of the pair of matrices).

**lda**

The leading dimension of the array \( a \).

Must be at least max(1, n).

**ldb**

The leading dimension of the array \( b \).

Must be at least max(1, n).

**ldvsl, ldvsr**

The leading dimensions of the output matrices \( vsl \) and \( vsr \), respectively.

Constraints:
If $\text{jobvsl} = 'V'$, $\text{ldvsl} \geq \max(1, n)$.

If $\text{jobvsr} = 'V'$, $\text{ldvsr} \geq \max(1, n)$.

Output Parameters

- **a**: On exit, this array has been overwritten by its generalized Schur form $S$.

- **b**: On exit, this array has been overwritten by its generalized Schur form $T$.

- **sdim**: If $\text{sort} = 'N'$, $\text{sdim} = 0$.

  If $\text{sort} = 'S'$, $\text{sdim}$ is equal to the number of eigenvalues (after sorting) for which $\text{select}$ is true.

  Note that for real flavors complex conjugate pairs for which $\text{select}$ is true for either eigenvalue count as 2.

- **alphar, alphai**: Arrays, size at least $\max(1, n)$ each. Contain values that form generalized eigenvalues in real flavors.

  See $\beta$.

- **alpha**: Array, size at least $\max(1, n)$. Contain values that form generalized eigenvalues in complex flavors. See $\beta$.

- **beta**: Array, size at least $\max(1, n)$.

  For real flavors:

  On exit, $\left(\text{alphar}[j] + \text{alphai}[j] \ast i\right) / \text{beta}[j], j=0,\ldots, n-1$ will be the generalized eigenvalues.

  $\text{alphar}[j] + \text{alphai}[j] \ast i$ and $\text{beta}[j], j=0,\ldots, n-1$ are the diagonals of the complex Schur form $(S,T)$ that would result if the 2-by-2 diagonal blocks of the real generalized Schur form of $(A,B)$ were further reduced to triangular form using complex unitary transformations. If $\text{alphai}[j]$ is zero, then the $j$-th eigenvalue is real; if positive, then the $j$-th and $(j+1)$-st eigenvalues are a complex conjugate pair, with $\text{alphai}[j+1]$ negative.

  For complex flavors:

  On exit, $\text{alpha}[j]/\text{beta}[j], j=0,\ldots, n-1$ will be the generalized eigenvalues. $\text{alpha}[j]$ and $\text{beta}[j], j=0,\ldots, n-1$ are the diagonals of the complex Schur form $(S,T)$ output by $\text{cggesx/zggesx}$. The $\text{beta}[j]$ will be non-negative real.

  See also Application Notes below.

- **vsl, vsr**: Arrays:

  $\text{vsl}$ (size at least $\max(1, \text{ldvsl} \ast n)$).

  If $\text{jobvsl} = 'V'$, this array will contain the left Schur vectors.

  If $\text{jobvsl} = 'N'$, $\text{vsl}$ is not referenced.

  $\text{vsr}$ (size at least $\max(1, \text{ldvsr} \ast n)$).

  If $\text{jobvsr} = 'V'$, this array will contain the right Schur vectors.

  If $\text{jobvsr} = 'N'$, $\text{vsr}$ is not referenced.

- **rconde, rcondv**: Arrays, size 2 each
If sense = 'E' or 'B', rconde(1) and rconde(2) contain the reciprocal condition numbers for the average of the selected eigenvalues.
Not referenced if sense = 'N' or 'V'.
If sense = 'V' or 'B', rcondv[0] and rcondv[1] contain the reciprocal condition numbers for the selected deflating subspaces.
Not referenced if sense = 'N' or 'E'.

Return Values

This function returns a value info.
If info=0, the execution is successful.
If info = -i, the i-th parameter had an illegal value.
If info = i, and
i≤n:
the QZ iteration failed. (A, B) is not in Schur form, but alphar[j], alphai[j] (for real flavors), or alpha[j] (for complex flavors), and beta[j], j = info, ..., n - 1 should be correct.
i > n: errors that usually indicate LAPACK problems:
i = n+1: other than QZ iteration failed in hgeqz;
i = n+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the generalized Schur form no longer satisfy select = 1. This could also be caused due to scaling;
i = n+3: reordering failed in tgsen.

Application Notes

The quotients alphar[j]/beta[j] and alphai[j]/beta[j] may easily over- or underflow, and beta[j] may even be zero. Thus, you should avoid simply computing the ratio. However, alphar and alphai will be always less than and usually comparable with norm(A) in magnitude, and beta always less than and usually comparable with norm(B).

?qgges3
Computes generalized Schur factorization for a pair of matrices.

Syntax

```c

Include Files
• mkl.h

Description
For a pair of \( n \times n \) real or complex nonsymmetric matrices (\( A,B \)), \( ?gges3 \) computes the generalized eigenvalues, the generalized real or complex Schur form (\( S,T \)), and optionally the left or right matrices of Schur vectors (\( VSL \) and \( VSR \)). This gives the generalized Schur factorization
\[
(A,B) = ( (VSL)*S*(VSR)^T, (VSL)*T*(VSR)^T ) \quad \text{for real } (A,B)
\]
or
\[
(A,B) = ( (VSL)*S*(VSR)^H, (VSL)*T*(VSR)^H ) \quad \text{for complex } (A,B)
\]
where \((VSR)^H\) is the conjugate-transpose of \( VSR \).

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix \( S \) and the upper triangular matrix \( T \). The leading columns of \( VSL \) and \( VSR \) then form an orthonormal basis for the corresponding left and right eigenspaces (deflating subspaces).

NOTE
If only the generalized eigenvalues are needed, use the driver \( ?ggev \) instead, which is faster.

A generalized eigenvalue for a pair of matrices \((A,B)\) is a scalar \( w \) or a ratio \( \alpha/\beta = w \), such that \( A - w \cdot B \) is singular. It is usually represented as the pair \((\alpha,\beta)\), as there is a reasonable interpretation for \( \beta = 0 \) or both being zero.

For real flavors:
A pair of matrices \((S,T)\) is in generalized real Schur form if \( T \) is upper triangular with non-negative diagonal and \( S \) is block upper triangular with 1-by-1 and 2-by-2 blocks. 1-by-1 blocks correspond to real generalized eigenvalues, while 2-by-2 blocks of \( S \) will be "standardized" by making the corresponding elements of \( T \) have the form:
\[
\begin{pmatrix}
  a & 0 \\
  0 & b
\end{pmatrix}
\]
and the pair of corresponding 2-by-2 blocks in \( S \) and \( T \) have a complex conjugate pair of generalized eigenvalues.

For complex flavors:
A pair of matrices \((S,T)\) is in generalized complex Schur form if \( S \) and \( T \) are upper triangular and, in addition, the diagonal elements of \( T \) are non-negative real numbers.
**Input Parameters**

- **matrix_layout**
  Specifies whether matrix storage layout is row major (**LAPACK_ROW_MAJOR**) or column major (**LAPACK_COL_MAJOR**).

- **jobvsl**
  = 'N': do not compute the left Schur vectors;

- **jobvsr**
  = 'N': do not compute the right Schur vectors;
  = 'V': compute the right Schur vectors.

- **sort**
  Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form.
  = 'N': Eigenvalues are not ordered;
  = 'S': Eigenvalues are ordered (see **selctg**).

- **selctg**
  * selctg is a function of three arguments for real flavors or two arguments for complex flavors. selctg must be declared EXTERNAL in the calling subroutine. If sort = 'N', selctg is not referenced. If sort = 'S', selctg is used to select eigenvalues to sort to the top left of the Schur form.

  For real flavors:
  An eigenvalue \((\text{alphar}[j - 1] + \text{alphai}[j - 1])/\text{beta}[j - 1]\) is selected if \(\text{selctg}(\text{alphar}[j - 1], \text{alphai}[j - 1], \text{beta}[j - 1])\) is true.

  In other words, if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected.

  Note that in the ill-conditioned case, a selected complex eigenvalue may no longer satisfy \(\text{selctg}(\text{alphar}[j - 1], \text{alphai}[j - 1], \text{beta}[j - 1]) \neq 0\) after ordering. info is to be set to \(n+2\) in this case.

  For complex flavors:
  An eigenvalue \(\text{alpha}[j - 1]/\text{beta}[j - 1]\) is selected if \(\text{selctg}(\text{alpha}[j - 1], \text{beta}[j - 1])\) is true.

  Note that a selected complex eigenvalue may no longer satisfy \(\text{selctg}(\text{alpha}[j - 1], \text{beta}[j - 1]) \neq 0\) after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned), in this case ?gges3 returns \(n + 2\).

- **n**
  The order of the matrices \(A, B, VSL,\) and \(VSR. n \geq 0\).

- **a**
  Array, size \((lda*n)\). On entry, the first of the pair of matrices.

- **lda**
  The leading dimension of \(a. lda\geq max(1,n)\).

- **b**
  Array, size \((ldb*n)\). On entry, the second of the pair of matrices.

- **ldb**
  The leading dimension of \(b. ldb\geq max(1,n)\).

- **ldvsl**
  The leading dimension of the matrix \(VSL. ldvsl\geq 1\), and if \(jobvsl = 'V'\), \(ldvsl\geq n\).

- **ldvsr**
  The leading dimension of the matrix \(VSR. ldvsr\geq 1\), and if \(jobvsr = 'V'\), \(ldvsr\geq n\).
Output Parameters

On exit, \( a \) is overwritten by its generalized Schur form \( S \).

On exit, \( b \) is overwritten by its generalized Schur form \( T \).

If \( sort = 'N' \), \( sdim = 0 \). If \( sort = 'S' \), \( sdim = \) number of eigenvalues (after sorting) for which \( selctg \) is true.

\( \alpha \)

Array, size \( (n) \).

\( \text{alphar} \)

Array, size \( (n) \).

\( \text{alphai} \)

Array, size \( (n) \).

\( \beta \)

Array, size \( (n) \).

For real flavors:

On exit, \( (\text{alphar}[j - 1] + \text{alphai}[j - 1]*i)/\beta[j - 1], j=1,...,n \), are the generalized eigenvalues. \( \text{alphar}[j - 1] + \text{alphai}[j - 1]*i, \) and \( \beta[j - 1], j=1,...,n \) are the diagonals of the complex Schur form \( (S,T) \) that would result if the 2-by-2 diagonal blocks of the real Schur form of \( (a,b) \) were further reduced to triangular form using 2-by-2 complex unitary transformations. If \( \text{alphai}[j - 1] \) is zero, then the \( j \)-th eigenvalue is real; if positive, then the \( j \)-th and \( (j+1) \)-st eigenvalues are a complex conjugate pair, with \( \text{alphai}[j] \) negative.

Note: the quotients \( \text{alphar}[j - 1]/\beta[j - 1] \) and \( \text{alphai}[j - 1]/\beta[j - 1] \) can easily over- or underflow, and \( \beta[j - 1] \) might even be zero. Thus, you should avoid computing the ratio \( \alpha/\beta \) by simply dividing \( \alpha \) by \( \beta \). However, \( \text{alphar} \) and \( \text{alphai} \) is always less than and usually comparable with \( \text{norm}(a) \) in magnitude, and \( \beta \) is always less than and usually comparable with \( \text{norm}(b) \).

For complex flavors:

On exit, \( \text{alpha}[j - 1][j - 1]/\beta[j - 1], j=1,...,n \), are the generalized eigenvalues. \( \text{alpha}[j - 1], j=1,...,n \) and \( \beta[j - 1], j=1,...,n \) are the diagonals of the complex Schur form \( (a,b) \) output by \( \texttt{?gges3} \). The \( \beta[j - 1] \) is non-negative real.

Note: the quotient \( \text{alpha}[j - 1]/\beta[j - 1] \) can easily over- or underflow, and \( \beta[j - 1] \) might even be zero. Thus, you should avoid computing the ratio \( \alpha/\beta \) by simply dividing \( \alpha \) by \( \beta \). However, \( \alpha \) is always less than and usually comparable with \( \text{norm}(a) \) in magnitude, and \( \beta \) is always less than and usually comparable with \( \text{norm}(b) \).

\( \text{vsl} \)

Array, size \( (ldvsl*n) \).

If \( jobvsl = 'V' \), \( vsl \) contains the left Schur vectors. Not referenced if \( jobvsl = 'N' \).

\( \text{vsr} \)

Array, size \( (ldvsr*n) \).
If \( \text{jobvsr} = 'V' \), \( \text{vsr} \) contains the right Schur vectors. Not referenced if \( \text{jobvsr} = 'N' \).

**Return Values**

This function returns a value \( \text{info} \).

- \( = 0 \): successful exit
- \( < 0 \): if \( \text{info} = -i \), the \( i \)-th argument had an illegal value.
- \( = 1, \ldots, n \):
  - for real flavors: The QZ iteration failed. \((a,b)\) are not in Schur form, but \( \text{alphar} \[j \], \text{alphai} \[j \] \) and \( \text{beta} \[j \] \) should be correct for \( j=\text{info},\ldots,n-1 \).
  - for complex flavors:
    - \( > n \): \( =n+1 \): other than QZ iteration failed in \( \text{?hgeqz} \).
    - \( =n+2 \): after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Generalized Schur form no longer satisfy \( \text{selctg} \neq 0 \) This could also be caused due to scaling.
    - \( =n+3 \): reordering failed in \( \text{?tgsen} \).

**?ggev**

Computes the generalized eigenvalues, and the left and/or right generalized eigenvectors for a pair of nonsymmetric matrices.

**Syntax**

```c
lapack_int LAPACKE_sggev( int matrix_layout, char jobvl, char jobvr, lapack_int n, float* a, lapack_int lda, float* b, lapack_int ldb, float* alphar, float* alphai, float* beta, float* vl, lapack_int ldvl, float* vr, lapack_int ldvr );
```

```c
lapack_int LAPACKE_dggev( int matrix_layout, char jobvl, char jobvr, lapack_int n, double* a, lapack_int lda, double* b, lapack_int ldb, double* alphar, double* alphai, double* beta, double* vl, lapack_int ldvl, double* vr, lapack_int ldvr );
```

```c
lapack_int LAPACKE_cggev( int matrix_layout, char jobvl, char jobvr, lapack_int n, lapack_complex_float* a, lapack_int lda, lapack_complex_float* b, lapack_int ldb, lapack_complex_float* alpha, lapack_complex_float* beta, lapack_complex_float* vl, lapack_int ldvl, lapack_complex_float* vr, lapack_int ldvr );
```

```c
lapack_int LAPACKE_zggev( int matrix_layout, char jobvl, char jobvr, lapack_int n, lapack_complex_double* a, lapack_int lda, lapack_complex_double* b, lapack_int ldb, lapack_complex_double* alpha, lapack_complex_double* beta, lapack_complex_double* vl, lapack_int ldvl, lapack_complex_double* vr, lapack_int ldvr );
```

**Include Files**

- \text{mkl.h}

**Description**

The \( ?ggev \) routine computes the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors for a pair of \( n \)-by-\( n \) real/complex nonsymmetric matrices \((A,B)\).
A generalized eigenvalue for a pair of matrices \((A,B)\) is a scalar \(\lambda\) or a ratio \(\frac{\alpha}{\beta} = \lambda\), such that \(A - \lambda B\) is singular. It is usually represented as the pair \((\alpha, \beta)\), as there is a reasonable interpretation for \(\beta = 0\) and even for both being zero.

The right generalized eigenvector \(v(j)\) corresponding to the generalized eigenvalue \(\lambda(j)\) of \((A,B)\) satisfies
\[
A*v(j) = \lambda(j)*B*v(j).
\]

The left generalized eigenvector \(u(j)\) corresponding to the generalized eigenvalue \(\lambda(j)\) of \((A,B)\) satisfies
\[
u(j)^H*A = \lambda(j)*u(j)^H*B
\]
where \(u(j)^H\) denotes the conjugate transpose of \(u(j)\).

The \(?\text{ggev}\) routine replaces the deprecated \(?\text{gegv}\) routine.

**Input Parameters**

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **jobvl**
  Must be \('N'\) or \('V'\).
  - If \(\text{jobvl} = \text{'N'}\), the left generalized eigenvectors are not computed;
  - If \(\text{jobvl} = \text{'V'}\), the left generalized eigenvectors are computed.

- **jobvr**
  Must be \('N'\) or \('V'\).
  - If \(\text{jobvr} = \text{'N'}\), the right generalized eigenvectors are not computed;
  - If \(\text{jobvr} = \text{'V'}\), the right generalized eigenvectors are computed.

- **n**
  The order of the matrices \(A, B, vl, \text{and } vr\) \((n \geq 0)\).

- **a, b**
  Arrays:
  - \(a\) (size at least \(\max(1, lda*n)\)) is an array containing the \(n\)-by-\(n\) matrix \(A\) (first of the pair of matrices).
  - \(b\) (size at least \(\max(1, ldb*n)\)) is an array containing the \(n\)-by-\(n\) matrix \(B\) (second of the pair of matrices).

- **lda**
  The leading dimension of the array \(a\). Must be at least \(\max(1, n)\).

- **ldb**
  The leading dimension of the array \(b\). Must be at least \(\max(1, n)\).

- **ldvl, ldvr**
  The leading dimensions of the output matrices \(vl\) and \(vr\), respectively.

  Constraints:
  - \(ldvl \geq 1\). If \(\text{jobvl} = \text{'V'}\), \(ldvl \geq \max(1, n)\).
  - \(ldvr \geq 1\). If \(\text{jobvr} = \text{'V'}\), \(ldvr \geq \max(1, n)\).

**Output Parameters**

- **a, b**
  On exit, these arrays have been overwritten.

- **alphar, alphai**
  Arrays, size at least \(\max(1, n)\) each. Contain values that form generalized eigenvalues in real flavors.

  See \(\beta\).
alpha

Array, size at least max(1, n). Contain values that form generalized eigenvalues in complex flavors. See beta.

beta

Array, size at least max(1, n).

For real flavors:

On exit, $(\text{alphar}[j] + \text{alpha}[j]*i)/\text{beta}[j], j=0,..., n - 1$, are the generalized eigenvalues.

If $\text{alpha}[j]$ is zero, then the $j$-th eigenvalue is real; if positive, then the $j$-th and $(j+1)$-st eigenvalues are a complex conjugate pair, with $\text{alpha}[j+1]$ negative.

For complex flavors:

On exit, $\alpha[j]/\beta[j], j=0,..., n - 1$, are the generalized eigenvalues.

See also Application Notes below.

$vl, vr$

$vl$ (size at least max(1, ldvl*n)). Contains the matrix of left generalized eigenvectors $VL$.

If $\text{jobvl} = 'V'$, the left generalized eigenvectors $u_j$ are stored one after another in the columns of $VL$, in the same order as their eigenvalues. Each eigenvector is scaled so the largest component has $\text{abs(Re)} + \text{abs(Im)} = 1$.

If $\text{jobvl} = 'N'$, $vl$ is not referenced.

For real flavors:

If the $j$-th eigenvalue is real, then the $k$-th component of the $j$-th left eigenvector $u_j$ is stored in $vl[(k - 1) + (j - 1)*ldvl]$ for column major layout and in $vl[(k - 1)*ldvl + (j - 1)]$ for row major layout.

If the $j$-th and $(j+1)$-st eigenvalues form a complex conjugate pair, then for $i = \sqrt{-1}$, the $k$-th components of the $j$-th left eigenvector $u_j$ are $vl[(k - 1) + (j - 1)*ldvl] + i*vl[(k - 1) + j*ldvl]$ for column major layout and $vl[(k - 1)*ldvl + (j - 1)] + i*vl[(k - 1)*ldvl + j]$ for row major layout.

For complex flavors:

The $k$-th component of the $j$-th left eigenvector $u_j$ is stored in $vl[(k - 1) + (j - 1)*ldvl]$ for column major layout and in $vl[(k - 1)*ldvl + (j - 1)]$ for row major layout.

$vr$ (size at least max(1, ldvr*n)). Contains the matrix of right generalized eigenvectors $VR$.

If $\text{jobvr} = 'V'$, the right generalized eigenvectors $v_j$ are stored one after another in the columns of $VR$, in the same order as their eigenvalues. Each eigenvector is scaled so the largest component has $\text{abs(Re)} + \text{abs(Im)} = 1$.

If $\text{jobvr} = 'N'$, $vr$ is not referenced.

For real flavors:
If the \( j \)-th eigenvalue is real, then the \( k \)-th component of the \( j \)-th right eigenvector \( v_j \) is stored in \( vr[(k - 1) + (j - 1) \cdot ldvr] \) for column major layout and in \( vr[(k - 1) \cdot ldvr + (j - 1)] \) for row major layout.

If the \( j \)-th and \((j+1)\)-st eigenvalues form a complex conjugate pair, then the \( k \)-th components of the \( j \)-th right eigenvector \( v_j \) can be computed as \( vr[(k - 1) + (j - 1) \cdot ldvr] + i \cdot vr[(k - 1) + j \cdot ldvr] \) for column major layout and \( vr[(k - 1) \cdot ldvr + (j - 1)] + i \cdot vr[(k - 1) \cdot ldvr + j] \) for row major layout. Similarly, the \( k \)-th components of the right eigenvector \( v_{j+1} \) can be computed as \( vr[(k - 1) + (j - 1) \cdot ldvr] - i \cdot vr[(k - 1) + j \cdot ldvr] \) for column major layout and \( vr[(k - 1) \cdot ldvr + (j - 1)] - i \cdot vr[(k - 1) \cdot ldvr + j] \) for row major layout.

\textit{For complex flavors:}

The \( k \)-th component of the \( j \)-th right eigenvector \( v_j \) is stored in \( vr[(k - 1) + (j - 1) \cdot ldvr] \) for column major layout and in \( vr[(k - 1) \cdot ldvr + (j - 1)] \) for row major layout.

\textbf{Return Values}

This function returns a value \( \text{info} \).

If \( \text{info}=0 \), the execution is successful.

If \( \text{info} = -i \), the \( i \)-th parameter had an illegal value.

If \( \text{info} = i \), and

\( i \leq n \): the QZ iteration failed. No eigenvectors have been calculated, but \( \text{alphar}[j] \), \( \text{alphai}[j] \) (for real flavors), or \( \text{alpha}[j] \) (for complex flavors), and \( \text{beta}[j], j=\text{info}, \ldots, n-1 \) should be correct.

\( i > n \): errors that usually indicate LAPACK problems:

\( i = n+1 \): other than QZ iteration failed in \( \text{hgeqz} \);

\( i = n+2 \): error return from \( \text{tgevc} \).

\textbf{Application Notes}

The quotients \( \text{alphar}[j]/\text{beta}[j] \) and \( \text{alphai}[j]/\text{beta}[j] \) may easily over- or underflow, and \( \text{beta}[j] \) may even be zero. Thus, you should avoid simply computing the ratio. However, \( \text{alphar} \) and \( \text{alphai} \) (for real flavors) or \( \text{alpha} \) (for complex flavors) will be always less than and usually comparable with norm(\( A \)) in magnitude, and \( \text{beta} \) always less than and usually comparable with norm(\( B \)).

?ggevx

\textit{Computes the generalized eigenvalues, and, optionally, the left and/or right generalized eigenvectors.}

Description
The routine computes for a pair of \( n \times n \) real/complex nonsymmetric matrices \((A,B)\), the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors. Optionally also, it computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (ilo, ihi, lscale, rscale, abnrm, and bbnrm), reciprocal condition numbers for the eigenvalues (rconde), and reciprocal condition numbers for the right eigenvectors (rcondv).

A generalized eigenvalue for a pair of matrices \((A,B)\) is a scalar \( \lambda \) or a ratio \( \alpha / \beta = \lambda \), such that \( A - \lambda B \) is singular. It is usually represented as the pair \((\alpha, \beta)\), as there is a reasonable interpretation for \( \beta = 0 \) and even for both being zero. The right generalized eigenvector \( v(j) \) corresponding to the generalized eigenvalue \( \lambda(j) \) of \((A,B)\) satisfies
\[
A v(j) = \lambda(j) B v(j).
\]
The left generalized eigenvector \( u(j) \) corresponding to the generalized eigenvalue \( \lambda(j) \) of \((A,B)\) satisfies
\[
u(j)^H A = \lambda(j) u(j)^H B
\]
where \( u(j)^H \) denotes the conjugate transpose of \( u(j) \).

Input Parameters

\textbf{matrix_layout} \hspace{1cm} Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

\textbf{balanc} \hspace{1cm} Must be 'N', 'P', 'S', or 'B'. Specifies the balance option to be performed.
- If \text{balanc} = 'N', do not diagonally scale or permute;
- If \text{balanc} = 'P', permute only;
- If \text{balanc} = 'S', scale only;
- If \text{balanc} = 'B', both permute and scale.
Computed reciprocal condition numbers will be for the matrices after balancing and/or permuting. Permuting does not change condition numbers (in exact arithmetic), but balancing does.

**jobvl**
Must be 'N' or 'V'.

If jobvl = 'N', the left generalized eigenvectors are not computed;
If jobvl = 'V', the left generalized eigenvectors are computed.

**jobvr**
Must be 'N' or 'V'.

If jobvr = 'N', the right generalized eigenvectors are not computed;
If jobvr = 'V', the right generalized eigenvectors are computed.

**sense**
Must be 'N', 'E', 'V', or 'B'. Determines which reciprocal condition number are computed.

If sense = 'N', none are computed;
If sense = 'E', computed for eigenvalues only;
If sense = 'V', computed for eigenvectors only;
If sense = 'B', computed for eigenvalues and eigenvectors.

**n**
The order of the matrices A, B, vl, and vr (n ≥ 0).

**a, b**
Arrays:

a (size at least max(1, lda*n)) is an array containing the n-by-n matrix A (first of the pair of matrices).

b (size at least max(1, ldb*n)) is an array containing the n-by-n matrix B (second of the pair of matrices).

**lda**
The leading dimension of the array a.
Must be at least max(1, n).

**ldb**
The leading dimension of the array b.
Must be at least max(1, n).

**ldvl, ldvr**
The leading dimensions of the output matrices vl and vr, respectively.

Constraints:

ldvl≥ 1. If jobvl = 'V', ldvl≥ max(1, n).
ldvr≥ 1. If jobvr = 'V', ldvr≥ max(1, n).

**Output Parameters**

**a, b**
On exit, these arrays have been overwritten.

If jobvl = 'V' or jobvr = 'V' or both, then a contains the first part of the real Schur form of the "balanced" versions of the input A and B, and b contains its second part.

**alphar, alphai**
Arrays, size at least max(1, n) each. Contain values that form generalized eigenvalues in real flavors.

See beta.
**alpha**

Array, size at least max(1, n). Contain values that form generalized eigenvalues in complex flavors. See **beta**.

**beta**

Array, size at least max(1, n).

---

**For real flavors:**

On exit, \((\text{alphar}[j] + \text{alphai}[j]*i)/\text{beta}[j], j=0,..., n - 1\), will be the generalized eigenvalues.

If \(\text{alphai}[j]\) is zero, then the \(j\)-th eigenvalue is real; if positive, then the \(j\)-th and \((j+1)\)-st eigenvalues are a complex conjugate pair, with \(\text{alphai}[j+1]\) negative.

**For complex flavors:**

On exit, \(\text{alphar}[j]/\text{beta}[j], j=0,..., n - 1\), will be the generalized eigenvalues.

See also Application Notes below.

---

**vl, vr**

Arrays:

\(vl\) (size at least max(1, ldvl*n)).

If \(jobvl = 'V'\), the left generalized eigenvectors \(u(j)\) are stored one after another in the columns of \(vl\), in the same order as their eigenvalues. Each eigenvector will be scaled so the largest component have abs(Re) + abs(Im) = 1.

If \(jobvl = 'N'\), \(vl\) is not referenced.

**For real flavors:**

If the \(j\)-th eigenvalue is real, then \(k\)-th component of \(j\)-th left eigenvector \(u_j\) is stored in \(vl[(k - 1) + (j - 1)*ldvl]\) for column major layout and in \(vl[(k - 1)*ldvl + (j - 1)]\) for row major layout.

If the \(j\)-th and \((j+1)\)-st eigenvalues form a complex conjugate pair, then for \(i = \text{sqrt}(-1)\), the \(k\)-th components of the \(j\)-th left eigenvector \(u_j\) can be computed as \(vl[(k - 1) + (j - 1)*ldvl] + i*vl[(k - 1) + j*ldvl]\) for column major layout and \(vl[(k - 1)*ldvl + (j - 1)] + i*vl[(k - 1)*ldvl + j]\) for row major layout. Similarly, the \(k\)-th components of the left eigenvector \(u_{j+1}\) can be computed as \(vl[(k - 1) + (j - 1)*ldvl] - i*vl[(k - 1) + j*ldvl]\) for column major layout and \(vl[(k - 1)*ldvl + (j - 1)] - i*vl[(k - 1)*ldvl + j]\) for row major layout.

**For complex flavors:**

The \(k\)-th component of the \(j\)-th left eigenvector \(u_j\) is stored in \(vl[(k - 1) + (j - 1)*ldvl]\) for column major layout and in \(vl[(k - 1)*ldvl + (j - 1)]\) for row major layout.

\(vr\) (size at least max(1, ldvr*n)).

If \(jobvr = 'V'\), the right generalized eigenvectors \(v(j)\) are stored one after another in the columns of \(vr\), in the same order as their eigenvalues. Each eigenvector will be scaled so the largest component have abs(Re) + abs(Im) = 1.

If \(jobvr = 'N'\), \(vr\) is not referenced.

**For real flavors:**
If the j-th eigenvalue is real, then the k-th component of the j-th right eigenvector \( v_j \) is stored in \( vr[(k - 1) + (j - 1) * ldvr] \) for column major layout and in \( vr[(k - 1) * ldvr + (j - 1)] \) for row major layout.

If the j-th and (j+1)-st eigenvalues form a complex conjugate pair, then

The k-th components of the j-th right eigenvector \( v_j \) can be computed as

\[
vr[(k - 1) + (j - 1) * ldvr] + i * vr[(k - 1) + j * ldvr]
\]

for column major layout and

\[
v[k - 1) * ldvr + (j - 1)] + i * vr[(k - 1) * ldvr + j]
\]

for row major layout. Respectively, the k-th components of right eigenvector \( v_{j+1} \) can be computed as

\[
vr[(k - 1) + (j - 1) * ldvr] - i * vr[(k - 1) + j * ldvr]
\]

for column major layout and

\[
v[k - 1) * ldvr + (j - 1)] - i * vr[(k - 1) * ldvr + j]
\]

for row major layout.

For complex flavors:

The k-th component of the j-th right eigenvector \( v_j \) is stored in \( vr[(k - 1) + (j - 1) * ldvr] \) for column major layout and in \( vr[(k - 1) * ldvr + (j - 1)] \) for row major layout.

\[ilo, ihi\]

ilo and ihi are integer values such that on exit \( A_{i,j} = 0 \) and \( B_{i,j} = 0 \) if \( i > j \) and \( j = 1, \ldots, ilo-1 \) or \( i = ihi+1, \ldots, n \).

If \( \text{balanc} = 'N' \) or \( 'S' \), ilo = 1 and ihi = n.

\[lscale, rscale\]

Arrays, size at least \( \max(1, n) \) each.

\( lscale \) contains details of the permutations and scaling factors applied to the left side of \( A \) and \( B \).

If \( PL(j) \) is the index of the row interchanged with row \( j \), and \( DL(j) \) is the scaling factor applied to row \( j \), then

\[
lscale[j - 1] = PL(j), \text{ for } j = 1, \ldots, ilo-1
\]

\[
= DL(j), \text{ for } j = ilo, \ldots, ihi
\]

\[
= PL(j) \text{ for } j = ihi+1, \ldots, n.
\]

The order in which the interchanges are made is \( n \) to \( ihi+1 \), then \( 1 \) to \( ilo-1 \).

\( rscale \) contains details of the permutations and scaling factors applied to the right side of \( A \) and \( B \).

If \( PR(j) \) is the index of the column interchanged with column \( j \), and \( DR(j) \) is the scaling factor applied to column \( j \), then

\[
rscale[j - 1] = PR(j), \text{ for } j = 1, \ldots, ilo-1
\]

\[
= DR(j), \text{ for } j = ilo, \ldots, ihi
\]

\[
= PR(j) \text{ for } j = ihi+1, \ldots, n.
\]

The order in which the interchanges are made is \( n \) to \( ihi+1 \), then \( 1 \) to \( ilo-1 \).

\[abnrm, bbnrm\]

The one-norms of the balanced matrices \( A \) and \( B \), respectively.

\[rconde, rcondv\]

Arrays, size at least \( \max(1, n) \) each.

If \( \text{sense} = 'E' \), or \( 'B' \), \( rconde \) contains the reciprocal condition numbers of the eigenvalues, stored in consecutive elements of the array. For a complex conjugate pair of eigenvalues two consecutive elements of \( rconde \)
are set to the same value. Thus $rconde[j]$, $rcondv[j]$, and the $j$-th columns of $vl$ and $vr$ all correspond to the same eigenpair (but not in general the $j$-th eigenpair, unless all eigenpairs are selected).

If $sense = 'N'$, or 'V', $rconde$ is not referenced.

If $sense = 'V'$, or 'B', $rcondv$ contains the estimated reciprocal condition numbers of the eigenvectors, stored in consecutive elements of the array. For a complex eigenvector two consecutive elements of $rcondv$ are set to the same value.

If the eigenvalues cannot be reordered to compute , $rcondv[j]$ is set to 0; this can only occur when the true value would be very small anyway.

If $sense = 'N'$, or 'E', $rcondv$ is not referenced.

**Return Values**

This function returns a value $info$.

If $info=0$, the execution is successful.

If $info = -i$, the $i$-th parameter had an illegal value.

If $info = i$, and

i≤n: the QZ iteration failed. No eigenvectors have been calculated, but $alphar[j]$, $alphai[j]$ (for real flavors), or $alpha[j]$ (for complex flavors), and $beta[j]$, $j=info,\ldots, n - 1$ should be correct.

i > n: errors that usually indicate LAPACK problems:

i = n+1: other than QZ iteration failed in hgeqz;

i = n+2: error return from tgevc.

**Application Notes**

The quotients $alphar[j]/beta[j]$ and $alphai[j]/beta[j]$ may easily over- or underflow, and $beta[j]$ may even be zero. Thus, you should avoid simply computing the ratio. However, $alphar$ and $alphai$ (for real flavors) or $alpha$ (for complex flavors) will be always less than and usually comparable with $\text{norm}(A)$ in magnitude, and $beta$ always less than and usually comparable with $\text{norm}(B)$.

**?ggev3**

Computes the generalized eigenvalues and the left and right generalized eigenvectors for a pair of matrices.

**Syntax**

```c

vl, lapack_int ldvl, lapack_complex_double * vr, lapack_int ldvr);

Include Files

• mkl.h

Description

For a pair of \( n \)-by-\( n \) real or complex nonsymmetric matrices \((A, B)\), \( \text{?ggev3} \) computes the generalized eigenvalues, and optionally, the left and right generalized eigenvectors.

A generalized eigenvalue for a pair of matrices \((A, B)\) is a scalar \( \lambda \) or a ratio \( \alpha/\beta = \lambda \), such that \( A - \lambda B \) is singular. It is usually represented as the pair \((\alpha, \beta)\), as there is a reasonable interpretation for \( \beta = 0 \), and even for both being zero.

For real flavors:

The right eigenvector \( v_j \) corresponding to the eigenvalue \( \lambda_j \) of \((A, B)\) satisfies

\[ A * v_j = \lambda_j * B * v_j. \]

The left eigenvector \( u_j \) corresponding to the eigenvalue \( \lambda_j \) of \((A, B)\) satisfies

\[ u_j^H * A = \lambda_j * u_j^H * B \]

where \( u_j^H \) is the conjugate-transpose of \( u_j \).

For complex flavors:

The right generalized eigenvector \( v_j \) corresponding to the generalized eigenvalue \( \lambda_j \) of \((A, B)\) satisfies

\[ A * v_j = \lambda_j * B * v_j. \]

The left generalized eigenvector \( u_j \) corresponding to the generalized eigenvalues \( \lambda_j \) of \((A, B)\) satisfies

\[ u_j^H * A = \lambda_j * u_j^H * B \]

where \( u_j^H \) is the conjugate-transpose of \( u_j \).

Input Parameters

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **jobvl**
  = 'N': do not compute the left generalized eigenvectors;
  = 'V': compute the left generalized eigenvectors.

- **jobvr**
  = 'N': do not compute the right generalized eigenvectors;
  = 'V': compute the right generalized eigenvectors.

- **n**
  The order of the matrices \( A, B, VL, \) and \( VR \).
  \( n \geq 0. \)

- **a**
  Array, size \((lda*n)\).
  On entry, the matrix \( A \) in the pair \((A, B)\).

- **lda**
  The leading dimension of \( a \).
  \( lda \geq \text{max}(1,n) \).
Array, size ($ldb \times n$).
On entry, the matrix $B$ in the pair $(A, B)$.

The leading dimension of $b$.
$ldb \geq \max(1, n)$.

The leading dimension of the matrix $VL$.
$ldvl \geq 1$, and if $jobvl = 'V'$, $ldvl \geq n$.

The leading dimension of the matrix $VR$.
$ldvr \geq 1$, and if $jobvr = 'V'$, $ldvr \geq n$.

### Output Parameters

- $a$
  - On exit, $a$ is overwritten.

- $b$
  - On exit, $b$ is overwritten.

- $alphar$
  - Array, size ($n$).

- $alphai$
  - Array, size ($n$).

- $alpha$
  - Array, size ($n$).

- $beta$
  - Array, size ($n$).

  For real flavors:
  - On exit, $(alphar[j] + alphai[j]*i)/beta[j], j=0,\ldots,n-1$, are the generalized eigenvalues. If $alphai[j - 1]$ is zero, then the $j$-th eigenvalue is real; if positive, then the $j$-th and $(j+1)$-st eigenvalues are a complex conjugate pair, with $alphai[j]$ negative.

  Note: the quotients $alphar[j - 1]/beta[j - 1]$ and $alphai[j - 1]/beta[j - 1]$ can easily over- or underflow, and $beta[j]$ might even be zero. Thus, you should avoid computing the ratio $alpha/beta$ by simply dividing $alpha$ by $beta$. However, $alphar$ and $alphai$ are always less than and usually comparable with $\text{norm}(A)$ in magnitude, and $beta$ is always less than and usually comparable with $\text{norm}(B)$.

  For complex flavors:
  - On exit, $alpha[j]/beta[j], j=0,\ldots,n-1$, are the generalized eigenvalues.

  Note: the quotients $alpha[j - 1]/beta[j - 1]$ may easily over- or underflow, and $beta[j]$ can even be zero. Thus, you should avoid computing the ratio $alpha/beta$ by simply dividing $alpha$ by $beta$. However, $alpha$ is always less than and usually comparable with $\text{norm}(A)$ in magnitude, and $beta$ is always less than and usually comparable with $\text{norm}(B)$.

- $vl$
  - Array, size ($ldvl \times n$).

  For real flavors:
If \textit{jobvl} = 'V', the left eigenvectors \( u_j \) are stored one after another in the columns of \( vl \), in the same order as their eigenvalues. If the \( j \)-th eigenvalue is real, then \( u_j = \) the \( j \)-th column of \( vl \). If the \( j \)-th and \((j + 1)\)-st eigenvalues form a complex conjugate pair, then the real part of \( u_j = \) the \( j \)-th column of \( vl \) and the imaginary part of \( v_j = \) the \((j + 1)\)-st column of \( vl \).

Each eigenvector is scaled so the largest component has \( \text{abs}(\text{real part}) + \text{abs}(\text{imag. part}) = 1 \).

Not referenced if \textit{jobvl} = 'N'.

For complex flavors:

If \textit{jobvl} = 'V', the left generalized eigenvectors \( u_j \) are stored one after another in the columns of \( vl \), in the same order as their eigenvalues.

Each eigenvector is scaled so the largest component has \( \text{abs}(\text{real part}) + \text{abs}(\text{imag. part}) = 1 \).

Not referenced if \textit{jobvl} = 'N'.

\textit{vr}

Array, size \((ldvr*n)\).

For real flavors:

If \textit{jobvr} = 'V', the right eigenvectors \( v_j \) are stored one after another in the columns of \( vr \), in the same order as their eigenvalues. If the \( j \)-th eigenvalue is real, then \( v_j = \) the \( j \)-th column of \( vr \). If the \( j \)-th and \((j + 1)\)-st eigenvalues form a complex conjugate pair, then the real part of \( v_j = \) the \( j \)-th column of \( vr \) and the imaginary part of \( v_j = \) the \((j + 1)\)-st column of \( vr \).

Each eigenvector is scaled so the largest component has \( \text{abs}(\text{real part}) + \text{abs}(\text{imag. part}) = 1 \).

Not referenced if \textit{jobvr} = 'N'.

For complex flavors:

If \textit{jobvr} = 'V', the right generalized eigenvectors \( v_j \) are stored one after another in the columns of \( vr \), in the same order as their eigenvalues. Each eigenvector is scaled so the largest component has \( \text{abs}(\text{real part}) + \text{abs}(\text{imag. part}) = 1 \).

Not referenced if \textit{jobvr} = 'N'.

\textbf{Return Values}

This function returns a value \textit{info}.

\( = 0 \): successful exit
\( < 0 \): if \textit{info} = \(-i\), the \( i \)-th argument had an illegal value.
\( =1,\ldots,n \):

for real flavors:

The QZ iteration failed. No eigenvectors have been calculated, but \textit{alphar}[,], \textit{alphar}[j] and \textit{beta}[j] should be correct for \( j=\textit{info},\ldots,n - 1 \).

for complex flavors:
The QZ iteration failed. No eigenvectors have been calculated, but \( \alpha[j] \) and \( \beta[j] \) should be correct for \( j = \text{info}, \ldots, n-1 \).

\[
> n:
\]
\[
= n + 1: \text{other than QZ iteration failed in } \text{?hgeqz},
\]
\[
= n + 2: \text{error return from } \text{?tgevc}.
\]

## LAPACK Auxiliary Routines

Routine naming conventions, mathematical notation, and matrix storage schemes used for LAPACK auxiliary routines are the same as for the driver and computational routines described in previous chapters.

### \text{?lacgv}

**Conjugates a complex vector.**

**Syntax**

```
lapack_int LAPACKE_clacgv (lapack_int n, lapack_complex_float* x, lapack_int incx);
lapack_int LAPACKE_zlacgv (lapack_int n, lapack_complex_double* x, lapack_int incx);
```

**Include Files**

- `mkl.h`

**Description**

The routine conjugates a complex vector \( x \) of length \( n \) and increment \( \text{incx} \) (see "Vector Arguments in BLAS" in Appendix B).

**Input Parameters**

- \( n \)  
  The length of the vector \( x \) \( (n \geq 0) \).
- \( x \)  
  Array, dimension \((1+(n-1)\times |\text{incx}|)\).  
  Contains the vector of length \( n \) to be conjugated.
- \( \text{incx} \)  
  The spacing between successive elements of \( x \).

**Output Parameters**

- \( x \)  
  On exit, overwritten with \( \text{conjg}(x) \).

### \text{?lacrm}

**Multiplies a complex matrix by a square real matrix.**

**Syntax**

```
call clacrm( m, n, a, lda, b, ldb, c, ldc, rwork )
call zlacrm( m, n, a, lda, b, ldb, c, ldc, rwork )
```

**Include Files**

- `mkl.h`
Description

The routine performs a simple matrix-matrix multiplication of the form
\[ C = A \cdot B, \]
where \( A \) is \( m \)-by-\( n \) and complex, \( B \) is \( n \)-by-\( n \) and real, \( C \) is \( m \)-by-\( n \) and complex.

Input Parameters

- \( m \) - INTEGER. The number of rows of the matrix \( A \) and of the matrix \( C \) \((m \geq 0)\).
- \( n \) - INTEGER. The number of columns and rows of the matrix \( B \) and the number of columns of the matrix \( C \) \((n \geq 0)\).
- \( a \) - COMPLEX for \texttt{clacrm}
  DOUBLE COMPLEX for \texttt{zlacrm}
  Array, \texttt{DIMENSION(lda, n)}. Contains the \( m \)-by-\( n \) matrix \( A \).
- \( lda \) - INTEGER. The leading dimension of the array \( a \), \( lda \geq \text{max}(1, m) \).
- \( b \) - REAL for \texttt{clacrm}
  DOUBLE PRECISION for \texttt{zlacrm}
  Array, \texttt{DIMENSION(ldb, n)}. Contains the \( n \)-by-\( n \) matrix \( B \).
- \( ldb \) - INTEGER. The leading dimension of the array \( b \), \( ldb \geq \text{max}(1, n) \).
- \( ldc \) - INTEGER. The leading dimension of the output array \( c \), \( ldc \geq \text{max}(1, n) \).
- \( rwork \) - REAL for \texttt{clacrm}
  DOUBLE PRECISION for \texttt{zlacrm}
  Workspace array, \texttt{DIMENSION(2*m*n)}.

Output Parameters

- \( c \) - COMPLEX for \texttt{clacrm}
  DOUBLE COMPLEX for \texttt{zlacrm}
  Array, \texttt{DIMENSION(ldc, n)}. Contains the \( m \)-by-\( n \) matrix \( C \).

\texttt{?syconv}

Converts a symmetric matrix given by a triangular matrix factorization into two matrices and vice versa.

Syntax

\begin{verbatim}
lapack_int LAPACKE_ssyconv (int matrix_layout, char uplo, char way, lapack_int n, float * a, lapack_int lda, const lapack_int * ipiv, float * e);

lapack_int LAPACKE_dsyconv (int matrix_layout, char uplo, char way, lapack_int n, double* a, lapack_int lda, const lapack_int * ipiv, double * e);
\end{verbatim}
lapack_int LAPACKE_csyconv (int matrix_layout, char uplo, char way, lapack_int n,
lapack_complex_float * a, lapack_int lda, const lapack_int * ipiv,
lapack_complex_float * e);

lapack_int LAPACKE_zsyconv (int matrix_layout, char uplo, char way, lapack_int n,
lapack_complex_double* a, lapack_int lda, const lapack_int * ipiv,
lapack_complex_double * e);

Include Files

• mkl.h

Description

The routine converts matrix $A$, which results from a triangular matrix factorization, into matrices $L$ and $D$ and vice versa. The routine returns non-diagonalized elements of $D$ and applies or reverses permutation done with the triangular matrix factorization.

Input Parameters

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **uplo**
  Must be 'U' or 'L'.
  Indicates whether the details of the factorization are stored as an upper or lower triangular matrix:
  If $uplo = 'U'$: the upper triangular, $A = U*D*U^T$.
  If $uplo = 'L'$: the lower triangular, $A = L*D*L^T$.

- **way**
  Must be 'C' or 'R'.

- **n**
  The order of matrix $A$; $n \geq 0$.

- **a**
  Array of size max(1,lda *n).
  The block diagonal matrix $D$ and the multipliers used to obtain the factor $U$ or $L$ as computed by ?sytrf.

- **lda**
  The leading dimension of $a$; $lda \geq \text{max}(1, n)$.

- **ipiv**
  Array, size at least max(1, n).
  Details of the interchanges and the block structure of $D$, as returned by ?sytrf.

Output Parameters

- **e**
  Array of size max(1, n) containing the superdiagonal/subdiagonal of the symmetric 1-by-1 or 2-by-2 block diagonal matrix $D$ in $L*D*L^T$.

Return Values

- **info**
  If $info = 0$, the execution is successful.
  If $info < 0$, the $i$-th parameter had an illegal value.
  If $info = -1011$, memory allocation error occurred.
See Also

?sytrf

?syr
Performs the symmetric rank-1 update of a complex symmetric matrix.

Syntax

```c
lapack_int LAPACKE_csyr (int matrix_layout, char uplo, lapack_int n,
lapack_complex_float alpha, const lapack_complex_float * x, lapack_int incx,
lapack_complex_float * a, lapack_int lda);
```

```c
lapack_int LAPACKE_zsyr (int matrix_layout, char uplo, lapack_int n,
lapack_complex_double alpha, const lapack_complex_double * x, lapack_int incx,
lapack_complex_double * a, lapack_int lda);
```

Include Files

- mkl.h

Description

The routine performs the symmetric rank 1 operation defined as

\[ a := \alpha x^H x + a, \]

where:
- \( \alpha \) is a complex scalar.
- \( x \) is an \( n \)-element complex vector.
- \( a \) is an \( n \times n \) complex symmetric matrix.

These routines have their real equivalents in BLAS (see ?syr in Chapter 2).

Input Parameters

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **uplo**
  Specifies whether the upper or lower triangular part of the array \( a \) is used:
  - If \( \text{uplo} = \text{'U'} \) or \( \text{'u'} \), then the upper triangular part of the array \( a \) is used.
  - If \( \text{uplo} = \text{'L'} \) or \( \text{'l'} \), then the lower triangular part of the array \( a \) is used.

- **n**
  Specifies the order of the matrix \( a \). The value of \( n \) must be at least zero.

- **alpha**
  Specifies the scalar \( \alpha \).

- **x**
  Array, size at least \((1 + (n - 1) \times \text{abs}(\text{incx}))\). Before entry, the incremented array \( x \) must contain the \( n \)-element vector \( x \).

- **incx**
  Specifies the increment for the elements of \( x \). The value of \( \text{incx} \) must not be zero.

- **a**
  Array, size max(1, \( \text{lda} \times n \)). Before entry with \( \text{uplo} = \text{'U'} \) or \( \text{'u'} \), the leading \( n \)-by-\( n \) upper triangular part of the array \( a \) must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of \( a \) is not referenced.
Before entry with `uplo = 'L'` or `l'`, the leading \(n\)-by-\(n\) lower triangular part of the array \(a\) must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of \(a\) is not referenced.

\textbf{lda}

Specifies the leading dimension of \(a\) as declared in the calling (sub)program. The value of \(lda\) must be at least \(\max(1, n)\).

\textbf{Output Parameters}

\textbf{a}

With `uplo = 'U'` or `u'`, the upper triangular part of the array \(a\) is overwritten by the upper triangular part of the updated matrix.

With `uplo = 'L'` or `l'`, the lower triangular part of the array \(a\) is overwritten by the lower triangular part of the updated matrix.

\textbf{Return Values}

This function returns a value \(info\).

If \(info = 0\), the execution is successful.

If \(info < 0\), the \(i\)-th parameter had an illegal value.

If \(info = -1011\), memory allocation error occurred.

\textbf{i?max1}

\textit{Finds the index of the vector element whose real part has maximum absolute value.}

\textbf{Syntax}

\begin{verbatim}
MKL_INT icmax1(const MKL_INT *n, const MKL_Complex8 *cx, const MKL_INT *incx)
MKL_INT izmax1(const MKL_INT *n, const MKL_Complex16 *cx, const MKL_INT *incx)
\end{verbatim}

\textbf{Include Files}

\begin{itemize}
  \item mkl.h
\end{itemize}

\textbf{Description}

Given a complex vector \(cx\), the \textbf{i?max1} functions return the index of the first vector element of maximum absolute value. These functions are based on the BLAS functions \textit{icamax}/\textit{izamax}, but using the absolute value of components. They are designed for use with \textit{clacon}/\textit{zlacon}.

\textbf{Input Parameters}

\begin{itemize}
  \item \textit{n}
    \begin{itemize}
      \item Specifies the number of elements in the vector \(cx\).
    \end{itemize}
  \item \textit{cx}
    \begin{itemize}
      \item \textit{Array, size at least} \((1+(n-1)\text{abs}(\text{incx}))\).
      \item Contains the input vector.
    \end{itemize}
  \item \textit{incx}
    \begin{itemize}
      \item Specifies the spacing between successive elements of \(cx\).
    \end{itemize}
\end{itemize}

\textbf{Return Values}

Index of the vector element of maximum absolute value.
**scsum1**
*Forms the 1-norm of the complex vector using the true absolute value.*

**Syntax**

```c
float scsum1(const MKL_INT*n, const MKL_Complex8*cx, const MKL_INT*incx)
double dzsum1(const MKL_INT*n, const MKL_Complex16*cx, const MKL_INT*incx)
```

**Include Files**

- mkl.h

**Description**

Given a complex vector \( cx \), \( scsum1/dzsum1 \) functions take the sum of the absolute values of vector elements and return a single/double precision result, respectively. These functions are based on \( scasum/dzasum \) from Level 1 BLAS, but use the true absolute value and were designed for use with \( clacon/zlacon \).

**Input Parameters**

- \( n \)  
  Specifies the number of elements in the vector \( cx \).

- \( cx \)  
  Array, size at least \( (1+(n-1)\times\text{abs}(incx)) \).  
  Contains the input vector whose elements will be summed.

- \( incx \)  
  Specifies the spacing between successive elements of \( cx \) (\( incx > 0 \)).

**Return Values**

Sum of absolute values.

**zgelq2**
*Computes the LQ factorization of a general rectangular matrix using an unblocked algorithm.*

**Syntax**

```c
lapack_int LAPACKE_sgelq2 (int matrix_layout, lapack_int m, lapack_int n, float* a, lapack_int lda, float* tau);
lapack_int LAPACKE_dgelq2 (int matrix_layout, lapack_int m, lapack_int n, double* a, lapack_int lda, double* tau);
lapack_int LAPACKE_cgelq2 (int matrix_layout, lapack_int m, lapack_int n, lapack_complex_float* a, lapack_int lda, lapack_complex_float* tau);
lapack_int LAPACKE_zgelq2 (int matrix_layout, lapack_int m, lapack_int n, lapack_complex_double* a, lapack_int lda, lapack_complex_double* tau);
```

**Include Files**

- mkl.h

**Description**

The routine computes an \( LQ \) factorization of a real/complex \( m \)-by-\( n \) matrix \( A \) as \( A = LQ \).
The routine does not form the matrix \( Q \) explicitly. Instead, \( Q \) is represented as a product of \( \min(m, n) \) elementary reflectors:

\[
Q = H(k) \ldots H(2) H(1) \quad (\text{or } Q = H(k)H^\dagger \ldots H(2)H(1)H^\dagger \text{ for complex flavors}), \quad \text{where } k = \min(m, n)
\]

Each \( H(i) \) has the form

\[
H(i) = I - \tau v^* v^T \quad \text{for real flavors, or}
\]

\[
H(i) = I - \tau v^* H^\dagger \quad \text{for complex flavors},
\]

where \( \tau \) is a real/complex scalar stored in \( \tau(i) \), and \( v \) is a real/complex vector with \( v_{1:i-1} = 0 \) and \( v_i = 1 \).

On exit, the \( j \)-th \( (i+1 \leq j \leq n) \) component of vector \( v \) (for real functions) or its conjugate (for complex functions) is stored in \( a[i - 1 + \text{lda}^*(j - 1)] \) for column major layout or in \( a[j - 1 + \text{lda}^*(i - 1)] \) for row major layout.

**Input Parameters**

- \( m \)  
  The number of rows in the matrix \( A \) \( (m \geq 0) \).

- \( n \)  
  The number of columns in \( A \) \( (n \geq 0) \).

- \( a \)  
  Array, size at least \( \max(1, \text{lda}^*n) \) for column major and \( \max(1, \text{lda}^*m) \) for row major layout. Array \( a \) contains the \( m \)-by-\( n \) matrix \( A \).

- \( \text{lda} \)  
  The leading dimension of \( a \); at least \( \max(1, m) \) for column major layout and \( \max(1, n) \) for row major layout.

**Output Parameters**

- \( a \)  
  Overwritten by the factorization data as follows:

  on exit, the elements on and below the diagonal of the array \( a \) contain the \( m \)-by-\( \min(n,m) \) lower trapezoidal matrix \( L \) \( (L \) is lower triangular if \( n \geq m) \); the elements above the diagonal, with the array \( \tau \), represent the orthogonal/unitary matrix \( Q \) as a product of \( \min(n,m) \) elementary reflectors.

- \( \tau \)  
  Array, size at least \( \max(1, \min(m, n)) \).

  Contains scalar factors of the elementary reflectors.

**Return Values**

This function returns a value \( \text{info} \).

If \( \text{info} = 0 \), the execution is successful.

If \( \text{info} = -i \), the \( i \)-th parameter had an illegal value.

If \( \text{info} = -1011 \), memory allocation error occurred.

**?geqr2**

Computes the QR factorization of a general rectangular matrix using an unblocked algorithm.

**Syntax**

```c
lapack_int LAPACKE_sgeqr2 (int matrix_layout, lapack_int m, lapack_int n, float* a, lapack_int lda, float* tau);
```
lapack_int LAPACKE_dgeqr2 (int matrix_layout, lapack_int m, lapack_int n, double* a, lapack_int lda, double* tau);

lapack_int LAPACKE_cgeqr2 (int matrix_layout, lapack_int m, lapack_int n, lapack_complex_float* a, lapack_int lda, lapack_complex_float* tau);

lapack_int LAPACKE_zgeqr2 (int matrix_layout, lapack_int m, lapack_int n, lapack_complex_double* a, lapack_int lda, lapack_complex_double* tau);

**Include Files**
- mkl.h

**Description**
The routine computes a QR factorization of a real/complex $m$-by-$n$ matrix $A$ as $A = Q \cdot R$.
The routine does not form the matrix $Q$ explicitly. Instead, $Q$ is represented as a product of $\min(m, n)$ 
**elementary reflectors** :

$$Q = H(1) \cdot H(2) \cdots \cdot H(k), \text{ where } k = \min(m, n).$$

Each $H(i)$ has the form

$$H(i) = I - \tau * v * v^T$$
for real flavors, or

$$H(i) = I - \tau * v * v^H$$
for complex flavors

where $\tau$ is a real/complex scalar stored in $\tau[i]$, and $v$ is a real/complex vector with $v_{1:i-1} = 0$ and $v_i = 1$.

On exit, $v_{i+1:m}$ is stored in $a(i+1:m, i)$.

**Input Parameters**
- $m$ The number of rows in the matrix $A$ ($m \geq 0$).
- $n$ The number of columns in $A$ ($n \geq 0$).
- $a$ Array, size at least $\max(1, lda \cdot n)$ for column major and $\max(1, lda \cdot m)$ for row major layout. Array $a$ contains the $m$-by-$n$ matrix $A$.
- $lda$ The leading dimension of $a$; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout.

**Output Parameters**
- $a$ Overwritten by the factorization data as follows:
  on exit, the elements on and above the diagonal of the array $a$ contain the $\min(n,m)$-by-$n$ upper trapezoidal matrix $R$ ($R$ is upper triangular if $n \geq n$); the elements below the diagonal, with the array $\tau$, represent the orthogonal/unitary matrix $Q$ as a product of elementary reflectors.
- $\tau$ Array, size at least $\max(1, \min(m, n))$.
  Contains scalar factors of the elementary reflectors.

**Return Values**
This function returns a value $info$.
If $info = 0$, the execution is successful.
If $info = -i$, the $i$-th parameter had an illegal value.
If $info = -1011$, memory allocation error occurred.

**?geqrt2**

Computes a QR factorization of a general real or complex matrix using the compact WY representation of $Q$.

**Syntax**

```c
lapack_int LAPACKE_sgeqrt2 (int matrix_layout, lapack_int m, lapack_int n, float * a, lapack_int lda, float * t, lapack_int ldt );
```

```c
lapack_int LAPACKE_dgeqrt2 (int matrix_layout, lapack_int m, lapack_int n, double * a, lapack_int lda, double * t, lapack_int ldt );
```

```c
lapack_int LAPACKE_cgeqrt2 (int matrix_layout, lapack_int m, lapack_int n, lapack_complex_float * a, lapack_int lda, lapack_complex_float * t, lapack_int ldt );
```

```c
lapack_int LAPACKE_zgeqrt2 (int matrix_layout, lapack_int m, lapack_int n, lapack_complex_double * a, lapack_int lda, lapack_complex_double * t, lapack_int ldt );
```

**Include Files**
- mkl.h

**Description**

The strictly lower triangular matrix $V$ contains the elementary reflectors $H(i)$ in the $i$th column below the diagonal. For example, if $m=5$ and $n=3$, the matrix $V$ is

$$
V = \begin{bmatrix}
1 \\
v_1 & 1 \\
v_1 & v_2 & 1 \\
v_1 & v_2 & v_3 \\
v_1 & v_2 & v_3 \\
\end{bmatrix}
$$

where $v_i$ represents the vector that defines $H(i)$. The vectors are returned in the lower triangular part of array $a$.

**NOTE**
The 1s along the diagonal of $V$ are not stored in $a$.

The block reflector $H$ is then given by

$H = I - V^T V$ for real flavors, and

$H = I - V^* V^H$ for complex flavors,

where $V^T$ is the transpose and $V^H$ is the conjugate transpose of $V$. 
Input Parameters

\( m \)

The number of rows in the matrix \( A \) \((m \geq n)\).

\( n \)

The number of columns in \( A \) \((n \geq 0)\).

\( a \)

Array, size at least \( \max(1, \text{lda} \cdot n) \) for column major and \( \max(1, \text{lda} \cdot m) \) for row major layout. Array \( a \) contains the \( m \)-by-\( n \) matrix \( A \).

\( \text{lda} \)

The leading dimension of \( a \); at least \( \max(1, m) \) for column major layout and \( \max(1,n) \) for row major layout.

\( \text{ldt} \)

The leading dimension of \( t \); at least \( \max(1, n) \).

Output Parameters

\( a \)

Overwritten by the factorization data as follows:

The elements on and above the diagonal of the array contain the \( n \)-by-\( n \) upper triangular matrix \( R \). The elements below the diagonal are the columns of \( V \).

\( t \)

Array, size at least \( \max(1, \text{ldt} \cdot n) \).

The \( n \)-by-\( n \) upper triangular factor of the block reflector. The elements on and above the diagonal contain the block reflector \( T \). The elements below the diagonal are not used.

Return Values

This function returns a value \( info \).

If \( info = 0 \), the execution is successful.

If \( info < 0 \) and \( info = -i \), the \( i \)th argument had an illegal value.

If \( info = -1011 \), memory allocation error occurred.

\(?\text{geqrt3}\)

Recursively computes a QR factorization of a general real or complex matrix using the compact WY representation of \( Q \).

Syntax

\[
\text{lapack_int LAPACKE_sgeqrt3 (int matrix_layout, lapack_int m, lapack_int n, float * a, lapack_int lda, float * t, lapack_int ldt \});
\]

\[
\text{lapack_int LAPACKE_dgeqrt3 (int matrix_layout, lapack_int m, lapack_int n, double * a, lapack_int lda, double * t, lapack_int ldt \});
\]

\[
\text{lapack_int LAPACKE_cgeqrt3 (int matrix_layout, lapack_int m, lapack_int n, lapack_complex_float * a, lapack_int lda, lapack_complex_float * t, lapack_int ldt \});
\]

\[
\text{lapack_int LAPACKE_zgeqrt3 (int matrix_layout, lapack_int m, lapack_int n, lapack_complex_double * a, lapack_int lda, lapack_complex_double * t, lapack_int ldt \});
\]
Include Files

- mkl.h

Description

The strictly lower triangular matrix \( V \) contains the elementary reflectors \( H(i) \) in the \( i \)th column below the diagonal. For example, if \( m=5 \) and \( n=3 \), the matrix \( V \) is

\[
V = \begin{bmatrix}
1 & & \\
v_1 & 1 & \\
v_1 & v_2 & 1 \\
v_1 & v_2 & v_3 \\
v_1 & v_2 & v_3
\end{bmatrix}
\]

where \( v_i \) represents one of the vectors that define \( H(i) \). The vectors are returned in the lower part of the triangular array \( a \).

**NOTE**
The 1s along the diagonal of \( V \) are not stored in \( a \).

The block reflector \( H \) is then given by

\[
H = I - V^* V^T \quad \text{for real flavors, and}
\]

\[
H = I - V^* V^H \quad \text{for complex flavors,}
\]

where \( V^T \) is the transpose and \( V^H \) is the conjugate transpose of \( V \).

Input Parameters

- \( m \)
  The number of rows in the matrix \( A (m \geq n) \).

- \( n \)
  The number of columns in \( A (n \geq 0) \).

- \( a \)
  Array, size at least \( \max(1, lda \times n) \) for column major and \( \max(1, lda \times m) \) for row major layout. Array \( a \) contains the \( m \)-by-\( n \) matrix \( A \).

- \( lda \)
  The leading dimension of \( a \); at least \( \max(1, m) \) for column major layout and \( \max(1,n) \) for row major layout.

- \( ldt \)
  The leading dimension of \( t \); at least \( \max(1, n) \).

Output Parameters

- \( a \)
  The elements on and above the diagonal of the array contain the \( n \)-by-\( n \) upper triangular matrix \( R \). The elements below the diagonal are the columns of \( V \).

- \( t \)
  Array, size \( ldt \) by \( n \).
The $n$-by-$n$ upper triangular factor of the block reflector. The elements on and above the diagonal contain the block reflector $T$. The elements below the diagonal are not used.

**Return Values**

This function returns a value $info$.

- If $info = 0$, the execution is successful.
- If $info < 0$ and $info = -i$, the $i$th argument had an illegal value.
- If $info = -1011$, memory allocation error occurred.

**?getf2**

*Computes the LU factorization of a general $m$-by-$n$ matrix using partial pivoting with row interchanges (unblocked algorithm).*

**Syntax**

```c
lapack_int LAPACKE_sgetf2 (int matrix_layout, lapack_int m, lapack_int n, float* a, lapack_int lda, lapack_int * ipiv);

lapack_int LAPACKE_dgetf2 (int matrix_layout, lapack_int m, lapack_int n, double* a, lapack_int lda, lapack_int * ipiv);

lapack_int LAPACKE_cgetf2 (int matrix_layout, lapack_int m, lapack_int n, lapack_complex_float* a, lapack_int lda, lapack_int * ipiv);

lapack_int LAPACKE_zgetf2 (int matrix_layout, lapack_int m, lapack_int n, lapack_complex_double* a, lapack_int lda, lapack_int * ipiv);
```

**Include Files**

- mkl.h

**Description**

The routine computes the $LU$ factorization of a general $m$-by-$n$ matrix $A$ using partial pivoting with row interchanges. The factorization has the form

$$A = P*L*U$$

where $P$ is a permutation matrix, $L$ is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$) and $U$ is upper triangular (upper trapezoidal if $m < n$).

**Input Parameters**

- $m$
  - The number of rows in the matrix $A$ ($m \geq 0$).

- $n$
  - The number of columns in $A$ ($n \geq 0$).

- $a$
  - Array, size at least $\max(1, lda*n)$ for column major and $\max(1, lda*m)$ for row major layout. Array $a$ contains the $m$-by-$n$ matrix $A$.

- $lda$
  - The leading dimension of $a$; at least $\max(1, m)$ for column major layout and $\max(1,n)$ for row major layout.
Output Parameters

\( a \)  
Overwritten by \( L \) and \( U \). The unit diagonal elements of \( L \) are not stored.

\( ipiv \)  
Array, size at least \( \max(1, \min(m,n)) \).
The pivot indices: for \( 1 \leq i \leq n \), row \( i \) was interchanged with row \( ipiv(i) \).

Return Values

This function returns a value \( info \).

If \( info = -i \), the \( i \)-th parameter had an illegal value.

If \( info = i > 0 \), \( u_{ii} \) is 0. The factorization has been completed, but \( U \) is exactly singular. Division by 0 will occur if you use the factor \( U \) for solving a system of linear equations.

If \( info = -1011 \), memory allocation error occurred.

\texttt{lacn2}

Estimates the 1-norm of a square matrix, using reverse communication for evaluating matrix-vector products.

Syntax

C:

\begin{verbatim}
lapack_int LAPACKE_slacn2 (lapack_int n, float * v, float * x, lapack_int * isgn, float * est, lapack_int * kase, lapack_int * isave);

lapack_int LAPACKE_clacn2 (lapack_int n, lapack_complex_float * v, lapack_complex_float * x, float * est, lapack_int * kase, lapack_int * isave);

lapack_int LAPACKE_dlacn2 (lapack_int n, double * v, double * x, lapack_int * isgn, double * est, lapack_int * kase, lapack_int * isave);

lapack_int LAPACKE_zlacn2 (lapack_int n, lapack_complex_double * v, lapack_complex_double * x, double * est, lapack_int * kase, lapack_int * isave);
\end{verbatim}

Include Files

- mkl.h

Description

The routine estimates the 1-norm of a square, real or complex matrix \( A \). Reverse communication is used for evaluating matrix-vector products.

Input Parameters

\( n \)  
The order of the matrix \( A \) \((n \geq 1)\).

\( v, x \)  
Arrays, size \((n)\) each.

\( v \) is a workspace array.

\( x \) is used as input after an intermediate return.

\( isgn \)  
Workspace array, size \((n)\), used with real flavors only.
On entry with kase set to 1 or 2, and isave(1) = 1, est must be unchanged from the previous call to the routine.

On the initial call to the routine, kase must be set to 0.

Array, size (3).
Contains variables from the previous call to the routine.

Output Parameters

An estimate (a lower bound) for norm(A).

On an intermediate return, kase is set to 1 or 2, indicating whether x is overwritten by A*x or A^T*x for real flavors and A*x or A^H*x for complex flavors.

On the final return, kase is set to 0.

On the final return, v = A*w, where est = norm(v)/norm(w) (w is not returned).

On an intermediate return, x is overwritten by
A*x, if kase = 1,
A^T*x, if kase = 2 (for real flavors),
A^H*x, if kase = 2 (for complex flavors),
and the routine must be re-called with all the other parameters unchanged.

This parameter is used to save variables between calls to the routine.

Return Values

This function returns a value info.
If info = 0, the execution is successful.
If info = -i, the i-th parameter had an illegal value.

?lacpy
Copies all or part of one two-dimensional array to another.

Syntax

lapack_int LAPACKE_slacpy (int matrix_layout, char uplo, lapack_int m, lapack_int n, const float* a, lapack_int lda, float* b, lapack_int ldb);
lapack_int LAPACKE_dlacpy (int matrix_layout, char uplo, lapack_int m, lapack_int n, const double* a, lapack_int lda, double* b, lapack_int ldb);
lapack_int LAPACKE_clacpy (int matrix_layout, char uplo, lapack_int m, lapack_int n, const lapack_complex_float* a, lapack_int lda, lapack_complex_float* b, lapack_int ldb);
lapack_int LAPACKE_zlacpy (int matrix_layout, char uplo, lapack_int m, lapack_int n, const lapack_complex_double* a, lapack_int lda, lapack_complex_double* b, lapack_int ldb);
Include Files

- mkl.h

Description

The routine copies all or part of a two-dimensional matrix \( A \) to another matrix \( B \).

Input Parameters

\( uplo \)

Specifies the part of the matrix \( A \) to be copied to \( B \).

If \( uplo = 'U' \), the upper triangular part of \( A \);
if \( uplo = 'L' \), the lower triangular part of \( A \).
Otherwise, all of the matrix \( A \) is copied.

\( m \)

The number of rows in the matrix \( A \) \((m \geq 0)\).

\( n \)

The number of columns in \( A \) \((n \geq 0)\).

\( a \)

Array, size at least \( \max(1, lda*n) \) for column major and \( \max(1, lda*m) \) for row major layout. \( A \) contains the \( m \)-by-\( n \) matrix \( A \).
If \( uplo = 'U' \), only the upper triangle or trapezoid is accessed; if \( uplo = 'L' \), only the lower triangle or trapezoid is accessed.

\( lda \)

The leading dimension of \( a \); \( lda \geq \max(1, m) \) for column major layout and \( \max(1, n) \) for row major layout.

\( ldb \)

The leading dimension of the output array \( b \); \( ldb \geq \max(1, m) \) for column major layout and \( \max(1, n) \) for row major layout.

Output Parameters

\( b \)

Array, size at least \( \max(1, ldb*n) \) for column major and \( \max(1, ldb*m) \) for row major layout. Array \( a \) contains the \( m \)-by-\( n \) matrix \( B \).
On exit, \( B = A \) in the locations specified by \( uplo \).

Return Values

This function returns a value \( info \).
If \( info = 0 \), the execution is successful.
If \( info = -i \), the \( i \)-th parameter had an illegal value.

?lakf2

Forms a matrix containing Kronecker products between the given matrices.

Syntax

\[
\text{void slakf2 (lapack_int *m, lapack_int *n, float *a, lapack_int *lda, float *b, float *d, float *e, float *z, lapack_int *ldz);}\\
\text{void dlakf2 (lapack_int *m, lapack_int *n, double *a, lapack_int *lda, double *b, double *d, double *e, double *z, lapack_int *ldz);}\\
\]
void clakf2 (lapack_int *m, lapack_int *n, lapack_complex *a, lapack_int *lda, 
      lapack_complex *b, lapack_complex *d, lapack_complex *e, lapack_complex *z, lapack_int *ldz);
void zlakf2 (lapack_int *m, lapack_int *n, lapack_complex_double *a, lapack_int *lda, 
      lapack_complex_double *b, lapack_complex_double *d, lapack_complex_double *e, 
      lapack_complex_double *z, lapack_int *ldz);

Include Files
• mkl.h

Description
The routine ?lakf2 forms the 2*m*n by 2*m*n matrix Z.

\[ Z = \begin{bmatrix}
    \text{kron}(I_n, A) & -\text{kron}(B^T, I_m) \\
    \text{kron}(I_n, D) & -\text{kron}(B^T, I_m)
\end{bmatrix}, \]

where In is the identity matrix of size n and X^T is the transpose of X. kron(X, Y) is the Kronecker product between the matrices X and Y.

Input Parameters

- \( m \) Size of matrix, \( m \geq 1 \)
- \( n \) Size of matrix, \( n \geq 1 \)
- \( a \) Array, size lda-by-n. The matrix A in the output matrix Z.
- \( lda \) The leading dimension of a, b, d, and e. \( lda \geq m+n \).
- \( b \) Array, size lda by n. Matrix used in forming the output matrix Z.
- \( d \) Array, size lda by m. Matrix used in forming the output matrix Z.
- \( e \) Array, size lda by n. Matrix used in forming the output matrix Z.
- \( ldz \) The leading dimension of Z. \( ldz \geq 2 \times m \times n \).

Output Parameters

- \( z \) Array, size ldz-by-2*m*n. The resultant Kronecker m*n*2-by-m*n*2 matrix.

?lange

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element of a general rectangular matrix.

Syntax

float LAPACKE_slange (int matrix_layout, char norm, lapack_int m, lapack_int n, const float * a, lapack_int lda);
double LAPACKE_dlange (int matrix_layout, char norm, lapack_int m, lapack_int n, const double * a, lapack_int lda);
float LAPACKE_clange (int matrix_layout, char norm, lapack_int m, lapack_int n, const lapack_complex_float * a, lapack_int lda);

double LAPACKE_zlange (int matrix_layout, char norm, lapack_int m, lapack_int n, const lapack_complex_double * a, lapack_int lda);

Include Files
• mkl.h

Description
The function ?lange returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real/complex matrix A.

Input Parameters

specifies the value to be returned by the routine:
= 'M' or 'm': val = max(abs(Aij)), largest absolute value of the matrix A.
= '1' or 'O' or 'o': val = norm1(A), 1-norm of the matrix A (maximum column sum),
= 'I' or 'i': val = normI(A), infinity norm of the matrix A (maximum row sum),
= 'F', 'f', 'E' or 'e': val = normF(A), Frobenius norm of the matrix A (square root of sum of squares).

m
The number of rows of the matrix A.
m≥ 0. When m = 0, ?lange is set to zero.

n
The number of columns of the matrix A.
n≥ 0. When n = 0, ?lange is set to zero.

Array, size at least max(1, lda*n) for column major and max(1, lda*m) for row major layout. Array a contains the m-by-n matrix A.

lda
The leading dimension of the array a.
lda≥ max(n,1) for column major layout and max(1,n) for row major layout.

?lansy
Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real/complex symmetric matrix.

Syntax
float LAPACKE_slansy (int matrix_layout, char norm, char uplo, lapack_int n, const float * a, lapack_int lda);

double LAPACKE_dlansy (int matrix_layout, char norm, char uplo, lapack_int n, const double * a, lapack_int lda);
float LAPACKE_clansy (int matrix_layout, char norm, char uplo, lapack_int n, const
       lapack_complex_float * a, lapack_int lda);

double LAPACKE_zlansy (int matrix_layout, char norm, char uplo, lapack_int n, const
       lapack_complex_double * a, lapack_int lda);

Include Files

- mkl.h

Description

The function ?lansy returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the
element of largest absolute value of a real/complex symmetric matrix A.

Input Parameters

- **norm**
  Specifies the value to be returned by the routine:
  = 'M' or 'm': val = max(abs(A_{ij})), largest absolute value of the matrix A.
  = '1' or 'O' or 'o': val = norm1(A), 1-norm of the matrix A (maximum column sum),
  = 'I' or 'i': val = normI(A), infinity norm of the matrix A (maximum row sum),
  = 'F', 'f', 'E' or 'e': val = normF(A), Frobenius norm of the matrix A (square root of sum of squares).

- **uplo**
  Specifies whether the upper or lower triangular part of the symmetric matrix A is to be referenced.
  = 'U': Upper triangular part of A is referenced.
  = 'L': Lower triangular part of A is referenced

- **n**
  The order of the matrix A. \( n \geq 0 \). When \( n = 0 \), ?lansy is set to zero.

- **a**
  Array, size at least max(1,lda*n). The symmetric matrix A.
  If \( uplo = 'U' \), the leading \( n \)-by-\( n \) upper triangular part of a contains the
  upper triangular part of the matrix A, and the strictly lower triangular part
  of a is not referenced.
  If \( uplo = 'L' \), the leading \( n \)-by-\( n \) lower triangular part of a contains the
  lower triangular part of the matrix A, and the strictly upper triangular part
  of a is not referenced.

- **lda**
  The leading dimension of the array a.
  \( lda \geq \max(n,1) \).

?lanhe

*Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex Hermitian matrix.*
Syntax

float LAPACKE_clanhe (int matrix_layout, char norm, char uplo, lapack_int n, const lapack_complex_float * a, lapack_int lda);

double LAPACKE_zlanhe (int matrix_layout, char norm, char uplo, lapack_int n, const lapack_complex_double * a, lapack_int lda);

Include Files
• mkl.h

Description
The function ?lanhe returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex Hermitian matrix A.

Input Parameters

\( \text{norm} \)

Specifies the value to be returned by the routine:

\( = 'M' \) or \( 'm' \): \( val = \max(\text{abs}(A)) \), largest absolute value of the matrix A.
\( = '1' \) or \( 'O' \) or \( 'o' \): \( val = \text{norm1}(A) \), 1-norm of the matrix A (maximum column sum),
\( = 'I' \) or \( 'i' \): \( val = \text{normI}(A) \), infinity norm of the matrix A (maximum row sum),
\( = 'F', 'f', 'E' \) or \( 'e' \): \( val = \text{normF}(A) \), Frobenius norm of the matrix A (square root of sum of squares).

\( \text{uplo} \)

Specifies whether the upper or lower triangular part of the Hermitian matrix A is to be referenced.

\( = 'U' \): Upper triangular part of A is referenced.
\( = 'L' \): Lower triangular part of A is referenced

\( n \)

The order of the matrix A. \( n \geq 0 \). When \( n = 0 \), ?lanhe is set to zero.

\( a \)

Array, size at least \( \max(1, lda*n) \). The Hermitian matrix A.

If \( \text{uplo} = 'U' \), the leading \( n \)-by-\( n \) upper triangular part of \( a \) contains the upper triangular part of the matrix \( A \), and the strictly lower triangular part of \( a \) is not referenced.

If \( \text{uplo} = 'L' \), the leading \( n \)-by-\( n \) lower triangular part of \( a \) contains the lower triangular part of the matrix \( A \), and the strictly upper triangular part of \( a \) is not referenced.

\( lda \)

The leading dimension of the array \( a \).

\( lda \geq \max(n,1) \).

?lantr

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a trapezoidal or triangular matrix.
Syntax

float LAPACKE_slantr (char * norm, char * uplo, char * diag, lapack_int * m, lapack_int * n, const float * a, lapack_int * lda, float * work);
double LAPACKE_dlantr (char * norm, char * uplo, char * diag, lapack_int * m, lapack_int * n, const double * a, lapack_int * lda, double * work);
float LAPACKE_clantr (char * norm, char * uplo, char * diag, lapack_int * m, lapack_int * n, const lapack_complex_float * a, lapack_int * lda, float * work);
double LAPACKE_zlantr (char * norm, char * uplo, char * diag, lapack_int * m, lapack_int * n, const lapack_complex_double * a, lapack_int * lda, double * work);

Include Files

• mkl.h

Description

The function ?lantr returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a trapezoidal or triangular matrix A.

Input Parameters

norm

Specifies the value to be returned by the routine:
= 'M' or 'm': \( \text{val} = \max(\text{abs}(A_{ij})) \), largest absolute value of the matrix A.
= '1' or '0' or 'o': \( \text{val} = \text{norm}_1(A) \), 1-norm of the matrix A (maximum column sum),
= 'I' or 'i': \( \text{val} = \text{norm}_\infty(A) \), infinity norm of the matrix A (maximum row sum),
= 'F', 'f', 'E' or 'e': \( \text{val} = \text{norm}_F(A) \), Frobenius norm of the matrix A (square root of sum of squares).

uplo

Specifies whether the matrix A is upper or lower trapezoidal.
= 'U': Upper trapezoidal
= 'L': Lower trapezoidal.

Note that A is triangular instead of trapezoidal if \( m = n \).

diag

Specifies whether or not the matrix A has unit diagonal.
= 'N': Non-unit diagonal
= 'U': Unit diagonal.

m

The number of rows of the matrix A. \( m \geq 0 \), and if uplo = 'U', \( m \leq n \).

When \( m = 0 \), ?lantr is set to zero.

n

The number of columns of the matrix A. \( n \geq 0 \), and if uplo = 'L', \( n \leq m \).

When \( n = 0 \), ?lantr is set to zero.

a

Array, size at least \( \max(1, \text{lda} \times n) \) for column major and \( \max(1, \text{lda} \times m) \) for row major layout.
The trapezoidal matrix $A$ ($A$ is triangular if $m = n$).

If $\text{uplo} = 'U'$, the leading $m$-by-$n$ upper trapezoidal part of the array $a$ contains the upper trapezoidal matrix, and the strictly lower triangular part of $A$ is not referenced.

If $\text{uplo} = 'L'$, the leading $m$-by-$n$ lower trapezoidal part of the array $a$ contains the lower trapezoidal matrix, and the strictly upper triangular part of $A$ is not referenced. Note that when $\text{diag} = 'U'$, the diagonal elements of $A$ are not referenced and are assumed to be one.

**lda**

The leading dimension of the array $a$.

$lda \geq \max(m,1)$ for column major layout and $\geq \max(1,n)$ for row major layout.

---

**LAPACKE_set_nancheck**

*Turns NaN checking off or on*

LAPACKE_set_nancheck(int flag);

**Description**

The routine sets a value for the LAPACKE NaN checking flag, which indicates whether or not LAPACKE routines check input matrices for NaNs.

**Input Parameters**

*flag*;

If $flag = 0$, NaN checking is turned OFF. Otherwise, it is turned ON.

**LAPACKE_get_nancheck**

*Gets the current NaN checking flag, which indicates whether NaN checking has been turned off or on.*

int flag = LAPACKE_get_nancheck();

**Description**

The function returns the current value for the LAPACKE NaN checking flag, which indicates whether or not LAPACKE routines check input matrices for NaNs.

**Return Value**

An integer value is returned which indicates the current NaN checking status.

The returned flag value is either 0 (OFF) or 1 (ON), even though any integer value can be used as an input parameter for LAPACKE_set_nancheck.

For example, the following code turns on NaN checking:

LAPACKE_set_nancheck(100);
int flag = LAPACKE_get_nancheck(); // flag==1, not 100.

---

**?lapmr**

*Rearranges rows of a matrix as specified by a permutation vector.*
Syntax

```c
lapack_int LAPACKE_slapmr (int matrix_layout, lapack_logical forwrd, lapack_int m,
lapack_int n, float* x, lapack_int ldx, lapack_int * k);
```

```c
lapack_int LAPACKE_dlapmr (int matrix_layout, lapack_logical forwrd, lapack_int m,
lapack_int n, double* x, lapack_int ldx, lapack_int * k);
```

```c
lapack_int LAPACKE_clapmr (int matrix_layout, lapack_logical forwrd, lapack_int m,
lapack_int n, lapack_complex_float* x, lapack_int ldx, lapack_int * k);
```

```c
lapack_int LAPACKE_zlapmr (int matrix_layout, lapack_logical forwrd, lapack_int m,
lapack_int n, lapack_complex_double* x, lapack_int ldx, lapack_int * k);
```

Include Files

- mkl.h

Description

The ?lapmr routine rearranges the rows of the \( m \)-by-\( n \) matrix \( X \) as specified by the permutation \( k[0], k[1], \ldots, k[m-1] \) of the integers \( 1, \ldots, m \).

If \( \text{forwrd} \) is true, forward permutation:

\[ X(k[i-1,:]) \] is moved to \( X(i,:) \) for \( i = 1, 2, \ldots, m \).

If \( \text{forwrd} \) is false, backward permutation:

\[ X(i,:) \] is moved to \( X(k[i-1,:]) \) for \( i = 1, 2, \ldots, m \).

Input Parameters

- **forwrd**
  - If \( \text{forwrd} \) is true, forward permutation.
  - If \( \text{forwrd} \) is false, backward permutation.

- **m**
  - The number of rows of the matrix \( X \). \( m \geq 0 \).

- **n**
  - The number of columns of the matrix \( X \). \( n \geq 0 \).

- **x**
  - Array, size at least \( \max(1, \ c x + n) \) for column major and \( \max(1, \ l d x + m) \) for row major layout. On entry, the \( m \)-by-\( n \) matrix \( X \).

- **ldx**
  - The leading dimension of the array \( X \). \( l d x \geq \max(1, m) \) for column major layout and \( l d x \geq \max(1, n) \) for row major layout.

- **k**
  - Array, size \( (m) \). On entry, \( k \) contains the permutation vector and is used as internal workspace.

Output Parameters

- **x**
  - On exit, \( x \) contains the permuted matrix \( X \).

- **k**
  - On exit, \( k \) is reset to its original value.

Return Values

This function returns a value \( \text{info} \).

If \( \text{info} = 0 \), the execution is successful.
If $info = -i$, the $i$-th parameter had an illegal value.
If $info = -1011$, memory allocation error occurred.

See Also

?lapmt
Performs a forward or backward permutation of the columns of a matrix.

Syntax

```c
lapack_int LAPACKE_slapmt (int matrix_layout, lapack_logical forwrd, lapack_int m, 
lapack_int n, float * x, lapack_int ldx, lapack_int * k);
lapack_int LAPACKE_dlapmt (int matrix_layout, lapack_logical forwrd, lapack_int m, 
lapack_int n, double * x, lapack_int ldx, lapack_int * k);
lapack_int LAPACKE_clapmt (int matrix_layout, lapack_logical forwrd, lapack_int m, 
lapack_int n, lapack_complex_float * x, lapack_int ldx, lapack_int * k);
lapack_int LAPACKE_zlapmt (int matrix_layout, lapack_logical forwrd, lapack_int m, 
lapack_int n, lapack_complex_double * x, lapack_int ldx, lapack_int * k);
```

Include Files

- mkl.h

Description

The routine ?lapmt rearranges the columns of the $m$-by-$n$ matrix $X$ as specified by the permutation $k[i - 1]$ for $i = 1, \ldots, n$.

If $forwrd \neq 0$, forward permutation:

$X(*,k(j))$ is moved to $X(*,j)$ for $j=1,2,\ldots,n$.

If $forwrd = 0$, backward permutation:

$X(*,j)$ is moved to $X(*,k(j))$ for $j=1,2,\ldots,n$.

Input Parameters

- **matrix_layout**: Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- **forwrd**: If $forwrd \neq 0$, forward permutation
  If $forwrd = 0$, backward permutation
- **m**: The number of rows of the matrix $X$. $m \geq 0$.
- **n**: The number of columns of the matrix $X$. $n \geq 0$.
- **x**: Array, size $ldx*n$. On entry, the $m$-by-$n$ matrix $X$.
- **ldx**: The leading dimension of the array $x$. $ldx \geq \max(1,m)$.
- **k**: Array, size ($n$). On entry, $k$ contains the permutation vector and is used as internal workspace.
**Output Parameters**

x  
On exit, x contains the permuted matrix X.

k  
On exit, k is reset to its original value.

**See Also**

?lapmr

?lapy2

*Returns* $\sqrt{x^2+y^2}$.

**Syntax**

float LAPACKE_slapy2 (float x, float y);
double LAPACKE_dlapy2 (double x, double y);

**Include Files**

- mkl.h

**Description**

The function ?lapy2 returns $\sqrt{x^2+y^2}$, avoiding unnecessary overflow or harmful underflow.

**Input Parameters**

x, y  
Specify the input values x and y.

**Return Values**

The function returns a value *val*.

If *val*=-1D0, the first argument was NaN.
If *val*=-2D0, the second argument was NaN.

?lapy3

*Returns* $\sqrt{x^2+y^2+z^2}$.

**Syntax**

float LAPACKE_slapy3 (float x, float y, float z);
double LAPACKE_dlapy3 (double x, double y, double z);

**Include Files**

- mkl.h

**Description**

The function ?lapy3 returns $\sqrt{x^2+y^2+z^2}$, avoiding unnecessary overflow or harmful underflow.

**Input Parameters**
Specify the input values x, y and z.

Return Values
This function returns a value val.
If val = -1D0, the first argument was NaN.
If val = -2D0, the second argument was NaN.
If val = -3D0, the third argument was NaN.

?laran
Returns a random real number from a uniform distribution.

Syntax
float slaran (lapack_int *iseed);
double dlaran (lapack_int *iseed);

Description
The ?laran routine returns a random real number from a uniform (0,1) distribution. This routine uses a multiplicative congruential method with modulus $2^{48}$ and multiplier 33952834046453. 48-bit integers are stored in four integer array elements with 12 bits per element. Hence the routine is portable across machines with integers of 32 bits or more.

Input Parameters
iseed
Array, size 4. On entry, the seed of the random number generator. The array elements must be between 0 and 4095, and iseed[3] must be odd.

Output Parameters
iseed
On exit, the seed is updated.

Return Values
The function returns a random number.

?larfb
Applies a block reflector or its transpose/conjugate-transpose to a general rectangular matrix.

Syntax

```c
lapack_int LAPACKE_slarfb (int matrix_layout , char side , char trans , char direct ,
char storev , lapack_int m , lapack_int n , lapack_int k , const float * v , lapack_int ldv ,
const float * t , lapack_int ldt , float * c , lapack_int ldc );
```

```c
lapack_int LAPACKE_dlarfb (int matrix_layout , char side , char trans , char direct ,
char storev , lapack_int m , lapack_int n , lapack_int k , const double * v ,
lapack_int ldv , const double * t , lapack_int ldt , double * c , lapack_int ldc );
```

```c
lapack_int LAPACKE_clarfb (int matrix_layout , char side , char trans , char
```
direct, char storev, lapack_int m, lapack_int n, lapack_int k, const
lapack_complex_float * v, lapack_int ldv, const lapack_complex_float * t, lapack_int
ldt, lapack_complex_float * c, lapack_int ldc);
lapack_int LAPACKE_zlarfb (int matrix_layout, char side, char trans, char direct,
char storev, lapack_int m, lapack_int n, lapack_int k, const lapack_complex_double
* v, lapack_int ldv, const lapack_complex_double * t, lapack_int ldt,
lapack_complex_double * c, lapack_int ldc);

Include Files
- mkl.h

Description
The real flavors of the routine ?larfb apply a real block reflector \( H \) or its transpose \( H^T \) to a real \( m \)-by-\( n \)
matrix \( C \) from either left or right.
The complex flavors of the routine ?larfb apply a complex block reflector \( H \) or its conjugate transpose \( H^H \) to
a complex \( m \)-by-\( n \) matrix \( C \) from either left or right.

Input Parameters

\( \text{side} \)
If \( \text{side} = 'L' \): apply \( H \) or \( H^T \) for real flavors and \( H \) or \( H^H \) for complex
flavors from the left.
If \( \text{side} = 'R' \): apply \( H \) or \( H^T \) for real flavors and \( H \) or \( H^H \) for complex
flavors from the right.

\( \text{trans} \)
If \( \text{trans} = 'N' \): apply \( H \) (No transpose).
If \( \text{trans} = 'C' \): apply \( H^H \) (Conjugate transpose).
If \( \text{trans} = 'T' \): apply \( H^T \) (Transpose).

\( \text{direct} \)
Indicates how \( H \) is formed from a product of elementary reflectors
If \( \text{direct} = 'F' \): \( H = H(1)*H(2)*...*H(k) \) (forward)
If \( \text{direct} = 'B' \): \( H = H(k)*...*H(2)*H(1) \) (backward)

\( \text{storev} \)
Indicates how the vectors which define the elementary reflectors are
stored:
If \( \text{storev} = 'C' \): Column-wise
If \( \text{storev} = 'R' \): Row-wise

\( m \)
The number of rows of the matrix \( C \).

\( n \)
The number of columns of the matrix \( C \).

\( k \)
The order of the matrix \( T \) (equal to the number of elementary reflectors
whose product defines the block reflector).

\( v \)
The size limitations depend on values of parameters \( \text{storev} \) and \( \text{side} \) as
described in the following table:

| \( \text{storev} = C \) | \( \text{storev} = R \) |
The matrix \( v \). See Application Notes below.

### \( ldv \)

The leading dimension of the array \( v \). It should satisfy the following conditions:

<table>
<thead>
<tr>
<th>side</th>
<th>Column major</th>
<th>Row major</th>
</tr>
</thead>
<tbody>
<tr>
<td>( LD)</td>
<td>( \max(1, ldv \times k) )</td>
<td>( \max(1, ldv \times m) )</td>
</tr>
<tr>
<td>( RD)</td>
<td>( \max(1, ldv \times m) )</td>
<td>( \max(1, ldv \times n) )</td>
</tr>
</tbody>
</table>

### \( t \)

Array, size at least \( \max(1, ldt \times k) \).

Contains the triangular \( k \)-by-\( k \) matrix \( T \) in the representation of the block reflector.

### \( ldt \)

The leading dimension of the array \( t \).

\( ldt \geq k \).

### \( c \)

Array, size at least \( \max(1, ldc \times n) \) for column major layout and \( \max(1, ldc \times m) \) for row major layout.

On entry, the \( m \)-by-\( n \) matrix \( C \).

### \( ldc \)

The leading dimension of the array \( c \).

\( ldc \geq \max(1, m) \) for column major layout and \( ldc \geq \max(1, n) \) for row major layout.

#### Output Parameters

### \( c \)

On exit, \( c \) is overwritten by the product of the following:

- \( H^*C \) or \( H^*C \) or \( C^*H \) or \( C^*H^T \) for real flavors
- \( H^*C \) or \( H^*C \) or \( C^*H \) or \( C^*H^H \) for complex flavors

#### Return Values

This function returns a value \( info \).

If \( info = 0 \), the execution is successful.

If \( info = -i \), the \( i \)-th parameter had an illegal value.

If \( info = -1011 \), memory allocation error occurred.

---

*Intel Math Kernel Library Developer Reference*
Application Notes

The shape of the matrix $V$ and the storage of the vectors which define the $H(i)$ is best illustrated by the following example with $n = 5$ and $k = 3$. The elements equal to 1 are not stored; the corresponding array elements are modified but restored on exit. The rest of the array is not used.

$$
\begin{bmatrix}
1 & 1 \\
v_1 & v_2 & 1 \\
v_1 & v_2 & v_3 \\
v_1 & v_2 & v_3 \\
\end{bmatrix}
$$

$direct = 'F' and storev = 'C'$:  \quad $direct = 'F' and storev = 'R'$:

$$
\begin{bmatrix}
1 & v_1 & v_1 & v_1 \\
1 & v_2 & v_2 & v_2 \\
1 & v_3 & v_3 \\
\end{bmatrix}
$$

$direct = 'B' and storev = 'C'$:  \quad $direct = 'B' and storev = 'R'$:

$$
\begin{bmatrix}
v_1 & v_2 & v_3 \\
v_1 & v_2 & v_3 \\
1 & v_2 & v_3 \\
1 & v_3 \\
\end{bmatrix}
$$

?larfg

Generates an elementary reflector (Householder matrix).

**Syntax**

```c
lapack_int LAPACKE_slarfg (lapack_int n, float * alpha, float * x, lapack_int incx, float * tau);

lapack_int LAPACKE_dlarfg (lapack_int n, double * alpha, double * x, lapack_int incx, double * tau);

lapack_int LAPACKE_clarfg (lapack_int n, lapack_complex_float * alpha, lapack_complex_float * x, lapack_int incx, lapack_complex_float * tau);

lapack_int LAPACKE_zlarfg (lapack_int n, lapack_complex_double * alpha, lapack_complex_double * x, lapack_int incx, lapack_complex_double * tau);
```

**Include Files**

- `mkl.h`

**Description**

The routine ?larfg generates a real/complex elementary reflector $H$ of order $n$, such that
for real flavors and

\[
H^* \begin{bmatrix} \alpha \\ x \end{bmatrix} = \begin{bmatrix} \beta \\ 0 \end{bmatrix}, \quad H^*H = I,
\]
for complex flavors,

where \( \alpha \) and \( \beta \) are scalars (with \( \beta \) real for all flavors), and \( x \) is an \((n-1)\)-element real/complex vector. \( H \) is represented in the form

\[
H = I - \tau \begin{bmatrix} 1 \\ \nu^T \end{bmatrix} \quad \text{for real flavors and}
\]

\[
H = I - \tau \begin{bmatrix} 1 \\ \nu^H \end{bmatrix} \quad \text{for complex flavors},
\]

where \( \tau \) is a real/complex scalar and \( \nu \) is a real/complex \((n-1)\)-element vector, respectively. Note that for \text{clarfg/zlarfg}, \( H \) is not Hermitian.

If the elements of \( x \) are all zero (and, for complex flavors, \( \alpha \) is real), then \( \tau = 0 \) and \( H \) is taken to be the unit matrix.

Otherwise, \( 1 \leq \tau \leq 2 \) (for real flavors), or \( 1 \leq \text{Re}(\tau) \leq 2 \) and \( \text{abs}(\tau-1) \leq 1 \) (for complex flavors).

**Input Parameters**

- \( n \)  
  The order of the elementary reflector.

- \( \alpha \)  
  Array, size \((1+(n-2)\times\text{abs}(\text{incx}))\).
  On entry, the vector \( x \).

- \( \text{incx} \)  
  The increment between elements of \( x \). \( \text{incx} > 0 \).

**Output Parameters**

- \( \alpha \)  
  On exit, it is overwritten with the value \( \beta \).

- \( x \)  
  On exit, it is overwritten with the vector \( \nu \).

- \( \tau \)

**Return Values**

This function returns a value \( \text{info} \).

If \( \text{info} = 0 \), the execution is successful.

If \( \text{info} = -2 \), \( \alpha \) is NaN

If \( \text{info} = -3 \), array \( x \) contains NaN components.
?larft
Forms the triangular factor T of a block reflector H = I - V*T*V**H.

Syntax

```c
lapack_int LAPACKE_slarft (int matrix_layout, char direct, char storev, lapack_int n, lapack_int k, const float * v, lapack_int ldv, const float * tau, float * t, lapack_int ldt);
```

```c
lapack_int LAPACKE_dlarft (int matrix_layout, char direct, char storev, lapack_int n, lapack_int k, const double * v, lapack_int ldv, const double * tau, double * t, lapack_int ldt);
```

```c
lapack_int LAPACKE_clarft (int matrix_layout, char direct, char storev, lapack_int n, lapack_int k, const lapack_complex_float * v, lapack_int ldv, const lapack_complex_float * tau, lapack_complex_float * t, lapack_int ldt);
```

```c
lapack_int LAPACKE_zlarft (int matrix_layout, char direct, char storev, lapack_int n, lapack_int k, const lapack_complex_double * v, lapack_int ldv, const lapack_complex_double * tau, lapack_complex_double * t, lapack_int ldt);
```

Include Files

- mkl.h

Description

The routine ?larft forms the triangular factor T of a real/complex block reflector H of order n, which is defined as a product of k elementary reflectors.

If `direct` = 'F', H = H(1)*H(2)*...*H(k) and T is upper triangular;

If `direct` = 'B', H = H(k)*...*H(2)*H(1) and T is lower triangular.

If `storev` = 'C', the vector which defines the elementary reflector H(i) is stored in the i-th column of the array v, and H = I - V*T*V (for real flavors) or H = I - V*H*V (for complex flavors).

If `storev` = 'R', the vector which defines the elementary reflector H(i) is stored in the i-th row of the array v, and H = I - V**T*T*V (for real flavors) or H = I - V**H*T*V (for complex flavors).

Input Parameters

- `direct` Specifies the order in which the elementary reflectors are multiplied to form the block reflector:
  - '='F': H = H(1)*H(2)*...*H(k) (forward)
  - '='B': H = H(k)*...*H(2)*H(1) (backward)

- `storev` Specifies how the vectors which define the elementary reflectors are stored (see also Application Notes below):
  - '='C': column-wise
  - '='R': row-wise.

- `n` The order of the block reflector H. n ≥ 0.
The order of the triangular factor $T$ (equal to the number of elementary reflectors). $k \geq 1$.

The size limitations depend on values of parameters $\text{storev}$ and $\text{side}$ as described in the following table:

<table>
<thead>
<tr>
<th></th>
<th>$\text{storev} = C$</th>
<th>$\text{storev} = R$</th>
</tr>
</thead>
<tbody>
<tr>
<td>Column major</td>
<td>$\max(1,ldv*k)$</td>
<td>$\max(1,ldv*n)$</td>
</tr>
<tr>
<td>Row major</td>
<td>$\max(1,ldv*n)$</td>
<td>$\max(1,ldv*k)$</td>
</tr>
</tbody>
</table>

The matrix $v$. See Application Notes below.

The leading dimension of the array $v$.

If $\text{storev} = 'C'$, $ldv \geq \max(1,n)$ for column major and $ldv \geq \max(1,k)$ for row major;

if $\text{storev} = 'R'$, $ldv \geq k$ for column major and $ldv \geq \max(1,n)$ for row major.

Array, size $(k)$. $\tau[i-1]$ must contain the scalar factor of the elementary reflector $H(i)$.

The leading dimension of the output array $t$. $ldt \geq k$.

**Output Parameters**

Array, size $ldt \times k$. The $k$-by-$k$ triangular factor $T$ of the block reflector. If $\text{direct} = 'F'$, $T$ is upper triangular; if $\text{direct} = 'B'$, $T$ is lower triangular. The rest of the array is not used.

The matrix $V$.

**Application Notes**

The shape of the matrix $V$ and the storage of the vectors which define the $H(i)$ is best illustrated by the following example with $n = 5$ and $k = 3$. The elements equal to 1 are not stored; the corresponding array elements are modified but restored on exit. The rest of the array is not used.

**direct = 'F' and storev = 'C':**

$$
\begin{bmatrix}
1 & 1 \\
v_1 & 1 \\
v_1 & v_2 & 1 \\
v_1 & v_2 & v_3 \\
v_1 & v_2 & v_3
\end{bmatrix}
$$

**direct = 'F' and storev = 'R':**

$$
\begin{bmatrix}
1 & v_1 & v_1 & v_1 \\
v_1 & v_2 & v_1 & v_1 \\
v_1 & v_2 & v_2 & v_1 \\
v_1 & v_2 & v_3 & v_1 \\
v_1 & v_2 & v_3 & v_1 \\
v_1 & v_2 & v_3 & v_2 \\
v_1 & v_2 & v_3 & v_3
\end{bmatrix}
$$
Applies an elementary reflector to a general rectangular matrix, with loop unrolling when the reflector has order less than or equal to 10.

**Syntax**

```c
lapack_int LAPACKE_slarfx (int matrix_layout, char side, lapack_int m, lapack_int n, const float * v, float tau, float * c, lapack_int ldc, float * work);

lapack_int LAPACKE_dlarfx (int matrix_layout, char side, lapack_int m, lapack_int n, const double * v, double tau, double * c, lapack_int ldc, double * work);

lapack_int LAPACKE_clarfx (int matrix_layout, char side, lapack_int m, lapack_int n, const lapack_complex_float * v, lapack_complex_float tau, lapack_complex_float * c, lapack_int ldc, lapack_complex_float * work);

lapack_int LAPACKE_zlarfx (int matrix_layout, char side, lapack_int m, lapack_int n, const lapack_complex_double * v, lapack_complex_double tau, lapack_complex_double * c, lapack_int ldc, lapack_complex_double * work);
```

**Include Files**

- mkl.h

**Description**

The routine ?larfx applies a real/complex elementary reflector $H$ to a real/complex $m$-by-$n$ matrix $C$, from either the left or the right.

$H$ is represented in the following forms:

- $H = I - \tau v^* v$, where $\tau$ is a real scalar and $v$ is a real vector.
- $H = I - \tau v^* v^T$, where $\tau$ is a complex scalar and $v$ is a complex vector.

If $\tau = 0$, then $H$ is taken to be the unit matrix.

**Input Parameters**

- **side**
  - If $\text{side} = 'L'$: form $H^* C$
  - If $\text{side} = 'R'$: form $C^* H$.

- **m**
  - The number of rows of the matrix $C$. 

\[ \begin{bmatrix} v_1 & v_2 & v_3 \\ v_1 & v_2 & v_3 \\ 1 & v_2 & v_3 \\ 1 & v_3 \\ 1 \end{bmatrix} \]
The number of columns of the matrix $C$.

$\nu$

Array, size

$(m)$ if $side = 'L'$ or

$(n)$ if $side = 'R'$.

The vector $v$ in the representation of $H$.

$\tau$

The value $\tau$ in the representation of $H$.

$c$

Array, size at least max(1, $ldc*n$) for column major layout and max (1, $ldc*n$) for row major layout. On entry, the $m$-by-$n$ matrix $C$.

$\text{ldc}$

The leading dimension of the array $c$. $\text{ldc} \geq (1,m)$.

$\text{work}$

Workspace array, size

$(n)$ if $side = 'L'$ or

$(m)$ if $side = 'R'$.

$\text{work}$ is not referenced if $H$ has order < 11.

**Output Parameters**

$c$

On exit, $C$ is overwritten by the matrix $H*C$ if $side = 'L'$, or $C*H$ if $side = 'R'$.

**?large**

*Pre- and post-multiplies a real general matrix with a random orthogonal matrix.*

**Syntax**

```c
void slarge (lapack_int *n, float *a, lapack_int *lda, lapack_int *iseed, float * work, lapack_int *info);
void dlarge (lapack_int *n, double *a, lapack_int *lda, lapack_int *iseed, double * work, lapack_int *info);
void clarge (lapack_int *n, lapack_complex *a, lapack_int *lda, lapack_int *iseed, lapack_complex * work, lapack_int *info);
void zlarge (lapack_int *n, lapack_complex_double *a, lapack_int *lda, lapack_int *iseed, lapack_complex_double * work, lapack_int *info);
```

**Include Files**

- mkl.h

**Description**

The routine ?large pre- and post-multiplies a general $n$-by-$n$ matrix $A$ with a random orthogonal or unitary matrix: $A = U*D*U^\top$.

**Input Parameters**

$n$

The order of the matrix $A$. $n \geq 0$
Array, size \( ld a \) by \( n \).
On entry, the original \( n \)-by-\( n \) matrix \( A \).

\( lda \)
The leading dimension of the array \( a \). \( lda \geq n \).

\( iseed \)
Array, size 4.
On entry, the seed of the random number generator. The array elements must be between 0 and 4095, and \( iseed[3] \) must be odd.

Workspace array, size \( 2n \).

\section*{Output Parameters}

On exit, \( A \) is overwritten by \( U^*A^*U' \) for some random orthogonal matrix \( U \).

On exit, the seed is updated.

If \( info = 0 \), the execution is successful.
If \( info < 0 \), the \( i \)-th parameter had an illegal value.

\texttt{?larnd}

\textit{Returns a random real number from a uniform or normal distribution.}

\textbf{Syntax}

\begin{verbatim}
float slarnd (lapack_int *idist, lapack_int *iseed);
double dlarnd (lapack_int *idist, lapack_int *iseed);
\end{verbatim}

The data types for complex variations depend on whether or not the application links with Gnu Fortran (gfortran) libraries.

For non-gfortran (libmkl_intel_*) interface libraries:

\begin{verbatim}
void clarnd (lapack_complex_float *res, lapack_int *idist, lapack_int *iseed);
void zlarnd (lapack_complex_double *res, lapack_int *idist, lapack_int *iseed);
\end{verbatim}

For gfortran (libmkl_gf_*) interface libraries:

\begin{verbatim}
lapack_complex_float clarnd (lapack_int *idist, lapack_int *iseed);
lapack_complex_double zlarnd (lapack_int *idist, lapack_int *iseed);
\end{verbatim}

To understand the difference between the non-gfortran and gfortran interfaces and when to use each of them, see Dynamic Libraries in the lib/intel64 Directory in the \textit{Intel® MKL Developer Guide}.

\textbf{Include Files}

\begin{itemize}
  \item mkl.h
\end{itemize}

\textbf{Description}

The routine \texttt{?larnd} returns a random number from a uniform or normal distribution.

\textbf{Input Parameters}

\texttt{idist}

\textit{Specifies the distribution of the random numbers. For \texttt{slarnd} and \texttt{dlarnd}:}
= 1: uniform (0,1)
= 2: uniform (-1,1)
= 3: normal (0,1).

For clarnd and zlanrd:
= 1: real and imaginary parts each uniform (0,1)
= 2: real and imaginary parts each uniform (-1,1)
= 3: real and imaginary parts each normal (0,1)
= 4: uniformly distributed on the disc abs(z) ≤ 1
= 5: uniformly distributed on the circle abs(z) = 1

iseed
Array, size 4.

On entry, the seed of the random number generator. The array elements
must be between 0 and 4095, and iseed[3] must be odd.

Output Parameters

iseed
On exit, the seed is updated.

Return Values

The function returns a random number (for complex variations libmkl_gf_*
interface layer/libraries return
the result as the parameter res).

?larnv
Returns a vector of random numbers from a uniform
or normal distribution.

Syntax

lapack_int LAPACKE_slarnv (lapack_int idist , lapack_int * iseed , lapack_int n , float
* x );
lapack_int LAPACKE_dlarnv (lapack_int idist , lapack_int * iseed , lapack_int n ,
double * x );
lapack_int LAPACKE_clarnv (lapack_int idist , lapack_int * iseed , lapack_int n ,
lapack_complex_float * x );
lapack_int LAPACKE_zlarnv (lapack_int idist , lapack_int * iseed , lapack_int n ,
lapack_complex_double * x );

Include Files

• mkl.h

Description

The routine ?larnv returns a vector of n random real/complex numbers from a uniform or normal
distribution.

This routine calls the auxiliary routine ?laruv to generate random real numbers from a uniform (0,1)
distribution, in batches of up to 128 using vectorisable code. The Box-Muller method is used to transform
numbers from a uniform to a normal distribution.
Input Parameters

\textbf{idist}

Specifies the distribution of the random numbers: for \texttt{slarnv} and \texttt{dlarnv}:

\begin{itemize}
  \item $= 1$: uniform (0,1)
  \item $= 2$: uniform (-1,1)
  \item $= 3$: normal (0,1).
\end{itemize}

for \texttt{clarnv} and \texttt{zlarnv}:

\begin{itemize}
  \item $= 1$: real and imaginary parts each uniform (0,1)
  \item $= 2$: real and imaginary parts each uniform (-1,1)
  \item $= 3$: real and imaginary parts each normal (0,1)
  \item $= 4$: uniformly distributed on the disc $\text{abs}(z) < 1$
  \item $= 5$: uniformly distributed on the circle $\text{abs}(z) = 1$
\end{itemize}

\textbf{iseed}

Array, size (4).

On entry, the seed of the random number generator; the array elements must be between 0 and 4095, and \texttt{iseed(4)} must be odd.

\textbf{n}

The number of random numbers to be generated.

Output Parameters

\textbf{x}

Array, size (n). The generated random numbers.

\textbf{iseed}

On exit, the seed is updated.

Return Values

This function returns a value \texttt{info}.

If $\texttt{info} = 0$, the execution is successful.

\textbf{?laror}

Pre- or post-multiplies an m-by-n matrix by a random orthogonal/unitary matrix.

\textbf{Syntax}

\begin{verbatim}
void slaror (char *side, char *init, lapack_int *m, lapack_int *n, float *a, lapack_int *ida, lapack_int *iseed, float *x, lapack_int *info);
void dlaror (char *side, char *init, lapack_int *m, lapack_int *n, double *a, lapack_int *ida, lapack_int *iseed, double *x, lapack_int *info);
void claror (char *side, char *init, lapack_int *m, lapack_int *n, lapack_complex *a, lapack_int *ida, lapack_int *iseed, lapack_complex *x, lapack_int *info);
void zlaror (char *side, char *init, lapack_int *m, lapack_int *n, lapack_complex_double *a, lapack_int *ida, lapack_int *iseed, lapack_complex_double *x, lapack_int *info);
\end{verbatim}

\textbf{Include Files}

- mkl.h
Description

The routine ?laror pre- or post-multiplies an \( m \)-by-\( n \) matrix \( A \) by a random orthogonal or unitary matrix \( U \), overwriting \( A \). \( A \) may optionally be initialized to the identity matrix before multiplying by \( U \). \( U \) is generated using the method of G.W. Stewart (SIAM J. Numer. Anal. 17, 1980, 403-409).

Input Parameters

\textit{side}

Specifies whether \( A \) is multiplied by \( U \) on the left or right.

for \texttt{slaror} and \texttt{dlaror}:
- If \texttt{side} = 'L', multiply \( A \) on the left (premultiply) by \( U \).
- If \texttt{side} = 'R', multiply \( A \) on the right (postmultiply) by \( U^T \).
- If \texttt{side} = 'C' or 'T', multiply \( A \) on the left by \( U \) and the right by \( U^T \).

for \texttt{claror} and \texttt{zlaror}:
- If \texttt{side} = 'L', multiply \( A \) on the left (premultiply) by \( U \).
- If \texttt{side} = 'R', multiply \( A \) on the right (postmultiply) by \( U^C \).
- If \texttt{side} = 'C', multiply \( A \) on the left by \( U \) and the right by \( U^C \).
- If \texttt{side} = 'T', multiply \( A \) on the left by \( U \) and the right by \( U^T \).

\textit{init}

Specifies whether or not \( a \) should be initialized to the identity matrix.

- If \texttt{init} = 'I', initialize \( a \) to (a section of) the identity matrix before applying \( U \).
- If \texttt{init} = 'N', no initialization. Apply \( U \) to the input matrix \( A \).
- \texttt{init} = 'I' generates square or rectangular orthogonal matrices:
  - For \( m = n \) and \texttt{side} = 'L' or 'R', the rows and the columns are orthogonal to each other.
  - For rectangular matrices where \( m < n \):
    - If \texttt{side} = 'R', \texttt{slaror} produces a dense matrix in which rows are orthogonal and columns are not.
    - If \texttt{side} = 'L', \texttt{slaror} produces a matrix in which rows are orthogonal, first \( m \) columns are orthogonal, and remaining columns are zero.
  - For rectangular matrices where \( m > n \):
    - If \texttt{side} = 'L', \texttt{slaror} produces a dense matrix in which columns are orthogonal and rows are not.
    - If \texttt{side} = 'R', \texttt{slaror} produces a matrix in which columns are orthogonal, first \( m \) rows are orthogonal, and remaining rows are zero.

\textit{m}

The number of rows of \( A \).

\textit{n}

The number of columns of \( A \).

\textit{a}

Array, size \( \text{lda} \) by \( n \).

\textit{lda}

The leading dimension of the array \( a \).

\[ \text{lda} \geq \max(1, m) \]

\textit{iseed}

Array, size (4).
On entry, specifies the seed of the random number generator. The array elements must be between 0 and 4095; if not they are reduced mod 4096. Also, iseed[3] must be odd.

Workspace array, size \((3 \max(m, n))\).

<table>
<thead>
<tr>
<th>Value of side</th>
<th>Length of workspace</th>
</tr>
</thead>
<tbody>
<tr>
<td>'L'</td>
<td>(2m + n)</td>
</tr>
<tr>
<td>'R'</td>
<td>(2n + m)</td>
</tr>
<tr>
<td>'C' or 'T'</td>
<td>(3n)</td>
</tr>
</tbody>
</table>

Output Parameters

**a**

On exit, overwritten

by \(UA\) (if side = 'L'),

by \(AU\) (if side = 'R'),

by \(UAU^T\) (if side = 'C' or 'T').

**iseed**

The values of iseed are changed on exit, and can be used in the next call to continue the same random number sequence.

**info**

Array, size (4).

For slarot and dlaror:

If info = 0, the execution is successful.

If info < 0, the \(i\)-th parameter had an illegal value.

If info = 1, the random numbers generated by ?larot are bad.

For clarot and zlarot:

If info = 0, the execution is successful.

If info = -1, side is not 'L', 'R', 'C', or 'T'.

If info = -3, if \(m\) is negative.

If info = -4, if \(m\) is negative or if side is 'C' or 'T' and \(n\) is not equal to \(m\).

If info = -6, if lda is less than \(m\).

?larot

Applies a Givens rotation to two adjacent rows or columns.

**Syntax**

```c
void slarot (lapack_logical *lrows, lapack_logical * ileft, lapack_logical * iright, lapack_int * nl, float * c, float * s, float * a, lapack_int * lda, float * xleft, float * xright);
void dlarot (lapack_logical * lrows, lapack_logical * ileft, lapack_logical * iright, lapack_int * nl, double * c, double * s, double * a, lapack_int * lda, double * xleft, double * xright);
```
void clarot (lapack_logical *lrows, lapack_logical *illeft, lapack_logical *iright, lapack_int *nl, lapack_complex *c, lapack_complex *s, lapack_complex *a, lapack_int *lda, lapack_complex *xleft, lapack_complex *xright);

void zlarot (lapack_logical *lrows, lapack_logical *illeft, lapack_logical *iright, lapack_int *nl, lapack_complex_double *c, lapack_complex_double *s, lapack_complex_double *a, lapack_int *lda, lapack_complex_double *xleft, lapack_complex_double *xright);

Include Files
• mkl.h

Description
The routine ?larot applies a Givens rotation to two adjacent rows or columns, where one element of the first or last column or row is stored in some format other than GE so that elements of the matrix may be used or modified for which no array element is provided.

One example is a symmetric matrix in SB format (bandwidth = 4), for which uplo = 'L'. Two adjacent rows will have the format:

row j: C > C > C > C > . . . .
row j + 1: C > C > C > C > . . . .

'*' indicates elements for which storage is provided.
'. ' indicates elements for which no storage is provided, but are not necessarily zero; their values are determined by symmetry.
' ' indicates elements which are required to be zero, and have no storage provided.

Those columns which have two '***' entries can be handled by srot (for slarot and clarot), or by drot (for dlarot and zlarot).

Those columns which have no '***' entries can be ignored, since as long as the Givens rotations are carefully applied to preserve symmetry, their values are determined.

Those columns which have one '***' have to be handled separately, by using separate variables p and q:

row j: C > C > C > C > C > p . . . .
row j + 1: q C > C > C > C > . . . .

If element p is set correctly, ?larot rotates the column and sets p to its new value. The next call to ?larot rotates columns j and j +1, and restore symmetry. The element q is zero at the beginning, and non-zero after the rotation. Later, rotations would presumably be chosen to zero q out.

Typical Calling Sequences: rotating the i-th and (i +1)-st rows.

Input Parameters
lrows
If lrows = 1, ?larot rotates two rows.
If lrows = 0, ?larot rotates two columns.

illeft
If illeft = 1, xleft is used instead of the corresponding element of a for the first element in the second row (if lrows = 0) or column (if lrows=1).
If illeft = 0, the corresponding element of a is used.

iright
If \( lleft = 1 \), \( xright \) is used instead of the corresponding element of \( a \) for the first element in the second row (if \( lrows = 0 \)) or column (if \( lrows = 1 \)).

If \( lright = 0 \), the corresponding element of \( a \) is used.

\( nl \)

The length of the rows (if \( lrows = 1 \)) or columns (if \( lrows = 1 \)) to be rotated.

If \( xleft \) or \( xright \) are used, the columns or rows they are in should be included in \( nl \), e.g., if \( lleft = lright = 1 \), then \( nl \) must be at least 2.

The number of rows or columns to be rotated exclusive of those involving \( xleft \) and/or \( xright \) may not be negative, i.e., \( nl \) minus how many of \( lleft \) and \( lright \) are 1 must be at least zero; if not, xerbla is called.

\( c, s \)

Specify the Givens rotation to be applied.

If \( lrows = 1 \), then the matrix

\[
\begin{bmatrix}
C & S \\
-S & C
\end{bmatrix}
\]

is applied from the left.

If \( lrows = 0 \), then the transpose thereof is applied from the right.

\( a \)

The array containing the rows or columns to be rotated. The first element of \( a \) should be the upper left element to be rotated.

\( lda \)

The "effective" leading dimension of \( a \).

If \( a \) contains a matrix stored in GE or SY format, then this is just the leading dimension of \( A \).

If \( a \) contains a matrix stored in band (GB or SB) format, then this should be one less than the leading dimension used in the calling routine. Thus, if \( a \) in \( ?larot \) is of size \( lda \times n \), then \( a[(j - 1) \times lda] \) would be the \( j \)-th element in the first of the two rows to be rotated, and \( a[(j - 1) \times lda + 1] \) would be the \( j \)-th in the second, regardless of how the array may be stored in the calling routine. \( a \) cannot be dimensioned, because for band format the row number may exceed \( lda \), which is not legal FORTRAN.

If \( lrows = 1 \), then \( lda \) must be at least 1, otherwise it must be at least \( nl \) minus the number of 1 values in \( xleft \) and \( xright \).

\( xleft \)

If \( lrows = 1 \), \( xleft \) is used and modified instead of \( a[1] \) (if \( lrows = 1 \)) or \( a[lda + 1] \) (if \( lrows = 0 \)).

\( xright \)

If \( lright = 1 \), \( xright \) is used and modified instead of \( a[(nl - 1) \times lda] \) (if \( lrows = 1 \)) or \( a[nl - 1] \) (if \( lrows = 0 \)).

**Output Parameters**

\( a \)

On exit, modified array \( A \).
?lartgp
Generates a plane rotation.

Syntax
lapack_int LAPACKE_slartgp (float f, float g, float* cs, float* sn, float* r);
lapack_int LAPACKE_dlartgp (double f, double g, double* cs, double* sn, double* r);

Include Files
• mkl.h

Description
The routine generates a plane rotation so that

\[ \begin{bmatrix} cs & sn \\ -sn & cs \end{bmatrix} \cdot \begin{bmatrix} f \\ g \end{bmatrix} = \begin{bmatrix} r \\ 0 \end{bmatrix} \]

where \( cs^2 + sn^2 = 1 \)

This is a slower, more accurate version of the BLAS Level 1 routine ?rotg, except for the following differences:

• \( f \) and \( g \) are unchanged on return.
• If \( g = 0 \), then \( cs = (+/-)1 \) and \( sn = 0 \).
• If \( f = 0 \) and \( g \neq 0 \), then \( cs = 0 \) and \( sn = (+/-)1 \).

The sign is chosen so that \( r \geq 0 \).

Input Parameters
\( f, g \)  
The first and second component of the vector to be rotated.

Output Parameters
\( cs \)  
The cosine of the rotation.

\( sn \)  
The sine of the rotation.

\( r \)  
The nonzero component of the rotated vector.

Return Values
If \( info = 0 \), the execution is successful.
If \( info = -1 \), \( f \) is NaN.
If \( info = -2 \), \( g \) is NaN.

?rotg
?lartgs
?lartgs
Generates a plane rotation designed to introduce a bulge in implicit QR iteration for the bidiagonal SVD problem.

Syntax
lapack_int LAPACKE_slartgs (float x, float y, float sigma, float* cs, float* sn);
lapack_int LAPACKE_dlartgs (double x, double y, double sigma, double* cs, double* sn);

Include Files
• mkl.h

Description
The routine generates a plane rotation designed to introduce a bulge in Golub-Reinsch-style implicit QR iteration for the bidiagonal SVD problem. \( x \) and \( y \) are the top-row entries, and \( \sigma \) is the shift. The computed \( cs \) and \( sn \) define a plane rotation that satisfies the following:

\[
\begin{bmatrix}
\cos \theta & \sin \theta \\
-\sin \theta & \cos \theta \\
\end{bmatrix}
\begin{bmatrix}
    x^2 - \sigma \\
    x \cdot y \\
\end{bmatrix}
= \begin{bmatrix}
    r \\
    0 \\
\end{bmatrix}
\]

with \( r \) nonnegative.
If \( x^2 - \sigma \) and \( x \cdot y \) are 0, the rotation is by \( \pi/2 \).

Input Parameters
\( x, y \) The (1,1) and (1,2) entries of an upper bidiagonal matrix, respectively.
\( \sigma \) Shift

Output Parameters
\( cs \) The cosine of the rotation.
\( sn \) The sine of the rotation.

Return Values
If \( info = 0 \), the execution is successful.
If \( info = -1 \), \( x \) is NaN.
If \( info = -2 \), \( y \) is NaN.
If \( info = -3 \), \( \sigma \) is NaN.

?lascl
Multiplies a general rectangular matrix by a real scalar defined as \( c_{to}/c_{from} \).
Syntax

```c
lapack_int LAPACKE_slascl (int matrix_layout, char type, lapack_int kl, lapack_int ku,
float cfrom, float cto, lapack_int m, lapack_int n, float * a, lapack_int lda);

lapack_int LAPACKE_dlascl (int matrix_layout, char type, lapack_int kl, lapack_int ku,
double cfrom, double cto, lapack_int m, lapack_int n, double * a, lapack_int lda);

lapack_int LAPACKE_clascl (int matrix_layout, char type, lapack_int kl, lapack_int ku,
float cfrom, float cto, lapack_int m, lapack_int n, lapack_complex_float * a,
lapack_int lda);

lapack_int LAPACKE_zlascl (int matrix_layout, char type, lapack_int kl, lapack_int ku,
double cfrom, double cto, lapack_int m, lapack_int n, lapack_complex_double * a,
lapack_int lda);
```

Include Files

- mkl.h

Description

The routine **?lascl** multiplies the \( m \)-by-\( n \) real/complex matrix \( A \) by the real scalar \( cto/cfrom \). The operation is performed without over/underflow as long as the final result \( cto \times A(i,j)/cfrom \) does not over/underflow. The **type** specifies that \( A \) may be full, upper triangular, lower triangular, upper Hessenberg, or banded.

Input Parameters

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **type**
  This parameter specifies the storage type of the input matrix.

  - 'G': \( A \) is a full matrix.
  - 'L': \( A \) is a lower triangular matrix.
  - 'U': \( A \) is an upper triangular matrix.
  - 'H': \( A \) is an upper Hessenberg matrix.
  - 'B': \( A \) is a symmetric band matrix with lower bandwidth \( kl \) and upper bandwidth \( ku \) and with the only the lower half stored.
  - 'Q': \( A \) is a symmetric band matrix with lower bandwidth \( kl \) and upper bandwidth \( ku \) and with the only the upper half stored.
  - 'Z': \( A \) is a band matrix with lower bandwidth \( kl \) and upper bandwidth \( ku \). See description of the ?gbtrf function for storage details.

- **kl**
  The lower bandwidth of \( A \). Referenced only if **type** = 'B', 'Q' or 'Z'.

- **ku**
  The upper bandwidth of \( A \). Referenced only if **type** = 'B', 'Q' or 'Z'.

- **cfrom, cto**
  The matrix \( A \) is multiplied by \( cto/cfrom \). \( A(i,j) \) is computed without over/underflow if the final result \( cto \times A(i,j)/cfrom \) can be represented without over/underflow. \( cfrom \) must be nonzero.

- **m**
  The number of rows of the matrix \( A \). \( m \geq 0 \).

- **n**
  The number of columns of the matrix \( A \). \( n \geq 0 \).
Input Parameters

\( n \)

On entry, the row dimension of the upper bidiagonal matrix. This is also the dimension of the main diagonal array \( d \).

\( \text{sqre} \)

Specifies the column dimension of the bidiagonal matrix.

- If \( \text{sqre} = 0 \): the bidiagonal matrix has column dimension \( m = n \).
- If \( \text{sqre} = 1 \): the bidiagonal matrix has column dimension \( m = n+1 \).

Output Parameters

\( a \)

The multiplied matrix \( A \).

\( \text{info} \)

- If \( \text{info} = 0 \): successful exit
- If \( \text{info} = -i < 0 \), the \( i \)-th argument had an illegal value.

- \?gbtrf

\?lasd0

Computes the singular values of a real upper bidiagonal \( n \)-by-\( m \) matrix \( B \) with diagonal \( d \) and off-diagonal \( e \). Used by \?bdsdc.

Syntax

```c
void slasd0( lapack_int *n, lapack_int *sqre, float *d, float *e, float *u, lapack_int *ldu, float *vt, lapack_int *ldvt, lapack_int *smlsiz, lapack_int *iwork, float *work, lapack_int *info);
void dlasd0( lapack_int *n, lapack_int *sqre, double *d, double *e, double *u, lapack_int *ldu, double *vt, lapack_int *ldvt, lapack_int *smlsiz, lapack_int *iwork, double *work, lapack_int *info);
```

Include Files

- mkl.h

Description

Using a divide and conquer approach, the routine \?lasd0 computes the singular value decomposition (SVD) of a real upper bidiagonal \( n \)-by-\( m \) matrix \( B \) with diagonal \( d \) and offdiagonal \( e \), where \( m = n + \text{sqre} \).

The algorithm computes orthogonal matrices \( U \) and \( VT \) such that \( B = U^*S^*VT \). The singular values \( S \) are overwritten on \( d \).

The related subroutine \?lasda computes only the singular values, and optionally, the singular vectors in compact form.

Input Parameters

\( \text{lda} \)

The leading dimension of the array \( a \).

\( \text{lda} \geq \max(1, m) \).
Array, DIMENSION (n). On entry, d contains the main diagonal of the bidiagonal matrix.

e
Array, DIMENSION (m-1). Contains the subdiagonal entries of the bidiagonal matrix. On exit, e is destroyed.

ldu
On entry, leading dimension of the output array u.

ldvt
On entry, leading dimension of the output array vt.

smlsiz
On entry, maximum size of the subproblems at the bottom of the computation tree.

iwork
Workspace array, dimension must be at least (8n).

work
Workspace array, dimension must be at least (3m^2+2m).

Output Parameters

d
On exit d, If info = 0, contains singular values of the bidiagonal matrix.

Array, DIMENSION at least (ldq, n). On exit, u contains the left singular vectors.

vt
Array, DIMENSION at least (ldvt, m). On exit, vt^T contains the right singular vectors.

info
If info = 0: successful exit.
If info = -i < 0, the i-th argument had an illegal value.
If info = 1, a singular value did not converge.

?lasd1
Computes the SVD of an upper bidiagonal matrix B of the specified size. Used by ?bdsdc.

Syntax

void slasd1( lapack_int *nl, lapack_int *nr, lapack_int *sqre, float *d, float *alpha, float *beta, float *u, lapack_int *ldu, float *vt, lapack_int *ldvt, lapack_int *idxq, lapack_int *iwork, float *work, lapack_int *info );

void dlasd1( lapack_int *nl, lapack_int *nr, lapack_int *sqre, double *d, double *alpha, double *beta, double *u, lapack_int *ldu, double *vt, lapack_int *ldvt, lapack_int *idxq, lapack_int *iwork, double *work, lapack_int *info );

Include Files

• mkl.h

Description

The routine computes the SVD of an upper bidiagonal n-by-m matrix B, where n = nl + nr + 1 and m = n + sqre.

The routine ?lasd1 is called from ?lasd0.
A related subroutine `?lasd7` handles the case in which the singular values (and the singular vectors in factored form) are desired.

`?lasdi` computes the SVD as follows:

\[
VT = U(i\!n)^* \begin{bmatrix}
D(i\!n) & 0 & 0 \\
0 & a & 0 \\
0 & 0 & D2(i\!n)
\end{bmatrix} VT(i\!n)
\]

\[
= U(out)^*(D(out) 0)*VT(out)
\]

where \(Z^T = (Z1^T a Z2^T b) = u^T VT^T\), and \(u\) is a vector of dimension \(m\) with \(alpha\) and \(beta\) in the \(n\ell+1\) and \(n\ell+2\)-th entries and zeros elsewhere; and the entry \(b\) is empty if \(sqre = 0\).

The left singular vectors of the original matrix are stored in \(u\), and the transpose of the right singular vectors are stored in \(vT\), and the singular values are in \(d\). The algorithm consists of three stages:

1. The first stage consists of deflating the size of the problem when there are multiple singular values or when there are zeros in the \(Z\) vector. For each such occurrence the dimension of the secular equation problem is reduced by one. This stage is performed by the routine `?lasd2`.
2. The second stage consists of calculating the updated singular values. This is done by finding the square roots of the roots of the secular equation via the routine `?lasd4` (as called by `?lasd3`). This routine also calculates the singular vectors of the current problem.
3. The final stage consists of computing the updated singular vectors directly using the updated singular values. The singular vectors for the current problem are multiplied with the singular vectors from the overall problem.

**Input Parameters**

- \(nl\)
  - The row dimension of the upper block.
  - \(nl\geq 1\).

- \(nr\)
  - The row dimension of the lower block.
  - \(nr\geq 1\).

- \(sqre\)
  - If \(sqre = 0\): the lower block is an \(nr\)-by-\(nr\) square matrix.
  - If \(sqre = 1\): the lower block is an \(nr\)-by-\((nr+1)\) rectangular matrix. The bidiagonal matrix has row dimension \(n = nl + nr + 1\), and column dimension \(m = n + sqre\).

- \(d\)
  - Array, DIMENSION \((nl+nr+1)\). \(d(1:nl, 1:nl)\) contains the singular values of the upper block; and \(d(nl+2:n)\) contains the singular values of the lower block.

- \(alpha\)
  - Contains the diagonal element associated with the added row.

- \(beta\)
  - Contains the off-diagonal element associated with the added row.

- \(u\)
  - Array, DIMENSION \((ldu, n)\). \(u(1:nl, 1:nl)\) contains the left singular vectors of the upper block; \(u(nl+2:n, nl+2:n)\) contains the left singular vectors of the lower block.

- \(ldu\)
  - The leading dimension of the array \(U\).
  - \(ldu\geq \max(1, n)\).
vt

Array, DIMENSION (ldvt, m), where m = n + sqre.

On entry vt(1:nl+1, 1:nl+1)^T contains the right singular vectors of the upper block; vt(nl+2:m, nl+2:m)^T contains the right singular vectors of the lower block.

ldvt

The leading dimension of the array vt.

ldvt >= max(1, M).

iwork

Workspace array, DIMENSION (4n).

work

Workspace array, DIMENSION (3m^2 + 2m).

Output Parameters

d

On exit d(1:n) contains the singular values of the modified matrix.

alpha

On exit, the diagonal element associated with the added row deflated by max( abs( alpha ), abs( beta ), abs( D(I) ) ), I = 1,n.

beta

On exit, the off-diagonal element associated with the added row deflated by max( abs( alpha ), abs( beta ), abs( D(I) ) ), I = 1,n.

u

On exit u contains the left singular vectors of the bidiagonal matrix.

vt

On exit vt^T contains the right singular vectors of the bidiagonal matrix.

idxq

Array, DIMENSION (n). Contains the permutation which will reintegrate the subproblem just solved back into sorted order, that is, d(idxq( i = 1, n )) will be in ascending order.

info

If info = 0: successful exit.
If info = -i < 0, the i-th argument had an illegal value.
If info = 1, a singular value did not converge.

?lasd2

Merges the two sets of singular values together into a single sorted set. Used by ?bdsdc.

Syntax

void slasd2( lapack_int *nl, lapack_int *nr, lapack_int *sqre, lapack_int *k, float *d, float *z, float *alpha, float *beta, float *u, lapack_int *ldu, float *vt, lapack_int *ldvt, float *dsigma, float *u2, lapack_int *ldu2, float *vt2, lapack_int *ldvt2, lapack_int *idxp, lapack_int *idx, lapack_int *idxq, lapack_int *coltyp, lapack_int *info );

void dlasd2( lapack_int *nl, lapack_int *nr, lapack_int *sqre, lapack_int *k, double *d, double *z, double *alpha, double *beta, double *u, lapack_int *ldu, double *vt, lapack_int *ldvt, double *dsigma, double *u2, lapack_int *ldu2, double *vt2, lapack_int *ldvt2, lapack_int *idxp, lapack_int *idx, lapack_int *idxq, lapack_int *coltyp, lapack_int *info );
Include Files
- mkl.h

Description
The routine ?lasd2 merges the two sets of singular values together into a single sorted set. Then it tries to deflate the size of the problem. There are two ways in which deflation can occur: when two or more singular values are close together or if there is a tiny entry in the Z vector. For each such occurrence the order of the related secular equation problem is reduced by one. The routine ?lasd2 is called from ?lasd1.

Input Parameters

- \( nl \) 
  The row dimension of the upper block. \( nl \geq 1 \).

- \( nr \) 
  The row dimension of the lower block. \( nr \geq 1 \).

- \( sqre \) 
  If \( sqre = 0 \): the lower block is an \( nr \)-by-\( nr \) square matrix.
  If \( sqre = 1 \): the lower block is an \( nr \)-by-(\( nr \)+1) rectangular matrix. The bidiagonal matrix has \( n = nl + nr + 1 \) rows and \( m = n + sqre \geq n \) columns.

- \( d \) 
  Array, DIMENSION (\( n \)). On entry \( d \) contains the singular values of the two submatrices to be combined.

- \( alpha \) 
  Contains the diagonal element associated with the added row.

- \( beta \) 
  Contains the off-diagonal element associated with the added row.

- \( u \) 
  Array, DIMENSION (\( ldu, n \)). On entry \( u \) contains the left singular vectors of two submatrices in the two square blocks with corners at \((1,1), (nl, nl)\), and \((nl+2, nl+2), (n,n)\).

- \( ldu \) 
  The leading dimension of the array \( u \). \( ldu \geq n \).

- \( ldu2 \) 
  The leading dimension of the output array \( u2 \). \( ldu2 \geq n \).

- \( vt \) 
  Array, DIMENSION (\( ldvt, m \)). On entry, \( vt^T \) contains the right singular vectors of two submatrices in the two square blocks with corners at \((1,1), (nl+1, nl+1)\), and \((nl+2, nl+2), (m,m)\).

- \( ldvt \) 
  The leading dimension of the array \( vt \). \( ldvt \geq m \).

- \( ldvt2 \) 
  The leading dimension of the output array \( vt2 \). \( ldvt2 \geq m \).

- \( idxp \) 
  Workspace array, DIMENSION (\( n \)). This will contain the permutation used to place deflated values of \( D \) at the end of the array. On output \( idxp(2:k) \) points to the nondeflated \( d \)-values and \( idxp(k+1:n) \) points to the deflated singular values.

- \( idx \) 
  Workspace array, DIMENSION (\( n \)). This will contain the permutation used to sort the contents of \( d \) into ascending order.
**Workspace array, DIMENSION (n).** As workspace, this array contains a label that indicates which of the following types a column in the u2 matrix or a row in the vt2 matrix is:

1 : non-zero in the upper half only
2 : non-zero in the lower half only
3 : dense
4 : deflated.

**idxq Array, DIMENSION (n).** This parameter contains the permutation that separately sorts the two sub-problems in D in the ascending order. Note that entries in the first half of this permutation must first be moved one position backwards and entries in the second half must have \(nl+1\) added to their values.

### Output Parameters

**k**
Contains the dimension of the non-deflated matrix. This is the order of the related secular equation. \(1 \leq k \leq n\).

**d**
On exit D contains the trailing \((n-k)\) updated singular values (those which were deflated) sorted into increasing order.

**u**
On exit u contains the trailing \((n-k)\) updated left singular vectors (those which were deflated) in its last \(n-k\) columns.

**z**
Array, DIMENSION (n). On exit, z contains the updating row vector in the secular equation.

**dsigma**
Array, DIMENSION (ldu2, n). Contains a copy of the first \(k-1\) left singular values and one zero) in the secular equation.

**u2**
Array, DIMENSION (ldu2, n). Contains a copy of the first \(k-1\) left singular vectors which will be used by ?lasd3 in a matrix multiply (?gemm) to solve for the new left singular vectors. u2 is arranged into four blocks. The first block contains a column with 1 at \(nl+1\) and zero everywhere else; the second block contains non-zero entries only at and above \(nl\); the third contains non-zero entries only below \(nl+1\); and the fourth is dense.

**vt**
On exit, vt^T contains the trailing \((n-k)\) updated right singular vectors (those which were deflated) in its last \(n-k\) columns. In case \(sqre = 1\), the last row of vt spans the right null space.

**vt2**
Array, DIMENSION (ldvt2, n). vt2^T contains a copy of the first \(k\) right singular vectors which will be used by ?lasd3 in a matrix multiply (?gemm) to solve for the new right singular vectors. vt2 is arranged into three blocks. The first block contains a row that corresponds to the special 0 diagonal element in sigma; the second block contains non-zeros only at and before \(nl +1\); the third block contains non-zeros only at and after \(nl +2\).

**idxc**
Array, DIMENSION (n). This will contain the permutation used to arrange the columns of the deflated u matrix into three groups: the first group contains non-zero entries only at and above \(nl\), the second contains non-zero entries only below \(nl+2\), and the third is dense.
On exit, it is an array of dimension 4, with \textit{coltyp}(i) being the dimension of the \textit{i}-th type columns.

If \textit{info} = 0): successful exit

If \textit{info} = -i < 0, the \textit{i}-th argument had an illegal value.

\textbf{?lasd3}

\textit{Finds all square roots of the roots of the secular equation, as defined by the values in D and Z, and then updates the singular vectors by matrix multiplication. Used by ?bdsdc.}

\textbf{Syntax}

\begin{verbatim}
void slasd3( lapack_int *nl, lapack_int *nr, lapack_int *sqre, lapack_int *k, float *d, float *q, lapack_int *ldq, float *dsigma, float *u, lapack_int *ldu, float *u2, lapack_int *ldu2, float *vt, lapack_int *ldvt, float *vt2, lapack_int *ldvt2, lapack_int *idxc, lapack_int *ctot, float *z, lapack_int *info );
void dlasd3( lapack_int *nl, lapack_int *nr, lapack_int *sqre, lapack_int *k, double *d, double *q, lapack_int *ldq, double *dsigma, double *u, lapack_int *ldu, double *u2, lapack_int *ldu2, double *vt, lapack_int *ldvt, double *vt2, lapack_int *ldvt2, lapack_int *idxc, lapack_int *ctot, double *z, lapack_int *info );
\end{verbatim}

\textbf{Include Files}

• mk1.h

\textbf{Description}

The routine \textit{?lasd3} finds all the square roots of the roots of the secular equation, as defined by the values in \textit{D} and \textit{Z}.

It makes the appropriate calls to \textit{?lasd4} and then updates the singular vectors by matrix multiplication.

The routine \textit{?lasd3} is called from \textit{?lasd1}.

\textbf{Input Parameters}

\begin{itemize}
  \item \textit{nl} \quad The row dimension of the upper block. \quad \textit{nl} \geq 1.
  \item \textit{nr} \quad The row dimension of the lower block. \quad \textit{nr} \geq 1.
  \item \textit{sqre} \quad If \textit{sqre} = 0): the lower block is an \textit{nr}-by-\textit{nr} square matrix.
  \item \textit{q} \quad Workspace array, \textit{DIMENSION} at least \textit{(ldq, k)}.
  \item \textit{ldq} \quad The leading dimension of the array \textit{Q}.
\end{itemize}
$ldq \geq k$.

$dsigma$

Array, DIMENSION $(k)$. The first $k$ elements of this array contain the old roots of the deflated updating problem. These are the poles of the secular equation.

$ldu$

The leading dimension of the array $u$.

$ldu \geq n$.

$u2$

Array, DIMENSION $(ldu2, n)$.

The first $k$ columns of this matrix contain the non-deflated left singular vectors for the split problem.

$ldu2$

The leading dimension of the array $u2$.

$ldu2 \geq n$.

$ldvt$

The leading dimension of the array $vt$.

$ldvt \geq n$.

$vt2$

Array, DIMENSION $(ldvt2, n)$.

The first $k$ columns of $vt2'$ contain the non-deflated right singular vectors for the split problem.

$ldvt2$

The leading dimension of the array $vt2$.

$ldvt2 \geq n$.

$idxc$

Array, DIMENSION $(n)$.

The permutation used to arrange the columns of $u$ (and rows of $vt$) into three groups: the first group contains non-zero entries only at and above (or before) $nl +1$; the second contains non-zero entries only at and below (or after) $nl+2$; and the third is dense. The first column of $u$ and the row of $vt$ are treated separately, however. The rows of the singular vectors found by $?lasd4$ must be likewise permuted before the matrix multiplies can take place.

$ctot$

Array, DIMENSION $(4)$. A count of the total number of the various types of columns in $u$ (or rows in $vt$), as described in $idxc$.

The fourth column type is any column which has been deflated.

$z$

Array, DIMENSION $(k)$. The first $k$ elements of this array contain the components of the deflation-adjusted updating row vector.

**Output Parameters**

$d$

Array, DIMENSION $(k)$. On exit the square roots of the roots of the secular equation, in ascending order.

$u$

Array, DIMENSION $(ldu, n)$.

The last $n - k$ columns of this matrix contain the deflated left singular vectors.

$vt$

Array, DIMENSION $(ldvt, m)$.
The last \( m - k \) columns of \( vt' \) contain the deflated right singular vectors.

\[ vt2 \]

\[ z \]

\[ info \]

\( vt2 \) Destroyed on exit.

\( z \) Destroyed on exit.

If \( info = 0 \): successful exit.

If \( info = -i < 0 \), the \( i \)-th argument had an illegal value.

If \( info = 1 \), an singular value did not converge.

**Application Notes**

This code makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray XMP, Cray YMP, Cray C 90, or Cray 2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

void slasd4( lapack_int *n, lapack_int *i, float *d, float *z, float *delta, float *rho, float *sigma, float *work, lapack_int *info);

void dlasd4( lapack_int *n, lapack_int *i, double *d, double *z, double *delta, double *rho, double *sigma, double *work, lapack_int *info);

**Include Files**

- mkl.h

**Description**

The routine computes the square root of the \( i \)-th updated eigenvalue of a positive symmetric rank-one modification to a positive diagonal matrix whose entries are given as the squares of the corresponding entries in the array \( d \), and that \( 0 \leq d(i) < d(j) \) for \( i < j \) and that \( \rho > 0 \). This is arranged by the calling routine, and is no loss in generality. The rank-one modified system is thus

\[
\text{diag}(d) \cdot \text{diag}(d) + \rho \cdot Z \cdot Z^T,
\]

where the Euclidean norm of \( Z \) is equal to 1. The method consists of approximating the rational functions in the secular equation by simpler interpolating rational functions.

**Input Parameters**

\[ n \]

The length of all arrays.

\[ i \]

The index of the eigenvalue to be computed. \( 1 \leq i \leq n \).

\[ d \]

Array, DIMENSION(\( n \)).
The original eigenvalues. They must be in order, \(0 \leq d(i) < d(j)\) for \(i < j\).

\(z\)
Array, \text{DIMENSION}\((n)\).
The components of the updating vector.

\(\rho\)
The scalar in the symmetric updating formula.

\(\text{work}\)
Workspace array, \text{DIMENSION}\((n)\).
If \(n\neq 1\), \text{work} contains \((d(j) + \sigma_i)\) in its \(j\)-th component.
If \(n = 1\), then \text{work}(1) = 1.

\textbf{Output Parameters}

\(\delta\)
Array, \text{DIMENSION}\((n)\).
If \(n\neq 1\), \(\delta\) contains \((d(j) - \sigma_i)\) in its \(j\)-th component.
If \(n = 1\), then \(\delta(1) = 1\). The vector \(\delta\) contains the information necessary to construct the (singular) eigenvectors.

\(\sigma\)
The computed \(\sigma_i\), the \(i\)-th updated eigenvalue.

\(\text{info}\)
\(= 0\): successful exit
\(> 0\): If \(\text{info} = 1\), the updating process failed.

\(\text{?lasd5}\)
\textit{Computes the square root of the } i\textit{-th eigenvalue of a positive symmetric rank-one modification of a 2-by-2 diagonal matrix. Used by ?bdsdc.}\n
\textbf{Syntax}

\texttt{void slasd5( lapack_int *i, float *d, float *z, float *delta, float *rho, float *dsigma, float *work );}
\texttt{void dlasd5( lapack_int *i, double *d, double *z, double *delta, double *rho, double *dsigma, double *work );}

\textbf{Include Files}

• mkl.h

\textbf{Description}

The routine computes the square root of the \(i\)-th eigenvalue of a positive symmetric rank-one modification of a 2-by-2 diagonal matrix \(\text{diag}(d) \cdot \text{diag}(d) + \rho \cdot z \cdot z^T\).

The diagonal entries in the array \(d\) must satisfy \(0 \leq d(i) < d(j)\) for \(i < j\), \(\rho\) must be greater than 0, and that the Euclidean norm of the vector \(Z\) is equal to 1.

\textbf{Input Parameters}

\(i\)
The index of the eigenvalue to be computed. \(i = 1\) or \(i = 2\).
The original eigenvalues, $0 \leq d(1) < d(2)$.

The components of the updating vector.

The scalar in the symmetric updating formula.

Workspace array, dimension (2). Contains $(d(j) + sigma_i)$ in its $j$-th component.

Array, dimension (2).

Contains $(d(j) - sigma_i)$ in its $j$-th component. The vector $delta$ contains the information necessary to construct the eigenvectors.

The computed $sigma_i$, the $i$-th updated eigenvalue.

Computes the SVD of an updated upper bidiagonal matrix obtained by merging two smaller ones by appending a row. Used by ?bdsdc.

Include Files

- mkl.h

Description

The routine ?lasd6 computes the SVD of an updated upper bidiagonal matrix $B$ obtained by merging two smaller ones by appending a row. This routine is used only for the problem which requires all singular values and optionally singular vector matrices in factored form. $B$ is an $n$-by-$m$ matrix with $n = nl + nr + 1$ and $m = n + sqre$. A related subroutine, ?lasd1, handles the case in which all singular values and singular vectors of the bidiagonal matrix are desired. ?lasd6 computes the SVD as follows:
\[
B = V^{(in)} D^{(in)} U^{(in)} \quad (Z^{(in)} = 0)
\]

where \(Z' = (Z1' \ aZ2' \ b) = u'^*VT'\), and \(u\) is a vector of dimension \(m\) with \(alpha\) and \(beta\) in the \(nl+1\) and \(nl+2\)-th entries and zeros elsewhere; and the entry \(b\) is empty if \(sqre = 0\).

The singular values of \(B\) can be computed using \(D1\), \(D2\), the first components of all the right singular vectors of the lower block, and the last components of all the right singular vectors of the upper block. These components are stored and updated in \(vf\) and \(vl\), respectively, in \(?lasd6\). Hence \(U\) and \(VT\) are not explicitly referenced.

The singular values are stored in \(D\). The algorithm consists of two stages:

1. The first stage consists of deflating the size of the problem when there are multiple singular values or if there is a zero in the \(Z\) vector. For each such occurrence the dimension of the secular equation problem is reduced by one. This stage is performed by the routine \(?lasd7\).
2. The second stage consists of calculating the updated singular values. This is done by finding the roots of the secular equation via the routine \(?lasd4\) (as called by \(?lasd8\)). This routine also updates \(vf\) and \(vl\) and computes the distances between the updated singular values and the old singular values. \(?lasd6\) is called from \(?lasda\).

**Input Parameters**

- **icompq**
  Specifies whether singular vectors are to be computed in factored form:
  - \(= 0\): Compute singular values only
  - \(= 1\): Compute singular vectors in factored form as well.

- **nl**
  The row dimension of the upper block.
  \(nl \geq 1\).

- **nr**
  The row dimension of the lower block.
  \(nr \geq 1\).

- **sqre**
  - \(= 0\): the lower block is an \(nr\)-by-\(nr\) square matrix.
  - \(= 1\): the lower block is an \(nr\)-by-(\(nr+1\)) rectangular matrix.

  The bidiagonal matrix has row dimension \(n=nl+nr+1\), and column dimension \(m = n + sqre\).

- **d**
  Array, dimension \((nl+nr+1)\). On entry \(d(1:nl,1:nl)\) contains the singular values of the upper block, and \(d(nl+2:n)\) contains the singular values of the lower block.

- **vf**
  Array, dimension \((m)\).
  On entry, \(vf(1:nl+1)\) contains the first components of all right singular vectors of the upper block; and \(vf(nl+2:m)\) contains the first components of all right singular vectors of the lower block.

- **vl**
  Array, dimension \((m)\).
On entry, \( vl(1:n_l+1) \) contains the last components of all right singular vectors of the upper block; and \( vl(n_l+2:m) \) contains the last components of all right singular vectors of the lower block.

- **alpha**: Contains the diagonal element associated with the added row.
- **beta**: Contains the off-diagonal element associated with the added row.
- **ldgcol**: The leading dimension of the output array \( givcol \), must be at least \( n \).
- **ldgnum**: The leading dimension of the output arrays \( givnum \) and \( poles \), must be at least \( n \).
- **work**: Workspace array, dimension \( (4m) \).
- **iwork**: Workspace array, dimension \( (3n) \).

**Output Parameters**

- **d**: On exit \( d(1:n) \) contains the singular values of the modified matrix.
- **vf**: On exit, \( vf \) contains the first components of all right singular vectors of the bidiagonal matrix.
- **vl**: On exit, \( vl \) contains the last components of all right singular vectors of the bidiagonal matrix.
- **alpha**: On exit, the diagonal element associated with the added row deflated by \( \max(\|\alpha\|, \|\beta\|, \|D(I)\|), I = 1,n \).
- **beta**: On exit, the off-diagonal element associated with the added row deflated by \( \max(\|\alpha\|, \|\beta\|, \|D(I)\|), I = 1,n \).
- **idxq**: Array, dimension \( (n) \). This contains the permutation which will reintegrate the subproblem just solved back into sorted order, that is, \( d( idxq(i = 1, n) ) \) will be in ascending order.
- **perm**: Array, dimension \( (n) \). The permutations (from deflation and sorting) to be applied to each block. Not referenced if \( icompq = 0 \).
- **givpstr**: The number of Givens rotations which took place in this subproblem. Not referenced if \( icompq = 0 \).
- **givcol**: Array, dimension \( (ldgcol, 2) \). Each pair of numbers indicates a pair of columns to take place in a Givens rotation. Not referenced if \( icompq = 0 \).
- **givnum**: Array, dimension \( (ldgnum, 2) \). Each number indicates the C or S value to be used in the corresponding Givens rotation. Not referenced if \( icompq = 0 \).
- **poles**: Array, dimension \( (ldgnum, 2) \). On exit, \( poles(1,*) \) is an array containing the new singular values obtained from solving the secular equation, and \( poles(2,*) \) is an array containing the poles in the secular equation. Not referenced if \( icompq = 0 \).
- **difl**: Array, dimension \( (n) \). On exit, \( difl(i) \) is the distance between \( i \)-th updated (undeflated) singular value and the \( i \)-th (undeflated) old singular value.
difr: Array, dimension (ldgnum, 2) if icompq = 1 and dimension (n) if icompq = 0.

On exit, difr(i, 1) is the distance between i-th updated (undeflated) singular value and the i+1-th (undeflated) old singular value. If icompq = 1, difr(1: k, 2) is an array containing the normalizing factors for the right singular vector matrix.

See ?lasd8 for details on difl and difr.

z: Array, dimension (m).

The first elements of this array contain the components of the deflation-adjusted updating row vector.

k: Contains the dimension of the non-deflated matrix. This is the order of the related secular equation. 1 ≤ k ≤ n.

c: c contains garbage if sqre = 0 and the C-value of a Givens rotation related to the right null space if sqre = 1.

s: s contains garbage if sqre = 0 and the S-value of a Givens rotation related to the right null space if sqre = 1.

info: info = 0: successful exit.
< 0: if info = -i, the i-th argument had an illegal value.
> 0: if info = 1, an singular value did not converge

?lasd7: Merges the two sets of singular values together into a single sorted set. Then it tries to deflate the size of the problem. Used by ?bdsdc.

Syntax
void slasd7( lapack_int *icompq, lapack_int *nl, lapack_int *nr, lapack_int *sqre, lapack_int *k, float *d, float *z, float *zw, float *vf, float *vfw, float *vl, float *vlw, float *alpha, float *beta, float *dsigma, lapack_int *idx, lapack_int *idxp, lapack_int *idxq, lapack_int *perm, lapack_int *givptr, lapack_int *givcol, lapack_int *ldgcol, float *givnum, lapack_int *ldgnum, float *c, float *s, lapack_int *info );
void dlasd7( lapack_int *icompq, lapack_int *nl, lapack_int *nr, lapack_int *sqre, lapack_int *k, double *d, double *z, double *zw, double *vf, double *vfw, double *vl, double *vlw, double *alpha, double *beta, double *dsigma, lapack_int *idx, lapack_int *idxp, lapack_int *idxq, lapack_int *perm, lapack_int *givptr, lapack_int *givcol, lapack_int *ldgcol, double *givnum, lapack_int *ldgnum, double *c, double *s, lapack_int *info );

Include Files
• mkl.h

Description
The routine `?lasd7` merges the two sets of singular values together into a single sorted set. Then it tries to deflate the size of the problem. There are two ways in which deflation can occur: when two or more singular values are close together or if there is a tiny entry in the Z vector. For each such occurrence the order of the related secular equation problem is reduced by one. `?lasd7` is called from `?lasd6`.

**Input Parameters**

- **icompq**
  Specifies whether singular vectors are to be computed in compact form, as follows:
  - = 0: Compute singular values only.
  - = 1: Compute singular vectors of upper bidiagonal matrix in compact form.

- **nl**
  The row dimension of the upper block.
  \( nl \geq 1 \).

- **nr**
  The row dimension of the lower block.
  \( nr \geq 1 \).

- **sqre**
  - = 0: the lower block is an \( nr \)-by-\( nr \) square matrix.
  - = 1: the lower block is an \( nr \)-by-(\( nr+1 \)) rectangular matrix. The bidiagonal matrix has \( n = nl + nr + 1 \) rows and \( m = n + sqre \) columns.

- **d**
  Array, DIMENSION (\( n \)). On entry \( d \) contains the singular values of the two submatrices to be combined.

- **zw**
  Array, DIMENSION (\( m \)).
  Workspace for \( z \).

- **vf**
  Array, DIMENSION (\( m \)). On entry, \( vf(1:nl+1) \) contains the first components of all right singular vectors of the upper block; and \( vf(nl+2:m) \) contains the first components of all right singular vectors of the lower block.

- **vfw**
  Array, DIMENSION (\( m \)).
  Workspace for \( vf \).

- **vl**
  Array, DIMENSION (\( m \)).
  On entry, \( vl(1:nl+1) \) contains the last components of all right singular vectors of the upper block; and \( vl(nl+2:m) \) contains the last components of all right singular vectors of the lower block.

- **VLW**
  Array, DIMENSION (\( m \)).
  Workspace for \( VL \).

- **alpha**
  REAL for `slasd7`
  DOUBLE PRECISION for `dlasd7`.
  Contains the diagonal element associated with the added row.

- **beta**
  Contains the off-diagonal element associated with the added row.

- **idx**
  Workspace array, DIMENSION (\( n \)). This will contain the permutation used to sort the contents of \( d \) into ascending order.
Workspace array, DIMENSION (n). This will contain the permutation used to place deflated values of \( d \) at the end of the array.

Array, DIMENSION (n).

This contains the permutation which separately sorts the two sub-problems in \( d \) into ascending order. Note that entries in the first half of this permutation must first be moved one position backward; and entries in the second half must first have \( nl+1 \) added to their values.

The leading dimension of the output array \( givcol \), must be at least \( n \).

The leading dimension of the output array \( givnum \), must be at least \( n \).

**Output Parameters**

Contains the dimension of the non-deflated matrix, this is the order of the related secular equation.

\( 1 \leq k \leq n \).

On exit, \( d \) contains the trailing \( (n-k) \) updated singular values (those which were deflated) sorted into increasing order.

Array, DIMENSION (\( m \)).

On exit, \( Z \) contains the updating row vector in the secular equation.

On exit, \( vf \) contains the first components of all right singular vectors of the bidiagonal matrix.

On exit, \( vl \) contains the last components of all right singular vectors of the bidiagonal matrix.

Array, DIMENSION (n). Contains a copy of the diagonal elements \( (k-1) \) singular values and one zero) in the secular equation.

On output, \( idxp(2: k) \) points to the nondeflated \( d \)-values and \( idxp( k+1:n) \) points to the deflated singular values.

Array, DIMENSION (n).

The permutations (from deflation and sorting) to be applied to each singular block. Not referenced if \( icompq = 0 \).

The number of Givens rotations which took place in this subproblem. Not referenced if \( icompq = 0 \).

Array, DIMENSION ( \( ldgcol \), 2 ). Each pair of numbers indicates a pair of columns to take place in a Givens rotation. Not referenced if \( icompq = 0 \).

Array, DIMENSION ( \( ldgnum \), 2 ). Each number indicates the \( C \) or \( S \) value to be used in the corresponding Givens rotation. Not referenced if \( icompq = 0 \).

If \( sqre = 0 \), then \( c \) contains garbage, and if \( sqre = 1 \), then \( c \) contains \( C \)-value of a Givens rotation related to the right null space.

If \( sqre = 0 \), then \( s \) contains garbage, and if \( sqre = 1 \), then \( s \) contains \( S \)-value of a Givens rotation related to the right null space.
info

= 0: successful exit.
< 0: if info = -i, the i-th argument had an illegal value.

?lasd8

Finds the square roots of the roots of the secular equation, and stores, for each element in D, the distance to its two nearest poles. Used by ?bdsdc.

Syntax

void slasd8 ( lapack_int *icompq, lapack_int *k, float *d, float *z, float *vf, float *vl, float *difl, float *difr, lapack_int *lddifr, float *dsigma, float *work,
  lapack_int *info );

void dlasd8 ( lapack_int *icompq, lapack_int *k, double *d, double *z, double *vf, double *vl, double *difl, double *difr, lapack_int *lddifr, double *dsigma, double *work,
  lapack_int *info );

Include Files

• mkl.h

Description

The routine ?lasd8 finds the square roots of the roots of the secular equation, as defined by the values in dsigma and z. It makes the appropriate calls to ?lasd4, and stores, for each element in d, the distance to its two nearest poles (elements in dsigma). It also updates the arrays vf and vl, the first and last components of all the right singular vectors of the original bidiagonal matrix. ?lasd8 is called from ?lasd6.

Input Parameters

icompq

Specifies whether singular vectors are to be computed in factored form in the calling routine:

= 0: Compute singular values only.
= 1: Compute singular vectors in factored form as well.

k

The number of terms in the rational function to be solved by ?lasd4. k ≥ 1.

z

Array, DIMENSION ( k ).

The first k elements of this array contain the components of the deflation-adjusted updating row vector.

vf

Array, DIMENSION ( k ).

On entry, vf contains information passed through dbede8.

vl

Array, DIMENSION ( k ). On entry, vl contains information passed through dbede8.

lddifr

The leading dimension of the output array difr, must be at least k.

dsigma

Array, DIMENSION ( k ).

The first k elements of this array contain the old roots of the deflated updating problem. These are the poles of the secular equation.
work

Workspace array, DIMENSION at least (3k).

Output Parameters

d
Array, DIMENSION ( k ).
On output, D contains the updated singular values.

z
Updated on exit.

vf
On exit, vf contains the first k components of the first components of all right singular vectors of the bidiagonal matrix.

vl
On exit, vl contains the first k components of the last components of all right singular vectors of the bidiagonal matrix.

difl
Array, DIMENSION ( k ). On exit, difl(i) = d(i) - dsigma(i).

difr
Array,
DIMENSION ( lddifr, 2 ) if icompq = 1 and
DIMENSION ( k ) if icompq = 0.
On exit, difr(i,1) = d(i) - dsigma(i+1), difr(k,1) is not defined and will not be referenced. If icompq = 1, difr(1:k,2) is an array containing the normalizing factors for the right singular vector matrix.

dsigma
The elements of this array may be very slightly altered in value.

info
= 0: successful exit.
< 0: if info = -i, the i-th argument had an illegal value.
> 0: If info = 1, an singular value did not converge.

?lasd9

Finds the square roots of the roots of the secular equation, and stores, for each element in D, the distance to its two nearest poles. Used by ?bdsdc.

Syntax

void slasd9( lapack_int *icompq, lapack_int *k, float *d, float *z, float *vf, float *vl, float *difl, float *difr, float *dsigma, float *work, lapack_int *info );
void dlasd9( lapack_int *icompq, lapack_int *k, double *d, double *z, double *vf, double *vl, double *difl, double *difr, double *dsigma, double *work, lapack_int *info );

• mkl.h

Description

The routine ?lasd9 finds the square roots of the roots of the secular equation, as defined by the values in dsigma and z. It makes the appropriate calls to ?lasd4, and stores, for each element in d, the distance to its two nearest poles (elements in dsigma). It also updates the arrays vf and vl, the first and last components of all the right singular vectors of the original bidiagonal matrix. ?lasd9 is called from ?lasd7.
Input Parameters

icomq

Specifies whether singular vectors are to be computed in factored form in the calling routine:

If icomq = 0, compute singular values only;
If icomq = 1, compute singular vector matrices in factored form also.

k

The number of terms in the rational function to be solved by slasd4. k ≥ 1.

dsigma

Array, DIMENSION(k).
The first k elements of this array contain the old roots of the deflated updating problem. These are the poles of the secular equation.

z

Array, DIMENSION(k). The first k elements of this array contain the components of the deflation-adjusted updating row vector.

vf

Array, DIMENSION(k). On entry, vf contains information passed through sbede8.

vl

Array, DIMENSION(k). On entry, vl contains information passed through sbede8.

work

Workspace array, DIMENSION at least (3k).

Output Parameters

d

Array, DIMENSION(k). d(i) contains the updated singular values.

vf

On exit, vf contains the first k components of the first components of all right singular vectors of the bidiagonal matrix.

vl

On exit, vl contains the first k components of the last components of all right singular vectors of the bidiagonal matrix.

difl

Array, DIMENSION(k).
On exit, difl(i) = d(i) - dsigma(i).

difr

Array,
DIMENSION (ldu, 2) if icomq = 1 and
DIMENSION (k) if icomq = 0.
On exit, difr(i, 1) = d(i) - dsigma(i+1), difr(k, 1) is not defined and will not be referenced.
If icomq = 1, difr(1:k, 2) is an array containing the normalizing factors for the right singular vector matrix.

info

= 0: successful exit.
< 0: if info = -i, the i-th argument had an illegal value.
> 0: If info = 1, an singular value did not converge
?lasda

Computes the singular value decomposition (SVD) of a real upper bidiagonal matrix with diagonal d and off-diagonal e. Used by ?bdsdc.

Syntax

void slasda( lapack_int *icompq, lapack_int *smlsiz, lapack_int *n, lapack_int *sqre, float *d, float *e, float *u, lapack_int *ldu, float *vt, lapack_int *k, float *difl, float *difr, float *z, float *poles, lapack_int *givptr, lapack_int *givcol, lapack_int *ldgcol, lapack_int *perm, float *givnum, float *c, float *s, float *work, lapack_int *iwork, lapack_int *info );

void dlasda( lapack_int *icompq, lapack_int *smlsiz, lapack_int *n, lapack_int *sqre, double *d, double *e, double *u, lapack_int *ldu, double *vt, lapack_int *k, double *difl, double *difr, double *z, double *poles, lapack_int *givptr, lapack_int *givcol, lapack_int *ldgcol, lapack_int *perm, double *givnum, double *c, double *s, double *work, lapack_int *iwork, lapack_int *info );

Include Files

• mkl.h

Description

Using a divide and conquer approach, ?lasda computes the singular value decomposition (SVD) of a real upper bidiagonal n-by-m matrix B with diagonal d and off-diagonal e, where m = n + sqre.

The algorithm computes the singular values in the $\text{SVDB} = U*S*VT$. The orthogonal matrices $U$ and $VT$ are optionally computed in compact form. A related subroutine ?lasd0 computes the singular values and the singular vectors in explicit form.

Input Parameters

icompq

Specifies whether singular vectors are to be computed in compact form, as follows:

= 0: Compute singular values only.

= 1: Compute singular vectors of upper bidiagonal matrix in compact form.

smlsiz

The maximum size of the subproblems at the bottom of the computation tree.

n

The row dimension of the upper bidiagonal matrix. This is also the dimension of the main diagonal array d.

sqre

Specifies the column dimension of the bidiagonal matrix.

If sqre = 0: the bidiagonal matrix has column dimension $m = n$

If sqre = 1: the bidiagonal matrix has column dimension $m = n + 1$.

d

Array, DIMENSION (n). On entry, d contains the main diagonal of the bidiagonal matrix.

e

Array, DIMENSION (m - 1). Contains the subdiagonal entries of the bidiagonal matrix. On exit, e is destroyed.
The leading dimension of arrays $u$, $vt$, $difl$, $difr$, $poles$, $givnum$, and $z$. $ldu \geq n$.

The leading dimension of arrays $givcol$ and $perm$. $ldgcol \geq n$.

Workspace array, DIMENSION $(6n+smlsiz+1)^2$.

Workspace array, Dimension must be at least $(7n)$.

**Output Parameters**

On exit $d$, if $info = 0$, contains the singular values of the bidiagonal matrix.

Array, DIMENSION $(ldu, smlsiz)$ if $icompq = 1$.

Not referenced if $icompq = 0$.

If $icompq = 1$, on exit, $u$ contains the left singular vector matrices of all subproblems at the bottom level.

Array, DIMENSION $(ldu, smlsiz+1)$ if $icompq = 1$, and not referenced if $icompq = 0$. If $icompq = 1$, on exit, $vt'$ contains the right singular vector matrices of all subproblems at the bottom level.

Array, DIMENSION $(n)$ if $icompq = 1$ and

DIMENSION $(1)$ if $icompq = 0$.

If $icompq = 1$, on exit, $k(i)$ is the dimension of the $i$-th secular equation on the computation tree.

REAL for slasda

DOUBLE PRECISION for dlasda.

Array, DIMENSION $(ldu, nlvl)$,

where $nlvl = \text{floor}(\log_2(n/smlsiz))$.

Array,

DIMENSION $(ldu, 2nlvl)$ if $icompq = 1$ and

DIMENSION $(n)$ if $icompq = 0$.

If $icompq = 1$, on exit, $difl(1:n, i)$ and $difr(1:n, 2i-1)$ record distances between singular values on the $i$-th level and singular values on the $(i-1)$-th level, and $difr(1:n, 2i)$ contains the normalizing factors for the right singular vector matrix. See \texttt{?lasd8} for details.

Array,

DIMENSION $(ldu, nlvl)$ if $icompq = 1$ and

DIMENSION $(n)$ if $icompq = 0$. The first $k$ elements of $z(1, i)$ contain the components of the deflation-adjusted updating row vector for subproblems on the $i$-th level.

Array, DIMENSION$(ldu, 2*nlvl)$
if $\text{icompq} = 1$, and not referenced if $\text{icompq} = 0$. If $\text{icompq} = 1$, on exit, $\text{poles}(1, 2i - 1)$ and $\text{poles}(1, 2i)$ contain the new and old singular values involved in the secular equations on the $i$-th level.

$\text{givptr}$ Array, DIMENSION $(n)$ if $\text{icompq} = 1$, and not referenced if $\text{icompq} = 0$. If $\text{icompq} = 1$, on exit, $\text{givptr}(i)$ records the number of Givens rotations performed on the $i$-th problem on the computation tree.

$\text{givcol}$ Array, DIMENSION $(\text{ldgcol}, 2*\text{nlvl})$ if $\text{icompq} = 1$, and not referenced if $\text{icompq} = 0$. If $\text{icompq} = 1$, on exit, for each $i$, $\text{givcol}(1, 2i - 1)$ and $\text{givcol}(1, 2i)$ record the locations of Givens rotations performed on the $i$-th level on the computation tree.

$\text{perm}$ Array, DIMENSION $(\text{ldgcol}, 2*\text{nlvl})$ if $\text{icompq} = 1$, and not referenced if $\text{icompq} = 0$. If $\text{icompq} = 1$, on exit, $\text{perm}(1, i)$ records permutations done on the $i$-th level of the computation tree.

$\text{givnum}$ Array, DIMENSION $(\text{ldu}, 2*\text{nlvl})$ if $\text{icompq} = 1$, and not referenced if $\text{icompq} = 0$. If $\text{icompq} = 1$, on exit, for each $i$, $\text{givnum}(1, 2i - 1)$ and $\text{givnum}(1, 2i)$ record the $C$- and $S$-values of Givens rotations performed on the $i$-th level on the computation tree.

$c$ Array,
DIMENSION $(n)$ if $\text{icompq} = 1$, and
DIMENSION $(1)$ if $\text{icompq} = 0$.
If $\text{icompq} = 1$ and the $i$-th subproblem is not square, on exit, $c(i)$ contains the $C$-value of a Givens rotation related to the right null space of the $i$-th subproblem.

$s$ Array,
DIMENSION $(n)$ if $\text{icompq} = 1$, and
DIMENSION $(1)$ if $\text{icompq} = 0$.
If $\text{icompq} = 1$ and the $i$-th subproblem is not square, on exit, $s(i)$ contains the $S$-value of a Givens rotation related to the right null space of the $i$-th subproblem.

$info$ = 0: successful exit.
< 0: if $info = -i$, the $i$-th argument had an illegal value
> 0: If $info = 1$, an singular value did not converge

$\text{slasdq}$
Computes the SVD of a real bidiagonal matrix with diagonal $d$ and off-diagonal $e$. Used by $\text{bdsdc}$.

Syntax
void slasdq( char *uplo, lapack_int *sqre, lapack_int *n, lapack_int *ncvt, lapack_int *nru, lapack_int *ncc, float *d, float *e, float *vt, lapack_int *ldvt, float *u, lapack_int *ldu, float *c, lapack_int *ldc, float *work, lapack_int *info );
void dlasdq( char *uplo, lapack_int *sqre, lapack_int *n, lapack_int *ncvt, lapack_int *nru, lapack_int *ncc, double *d, double *e, double *vt, lapack_int *ldvt, double *u, lapack_int *ldu, double *c, lapack_int *ldc, double *work, lapack_int *info );

Include Files

- mkl.h

Description

The routine ?lasdq computes the singular value decomposition (SVD) of a real (upper or lower) bidiagonal matrix with diagonal \( d \) and off-diagonal \( e \), accumulating the transformations if desired. If \( B \) is the input bidiagonal matrix, the algorithm computes orthogonal matrices \( Q \) and \( P \) such that \( B = Q \cdot S \cdot P^T \). The singular values \( S \) are overwritten on \( d \).

The input matrix \( U \) is changed to \( U \cdot Q \) if desired.

The input matrix \( VT \) is changed to \( P^T \cdot VT \) if desired.

The input matrix \( C \) is changed to \( Q^T \cdot C \) if desired.

Input Parameters

\textbf{uplo}

On entry, \textit{uplo} specifies whether the input bidiagonal matrix is upper or lower bidiagonal.

If \textit{uplo} = 'U' or 'u', \( B \) is upper bidiagonal;

If \textit{uplo} = 'L' or 'l', \( B \) is lower bidiagonal.

\textbf{sqre}

\( = 0 \): then the input matrix is \( n \)-by-\( n \).

\( = 1 \): then the input matrix is \( n \)-by-(\( n + 1 \)) if \textit{uplo} = 'U' and \( (n + 1) \)-by-\( n \) if \textit{uplo} = 'L'. The bidiagonal matrix has \( n = n \cdot l + n \cdot r + 1 \) rows and \( m = n + sqre \geq n \) columns.

\textbf{n}

On entry, \( n \) specifies the number of rows and columns in the matrix. \( n \) must be at least 0.

\textbf{ncvt}

On entry, \( ncvt \) specifies the number of columns of the matrix \( VT \). \( ncvt \) must be at least 0.

\textbf{nru}

On entry, \( nru \) specifies the number of rows of the matrix \( U \). \( nru \) must be at least 0.

\textbf{ncc}

On entry, \( ncc \) specifies the number of columns of the matrix \( C \). \( ncc \) must be at least 0.

\textbf{d}

Array, DIMENSION \( (n) \). On entry, \( d \) contains the diagonal entries of the bidiagonal matrix.

\textbf{e}

Array, DIMENSION is \( (n-1) \) if \( sqre = 0 \) and \( n \) if \( sqre = 1 \). On entry, the entries of \( e \) contain the off-diagonal entries of the bidiagonal matrix.

\textbf{vt}

Array, DIMENSION \( (ldvt, ncvt) \). On entry, contains a matrix which on exit has been premultiplied by \( P^T \), dimension \( n \)-by-\( ncvt \) if \( sqre = 0 \) and \( (n + 1) \)-by-\( ncvt \) if \( sqre = 1 \) (not referenced if \( ncvt = 0 \)).
On entry, \textit{ldvt} specifies the leading dimension of \textit{vt} as declared in the calling (sub) program. \textit{ldvt} must be at least 1. If \textit{ncvt} is nonzero, \textit{ldvt} must also be at least \textit{n}.

\textit{u} Array, \textit{DIMENSION} (\textit{ldu}, \textit{n}). On entry, contains a matrix which on exit has been postmultiplied by \textit{Q}, dimension \textit{nru}-by-\textit{n} if \textit{sqre} = 0 and \textit{nru}-by-(\textit{n} + 1) if \textit{sqre} = 1 (not referenced if \textit{nru}=0).

On entry, \textit{ldu} specifies the leading dimension of \textit{u} as declared in the calling (sub) program. \textit{ldu} must be at least \textit{max}(1, \textit{nru}).

\textit{c} Array, \textit{DIMENSION} (\textit{ldc}, \textit{ncc}). On entry, contains an \textit{n}-by-\textit{ncc} matrix which on exit has been premultiplied by \textit{Q'}, dimension \textit{n}-by-\textit{ncc} if \textit{sqre} = 0 and (\textit{n}+1)-by-\textit{ncc} if \textit{sqre} = 1 (not referenced if \textit{ncc}=0).

On entry, \textit{ldc} specifies the leading dimension of \textit{C} as declared in the calling (sub) program. \textit{ldc} must be at least 1. If \textit{ncc} is non-zero, \textit{ldc} must also be at least \textit{n}.

\textit{work} Array, \textit{DIMENSION} (4\textit{n}). This is a workspace array. Only referenced if one of \textit{ncvt}, \textit{nru}, or \textit{ncc} is nonzero, and if \textit{n} is at least 2.

**Output Parameters**

\textit{d} On normal exit, \textit{d} contains the singular values in ascending order.

\textit{e} On normal exit, \textit{e} will contain 0. If the algorithm does not converge, \textit{d} and \textit{e} will contain the diagonal and superdiagonal entries of a bidiagonal matrix orthogonally equivalent to the one given as input.

On exit, the matrix has been premultiplied by \textit{P}'.

On exit, the matrix has been postmultiplied by \textit{Q}.

On exit, the matrix has been premultiplied by \textit{Q'}.

On exit, a value of 0 indicates a successful exit. If \textit{info} < 0, argument number \textit{-info} is illegal. If \textit{info} > 0, the algorithm did not converge, and \textit{info} specifies how many superdiagonals did not converge.

**?lasdt**

*Creates a tree of subproblems for bidiagonal divide and conquer. Used by ?bdsdc.*

**Syntax**

```c
void slasdt( lapack_int *n, lapack_int *lvl, lapack_int *nd, lapack_int *inode,
            lapack_int *ndiml, lapack_int *ndimr, lapack_int *msub );
void dlasdt( lapack_int *n, lapack_int *lvl, lapack_int *nd, lapack_int *inode,
            lapack_int *ndiml, lapack_int *ndimr, lapack_int *msub );
```

**Include Files**

- mkl.h
Description

The routine creates a tree of subproblems for bidiagonal divide and conquer.

Input Parameters

- \( n \)
  - On entry, the number of diagonal elements of the bidiagonal matrix.
- \( m_{sub} \)
  - On entry, the maximum row dimension each subproblem at the bottom of the tree can be of.

Output Parameters

- \( lvl \)
  - On exit, the number of levels on the computation tree.
- \( nd \)
  - On exit, the number of nodes on the tree.
- \( inode \)
  - Array, \( \text{DIMENSION} (n) \). On exit, centers of subproblems.
- \( ndiml \)
  - Array, \( \text{DIMENSION} (n) \). On exit, row dimensions of left children.
- \( ndimr \)
  - Array, \( \text{DIMENSION} (n) \). On exit, row dimensions of right children.

?laset

Initializes the off-diagonal elements and the diagonal elements of a matrix to given values.

Syntax

```c
lapack_int LAPACKE_slaset (int matrix_layout, char uplo, lapack_int m, lapack_int n, float alpha, float beta, float * a, lapack_int lda);
```

```c
lapack_int LAPACKE_dlaset (int matrix_layout, char uplo, lapack_int m, lapack_int n, double alpha, double beta, double * a, lapack_int lda);
```

```c
lapack_int LAPACKE_claset (int matrix_layout, char uplo, lapack_int m, lapack_int n, lapack_complex_float alpha, lapack_complex_float beta, lapack_complex_float * a, lapack_int lda);
```

```c
lapack_int LAPACKE_zlaset (int matrix_layout, char uplo, lapack_int m, lapack_int n, lapack_complex_double alpha, lapack_complex_double beta, lapack_complex_double * a, lapack_int lda);
```

Include Files

- mkl.h

Description

The routine initializes an \( m \)-by-\( n \) matrix \( A \) to \( beta \) on the diagonal and \( alpha \) on the off-diagonals.

Input Parameters

- \( matrix\_layout \)
  - Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- \( uplo \)
  - Specifies the part of the matrix \( A \) to be set.
If $\text{uplo} = 'U'$, upper triangular part is set; the strictly lower triangular part of $A$ is not changed.

If $\text{uplo} = 'L'$, lower triangular part is set; the strictly upper triangular part of $A$ is not changed.

Otherwise: All of the matrix $A$ is set.

$m$
The number of rows of the matrix $A$. $m \geq 0$.

$n$
The number of columns of the matrix $A$. $n \geq 0$.

$\alpha, \beta$
The constants to which the off-diagonal and diagonal elements are to be set, respectively.

$a$
Array, size at least $\max(1, \text{lda} \times n)$ for column major and $\max(1, \text{lda} \times m)$ for row major layout.

The array $a$ contains the $m$-by-$n$ matrix $A$.

$\text{lda}$
The leading dimension of the array $a$.

$\text{lda} \geq \max(1, m)$ for column major layout and $\text{lda} \geq \max(1, n)$ for row major layout.

Output Parameters

On exit, the leading $m$-by-$n$ submatrix of $A$ is set as follows:

- If $\text{uplo} = 'U'$, $A_{ij} = \alpha$, $1 \leq i \leq j - 1$, $1 \leq j \leq n$,
- If $\text{uplo} = 'L'$, $A_{ij} = \alpha$, $j + 1 \leq i \leq m$, $1 \leq j \leq n$,
- otherwise, $A_{ij} = \alpha$, $1 \leq i \leq m$, $1 \leq j \leq n$, $i \neq j$,
- and, for all $\text{uplo}$, $A_{ij} = \beta$, $1 \leq i \leq \min(m, n)$.

Return Values

This function returns a value $\text{info}$.

- If $\text{info} = 0$, the execution is successful.
- If $\text{info} = i < 0$, the $i$-th parameter had an illegal value.
- If $\text{info} = -1011$, memory allocation error occurred.

?lasrt

Sorts numbers in increasing or decreasing order.

Syntax

```c
lapack_int LAPACKE_slasrt (char id , lapack_int n , float * d );
lapack_int LAPACKE_dlasrt (char id , lapack_int n , double * d );
```

Include Files

- `mkl.h`
Description

The routine `?lasrt` sorts the numbers in `d` in increasing order (if `id = 'I'`) or in decreasing order (if `id = 'D'`). It uses Quick Sort, reverting to Insertion Sort on arrays of size \( \leq 20 \). Dimension of stack limits \( n \) to about \( 2^{32} \).

Input Parameters

\[ id \]
- `id = 'I'`: sort `d` in increasing order;
- `id = 'D'`: sort `d` in decreasing order.

\[ n \]
The length of the array `d`.

\[ d \]
On entry, the array to be sorted.

Output Parameters

\[ d \]
On exit, `d` has been sorted into increasing order

\[ d[0] \leq d[1] \leq ... \leq d[n-1] \] or into decreasing order

\[ d[0] \geq d[1] \geq ... \geq d[n-1] \], depending on `id`.

Return Values

This function returns a value `info`.

If `info = 0`, the execution is successful.

If `info < 0`, the i-th parameter had an illegal value.

?laswp

Performs a series of row interchanges on a general rectangular matrix.

Syntax

```c
lapack_int LAPACKE_slaswp (int matrix_layout, lapack_int n, float * a, lapack_int lda, lapack_int k1, lapack_int k2, const lapack_int * ipiv, lapack_int incx);
```

```c
lapack_int LAPACKE_dlaswp (int matrix_layout, lapack_int n, double * a, lapack_int lda, lapack_int k1, lapack_int k2, const lapack_int * ipiv, lapack_int incx);
```

```c
lapack_int LAPACKE_claswp (int matrix_layout, lapack_int n, lapack_complex_float * a, lapack_int lda, lapack_int k1, lapack_int k2, const lapack_int * ipiv, lapack_int incx);
```

```c
lapack_int LAPACKE_zlaswp (int matrix_layout, lapack_int n, lapack_complex_double * a, lapack_int lda, lapack_int k1, lapack_int k2, const lapack_int * ipiv, lapack_int incx);
```

Include Files

- mkl.h

Description

The routine performs a series of row interchanges on the matrix `A`. One row interchange is initiated for each of rows `k1` through `k2` of `A`. 
Input Parameters

matrix_layout
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

n
  The number of columns of the matrix A.

a
  Array, size max(1, lda*n) for column major and max(1, lda*mm) for row major layout. Here mm is not less than maximum of values ipiv[k1-1+j*|incx|], 0≤j<k2-k1.

Array a contains the m-by-n matrix A.

lda
  The leading dimension of the array a.

k1
  The first element of ipiv for which a row interchange will be done.

k2
  The last element of ipiv for which a row interchange will be done.

ipiv
  Array, size k1+(k2-k1)*|incx|).

The vector of pivot indices. Only the elements in positions k1 through k2 of ipiv are accessed.

ipiv(k) = l implies rows k and l are to be interchanged.

incx
  The increment between successive values of ipiv. If ipiv is negative, the pivots are applied in reverse order.

Output Parameters

a
  On exit, the permuted matrix.

Return Values

This function returns a value info.

If info = 0, the execution is successful.

If info = -i, the i-th parameter had an illegal value.

If info = -1011, memory allocation error occurred.

?latm1

Computes the entries of a matrix as specified.

Syntax

void slatm1 (lapack_int *mode, *cond, lapack_int *irsign, lapack_int *idist, lapack_int *iseed, float *d, lapack_int *n, lapack_int *info);
void dlatm1 (lapack_int *mode, *cond, lapack_int *irsign, lapack_int *idist, lapack_int *iseed, double *d, lapack_int *n, lapack_int *info);
void clatm1 (lapack_int *mode, *cond, lapack_int *irsign, lapack_int *idist, lapack_int *iseed, lapack_complex *d, lapack_int *n, lapack_int *info);
void zlatm1 (lapack_int *mode, *cond, lapack_int *irsign, lapack_int *idist, lapack_int *iseed, lapack_complex_double *d, lapack_int *n, lapack_int *info);
Include Files

- mkl.h

Description

The ?latm1 routine computes the entries of \(D(1..n)\) as specified by mode, cond and irsign. idist and iseed determine the generation of random numbers.

?latm1 is called by slatmr (for slatm1 and dlatm1), and by clatmr (for clatm1 and zlatm1) to generate random test matrices for LAPACK programs.

Input Parameters

- **mode**
  
  On entry describes how \(d\) is to be computed:
  
  - \(mode = 0\) means do not change \(d\).
  - \(mode = 1\) sets \(d[0] = 1\) and \(d[1:n - 1] = 1.0/\text{cond}\)
  - \(mode = 2\) sets \(d[0:n - 2] = 1\) and \(d[n - 1] = 1.0/\text{cond}\)
  - \(mode = 3\) sets \(d[i - 1] = \text{cond}**(-(i-1)/(n-1))\)
  - \(mode = 4\) sets \(d[i - 1] = 1 - (i-1)/(n-1)*(1 - 1/\text{cond})\)
  - \(mode = 5\) sets \(d\) to random numbers in the range \((1/\text{cond}, 1)\) such that their logarithms are uniformly distributed.
  - \(mode = 6\) sets \(d\) to random numbers from same distribution as the rest of the matrix.
  
  \(mode < 0\) has the same meaning as abs(\(mode\)), except that the order of the elements of \(d\) is reversed.
  
  Thus if \(mode\) is positive, \(d\) has entries ranging from 1 to 1/\text{cond}, if negative, from 1/\text{cond} to 1.

- **cond**
  
  On entry, used as described under mode above. If used, it must be \(\geq 1\).

- **irsign**
  
  On entry, if \(mode\) is not -6, 0, or 6, determines sign of entries of \(d\).
  
  If \(irsign = 0\), entries of \(d\) are unchanged.
  
  If \(irsign = 1\), each entry of \(d\) is multiplied by a random complex number uniformly distributed with absolute value 1.

- **idist**
  
  Specifies the distribution of the random numbers.
  
  For slatm1 and dlatm1:
  
  - \(= 1\): uniform \((0,1)\)
  - \(= 2\): uniform \((-1,1)\)
  - \(= 3\): normal \((0,1)\)
  
  For clatm1 and zlatm1:
  
  - \(= 1\): real and imaginary parts each uniform \((0,1)\)
  - \(= 2\): real and imaginary parts each uniform \((-1,1)\)
  - \(= 3\): real and imaginary parts each normal \((0,1)\)
  - \(= 4\): complex number uniform in disk(0, 1)
iseed Array, size (4).

Specifies the seed of the random number generator. The random number generator uses a linear congruential sequence limited to small integers, and so should produce machine independent random numbers. The values of iseed[3] are changed on exit, and can be used in the next call to ?latm1 to continue the same random number sequence.

d Array, size n.

Number of entries of d.

Output Parameters

iseed On exit, the seed is updated.

If info = 0, the execution is successful.

If info = -1, mode is not in range -6 to 6.

If info = -2, mode is neither -6, 0 nor 6, and irsign is neither 0 nor 1.

If info = -3, mode is neither -6, 0 nor 6 and cond is less than 1.

If info = -4, mode equals 6 or -6 and idist is not in range 1 to 4.

If info = -7, n is negative.

?latm2

Returns an entry of a random matrix.

Syntax

float slatm2 (lapack_int *m, lapack_int *n, lapack_int *i, lapack_int *j, lapack_int *kl, lapack_int *ku, lapack_int *idist, lapack_int *iseed, float *d, lapack_int *igrade, float *dl, float *dr, lapack_int *ipvtng, lapack_int *iwork, float *sparse);

double dlatm2 (lapack_int *m, lapack_int *n, lapack_int *i, lapack_int *j, lapack_int *kl, lapack_int *ku, lapack_int *idist, lapack_int *iseed, double *d, lapack_int *igrade, double *dl, double *dr, lapack_int *ipvtng, lapack_int *iwork, double *sparse);

The data types for complex variations depend on whether or not the application links with Gnu Fortran (gfortran) libraries.

For non-gfortran (libmkl_intel_*) interface libraries:

void clatm2 (lapack_complex_float *res, lapack_int *m, lapack_int *n, lapack_int *i, lapack_int *j, lapack_int *kl, lapack_int *ku, lapack_int *idist, lapack_int *iseed, lapack_complex_float *d, lapack_int *igrade, lapack_complex_float *dl, lapack_complex_float *dr, lapack_int *ipvtng, lapack_int *iwork, float *sparse);

void zlatm2 (lapack_complex_double *res, lapack_int *m, lapack_int *n, lapack_int *i, lapack_int *j, lapack_int *kl, lapack_int *ku, lapack_int *idist, lapack_int *iseed, lapack_complex_double *d, lapack_int *igrade, lapack_complex_double *dl, lapack_complex_double *dr, lapack_int *ipvtng, lapack_int *iwork, double *sparse);

For gfortran (libmkl_gf_*) interface libraries:
lapack_complex_float clatm2 (lapack_int *m, lapack_int *n, lapack_int *i, lapack_int *j, lapack_int *kl, lapack_int *ku, lapack_int *idist, lapack_int *iseed, lapack_complex_float *d, lapack_int *igrade, lapack_complex_float *dl, lapack_complex_float *dr, lapack_int *ipvtng, lapack_int *iwork, float *sparse);

lapack_complex_double zlatm2 (lapack_int *m, lapack_int *n, lapack_int *i, lapack_int *j, lapack_int *kl, lapack_int *ku, lapack_int *idist, lapack_int *iseed, lapack_complex_double *d, lapack_int *igrade, lapack_complex_double *dl, lapack_complex_double *dr, lapack_int *ipvtng, lapack_int *iwork, double *sparse);

To understand the difference between the non-gfortran and gfortran interfaces and when to use each of them, see Dynamic Libraries in the lib/intel64 Directory in the Intel® MKL Developer Guide.

Description

The ?latm2 routine returns entry \((i, j)\) of a random matrix of dimension \((m, n)\). It is called by the ?latmr routine in order to build random test matrices. No error checking on parameters is done, because this routine is called in a tight loop by ?latmr which has already checked the parameters.

Use of ?latm2 differs from ?latm3 in the order in which the random number generator is called to fill in random matrix entries. With ?latm2, the generator is called to fill in the pivoted matrix columnwise. With ?latm2, the generator is called to fill in the matrix columnwise, after which it is pivoted. Thus, ?latm3 can be used to construct random matrices which differ only in their order of rows and/or columns. ?latm2 is used to construct band matrices while avoiding calling the random number generator for entries outside the band (and therefore generating random numbers).

The matrix whose \((i, j)\) entry is returned is constructed as follows (this routine only computes one entry):

- If \(i\) is outside \((1..m)\) or \(j\) is outside \((1..n)\), returns zero (this is convenient for generating matrices in band format).
- Generate a matrix \(A\) with random entries of distribution \(idist\).
- Set the diagonal to \(D\).
- Grade the matrix, if desired, from the left (by \(dl\)) and/or from the right (by \(dr\) or \(dl\)) as specified by \(igrade\).
- Permute, if desired, the rows and/or columns as specified by \(ipvtng\) and \(iwork\).
- Band the matrix to have lower bandwidth \(kl\) and upper bandwidth \(ku\).
- Set random entries to zero as specified by \(sparse\).

Input Parameters

\(m\)  
Number of rows of the matrix.

\(n\)  
Number of columns of the matrix.

\(i\)  
Row of the entry to be returned.

\(j\)  
Column of the entry to be returned.

\(kl\)  
Lower bandwidth.

\(ku\)  
Upper bandwidth.

\(idist\)  
On entry, \(idist\) specifies the type of distribution to be used to generate a random matrix.

for slatm2 and dlatm2:
= 1: uniform (0,1)
= 2: uniform (-1,1)
= 3: normal (0,1)

for clatm2 and zlatm2:
= 1: real and imaginary parts each uniform (0,1)
= 2: real and imaginary parts each uniform (-1,1)
= 3: real and imaginary parts each normal (0,1)
= 4: complex number uniform in disk (0, 1)

**iseed**
Array, size 4.
Seed for the random number generator.

**d**
Array, size \( \min(i, j) \). Diagonal entries of matrix.

**igrade**
Specifies grading of matrix as follows:
= 0: no grading
= 1: matrix premultiplied by \( \text{diag}(dl) \)
= 2: matrix postmultiplied by \( \text{diag}(dr) \)
= 3: matrix premultiplied by \( \text{diag}(dl) \) and postmultiplied by \( \text{diag}(dr) \)
= 4: matrix premultiplied by \( \text{diag}(dl) \) and postmultiplied by \( \text{inv}(\text{diag}(dl)) \)

For slatm2 and slatm2:
= 5: matrix premultiplied by \( \text{diag}(dl) \) and postmultiplied by \( \text{diag}(dl) \)

For clatm2 and zlatm2:
= 5: matrix premultiplied by \( \text{diag}(dl) \) and postmultiplied by \( \text{diag(\text{conjg}(dl))} \)
= 6: matrix premultiplied by \( \text{diag}(dl) \) and postmultiplied by \( \text{diag}(dl) \)

**dl**
Array, size \((i \text{ or } j)\), as appropriate.
Left scale factors for grading matrix.

**dr**
Array, size \((i \text{ or } j)\), as appropriate.
Right scale factors for grading matrix.

**ipvtng**
On entry specifies pivoting permutations as follows:
= 0: none
= 1: row pivoting
= 2: column pivoting
= 3: full pivoting, i.e., on both sides

**iwork**
Array, size \((i \text{ or } j)\), as appropriate. This array specifies the permutation used. The row (or column) in position \(k\) was originally in position \(iwork[k-1]\). This differs from \(\text{iwork}\) for ?latm3.
Specifies the sparsity of the matrix. If sparse matrix is to be generated, sparse should lie between 0 and 1. A uniform \((0, 1)\) random number \(x\) is generated and compared to \(\text{sparse}\). If \(x\) is larger the matrix entry is unchanged and if \(x\) is smaller the entry is set to zero. Thus on the average a fraction \(\text{sparse}\) of the entries will be set to zero.

**Output Parameters**

\(\text{iseed}\)

On exit, the seed is updated.

**Return Values**

The function returns an entry of a random matrix (for complex variations `libmkl_gf_*` interface layer/libraries return the result as the parameter \(\text{res}\)).

**slatm3**

Returns set entry of a random matrix.

**Syntax**

```c
float slatm3 (lapack_int *m, lapack_int *n, lapack_int *i, lapack_int *j, lapack_int *isub, lapack_int *jsub, lapack_int *kl, lapack_int *ku, lapack_int *idist, lapack_int *iseed, float *d, lapack_int *igrade, float *dl, float *dr, lapack_int *ipvtng, lapack_int *iwork, float *sparse);

double dlatm3 (lapack_int *m, lapack_int *n, lapack_int *i, lapack_int *j, lapack_int *isub, lapack_int *jsub, lapack_int *kl, lapack_int *ku, lapack_int *idist, lapack_int *iseed, double *d, lapack_int *igrade, double *dl, double *dr, lapack_int *ipvtng, lapack_int *iwork, double *sparse);
```

The data types for complex variations depend on whether or not the application links with Gnu Fortran (gfortran) libraries.

**For non-gfortran (libmkl_intel_*) interface libraries:**

```c
void clatm3 (lapack_complex_float *res, lapack_int *m, lapack_int *n, lapack_int *i, lapack_int *j, lapack_int *isub, lapack_int *jsub, lapack_int *kl, lapack_int *ku, lapack_int *idist, lapack_int *iseed, lapack_complex_float *d, lapack_int *igrade, lapack_complex_float *dl, lapack_complex_float *dr, lapack_int *ipvtng, lapack_int *iwork, float *sparse);

void zlatm3 (lapack_complex_double *res, lapack_int *m, lapack_int *n, lapack_int *i, lapack_int *j, lapack_int *isub, lapack_int *jsub, lapack_int *kl, lapack_int *ku, lapack_int *idist, lapack_int *iseed, lapack_complex_double *d, lapack_int *igrade, lapack_complex_double *dl, lapack_complex_double *dr, lapack_int *ipvtng, lapack_int *iwork, double *sparse);
```

**For gfortran (libmkl_gf_*) interface libraries:**

```c
lapack_complex_float clatm3 (lapack_int *m, lapack_int *n, lapack_int *i, lapack_int *j, lapack_int *isub, lapack_int *jsub, lapack_int *kl, lapack_int *ku, lapack_int *idist, lapack_int *iseed, lapack_complex_float *d, lapack_int *igrade, lapack_complex_float *dl, lapack_complex_float *dr, lapack_int *ipvtng, lapack_int *iwork, float *sparse);
```
lapack_complex_double zlatm3 (lapack_int *m, lapack_int *n, lapack_int *i, lapack_int *j, lapack_int *isub, lapack_int *jsub, lapack_int *kl, lapack_int *ku, lapack_int *idist, lapack_int *iseed, lapack_complex_double *d, lapack_int *igrade, lapack_complex_double *dl, lapack_complex_double *dr, lapack_int *ipvtng, lapack_int *iwork, double *sparse);

To understand the difference between the non-gfortran and gfortran interfaces and when to use each of them, see Dynamic Libraries in the lib/intel64 Directory in the Intel® MKL Developer Guide.

Description
The ?latm3 routine returns the (isub, jsub) entry of a random matrix of dimension (m, n) described by the other parameters. (isub, jsub) is the final position of the (i, j) entry after pivoting according to ipvtng and iwork. ?latm3 is called by the ?latmr routine in order to build random test matrices. No error checking on parameters is done, because this routine is called in a tight loop by ?latmr which has already checked the parameters.

Use of ?latm3 differs from ?latm2 in the order in which the random number generator is called to fill in random matrix entries. With ?latm2, the generator is called to fill in the pivoted matrix columnwise. With ?latm3, the generator is called to fill in the matrix columnwise, after which it is pivoted. Thus, ?latm3 can be used to construct random matrices which differ only in their order of rows and/or columns. ?latm2 is used to construct band matrices while avoiding calling the random number generator for entries outside the band (and therefore generating random numbers in different orders for different pivot orders).

The matrix whose (isub, jsub) entry is returned is constructed as follows (this routine only computes one entry):
• If isub is outside (1..m) or jsub is outside (1..n), returns zero (this is convenient for generating matrices in band format).
• Generate a matrix A with random entries of distribution idist.
• Set the diagonal to D.
• Grade the matrix, if desired, from the left (by dl) and/or from the right (by dr or dl) as specified by igrade.
• Permute, if desired, the rows and/or columns as specified by ipvtng and iwork.
• Band the matrix to have lower bandwidth kl and upper bandwidth ku.
• Set random entries to zero as specified by sparse.

Input Parameters

m
Number of rows of matrix.

n
Number of columns of matrix.

i
Row of unpivoted entry to be returned.

j
Column of unpivoted entry to be returned.

isub
Row of pivoted entry to be returned.

jsub
Column of pivoted entry to be returned.

kl
Lower bandwidth.

ku
Upper bandwidth.
**idist**

On entry, idist specifies the type of distribution to be used to generate a random matrix.

For slatm2 and dlatm2:
- $1$: uniform $(0,1)$
- $2$: uniform $(-1,1)$
- $3$: normal $(0,1)$

For clatm2 and zlatm2:
- $1$: real and imaginary parts each uniform $(0,1)$
- $2$: real and imaginary parts each uniform $(-1,1)$
- $3$: real and imaginary parts each normal $(0,1)$
- $4$: complex number uniform in disk$(0, 1)$

**iseed**

Array, size 4.

Seed for random number generator.

**d**

Array, size $(\min(i, j))$. Diagonal entries of matrix.

**igrade**

Specifies grading of matrix as follows:
- $0$: no grading
- $1$: matrix premultiplied by $\text{diag}(dl)$
- $2$: matrix postmultiplied by $\text{diag}(dr)$
- $3$: matrix premultiplied by $\text{diag}(dl)$ and postmultiplied by $\text{diag}(dr)$
- $4$: matrix premultiplied by $\text{diag}(dl)$ and postmultiplied by $\text{inv}(\text{diag}(dl))$

For slatm2 and slatm2:
- $5$: matrix premultiplied by $\text{diag}(dl)$ and postmultiplied by $\text{diag}(di)$

For clatm2 and zlatm2:
- $5$: matrix premultiplied by $\text{diag}(dl)$ and postmultiplied by $\text{diag}(\text{conjg}(dl))$
- $6$: matrix premultiplied by $\text{diag}(dl)$ and postmultiplied by $\text{diag}(dl)$

**dl**

Array, size $(i \text{ or } j$, as appropriate). Left scale factors for grading matrix.

**dr**

Array, size $(i \text{ or } j$, as appropriate). Right scale factors for grading matrix.

**ipvtng**

On entry specifies pivoting permutations as follows:
- If $ipvtng = 0$: none.
- If $ipvtng = 1$: row pivoting.
- If $ipvtng = 2$: column pivoting.
- If $ipvtng = 3$: full pivoting, i.e., on both sides.
On entry, specifies the sparsity of the matrix if sparse matrix is to be generated. *sparse* should lie between 0 and 1. A uniform(0, 1) random number *x* is generated and compared to *sparse*; if *x* is larger the matrix entry is unchanged and if *x* is smaller the entry is set to zero. Thus on the average a fraction *sparse* of the entries will be set to zero.

Array, size (i or j, as appropriate). This array specifies the permutation used. The row (or column) originally in position *k* is in position *iwork*[k - 1] after pivoting. This differs from iwork for ?latm2.

**Output Parameters**

**isub**

On exit, row of pivoted entry is updated.

**jsub**

On exit, column of pivoted entry is updated.

**iseed**

On exit, the seed is updated.

**Return Values**

The function returns an entry of a random matrix (for complex variations libmkl_gf_* interface layer/libraries return the result as the parameter *res*).

**?latm5**

Generates matrices involved in the Generalized Sylvester equation.

**Syntax**

```c
void slatm5 (*prtype, lapack_int *m, lapack_int *n, float *a, lapack_int *lda, float *b, lapack_int *ldb, float *c, lapack_int *ldc, float *d, lapack_int *ldd, float *e, lapack_int *lde, float *f, lapack_int *ldf, float *r, lapack_int *ldr, float *l, lapack_int *ldl, float *alpha, lapack_int *qblcka, lapack_int *qblckb);
void dlatm5 (*prtype, lapack_int *m, lapack_int *n, double *a, lapack_int *lda, double *b, lapack_int *ldb, double *c, lapack_int *ldc, double *d, lapack_int *ldd, double *e, lapack_int *lde, double *f, lapack_int *ldf, double *r, lapack_int *ldr, double *l, lapack_int *ldl, double *alpha, lapack_int *qblcka, lapack_int *qblckb);
void clatm5 (*prtype, lapack_int *m, lapack_int *n, lapack_complex_float *a, lapack_int *lda, lapack_complex_float *b, lapack_int *ldb, lapack_complex_float *c, lapack_int *ldc, lapack_complex_float *d, lapack_int *ldd, lapack_complex_float *e, lapack_int *lde, lapack_complex_float *f, lapack_int *ldf, lapack_complex_float *r, lapack_int *ldr, lapack_complex_float *l, lapack_int *ldl, float *alpha, lapack_int *qblcka, lapack_int *qblckb);
void zlatm5 (*prtype, lapack_int *m, lapack_int *n, lapack_complex_double *a, lapack_int *lda, lapack_complex_double *b, lapack_int *ldb, lapack_complex_double *c, lapack_int *ldc, lapack_complex_double *d, lapack_int *ldd, lapack_complex_double *e, lapack_int *lde, lapack_complex_double *f, lapack_int *ldf, lapack_complex_double *r, lapack_int *ldr, lapack_complex_double *l, lapack_int *ldl, float *alpha, lapack_int *qblcka, lapack_int *qblckb);
```

**Include Files**

- mkl.h
Description

The \texttt{latm5} routine generates matrices involved in the Generalized Sylvester equation:

\[
A \ast R - L \ast B = C \\
D \ast R - L \ast E = F
\]

They also satisfy the diagonalization condition:

\[
\begin{bmatrix}
I & -L \\
I & B
\end{bmatrix}
\begin{bmatrix}
A & R \\
I & I
\end{bmatrix} = 
\begin{bmatrix}
A \\
B
\end{bmatrix}
\]

\[
\begin{bmatrix}
I & -L \\
I & E
\end{bmatrix}
\begin{bmatrix}
D & R \\
I & I
\end{bmatrix} = 
\begin{bmatrix}
D \\
E
\end{bmatrix}
\]

Input Parameters

\texttt{prtype}

- Specifies the type of matrices to generate.
  - If \texttt{prtype} = 1, \( A \) and \( B \) are Jordan blocks, \( D \) and \( E \) are identity matrices.
    
    \( A \):
    
    If \((i == j)\) then \( A_{i,j} = 1.0 \).
    
    If \((j == i + 1)\) then \( A_{i,j} = -1.0 \).
    
    Otherwise \( A_{i,j} = 0.0, i, j = 1...m \)
    
    \( B \):
    
    If \((i == j)\) then \( B_{i,j} = 1.0 - \alpha \).
    
    If \((j == i + 1)\) then \( B_{i,j} = 1.0 \).
    
    Otherwise \( B_{i,j} = 0.0, i, j = 1...n \).
    
    \( D \):
    
    If \((i == j)\) then \( D_{i,j} = 1.0 \).
    
    Otherwise \( D_{i,j} = 0.0, i, j = 1...m \).
    
    \( E \):
    
    If \((i == j)\) then \( E_{i,j} = 1.0 \).
    
    Otherwise \( E_{i,j} = 0.0, i, j = 1...n \).
  - \( L = R \) are chosen from \([-10...10]\), which specifies the right hand sides \((C, F)\).
  - If \texttt{prtype} = 2 or 3: Triangular and/or quasi- triangular.
    
    \( A \):
    
    If \((i \leq j)\) then \( A_{i,j} = [-1...1] \).
    
    Otherwise \( A_{i,j} = 0.0, i, j = 1...M \).
    
    If \( \texttt{prtype} = 3 \) then \( A_{k+1,k+1} = A_{k,k} \);
    
    \( A_{k+1,k} = [-1...1] \); 
    
    \( \text{sign}(A_{k,k+1}) = -(\text{sign}(A_{k+1,k})) \).
\( k = 1, \ m-1, \ qblcka \)

\( B : \)
If \((i \leq j)\) then \(B_{i,j} = [-1...1]\).
Otherwise \(B_{i,j} = 0.0, \ i, j = 1...n.\)
If \(\text{prtype} = 3\) then \(B_{k+1,k+1} = B_{k,k}\)
\(B_{k+1,k} = [-1...1]\)
\(\text{sign}(B_{k,k+1}) = -(\text{sign}(B_{k+1,k}))\)
\(k = 1, n - 1, \ qblckb.\)

\( D : \)
If \((i \leq j)\) then \(D_{i,j} = [-1...1]\).
Otherwise \(D_{i,j} = 0.0, \ i, j = 1...m.\)

\( E : \)
If \((i \leq j)\) then \(E_{i,j} = [-1...1]\).
Otherwise \(E_{i,j} = 0.0, \ i, j = 1...n.\)

L, R are chosen from \([-10...10]\), which specifies the right hand sides \((C, F)\).

- If \(\text{prtype} = 4\) Full
  \(A_{i,j} = [-10...10]\)
  \(D_{i,j} = [-1...1] \ i, j = 1...m\)
  \(B_{i,j} = [-10...10]\)
  \(E_{i,j} = [-1...1] \ i, j = 1...n\)
  \(R_{i,j} = [-10...10]\)
  \(L_{i,j} = [-1...1] \ i = 1..m \ j = 1...n\)

\( L \) and \( R \) specifies the right hand sides \((C, F)\).

- If \(\text{prtype} = 5\) special case common and/or close eigs.

\( m \)
Specifies the order of \(A\) and \(D\) and the number of rows in \(C, F, R\) and \(L\).

\( n \)
Specifies the order of \(B\) and \(E\) and the number of columns in \(C, F, R\) and \(L\).

\( lda \)
The leading dimension of \(a\).

\( ldb \)
The leading dimension of \(b\).

\( ldc \)
The leading dimension of \(c\).

\( ldd \)
The leading dimension of \(d\).

\( lde \)
The leading dimension of \(e\).

\( ldf \)
The leading dimension of \(f\).

\( ldr \)
The leading dimension of \(r\).

\( ldl \)
The leading dimension of \(l\).
**SLATM6**
Generates test matrices for the generalized eigenvalue problem, their corresponding right and left eigenvector matrices, and also reciprocal condition numbers for all eigenvalues and the reciprocal condition numbers of eigenvectors corresponding to the 1th and 5th eigenvalues.

### Syntax

```c
void slatm6 (lapack_int *type, lapack_int *n, float *a, lapack_int *lda, float *b, float *x, lapack_int *ldx, float *y, lapack_int *ldy, float *alpha, float *beta, float *wx, float *wy, float *s, float *dif);
void dlatm6 (lapack_int *type, lapack_int *n, double *a, lapack_int *lda, double *b, double *x, lapack_int *ldx, double *y, lapack_int *ldy, double *alpha, double *beta, double *wx, double *wy, double *s, double *dif);
void clatm6 (lapack_int *type, lapack_int *n, lapack_complex_float *a, lapack_int *lda, lapack_complex_float *b, lapack_complex_float *x, lapack_int *ldx, lapack_complex_float *y, lapack_int *ldy, lapack_complex_float *alpha, lapack_complex_float *beta, lapack_complex_float *wx, lapack_complex_float *wy, float *s, float *dif);
```
void zlatm6 (lapack_int *type, lapack_int *n, lapack_complex_double *a, lapack_int *lda, lapack_complex_double *b, lapack_complex_double *x, lapack_int *ldx, lapack_complex_double *y, lapack_int *ldy, lapack_complex_double *alpha, lapack_complex_double *beta, lapack_complex_double *wx, lapack_complex_double *wy, double *s, double *dif);

Include Files

- mkl.h

Description

The zlatm6 routine generates test matrices for the generalized eigenvalue problem, their corresponding right and left eigenvector matrices, and also reciprocal condition numbers for all eigenvalues and the reciprocal condition numbers of eigenvectors corresponding to the 1th and 5th eigenvalues.

There two kinds of test matrix pairs:

\[(A, B) = \text{inverse}(YH) \times (Da, Db) \times \text{inverse}(X)\]

Type 1:

\[
Da = \begin{bmatrix}
1+a & 0 & 0 & 0 & 0 \\
0 & 2+a & 0 & 0 & 0 \\
0 & 0 & 3+a & 0 & 0 \\
0 & 0 & 0 & 4+a & 0 \\
0 & 0 & 0 & 0 & 5+2
\end{bmatrix}, \quad Db = \begin{bmatrix}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1
\end{bmatrix}
\]

Type 2:

\[
Da = \begin{bmatrix}
1+i & 0 & 0 & 0 & 0 \\
0 & 1-i & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & (1+a) + (1+b)i & 0 \\
0 & 0 & 0 & 0 & (1+a) - (1+b)i
\end{bmatrix}, \quad Db = \begin{bmatrix}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1
\end{bmatrix}
\]

In both cases the same inverse(YH) and inverse(X) are used to compute (A, B), giving the exact eigenvectors to (A,B) as (YH, X):

\[
YH = \begin{bmatrix}
1 & 0 & -y & y & -y \\
0 & 1 & -y & y & -y \\
0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & 1
\end{bmatrix}, \quad X = \begin{bmatrix}
1 & 0 & -x & -x & x \\
0 & 1 & x & -x & -x \\
0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & 1
\end{bmatrix},
\]

where a, b, x and y will have all values independently of each other.

Input Parameters

- **type**
  - Specifies the problem type.

- **n**
  - Size of the matrices A and B.
lda
The leading dimension of $a$ and of $b$.

ldx
The leading dimension of $x$.

ldy
The leading dimension of $y$.

alpha, beta
Weighting constants for matrix $A$.

wx
Constant for right eigenvector matrix.

wy
Constant for left eigenvector matrix.

Output Parameters

$a$
Array, size $lda*n$. On exit, $a$ contains the $n$-by-$n$ matrix initialized according to type.

$b$
Array, size $lda*n$. On exit, $b$ contains the $n$-by-$n$ matrix initialized according to type.

$x$
Array, size $ldx*n$. On exit, $x$ contains the $n$-by-$n$ matrix of right eigenvectors.

$y$
Array, size $ldy*n$. On exit, $y$ is the $n$-by-$n$ matrix of left eigenvectors.

$s$
Array, size $(n)$. $s[i-1]$ is the reciprocal condition number for eigenvalue $i$.

$\text{dif}$
Array, size$(n)$. $\text{dif}[i-1]$ is the reciprocal condition number for eigenvector $i$.

\texttt{?latme}
\textit{Generates random non-symmetric square matrices with specified eigenvalues.}

\textbf{Syntax}

void slatme (lapack_int *n, char *dist, lapack_int *iseed, float *d, lapack_int *mode, float *cond, float *dmax, char *ei, char *rsign, char *upper, char *sim, float *ds, lapack_int *modes, float *conds, lapack_int *kl, lapack_int *ku, float *anorm, float *a, lapack_int *lda, float *work, lapack_int *info);

double dmax, char *ei, char *rsign, char *upper, char *sim, double *ds, lapack_int *modes, double *conds, lapack_int *kl, lapack_int *ku, double *anorm, lapack_int *lda, lapack_int *work, lapack_int *info);
Include Files

- mkl.h

Description

The ?latme routine generates random non-symmetric square matrices with specified eigenvalues. ?latme operates by applying the following sequence of operations:

1. Set the diagonal to \( d \), where \( d \) may be input or computed according to mode, cond, dmax, and rsign as described below.
2. If upper = 'T', the upper triangle of \( a \) is set to random values out of distribution dist.
3. If sim='T', \( a \) is multiplied on the left by a random matrix \( X \), whose singular values are specified by \( ds \), modes, and conds, and on the right by \( X \) inverse.
4. If \( kl < n-1 \), the lower bandwidth is reduced to \( kl \) using Householder transformations. If \( ku < n-1 \), the upper bandwidth is reduced to \( ku \).
5. If anorm is not negative, the matrix is scaled to have maximum-element-norm anorm.

NOTE
Since the matrix cannot be reduced beyond Hessenberg form, no packing options are available.

Input Parameters

\( n \)

The number of columns (or rows) of \( A \).

\( dist \)

On entry, \( dist \) specifies the type of distribution to be used to generate the random eigen-/singular values, and on the upper triangle (see upper).

- If \( dist = 'U' \): uniform( 0, 1 )
- If \( dist = 'S' \): uniform( -1, 1 )
- If \( dist = 'N' \): normal( 0, 1 )
- If \( dist = 'D' \): uniform on the complex disc \( |z| < 1 \).

\( iseed \)

Array, size 4.

On entry \( iseed \) specifies the seed of the random number generator. The elements should lie between 0 and 4095 inclusive, and \( iseed[3] \) should be odd. The random number generator uses a linear congruential sequence limited to small integers, and so should produce machine independent random numbers.

\( d \)

Array, size \((n)\). This array is used to specify the eigenvalues of \( A \).

If mode = 0, then \( d \) is assumed to contain the eigenvalues. Otherwise they are computed according to mode, cond, dmax, and rsign and placed in \( d \).

\( mode \)

On entry \( mode \) describes how the eigenvalues are to be specified:

- \( mode = 0 \) means use \( d \) (with \( ei \) for slatme and dlatme) as input.
- \( mode = 1 \) sets \( d[0] = 1 \) and \( d[2:n]=1.0/cond \).
- \( mode = 2 \) sets \( d[0:n-2] = 1 \) and \( d[n-1]=1.0/cond \).
- \( mode = 3 \) sets \( d[i - 1] = cond**((-i-1)/(n-1)) \).
mode = 4 sets $d[i - 1] = 1 - (i-1)/(n-1)*(1 - 1/\text{cond})$.

mode = 5 sets $d$ to random numbers in the range $(1/\text{cond}, 1)$ such that their logarithms are uniformly distributed.

mode = 6 sets $d$ to random numbers from same distribution as the rest of the matrix.

mode < 0 has the same meaning as $\text{abs}(\text{mode})$, except that the order of the elements of $d$ is reversed.

Thus if mode is between 1 and 4, $d$ has entries ranging from 1 to $1/\text{cond}$, if between -1 and -4, $d$ has entries ranging from $1/\text{cond}$ to 1.

On entry, this is used as described under mode above. If used, it must be $\geq 1$.

If mode is not -6, 0 or 6, the contents of $d$ as computed according to mode and cond are scaled by $dmax / \max(\text{abs}(d[i - 1]))$. Note that dmax needs not be positive or real: if dmax is negative or complex (or zero), $d$ will be scaled by a negative or complex number (or zero). If $rsign = 'F'$ then the largest (absolute) eigenvalue will be equal to $dmax$.

$cond$ used by slatme and dlatme only.

Array, size $(n)$.

If mode = 0, and $ei[0]$ is not ' ' (space character), this array specifies which elements of $d$ (on input) are real eigenvalues and which are the real and imaginary parts of a complex conjugate pair of eigenvalues. The elements of $ei$ may then only have the values 'R' and 'I'.

If $ei[j - 1] = 'R'$ and $ei[j] = 'I'$, then the $j$-th eigenvalue is $\text{cmplx}(d[j - 1], d[j])$, and the $(j+1)$-th is the complex conjugate thereof.

If $ei[j - 1] = ei[j] = 'R'$, then the $j$-th eigenvalue is $d[j - 1]$ (i.e., real). $ei[0]$ may not be 'I', nor may two adjacent elements of $ei$ both have the value 'I'.

If mode is not 0, then $ei$ is ignored. If mode is 0 and $ei[0] = ' ' $, then the eigenvalues will all be real.

$rsign$ if mode is not 0, 6, or -6, and $rsign = 'T'$, then the elements of $d$, as computed according to mode and cond, are multiplied by a random sign (+1 or -1) for slatme and dlatme or by a complex number from the unit circle $|z| = 1$ for clatme and zlatme.

If $rsign = 'F'$, the elements of $d$ are not multiplied. $rsign$ may only have the values 'T' or 'F'.

$upper$ if upper = 'T', then the elements of $a$ above the diagonal will be set to random numbers out of dist.

If upper = 'F', they will not. upper may only have the values 'T' or 'F'.

$sim$ if sim = 'T', then $a$ will be operated on by a "similarity transform", i.e., multiplied on the left by a matrix $X$ and on the right by $X$ inverse. $X = USV$, where $U$ and $V$ are random unitary matrices and $S$ is a (diagonal) matrix of singular values specified by $ds$, modes, and conds.
If sim = 'F', then a will not be transformed.

This array is used to specify the singular values of X, in the same way that
d specifies the eigenvalues of a. If mode = 0, the ds contains the singular
values, which may not be zero.

Similar to mode, but for specifying the diagonal of S. modes = -6 and +6
are not allowed (since they would result in randomly ill-conditioned
eigenvalues.)

Similar to cond, but for specifying the diagonal of S.

This specifies the lower bandwidth of the matrix. kl = 1 specifies upper
Hessenberg form. If kl is at least n-1, then A will have full lower
bandwidth.

This specifies the upper bandwidth of the matrix. ku = 1 specifies lower
Hessenberg form.

If ku is at least n-1, then a will have full upper bandwidth.

If ku and ku are both at least n-1, then a will be dense. Only one of ku and
kl may be less than n-1.

If anorm is not negative, then a is scaled by a non-negative real number to
make the maximum-element-norm of a to be anorm.

Number of rows of matrix A.

Array, size (3*n). Workspace.

On exit, the seed is updated.

Modified if mode is nonzero.

Modified if mode is nonzero.

Array, size lda*n. On exit, a is the desired test matrix.

If info = 0, execution is successful.

If info = -1, n is negative.

If info = -2, dist is an illegal string.

If info = -5, mode is not in range -6 to 6.

If info = -6, cond is less than 1.0, and mode is not -6, 0, or 6.

If info = -9, rsign is not 'T' or 'F'.

If info = -10, upper is not 'T' or 'F'.

If info = -11, sim is not 'T' or 'F'.

If info = -12, modes = 0 and ds has a zero singular value.

If info = -13, modes is not in the range -5 to 5.

If info = -14, modes is nonzero and conds is less than 1.
If info = -15, kl is less than 1.
If info = -16, ku is less than 1, or kl and ku are both less than n-1.
If info = -19, lda is less than m.
If info = 1, error return from ?latml (computing d).
If info = 2, cannot scale to dmax (max. eigenvalue is 0).
If info = 3, error return from slatml (for slatme and clatme), dlatml (for dlatme and zlatme).
If info = 4, error return from ?large.
If info = 5, zero singular value from slatml (for slatme and clatme), dlatml (for dlatme and zlatme).

?latmr

Generates random matrices of various types.

**Syntax**

```c
void slatmr (lapack_int *m, lapack_int *n, char *dist, lapack_int *iseed, char *sym, float *d, lapack_int *mode, float *cond, float *dmax, char *rsign, char *grade, float *dl, lapack_int *model, float *condl, float *dr, lapack_int *moder, float *condr, char *pivtn, lapack_int *ipivot, lapack_int *kl, lapack_int *ku, float *sparse, float *anorm, char *pack, float *a, lapack_int *lda, lapack_int *iwork, lapack_int *info);
void dlatmr (lapack_int *m, lapack_int *n, char *dist, lapack_int *iseed, char *sym, char *dl, lapack_int *mode, double *cond, double *dmax, char *rsign, char *grade, double *dl, lapack_int *model, double *condl, double *dr, lapack_int *moder, double *condr, char *pivtn, lapack_int *ipivot, lapack_int *kl, lapack_int *ku, double *sparse, double *anorm, char *pack, double *a, lapack_int *lda, lapack_int *iwork, lapack_int *info);
void clatmr (lapack_int *m, lapack_int *n, char *dist, lapack_int *iseed, char *sym, lapack_complex _d, lapack_int *mode, float *cond, lapack_complex *dmax, char *rsign, char *grade, lapack_complex _d, lapack_int *model, float *condl, lapack_complex _dr, lapack_int *moder, float *condr, char *pivtn, lapack_int *ipivot, lapack_int *kl, lapack_int *ku, float *sparse, float *anorm, char *pack, float *a, lapack_int *lda, lapack_int *iwork, lapack_int *info);
void zlatmr (lapack_int *m, lapack_int *n, char *dist, lapack_int *iseed, char *sym, lapack_complex_double _d, lapack_int *mode, float *cond, lapack_complex_double *dmax, char *rsign, char *grade, lapack_complex_double _d, lapack_int *model, float *condl, lapack_complex_double _dr, lapack_int *moder, float *condr, char *pivtn, lapack_int *ipivot, lapack_int *kl, lapack_int *ku, float *sparse, float *anorm, char *pack, float *a, lapack_int *lda, lapack_int *iwork, lapack_int *info);
```

**Description**

The ?latmr routine operates by applying the following sequence of operations:

1. Generate a matrix $A$ with random entries of distribution $\text{dist}$:
   - If $\text{sym} = 'S'$, the matrix is symmetric,
   - If $\text{sym} = 'H$', the matrix is Hermitian,
If \( \text{sym} = 'N' \), the matrix is nonsymmetric.

2. Set the diagonal to \( D \), where \( D \) may be input or computed according to \( \text{mode} \), \( \text{cond} \), \( \text{dmax} \) and \( \text{rsign} \) as described below.

3. Grade the matrix, if desired, from the left or right as specified by grade. The inputs \( \text{dl} \), \( \text{modl} \), \( \text{condl} \), \( \text{dr} \), \( \text{modr} \) and \( \text{condr} \) also determine the grading as described below.

4. Permute, if desired, the rows and/or columns as specified by \( \text{pivtng} \) and \( \text{ipivot} \).

5. Make \( A \) a band matrix, if desired, by zeroing out the matrix outside a band of lower bandwidth \( kl \) and upper bandwidth \( ku \).

6. Scale \( A \), if desired, to have maximum entry \( \text{anorm} \).

7. Pack the matrix if desired. See options specified by the \( \text{pack} \) parameter.

---

**NOTE**

If two calls to \(?latmr\) differ only in the \( \text{pack} \) parameter, they generate mathematically equivalent matrices. If two calls to \(?latmr\) both have full bandwidth \((kl = m-1 \text{ and } ku = n-1)\), and differ only in the \( \text{pivtng} \) and \( \text{pack} \) parameters, then the matrices generated differ only in the order of the rows and columns, and otherwise contain the same data. This consistency cannot be and is not maintained with less than full bandwidth.

---

**Input Parameters**

\( m \)  
Number of rows of \( A \).

\( n \)  
Number of columns of \( A \).

\( \text{dist} \)  
On entry, \( \text{dist} \) specifies the type of distribution to be used to generate a random matrix.

- If \( \text{dist} = 'U' \), real and imaginary parts are independent uniform\(( 0, 1 )\).
- If \( \text{dist} = 'S' \), real and imaginary parts are independent uniform\(( -1, 1 )\).
- If \( \text{dist} = 'N' \), real and imaginary parts are independent normal\(( 0, 1 )\).
- If \( \text{dist} = 'D' \), distribution is uniform on interior of unit disk.

\( \text{iseed} \)  
Array, size 4.

On entry, \( \text{iseed} \) specifies the seed of the random number generator. They should lie between 0 and 4095 inclusive, and \( \text{iseed}[3] \) should be odd. The random number generator uses a linear congruential sequence limited to small integers, and so should produce machine independent random numbers.

\( \text{sym} \)  
If \( \text{sym} = 'S' \), generated matrix is symmetric.

If \( \text{sym} = 'H' \), generated matrix is Hermitian.

If \( \text{sym} = 'N' \), generated matrix is nonsymmetric.

\( d \)  
On entry this array specifies the diagonal entries of the diagonal of \( A \). \( d \) may either be specified on entry, or set according to \( \text{mode} \) and \( \text{cond} \) as described below. If the matrix is Hermitian, the real part of \( d \) is taken. May be changed on exit if \( \text{mode} \) is nonzero.

\( \text{mode} \)  
On entry describes how \( d \) is to be used:
mode = 0 means use $d$ as input.

mode = 1 sets $d[0]=1$ and $d[1:n-1]=1.0/\text{cond}$.

mode = 2 sets $d[0:n-2]=1$ and $d[n-1]=1.0/\text{cond}$.

mode = 3 sets $d[1-i]=\text{cond}^*\left(-1-i/(n-1)\right)$.

mode = 4 sets $d[1-i]=1 - (1-i)/(n-1)*(1 - 1/\text{cond})$.

mode = 5 sets $d$ to random numbers in the range $(1/\text{cond}, 1)$ such that their logarithms are uniformly distributed.

mode = 6 sets $d$ to random numbers from same distribution as the rest of the matrix.

mode < 0 has the same meaning as $\text{abs}(\text{mode})$, except that the order of the elements of $d$ is reversed.

Thus if mode is between 1 and 4, $d$ has entries ranging from 1 to $1/\text{cond}$, if between -1 and -4, $D$ has entries ranging from $1/\text{cond}$ to 1.

On entry, used as described under mode above. If used, $\text{cond}$ must be $\geq 1$.

If mode is not -6, 0, or 6, the diagonal is scaled by $d_{\text{max}} / \max(\text{abs}(d[i]))$, so that maximum absolute entry of diagonal is $\text{abs}(d_{\text{max}})$. If $d_{\text{max}}$ is complex (or zero), the diagonal is scaled by a complex number (or zero).

If mode is not -6, 0, or 6, specifies the sign of the diagonal as follows:

For slatmr and dlatmr, if $rsign = 'T'$, diagonal entries are multiplied 1 or -1 with a probability of 0.5.

For clatmr and zlatmr, if $rsign = 'T'$, diagonal entries are multiplied by a random complex number uniformly distributed with absolute value 1.

If $rsign = 'F'$, diagonal entries are unchanged.

Specifies grading of matrix as follows:

If grade = 'N', there is no grading

If grade = 'L', matrix is premultiplied by $\text{diag}(dl)$ (only if matrix is nonsymmetric)

If grade = 'R', matrix is postmultiplied by $\text{diag}(dr)$ (only if matrix is nonsymmetric)

If grade = 'B', matrix is premultiplied by $\text{diag}(dl)$ and postmultiplied by $\text{diag}(dr)$ (only if matrix is nonsymmetric)

If grade = 'H', matrix is premultiplied by $\text{diag}(dl)$ and postmultiplied by $\text{diag}(\text{conjg}(dl))$ (only if matrix is Hermitian or nonsymmetric)

If grade = 'S', matrix is premultiplied by $\text{diag}(dl)$ and postmultiplied by $\text{diag}(dl)$ (only if matrix is symmetric or nonsymmetric)

If grade = 'E', matrix is premultiplied by $\text{diag}(dl)$ and postmultiplied by $\text{inv(\text{diag}(dl))}$ (only if matrix is nonsymmetric)
NOTE
if grade = 'E', then m must equal n.

dl
Array, size (m).
If model = 0, then on entry this array specifies the diagonal entries of a diagonal matrix used as described under grade above.
If model is not zero, then dl is set according to model and condl, analogous to the way D is set according to mode and cond (except there is no dmax parameter for dl).
If grade = 'E', then dl cannot have zero entries.
Not referenced if grade = 'N' or 'R'. Changed on exit.

model
This specifies how the diagonal array dl is computed, just as mode specifies how D is computed.

condl
When model is not zero, this specifies the condition number of the computed dl.

dr
If moder = 0, then on entry this array specifies the diagonal entries of a diagonal matrix used as described under grade above.
If moder is not zero, then dr is set according to moder and condr, analogous to the way d is set according to mode and cond (except there is no dmax parameter for dr).
Not referenced if grade = 'N', 'L', 'H', 'S' or 'E'.

moder
This specifies how the diagonal array dr is to be computed, just as mode specifies how d is to be computed.

condr
When moder is not zero, this specifies the condition number of the computed dr.

pivtng
On entry specifies pivoting permutations as follows:
If pivtng = 'N' or ' ': no pivoting permutation.
If pivtng = 'L': left or row pivoting (matrix must be nonsymmetric).
If pivtng = 'R': right or column pivoting (matrix must be nonsymmetric).
If pivtng = 'B' or 'F': both or full pivoting, i.e., on both sides. In this case, m must equal n.
If two calls to ?latmr both have full bandwidth (ki = m - 1 and ku = n-1), and differ only in the pivtng and pack parameters, then the matrices generated differs only in the order of the rows and columns, and otherwise contain the same data. This consistency cannot be maintained with less than full bandwidth.

ipivot
Array, size (n or m) This array specifies the permutation used. After the basic matrix is generated, the rows, columns, or both are permuted.
If row pivoting is selected, ?latmr starts with the last row and interchanges row \( m \) and row \( \text{ipivot}[m - 1] \), then moves to the next-to-last row, interchanging rows \( [m - 2] \) and row \( \text{ipivot}[m - 2] \), and so on. In terms of "2-cycles", the permutation is \((1 \text{ipivot}[0]) (2 \text{ipivot}[1]) \ldots (\text{mipivot}[m - 1])\) where the rightmost cycle is applied first. This is the inverse of the effect of pivoting in LINPACK. The idea is that factoring (with pivoting) an identity matrix which has been inverse-pivoted in this way should result in a pivot vector identical to \( \text{ipivot} \). Not referenced if \( \text{pivtn} = 'N' \).

\( \text{sparse} \)

On entry, specifies the sparsity of the matrix if a sparse matrix is to be generated. \( \text{sparse} \) should lie between 0 and 1. To generate a sparse matrix, for each matrix entry a uniform \((0, 1)\) random number \( x \) is generated and compared to \( \text{sparse} \); if \( x \) is larger the matrix entry is unchanged and if \( x \) is smaller the entry is set to zero. Thus on the average a fraction \( \text{sparse} \) of the entries is set to zero.

\( \text{kl} \)

On entry, specifies the lower bandwidth of the matrix. For example, \( \text{kl} = 0 \) implies upper triangular, \( \text{kl} = 1 \) implies upper Hessenberg, and \( \text{kl} \) at least \( m-1 \) implies the matrix is not banded. Must equal \( \text{ku} \) if matrix is symmetric or Hermitian.

\( \text{ku} \)

On entry, specifies the upper bandwidth of the matrix. For example, \( \text{ku} = 0 \) implies lower triangular, \( \text{ku} = 1 \) implies lower Hessenberg, and \( \text{ku} \) at least \( n-1 \) implies the matrix is not banded. Must equal \( \text{kl} \) if matrix is symmetric or Hermitian.

\( \text{anorm} \)

On entry, specifies maximum entry of output matrix (output matrix is multiplied by a constant so that its largest absolute entry equal \( \text{anorm} \)) if \( \text{anorm} \) is nonnegative. If \( \text{anorm} \) is negative no scaling is done.

\( \text{pack} \)

On entry, specifies packing of matrix as follows:

- If \( \text{pack} = 'N' \): no packing
- If \( \text{pack} = 'U' \): zero out all subdiagonal entries (if symmetric or Hermitian)
- If \( \text{pack} = 'L' \): zero out all superdiagonal entries (if symmetric or Hermitian)
- If \( \text{pack} = 'C' \): store the upper triangle columnwise (only if matrix symmetric or Hermitian or square upper triangular)
- If \( \text{pack} = 'R' \): store the lower triangle columnwise (only if matrix symmetric or Hermitian or square lower triangular) (same as upper half rowwise if symmetric) (same as conjugate upper half rowwise if Hermitian)
- If \( \text{pack} = 'B' \): store the lower triangle in band storage scheme (only if matrix symmetric or Hermitian)
- If \( \text{pack} = 'Q' \): store the upper triangle in band storage scheme (only if matrix symmetric or Hermitian)
- If \( \text{pack} = 'Z' \): store the entire matrix in band storage scheme (pivoting can be provided for by using this option to store \( A \) in the trailing rows of the allocated storage)

Using these options, the various LAPACK packed and banded storage schemes can be obtained:
### LAPACK storage scheme

<table>
<thead>
<tr>
<th>Value of pack</th>
</tr>
</thead>
<tbody>
<tr>
<td>'Z'</td>
</tr>
<tr>
<td>'B' or 'Q'</td>
</tr>
<tr>
<td>'C' or 'R'</td>
</tr>
</tbody>
</table>

If two calls to `?latmr` differ only in the pack parameter, they generate mathematically equivalent matrices.

#### lda

On entry, `lda` specifies the first dimension of `a` as declared in the calling program.

If `pack` = 'N', 'U' or 'L', `lda` must be at least `max( 1, m )`.

If `pack` = 'C' or 'R', `lda` must be at least 1.

If `pack` = 'B', or 'Q', `lda` must be `min( ku + 1, n )`.

If `pack` = 'Z', `lda` must be at least `kuu + kll + 1`, where `kuu = min( ku, n-1 )` and `kll = min( kl, n-1 )`.

#### iwork

Array, size `(n or m)`. Workspace. Not referenced if `pivtng` = 'N'. Changed on exit.

### Output Parameters

#### iseed

On exit, the seed is changed.

May be changed on exit if `mode` is nonzero.

#### d

On exit, array is changed.

On exit, array is changed.

On exit, `a` is the desired test matrix. Only those entries of `a` which are significant on output is referenced (even if `a` is in packed or band storage format). The unoccupied corners of `a` in band format are zeroed out.

#### info

If `info` = 0, the execution is successful.

If `info` = -1, `m` is negative or unequal to `n` and `sym` = 'S' or 'H'.

If `info` = -2, `n` is negative.

If `info` = -3, `dist` is an illegal string.

If `info` = -5, `sym` is an illegal string.

If `info` = -7, `mode` is not in range -6 to 6.

If `info` = -8, `cond` is less than 1.0, and `mode` is neither -6, 0 nor 6.

If `info` = -10, `mode` is neither -6, 0 nor 6 and `rsign` is an illegal string.

If `info` = -11, `grade` is an illegal string, or `grade` = 'E' and `m` is not equal to `n`, or `grade='L', 'R', 'B', 'S' or 'E' and sym = 'H', or `grade = 'L', 'R', 'B', 'H' or 'E' and sym = 'S'`

If `info` = -12, `grade` = 'E' and `dl` contains zero.
If $\text{info} = -13$, model is not in range -6 to 6 and grade = 'L', 'B', 'H', 'S' or 'E'.

If $\text{info} = -14$, condl is less than 1.0, grade = 'L', 'B', 'H', 'S' or 'E', and model is neither -6, 0 nor 6.

If $\text{info} = -16$, moder is not in range -6 to 6 and grade = 'R' or 'B'.

If $\text{info} = -17$, condr is less than 1.0, grade = 'R' or 'B', and moder is neither -6, 0 nor 6.

If $\text{info} = -18$, pivtng is an illegal string, or pivtng = 'B' or 'F' and $m$ is not equal to $n$, or pivtng = 'L' or 'R' and sym = 'S' or 'H'.

If $\text{info} = -19$, ipivot contains out of range number and pivtng is not equal to 'N'.

If $\text{info} = -20$, kl is negative.

If $\text{info} = -21$, ku is negative, or sym = 'S' or 'H' and ku not equal to kl.

If $\text{info} = -22$, sparse is not in range 0 to 1.

If $\text{info} = -24$, pack is an illegal string, or pack = 'U', 'L', 'B' or 'Q' and sym = 'N', or pack = 'C' and sym = 'N' and either kl is not equal to 0 or n is not equal to $m$, or pack = 'R' and sym = 'N', and either ku is not equal to 0 or n is not equal to $m$.

If $\text{info} = -26$, lda is too small.

If $\text{info} = 1$, error return from ?latm1 (computing $D$).

If $\text{info} = 2$, cannot scale to dmax (max. entry is 0).

If $\text{info} = 3$, error return from ?latm1 (computing dl).

If $\text{info} = 4$, error return from ?latm1 (computing dr).

If $\text{info} = 5$, anorm is positive, but matrix constructed prior to attempting to scale it to have norm anorm, is zero.

?lauum

Computes the product $U^T (U^T)^H$ or $L^H L^T$, where $U$ and $L$ are upper or lower triangular matrices (blocked algorithm).

Syntax

```c
lapack_int LAPACKE_slauum (int matrix_layout , char uplo , lapack_int n , float * a ,
lapack_int lda );

lapack_int LAPACKE_dlauum (int matrix_layout , char uplo , lapack_int n , double * a ,
lapack_int lda );

lapack_int LAPACKE_clauum (int matrix_layout , char uplo , lapack_int n ,
lapack_complex_float * a , lapack_int lda );

lapack_int LAPACKE_zlauum (int matrix_layout , char uplo , lapack_int n ,
lapack_complex_double * a , lapack_int lda );
```
Include Files

- mkl.h

Description

The routine ?lauum computes the product $U^T U$ or $L^T L$ for real flavors, and $U^H U$ or $L^H L$ for complex flavors. Here the triangular factor $U$ or $L$ is stored in the upper or lower triangular part of the array $a$.

If $uplo = 'U'$ or 'u', then the upper triangle of the result is stored, overwriting the factor $U$ in $A$.

If $uplo = 'L'$ or 'l', then the lower triangle of the result is stored, overwriting the factor $L$ in $A$.

This is the blocked form of the algorithm, calling BLAS Level 3 Routines.

Input Parameters

$uplo$

Specifies whether the triangular factor stored in the array $a$ is upper or lower triangular:

- $'U'$: Upper triangular
- $'L'$: Lower triangular

$n$

The order of the triangular factor $U$ or $L$. $n \geq 0$.

$a$

Array of size $\max(1, lda \times n)$.

On entry, the triangular factor $U$ or $L$.

$lda$

The leading dimension of the array $a$. $lda \geq \max(1, n)$.

Output Parameters

$a$

On exit,

- if $uplo = 'U'$, then the upper triangle of $a$ is overwritten with the upper triangle of the product $U^T (U^T U)$;
- if $uplo = 'L'$, then the lower triangle of $a$ is overwritten with the lower triangle of the product $L^T L (L^H L)$.

Return Values

This function returns a value $info$.

- If $info = 0$, the execution is successful.
- If $info = -k$, the $k$-th parameter had an illegal value.
- If $info = -1011$, memory allocation error occurred.

?syswapr

Applies an elementary permutation on the rows and columns of a symmetric matrix.

Syntax

```c
lapack_int LAPACKE_ssyswapr (int matrix_layout, char uplo, lapack_int n, float *a, lapack_int i1, lapack_int i2);
```
lapack_int LAPACKE_dsyswapr (int matrix_layout, char uplo, lapack_int n, double *a, lapack_int i1, lapack_int i2);

lapack_int LAPACKE_csyswapr (int matrix_layout, char uplo, lapack_int n, lapack_complex_float *a, lapack_int i1, lapack_int i2);

lapack_int LAPACKE_zsyswapr (int matrix_layout, char uplo, lapack_int n, lapack_complex_double *a, lapack_int i1, lapack_int i2);

Include Files

- mkl.h

Description

The routine applies an elementary permutation on the rows and columns of a symmetric matrix.

Input Parameters

- **matrix_layout**: Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- **uplo**: Must be 'U' or 'L'. Indicates how the input matrix A has been factored:
  - If uplo = 'U', the array a stores the upper triangular factor U of the factorization $A = U^*D*U$.
  - If uplo = 'L', the array a stores the lower triangular factor L of the factorization $A = L*L^T$.
- **n**: The order of matrix A; $n \geq 0$.
- **nrhs**: The number of right-hand sides; $nrhs \geq 0$.
- **a**: Array of size at least max(1, lda*n).
  - The array a contains the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ?sytrf.
- **i1**: Index of the first row to swap.
- **i2**: Index of the second row to swap.

Output Parameters

- **a**
  - If info = 0, the symmetric inverse of the original matrix.
  - If info = 'U', the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced.
  - If info = 'L', the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

Return Values

This function returns a value info.

- If info = 0, the execution is successful.
- If info = -i, the i-th parameter had an illegal value.
If \( \text{info} = -1011 \), memory allocation error occurred.

**See Also**

?sytrf

**?heswapr**

*Applies an elementary permutation on the rows and columns of a Hermitian matrix.*

**Syntax**

```c
lapack_int LAPACKE_cheswapr (int matrix_layout, char uplo, lapack_int n,
lapack_complex_float* a, lapack_int i1, lapack_int i2);
```

```c
lapack_int LAPACKE_zheswapr (int matrix_layout, char uplo, lapack_int n,
lapack_complex_double* a, lapack_int i1, lapack_int i2);
```

**Include Files**

- mkl.h

**Description**
The routine applies an elementary permutation on the rows and columns of a Hermitian matrix.

**Input Parameters**

- `matrix_layout` specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- `uplo` must be 'U' or 'L'.
  - Indicates how the input matrix \( A \) has been factored:
    - If `uplo = 'U'`, the array \( a \) stores the upper triangular factor \( U \) of the factorization \( A = U*D*U^H \).
    - If `uplo = 'L'`, the array \( a \) stores the lower triangular factor \( L \) of the factorization \( A = L*D*L^H \).
- `n` the order of matrix \( A \); \( n \geq 0 \).
- `nrhs` the number of right-hand sides; \( nrhs \geq 0 \).
- `a` array of size at least \( \max(1, lda*n) \).
  - The array \( a \) contains the block diagonal matrix \( D \) and the multipliers used to obtain the factor \( U \) or \( L \) as computed by ?hetrf.
- `i1` index of the first row to swap.
- `i2` index of the second row to swap.

**Output Parameters**

- `a` if \( \text{info} = 0 \), the inverse of the original matrix.
  - If \( \text{info} = 'U' \), the upper triangular part of the inverse is formed and the part of \( A \) below the diagonal is not referenced.
If \( \text{info} = 'L' \), the lower triangular part of the inverse is formed and the part of \( A \) above the diagonal is not referenced.

**Return Values**

This function returns a value \( \text{info} \).

- If \( \text{info} = 0 \), the execution is successful.
- If \( \text{info} = -i \), the \( i \)-th parameter had an illegal value.
- If \( \text{info} = -1011 \), memory allocation error occurred.

**See Also**

?hetrf

**?sfrk**

*Performs a symmetric rank-k operation for matrix in RFP format.*

**Syntax**

```c
lapack_int LAPACKE_ssfrk (int matrix_layout , char transr , char uplo , char trans ,
    lapack_int n , lapack_int k , float alpha , const float * a , lapack_int lda , float 
    beta , float * c);

lapack_int LAPACKE_dsfrk (int matrix_layout , char transr , char uplo , char trans ,
    lapack_int n , lapack_int k , double alpha , const double * a , lapack_int lda , double 
    beta , double * c);
```

**Include Files**

- mkl.h

**Description**

The ?sfrk routines perform a matrix-matrix operation using symmetric matrices. The operation is defined as

\[
\begin{align*}
C & := \alpha A A^T + \beta C, \\
\end{align*}
\]

or

\[
\begin{align*}
C & := \alpha A^T A + \beta C,
\end{align*}
\]

where:

- \( \alpha \) and \( \beta \) are scalars,
- \( C \) is an \( n \)-by-\( n \) symmetric matrix in rectangular full packed (RFP) format,
- \( A \) is an \( n \)-by-\( k \) matrix in the first case and a \( k \)-by-\( n \) matrix in the second case.

**Input Parameters**

- \( \text{matrix_layout} \) Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- \( \text{transr} \)

  - if \( \text{transr} = 'N' \) or \( 'n' \), the normal form of RFP \( C \) is stored;
  - if \( \text{transr} = 'T' \) or \( 't' \), the transpose form of RFP \( C \) is stored.
uplo

Specifies whether the upper or lower triangular part of the array \( c \) is used.

If \( \text{uplo} = 'U' \) or \( 'u' \), then the upper triangular part of the array \( c \) is used.

If \( \text{uplo} = 'L' \) or \( 'l' \), then the lower triangular part of the array \( c \) is used.

trans

Specifies the operation:

- If \( \text{trans} = 'N' \) or \( 'n' \), then \( C := \alpha A^T A + \beta C \);
- If \( \text{trans} = 'T' \) or \( 't' \), then \( C := \alpha A^T A + \beta C \);

\( n \)

Specifies the order of the matrix \( C \). The value of \( n \) must be at least zero.

\( k \)

On entry with \( \text{trans} = 'N' \) or \( 'n' \), \( k \) specifies the number of columns of the matrix \( A \), and on entry with \( \text{trans} = 'T' \) or \( 't' \), \( k \) specifies the number of rows of the matrix \( A \).

The value of \( k \) must be at least zero.

alpha

Specifies the scalar \( \alpha \).

\( a \)

Array, size \( \max(1, \text{lda} \times \text{ka}) \), where \( \text{ka} \) is in the following table:

<table>
<thead>
<tr>
<th>Trans</th>
<th>Col_major</th>
<th>Row_major</th>
</tr>
</thead>
<tbody>
<tr>
<td>'N'</td>
<td>( k )</td>
<td>( n )</td>
</tr>
<tr>
<td>'T'</td>
<td>( n )</td>
<td>( k )</td>
</tr>
</tbody>
</table>

Before entry with \( \text{trans} = 'N' \) or \( 'n' \), the leading \( n \)-by-\( k \) part of the array \( a \) must contain the matrix \( A \), otherwise the leading \( k \)-by-\( n \) part of the array \( a \) must contain the matrix \( A \).

lda

Specifies the leading dimension of \( a \) as declared in the calling (sub)program. \( \text{lda} \) is defined by the following table:

<table>
<thead>
<tr>
<th>Trans</th>
<th>Col_major</th>
<th>Row_major</th>
</tr>
</thead>
<tbody>
<tr>
<td>'N'</td>
<td>( \max(1, n) )</td>
<td>( \max(1, k) )</td>
</tr>
<tr>
<td>'T'</td>
<td>( \max(1, k) )</td>
<td>( \max(1, n) )</td>
</tr>
</tbody>
</table>

beta

Specifies the scalar \( \beta \).

\( c \)

Array, size \( (n \times (n+1)/2) \). Before entry contains the symmetric matrix \( C \) in RFP format.

Output Parameters

\( c \)

- If \( \text{trans} = 'N' \) or \( 'n' \), then \( c \) contains \( C := \alpha A^T A + \beta C \);
- If \( \text{trans} = 'T' \) or \( 't' \), then \( c \) contains \( C := \alpha A^T A + \beta C \);

Return Values

This function returns a value \( \text{info} \).

If \( \text{info} = 0 \), the execution is successful.

If \( \text{info} < 0 \), the \( i \)-th parameter had an illegal value.

If \( \text{info} = -1011 \), memory allocation error occurred.
?hfrk
Performs a Hermitian rank-k operation for matrix in RFP format.

Syntax
lapack_int LAPACKE_chfrk ( int matrix_layout, char transr, char uplo, char trans,
lapack_int n, lapack_int k, float alpha, const lapack_complex_float* a, lapack_int lda,
float beta, lapack_complex_float* c );

lapack_int LAPACKE_zhfrk ( int matrix_layout, char transr, char uplo, char trans,
lapack_int n, lapack_int k, double alpha, const lapack_complex_double* a, lapack_int lda,
double beta, lapack_complex_double* c );

Include Files
• mkl.h

Description
The ?hfrk routines perform a matrix-matrix operation using Hermitian matrices. The operation is defined as

\[ C := \alpha A^H A + \beta C, \]

or

\[ C := \alpha A A^H + \beta C, \]

where:
\( \alpha \) and \( \beta \) are real scalars,

\( C \) is an \( n \)-by-\( n \) Hermitian matrix in RFP format,

\( A \) is an \( n \)-by-\( k \) matrix in the first case and a \( k \)-by-\( n \) matrix in the second case.

Input Parameters

- matrix_layout
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- transr
  if \( \text{transr} = 'N' \) or \( 'n' \), the normal form of RFP \( C \) is stored;
  if \( \text{transr} = 'C' \) or \( 'c' \), the conjugate-transpose form of RFP \( C \) is stored.

- uplo
  Specifies whether the upper or lower triangular part of the array \( c \) is used.
  If \( \text{uplo} = 'U' \) or \( 'u' \), then the upper triangular part of the array \( c \) is used.
  If \( \text{uplo} = 'L' \) or \( 'l' \), then the low triangular part of the array \( c \) is used.

- trans
  Specifies the operation:
  if \( \text{trans} = 'N' \) or \( 'n' \), then \( C := \alpha A^H A + \beta C \);
  if \( \text{trans} = 'C' \) or \( 'c' \), then \( C := \alpha A A^H + \beta C \).

- n
  Specifies the order of the matrix \( C \). The value of \( n \) must be at least zero.

- k
  On entry with \( \text{trans} = 'N' \) or \( 'n' \), \( k \) specifies the number of columns of the matrix \( a \), and on entry with \( \text{trans} = 'T' \) or \( 't' \) or \( 'C' \) or \( 'c' \), \( k \) specifies the number of rows of the matrix \( a \).
The value of k must be at least zero.

Specifies the scalar alpha.

Array, size max(1, lda*ka), where ka is in the following table:

<table>
<thead>
<tr>
<th></th>
<th>Col_major</th>
<th>Row_major</th>
</tr>
</thead>
<tbody>
<tr>
<td>trans = 'N'</td>
<td>k</td>
<td>n</td>
</tr>
<tr>
<td>trans = 'T'</td>
<td>n</td>
<td>k</td>
</tr>
</tbody>
</table>

Before entry with trans = 'N' or 'n', the leading n-by-k part of the array a must contain the matrix A, otherwise the leading k-by-n part of the array a must contain the matrix A.

Specifies the leading dimension of a as declared in the calling (sub)program. lda is defined by the following table:

<table>
<thead>
<tr>
<th></th>
<th>Col_major</th>
<th>Row_major</th>
</tr>
</thead>
<tbody>
<tr>
<td>trans = 'N'</td>
<td>max(1, n)</td>
<td>max(1, k)</td>
</tr>
<tr>
<td>trans = 'T'</td>
<td>max(1, k)</td>
<td>max(1, n)</td>
</tr>
</tbody>
</table>

Specifies the scalar beta.

Array, size (n*(n+1)/2). Before entry contains the Hermitian matrix C in in RFP format.

Output Parameters

c

If trans = 'N' or 'n', then c contains C := alpha*A*A^H + beta*C;
if trans = 'C' or 'c', then c contains C := alpha*A^H*A + beta*C;

Return Values

This function returns a value info.

If info = 0, the execution is successful.
If info < 0, the i-th parameter had an illegal value.
If info = -1011, memory allocation error occurred.

?tfsm
Solves a matrix equation (one operand is a triangular matrix in RFP format).

Syntax

```c
lapack_int LAPACKE_stfsm (int matrix_layout, char transr, char side, char uplo, char trans, char diag, lapack_int m, lapack_int n, float alpha, const float * a, float * b, lapack_int ldb);
```

```c
lapack_int LAPACKE_dtfsm (int matrix_layout, char transr, char side, char uplo, char trans, char diag, lapack_int m, lapack_int n, double alpha, const double * a, double * b, lapack_int ldb);
```
lapack_int LAPACKE_ctfsm (int matrix_layout, char transr, char side, char uplo, char trans, char diag, lapack_int m, lapack_int n, lapack_complex_float alpha, const lapack_complex_float * a, lapack_complex_float * b, lapack_int ldb);
lapack_int LAPACKE_ztfsm (int matrix_layout, char transr, char side, char uplo, char trans, char diag, lapack_int m, lapack_int n, lapack_complex_double alpha, const lapack_complex_double * a, lapack_complex_double * b, lapack_int ldb);

Include Files

• mkl.h

Description

The ?tfsm routines solve one of the following matrix equations:

\[ \text{op}(A) \times X = \alpha B, \]

or

\[ X \times \text{op}(A) = \alpha B, \]

where:

\( \alpha \) is a scalar,

\( X \) and \( B \) are \( m \)-by-\( n \) matrices,

\( A \) is a unit, or non-unit, upper or lower triangular matrix in rectangular full packed (RFP) format.

\( \text{op}(A) \) can be one of the following:

• \( \text{op}(A) = A \) or \( \text{op}(A) = A^T \) for real flavors
• \( \text{op}(A) = A \) or \( \text{op}(A) = A^H \) for complex flavors

The matrix \( B \) is overwritten by the solution matrix \( X \).

Input Parameters

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **transr**
  if \( \text{transr} \) = 'N' or 'n', the normal form of RFP \( A \) is stored;
  if \( \text{transr} \) = 'T' or 't', the transpose form of RFP \( A \) is stored;
  if \( \text{transr} \) = 'C' or 'c', the conjugate-transpose form of RFP \( A \) is stored.

- **side**
  Specifies whether \( \text{op}(A) \) appears on the left or right of \( X \) in the equation:
  if \( \text{side} \) = 'L' or 'l', then \( \text{op}(A) \times X = \alpha B \);
  if \( \text{side} \) = 'R' or 'r', then \( X \times \text{op}(A) = \alpha B \).

- **uplo**
  Specifies whether the RFP matrix \( A \) is upper or lower triangular:
  if \( \text{uplo} \) = 'U' or 'u', then the matrix is upper triangular;
  if \( \text{uplo} \) = 'L' or 'l', then the matrix is lower triangular.

- **trans**
  Specifies the form of \( \text{op}(A) \) used in the matrix multiplication:
  if \( \text{trans} \) = 'N' or 'n', then \( \text{op}(A) = A \);
  if \( \text{trans} \) = 'T' or 't', then \( \text{op}(A) = A^T \);
if \( \text{trans} = 'C' \) or \( 'c' \), then \( \text{op}(A) = \text{conjg}(A') \).

**diag**

Specifies whether the RFP matrix \( A \) is unit triangular:
- if \( \text{diag} = 'U' \) or \( 'u' \) then the matrix is unit triangular;
- if \( \text{diag} = 'N' \) or \( 'n' \), then the matrix is not unit triangular.

**m**

Specifies the number of rows of \( B \). The value of \( m \) must be at least zero.

**n**

Specifies the number of columns of \( B \). The value of \( n \) must be at least zero.

**alpha**

Specifies the scalar \( \alpha \).
- When \( \alpha \) is zero, then \( a \) is not referenced and \( b \) need not be set before entry.

**a**

Array, size \((n*(n+1)/2)\). Contains the matrix \( A \) in RFP format.

**b**

Array, size \( \max(1, \text{ldb} \times n) \) for column major and \( \max(1, \text{ldb} \times m) \) for row major.
- Before entry, the leading \( m \)-by-\( n \) part of the array \( b \) must contain the right-hand side matrix \( B \).

**ldb**

Specifies the leading dimension of \( b \) as declared in the calling (sub)program. The value of \( \text{ldb} \) must be at least \( \max(1, m) \) for column major and \( \max(1, n) \) for row major.

**Output Parameters**

**b**

Overwritten by the solution matrix \( X \).

**Return Values**

This function returns a value \( \text{info} \).
- If \( \text{info} = 0 \), the execution is successful.
- If \( \text{info} < 0 \), the \( i \)-th parameter had an illegal value.
- If \( \text{info} = -1011 \), memory allocation error occurred.

**tfttp**

Copies a triangular matrix from the rectangular full packed format (TF) to the standard packed format (TP).

**Syntax**

```c
lapack_int LAPACKE_stfttp (int matrix_layout, char transr, char uplo, lapack_int n, const float * arf, float * ap);
lapack_int LAPACKE_dtfttp (int matrix_layout, char transr, char uplo, lapack_int n, const double * arf, double * ap);
lapack_int LAPACKE_ctfttp (int matrix_layout, char transr, char uplo, lapack_int n, const lapack_complex_float * arf, lapack_complex_float * ap);
lapack_int LAPACKE_ztfttp (int matrix_layout, char transr, char uplo, lapack_int n, const lapack_complex_double * arf, lapack_complex_double * ap);
```
Include Files

• mkl.h

Description

The routine copies a triangular matrix \( A \) from the Rectangular Full Packed (RFP) format to the standard packed format. For the description of the RFP format, see Matrix Storage Schemes.

Input Parameters

- \texttt{matrix\_layout} Specifies whether matrix storage layout is row major (\texttt{LAPACK\_ROW\_MAJOR}) or column major (\texttt{LAPACK\_COL\_MAJOR}).

- \texttt{transr} = 'N': \( arf \) is in the Normal format,
  = 'T': \( arf \) is in the Transpose format (for \texttt{stfttp} and \texttt{dtfttp}),
  = 'C': \( arf \) is in the Conjugate-transpose format (for \texttt{ctfttp} and \texttt{ztfttp}).

- \texttt{uplo} Specifies whether \( A \) is upper or lower triangular:
  = 'U': \( A \) is upper triangular,
  = 'L': \( A \) is lower triangular.

- \texttt{n} The order of the matrix \( A \). \( n \geq 0 \).

- \texttt{arf} Array, size at least \( \max (1, n \times (n+1)/2) \).
  On entry, the upper or lower triangular matrix \( A \) stored in the RFP format.

Output Parameters

- \texttt{ap} Array, size at least \( \max (1, n \times (n+1)/2) \).
  On exit, the upper or lower triangular matrix \( A \), packed columnwise in a linear array.

Return Values

This function returns a value \texttt{info}.

If \( \texttt{info} = 0 \), the execution is successful.

If \( \texttt{info} < 0 \), the \( i \)-th parameter had an illegal value.

If \( \texttt{info} = -1011 \), memory allocation error occurred.

\texttt{?tfttr}

Copies a triangular matrix from the rectangular full packed format (TF) to the standard full format (TR).

Syntax

\begin{verbatim}
lapack_int LAPACKE_stfttr (int matrix_layout , char transr , char uplo , lapack_int n , const float * arf , float * a , lapack_int lda );
lapack_int LAPACKE_dtfttr (int matrix_layout , char transr , char uplo , lapack_int n , const double * arf , double * a , lapack_int lda );
\end{verbatim}
lapack_int LAPACKE_ctfttr (int matrix_layout, char transr, char uplo, lapack_int n, const lapack_complex_float * arf, lapack_complex_float * a, lapack_int lda);
lapack_int LAPACKE_ztfttr (int matrix_layout, char transr, char uplo, lapack_int n, const lapack_complex_double * arf, lapack_complex_double * a, lapack_int lda);

Include Files
• mkl.h

Description
The routine copies a triangular matrix $A$ from the Rectangular Full Packed (RFP) format to the standard full format. For the description of the RFP format, see Matrix Storage Schemes.

Input Parameters
matrix_layout Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
transr = 'N': arf is in the Normal format,
= 'T': arf is in the Transpose format (for stfttr and dtfttr),
= 'C': arf is in the Conjugate-transpose format (for ctfttr and ztfttr).
uplo Specifies whether $A$ is upper or lower triangular:
= 'U': $A$ is upper triangular,
= 'L': $A$ is lower triangular.
n The order of the matrices arf and $a$. $n \geq 0$.
arf Array, size at least $\max(1, n*(n+1)/2)$.
on entry, the upper or lower triangular matrix $A$ stored in the RFP format.
lda The leading dimension of the array $a$. $lda \geq \max(1,n)$.

Output Parameters
a Array, size $\max(1,lda*n)$.
on exit, the triangular matrix $A$. If $uplo = 'U'$, the leading $n$-by-$n$ upper triangular part of the array $a$ contains the upper triangular matrix, and the strictly lower triangular part of $a$ is not referenced. If $uplo = 'L'$, the leading $n$-by-$n$ lower triangular part of the array $a$ contains the lower triangular matrix, and the strictly upper triangular part of $a$ is not referenced.

Return Values
This function returns a value info.
If info = 0, the execution is successful.
If info < 0, the $i$-th parameter had an illegal value.
If info = -1011, memory allocation error occurred.
 Computes a QR factorization of a real or complex "triangular-pentagonal" matrix, which is composed of a triangular block and a pentagonal block, using the compact WY representation for Q.

Syntax

```c
lapack_int LAPACKE_stpqrt2 (int matrix_layout, lapack_int m, lapack_int n, lapack_int l, float * a, lapack_int lda, float * b, lapack_int ldb, float * t, lapack_int ldt);
```

```c

```

Include Files

- mkl.h

Description

The input matrix C is an \( (n+m) \times n \) matrix

\[
C = \begin{bmatrix}
A & \leftarrow & n \times n \text{ upper triangular} \\
B & \leftarrow & m \times n \text{ pentagonal}
\end{bmatrix}
\]

where A is an \( n \times n \) upper triangular matrix, and B is an \( m \times n \) pentagonal matrix consisting of an \( (m-1) \times n \) rectangular matrix \( B1 \) on top of an \( l \times n \) upper trapezoidal matrix \( B2 \):

\[
B = \begin{bmatrix}
B1 & \leftarrow & (m-1) \times n \text{ rectangular} \\
B2 & \leftarrow & l \times n \text{ upper trapezoidal}
\end{bmatrix}
\]

The upper trapezoidal matrix \( B2 \) consists of the first \( l \) rows of an \( n \times n \) upper triangular matrix, where \( 0 \leq l \leq \min(m,n) \). If \( l=0 \), B is an \( m \times n \) rectangular matrix. If \( m=l=n \), B is upper triangular. The matrix W contains the elementary reflectors \( H(i) \) in the \( i \)th column below the diagonal (of A) in the \( (n+m) \times n \) input matrix C so that W can be represented as

\[
W = \begin{bmatrix}
I & \leftarrow & n \times n \text{ identity} \\
V & \leftarrow & m \times n \text{ pentagonal}
\end{bmatrix}
\]

Thus, V contains all of the information needed for W, and is returned in array b.
NOTE
V has the same form as B:

\[ V = \begin{bmatrix} V1 & \gets (m-l) \times n \text{ rectangular} \\ V2 & \gets l \times n \text{ upper trapezoidal} \end{bmatrix} \]

The columns of V represent the vectors which define the H(i) s.

The \((m+n)\)-by-\((m+n)\) block reflector \(H\) is then given by

\[ H = I - W^* T^* W \]

for real flavors, and

\[ H = I - W^* T^* W^H \]

for complex flavors

where \(W^T\) is the transpose of \(W\), \(W^H\) is the conjugate transpose of \(W\), and \(T\) is the upper triangular factor of the block reflector.

**Input Parameters**

- **matrix_layout**
  Specifies whether matrix storage layout is row major (`LAPACK_ROW_MAJOR`) or column major (`LAPACK_COL_MAJOR`).

- **m**
  The total number of rows in the matrix \(B\) \((m \geq 0)\).

- **n**
  The number of columns in \(B\) and the order of the triangular matrix \(A\) \((n \geq 0)\).

- **l**
  The number of rows of the upper trapezoidal part of \(B\) \((\min(m, n) \geq l \geq 0)\).

- **a, b**
  Arrays: \(a\), size `max(1, lda * n)` contains the \(n\)-by-\(n\) upper triangular matrix \(A\).

  \(b\), size `max(1, ldb * n)` for column major and `max(1, ldt * m)` for row major, the pentagonal \(m\)-by-\(n\) matrix \(B\). The first \((m-1)\) rows contain the rectangular \(B1\) matrix, and the next \(l\) rows contain the upper trapezoidal \(B2\) matrix.

- **lda**
  The leading dimension of \(a\); at least \(max(1, n)\).

- **ldb**
  The leading dimension of \(b\); at least \(max(1, m)\) for column major and \(max(1, n)\) for row major.

- **ldt**
  The leading dimension of \(t\); at least \(max(1, n)\).

**Output Parameters**

- **a**
  The elements on and above the diagonal of the array contain the upper triangular matrix \(R\).

- **b**
  The pentagonal matrix \(V\).

- **t**
  Array, size `max(1, ldt * n)`.

  The upper \(n\)-by-\(n\) upper triangular factor \(T\) of the block reflector.

**Return Values**

This function returns a value `info`. 

1206
If $info = 0$, the execution is successful.

If $info < 0$ and $info = -i$, the $i$th argument had an illegal value.

If $info = -1011$, memory allocation error occurred.

**?tprfb**

**Applies a real or complex "triangular-pentagonal"**

blocked reflector to a real or complex matrix, which is composed of two blocks.

**Syntax**

```c
lapack_int LAPACKE_stprfb (int matrix_layout, char side, char trans, char direct, char storev, lapack_int m, lapack_int n, lapack_int k, lapack_int l, const float * v, lapack_int ldv, const float * t, lapack_int ldt, float * a, lapack_int lda, float * b, lapack_int ldb);

lapack_int LAPACKE_dtprfb (int matrix_layout, char side, char trans, char direct, char storev, lapack_int m, lapack_int n, lapack_int k, lapack_int l, const double * v, lapack_int ldv, const double * t, lapack_int ldt, double * a, lapack_int lda, double * b, lapack_int ldb);

lapack_int LAPACKE_ctprfb (int matrix_layout, char side, char trans, char direct, char storev, lapack_int m, lapack_int n, lapack_int k, lapack_int l, const lapack_complex_float * v, lapack_int ldv, const lapack_complex_float * t, lapack_int ldt, lapack_complex_float * a, lapack_int lda, lapack_complex_float * b, lapack_int ldb);

lapack_int LAPACKE_ztprfb (int matrix_layout, char side, char trans, char direct, char storev, lapack_int m, lapack_int n, lapack_int k, lapack_int l, const lapack_complex_double * v, lapack_int ldv, const lapack_complex_double * t, lapack_int ldt, lapack_complex_double * a, lapack_int lda, lapack_complex_double * b, lapack_int ldb);
```

**Include Files**

- mkl.h

**Description**

The ?tprfb routine applies a real or complex "triangular-pentagonal" block reflector $H$, $H^\top$, or $H^H$ from either the left or the right to a real or complex matrix $C$, which is composed of two blocks $A$ and $B$.

The block $B$ is $m$-by-$n$. If $side = 'R'$, $A$ is $m$-by-$k$, and if $side = 'L'$, $A$ is of size $k$-by-$n$.

\[
\begin{align*}
\text{side} = 'R' & \quad C = \begin{bmatrix} A & B \end{bmatrix} & C = \begin{bmatrix} B & A \end{bmatrix} \\
\text{side} = 'L' & \quad C = \begin{bmatrix} A \\ B \end{bmatrix} & C = \begin{bmatrix} B \\ A \end{bmatrix}
\end{align*}
\]

The pentagonal matrix $V$ is composed of a rectangular block $V_1$ and a trapezoidal block $V_2$. The size of the trapezoidal block is determined by the parameter $l$, where $0 \leq l \leq k$. If $l = k$, the $V_2$ block of $V$ is triangular; if $l = 0$, there is no trapezoidal block, thus $V = V_1$ is rectangular.
### Input Parameters

<table>
<thead>
<tr>
<th>matrix_layout</th>
<th>Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).</th>
</tr>
</thead>
</table>
| side | = 'L': apply $H$, $H^T$, or $H^H$ from the left,  
= 'R': apply $H$, $H^T$, or $H^H$ from the right. |
| trans | = 'N': apply $H$ (no transpose),  
= 'T': apply $H^T$ (transpose),  
= 'C': apply $H^H$ (conjugate transpose). |
| direct | Indicates how $H$ is formed from a product of elementary reflectors:  
= 'F': $H = H(1) H(2) \ldots H(k)$ (Forward),  
= 'B': $H = H(k) \ldots H(2) H(1)$ (Backward). |
| storev | Indicates how the vectors that define the elementary reflectors are stored:  
= 'C': Columns,  
= 'R': Rows. |
| $m$ | The total number of rows in the matrix $B$ ($m \geq 0$). |
| $n$ | The number of columns in $B$ ($n \geq 0$). |
| $k$ | The order of the matrix $T$, which is the number of elementary reflectors whose product defines the block reflector. ($k \geq 0$) |
| $l$ | The order of the trapezoidal part of $V$. ($k \geq l \geq 0$). |
An array containing the pentagonal matrix \( V \) (the elementary reflectors \( H(1), H(2), \ldots, H(k) \)). The size limitations depend on values of parameters \( \text{storev} \) and \( \text{side} \) as described in the following table:

<table>
<thead>
<tr>
<th>( \text{storev} = C )</th>
<th>( \text{storev} = R )</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \text{side} = L )</td>
<td>( \text{side} = R )</td>
</tr>
<tr>
<td>( \text{side} = L )</td>
<td>( \text{side} = R )</td>
</tr>
<tr>
<td>Column major</td>
<td></td>
</tr>
<tr>
<td>( \max(1, \text{ldv}*k) )</td>
<td>( \max(1, \text{ldv}*m) )</td>
</tr>
<tr>
<td>Row major</td>
<td></td>
</tr>
<tr>
<td>( \max(1, \text{ldv}*n) )</td>
<td>( \max(1, \text{ldv}*k) )</td>
</tr>
</tbody>
</table>

The leading dimension of the array \( v \). It should satisfy the following conditions:

<table>
<thead>
<tr>
<th>( \text{storev} = C )</th>
<th>( \text{storev} = R )</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \text{side} = L )</td>
<td>( \text{side} = R )</td>
</tr>
<tr>
<td>( \text{side} = L )</td>
<td>( \text{side} = R )</td>
</tr>
<tr>
<td>Column major</td>
<td></td>
</tr>
<tr>
<td>( \max(1, \text{ldv}*m) )</td>
<td>( \max(1, \text{ldv}*k) )</td>
</tr>
<tr>
<td>Row major</td>
<td></td>
</tr>
<tr>
<td>( \max(1, \text{ldv}*n) )</td>
<td>( \max(1, \text{ldv}*m) )</td>
</tr>
</tbody>
</table>

Array size \( \max(1, \text{ldt}*k) \). The triangular \( k \)-by-\( k \) matrix \( T \) in the representation of the block reflector.

The leading dimension of the array \( t \) (\( \text{ldt} \geq k \)).

The \( k \)-by-\( n \) or \( m \)-by-\( k \) matrix \( A \).

The leading dimension of the array \( a \) should satisfy the following conditions:

<table>
<thead>
<tr>
<th>( \text{side} = L )</th>
<th>( \text{side} = R )</th>
</tr>
</thead>
<tbody>
<tr>
<td>Column major</td>
<td></td>
</tr>
<tr>
<td>( \max(1, \text{lda}*n) )</td>
<td>( \max(1, \text{lda}*k) )</td>
</tr>
<tr>
<td>Row major</td>
<td></td>
</tr>
<tr>
<td>( \max(1, \text{lda}*k) )</td>
<td>( \max(1, \text{lda}*m) )</td>
</tr>
</tbody>
</table>

Array size at least \( \max(1, \text{ldb}*n) \) for column major layout and \( \max(1, \text{ldb}*m) \) for row major layout, the \( m \)-by-\( n \) matrix \( B \).

The leading dimension of the array \( b \) (\( \text{ldb} \geq \max(1, m) \) for column major layout and \( \text{ldb} \geq \max(1, n) \) for row major layout).
Output Parameters

- **a**
  
  Contains the corresponding block of \( H^*C, H^*H, H^*H^, C^*H, C^*H^, \) or \( C^*H^ \).

- **b**
  
  Contains the corresponding block of \( H^*C, H^*H, H^*H^, C^*H, C^*H^, \) or \( C^*H^ \).

Return Values

This function returns a value `info`.

- **If** `info = 0`, the execution is successful.
- **If** `info < 0`, the i-th parameter had an illegal value.
- **If** `info = -1011`, memory allocation error occurred.

**?tpttf**

*Copies a triangular matrix from the standard packed format (TP) to the rectangular full packed format (TF).*

**Syntax**

```c
lapack_int LAPACKE_stpttf (int matrix_layout, char transr, char uplo, lapack_int n, const float * ap, float * arf);
lapack_int LAPACKE_dtpttf (int matrix_layout, char transr, char uplo, lapack_int n, const double * ap, double * arf);
lapack_int LAPACKE_ctpttf (int matrix_layout, char transr, char uplo, lapack_int n, const lapack_complex_float * ap, lapack_complex_float * arf);
lapack_int LAPACKE_ztpttf (int matrix_layout, char transr, char uplo, lapack_int n, const lapack_complex_double * ap, lapack_complex_double * arf);
```

**Include Files**

- mkl.h

**Description**

The routine copies a triangular matrix \( A \) from the standard packed format to the Rectangular Full Packed (RFP) format. For the description of the RFP format, see Matrix Storage Schemes.

**Input Parameters**

- **matrix_layout**
  
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **transr**
  
  = 'N': \( arf \) must be in the Normal format,
  
  = 'T': \( arf \) must be in the Transpose format (for stpttf and dtpttf),
  
  = 'C': \( arf \) must be in the Conjugate-transpose format (for ctpttf and ztpttf).

- **uplo**
  
  Specifies whether \( A \) is upper or lower triangular:
  
  = 'U': \( A \) is upper triangular,
  
  = 'L': \( A \) is lower triangular.
The order of the matrix $A$. $n \geq 0$.

$ap$

Array, size at least max $(1, n*(n+1)/2)$.

On entry, the upper or lower triangular matrix $A$, packed in a linear array. See Matrix Storage Schemes for more information.

Output Parameters

$arf$

Array, size at least max $(1, n*(n+1)/2)$.

On exit, the upper or lower triangular matrix $A$ stored in the RFP format.

Return Values

This function returns a value $info$.

If $info = 0$, the execution is successful.

$< 0$: if $info = -i$, the $i$-th parameter had an illegal value.

If $info = -1011$, memory allocation error occurred.

?tpttr

Copies a triangular matrix from the standard packed format (TP) to the standard full format (TR).

Syntax

```c
lapack_int LAPACKE_stpttr (int matrix_layout, char uplo, lapack_int n, const float * ap, float * a, lapack_int lda);
lapack_int LAPACKE_dtpttr (int matrix_layout, char uplo, lapack_int n, const double * ap, double * a, lapack_int lda);
lapack_int LAPACKE_ctpttr (int matrix_layout, char uplo, lapack_int n, const lapack_complex_float * ap, lapack_complex_float * a, lapack_int lda);
lapack_int LAPACKE_ztpttr (int matrix_layout, char uplo, lapack_int n, const lapack_complex_double * ap, lapack_complex_double * a, lapack_int lda);
```

Include Files

- mkl.h

Description

The routine copies a triangular matrix $A$ from the standard packed format to the standard full format.

Input Parameters

$matrix_layout$

Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

$uplo$

Specifies whether $A$ is upper or lower triangular:

= 'U': $A$ is upper triangular,

= 'L': $A$ is lower triangular.
The order of the matrices \( a_{p} \) and \( a \). \( n \geq 0 \).

Array, size at least \( \max(1, n^*(n+1)/2) \). (see Matrix Storage Schemes).

The leading dimension of the array \( a \). \( lda \geq \max(1,n) \).

Output Parameters

Array, size \( \max(1,lda*n) \).

On exit, the triangular matrix \( A \). If \( uplo = \text{'U'} \), the leading \( n \)-by-\( n \) upper triangular part of the array \( a \) contains the upper triangular part of the matrix \( A \), and the strictly lower triangular part of \( a \) is not referenced. If \( uplo = \text{'L'} \), the leading \( n \)-by-\( n \) lower triangular part of the array \( a \) contains the lower triangular part of the matrix \( A \), and the strictly upper triangular part of \( a \) is not referenced.

Return Values

This function returns a value \( info \).

If \( info = 0 \), the execution is successful.

If \( info = -i \), the \( i \)-th parameter had an illegal value.

If \( info = -1011 \), memory allocation error occurred.

**?trttf**

Copies a triangular matrix from the standard full format (TR) to the rectangular full packed format (TF).

**Syntax**

```c
lapack_int LAPACKE_strttf (int matrix_layout, char transr, char uplo, lapack_int n, const float * a, lapack_int lda, float * arf);

lapack_int LAPACKE_dtrttf (int matrix_layout, char transr, char uplo, lapack_int n, const double * a, lapack_int lda, double * arf);

lapack_int LAPACKE_ctrttf (int matrix_layout, char transr, char uplo, lapack_int n, const lapack_complex_float * a, lapack_int lda, lapack_complex_float * arf);

lapack_int LAPACKE_ztrttf (int matrix_layout, char transr, char uplo, lapack_int n, const lapack_complex_double * a, lapack_int lda, lapack_complex_double * arf);
```

**Include Files**

- mkl.h

**Description**

The routine copies a triangular matrix \( A \) from the standard full format to the Rectangular Full Packed (RFP) format. For the description of the RFP format, see Matrix Storage Schemes.

**Input Parameters**

- `matrix_layout` Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
transr

= 'N': arf must be in the Normal format,
= 'T': arf must be in the Transpose format (for strttf and dtrttf),
= 'C': arf must be in the Conjugate-transpose format (for ctrttf and ztrttf).

uplo

Specifies whether $A$ is upper or lower triangular:
= 'U': $A$ is upper triangular,
= 'L': $A$ is lower triangular.

n

The order of the matrix $A$. $n \geq 0$.

a

Array, size max(1,(lda*$n$)).

On entry, the triangular matrix $A$. If uplo = 'U', the leading $n$-by-$n$ upper triangular part of the array $a$ contains the upper triangular matrix, and the strictly lower triangular part of $a$ is not referenced. If uplo = 'L', the leading $n$-by-$n$ lower triangular part of the array $a$ contains the lower triangular matrix, and the strictly upper triangular part of $a$ is not referenced.

lda

The leading dimension of the array $a$. lda $\geq$ max(1,$n$).

Output Parameters

arf

Array, size at least max (1, $n*(n+1)/2$).

On exit, the upper or lower triangular matrix $A$ stored in the RFP format.

Return Values

This function returns a value info.

If info = 0, the execution is successful.

If info < 0, the $i$-th parameter had an illegal value.

If info = -1011, memory allocation error occurred.

?trttp

Copies a triangular matrix from the standard full format (TR) to the standard packed format (TP).

Syntax

lapack_int LAPACKE_strttp (int matrix_layout , char uplo , lapack_int n , const float * a , lapack_int lda , float * ap );

lapack_int LAPACKE_dtrttp (int matrix_layout , char uplo , lapack_int n , const double * a , lapack_int lda , double * ap );

lapack_int LAPACKE_ctrttp (int matrix_layout , char uplo , lapack_int n , const lapack_complex_float * a , lapack_int lda , lapack_complex_float * ap );

lapack_int LAPACKE_ztrttp (int matrix_layout , char uplo , lapack_int n , const lapack_complex_double * a , lapack_int lda , lapack_complex_double * ap );
Include Files

- mkl.h

Description

The routine copies a triangular matrix $A$ from the standard full format to the standard packed format.

Input Parameters

$uplo$

Specifies whether $A$ is upper or lower triangular:

- 'U': $A$ is upper triangular,
- 'L': $A$ is lower triangular.

$n$

The order of the matrix $A$, $n\geq 0$.

$a$

Array, size $\max(1, lda \times n)$.

On entry, the triangular matrix $A$. If $uplo = 'U'$, the leading $n$-by-$n$ upper triangular part of the array $a$ contains the upper triangular matrix, and the strictly lower triangular part of $a$ is not referenced. If $uplo = 'L'$, the leading $n$-by-$n$ lower triangular part of the array $a$ contains the lower triangular matrix, and the strictly upper triangular part of $a$ is not referenced.

$lda$

The leading dimension of the array $a$. $lda \geq \max(1, n)$.

Output Parameters

$ap$

Array, size at least $\max(1, n \times (n+1)/2)$.

On exit, the upper or lower triangular matrix $A$, packed columnwise in a linear array. (see Matrix Storage Schemes)

Return Values

This function returns a value $info$.

If $info = 0$, the execution is successful.

If $info < 0$, the $i$-th parameter had an illegal value.

If $info = -1011$, memory allocation error occurred.

?lacp2

Copies all or part of a real two-dimensional array to a complex array.

Syntax

```c
lapack_int LAPACKE_clacp2 (int matrix_layout, char uplo, lapack_int m, lapack_int n, const float * a, lapack_int lda, lapack_complex_float * b, lapack_int ldb);
```

```c
lapack_int LAPACKE_zlacp2 (int matrix_layout, char uplo, lapack_int m, lapack_int n, const double * a, lapack_int lda, lapack_complex_double * b, lapack_int ldb);
```

Include Files

- mkl.h
Description

The routine copies all or part of a real matrix $A$ to another matrix $B$.

Input Parameters

$\textit{matrix\_layout}$

Specifies whether matrix storage layout is row major (LAPACK_RowMajor) or column major (LAPACK_ColMajor).

$\textit{uplo}$

Specifies the part of the matrix $A$ to be copied to $B$.

- If $\textit{uplo} = 'U'$, the upper triangular part of $A$;
- If $\textit{uplo} = 'L'$, the lower triangular part of $A$.

Otherwise, all of the matrix $A$ is copied.

$m$

The number of rows in the matrix $A$ ($m \geq 0$).

$n$

The number of columns in $A$ ($n \geq 0$).

$a$

Array, size at least $\text{max}(1, lda \times n)$ for column major and $\text{max}(1, lda \times m)$ for row major, contains the $m$-by-$n$ matrix $A$.

- If $\textit{uplo} = 'U'$, only the upper triangle or trapezoid is accessed;
- if $\textit{uplo} = 'L'$, only the lower triangle or trapezoid is accessed.

$\textit{lda}$

The leading dimension of $a$; $\text{lda} \geq \text{max}(1, m)$ for column major and $\text{lda} \geq \text{max}(1, n)$ for row major.

$\textit{ldb}$

The leading dimension of the output array $b$; $\text{ldb} \geq \text{max}(1, m)$ for column major and $\text{ldb} \geq \text{max}(1, n)$ for row major.

Output Parameters

$b$

Array, size at least $\text{max}(1, ldb \times n)$ for column major layout and $\text{max}(1, ldb \times m)$ for row major layout, contains the $m$-by-$n$ matrix $B$.

On exit, $B = A$ in the locations specified by $\textit{uplo}$.

Return Values

This function returns a value $\textit{info}$.

- If $\textit{info} = 0$, the execution is successful.
- If $\textit{info} < 0$, the $i$-th parameter had an illegal value.
- If $\textit{info} = -1011$, memory allocation error occurred.

$\texttt{?larcm}$

Multiplies a square real matrix by a complex matrix.

Syntax

```c
lapack_int LAPACKE_clarcm(int \textit{matrix\_layout}, \textit{lapack_int} \textit{m}, \textit{lapack_int} \textit{n}, \textit{const float} * \textit{a}, \textit{lapack_int} \textit{lda}, \textit{const lapack_complex_float} * \textit{b}, \textit{lapack_int} \textit{ldb}, \textit{lapack_complex_float} * \textit{c}, \textit{lapack_int} \textit{ldc});
```
lapack_int LAPACKE_zlarcm(int matrix_layout, lapack_int m, lapack_int n, const double * a, lapack_int lda, const lapack_complex_double *b, lapack_int ldb, lapack_complex_double *c, lapack_int ldc);

**Description**

The routine performs a simple matrix-matrix multiplication of the form

\[ C = A \times B, \]

where \( A \) is \( m \)-by-\( m \) and real, \( B \) is \( m \)-by-\( n \) and complex, and \( C \) is \( m \)-by-\( n \) and complex.

**Input Parameters**

- **m**
  - The number of rows and columns of matrix \( A \) and the number of rows of matrix \( C \) (\( m \geq 0 \)).

- **n**
  - The number of columns of matrix \( B \) and the number of columns of matrix \( C \) (\( n \geq 0 \)).

- **a**
  - Array, size \([lda \times m]\). Contains the \( m \)-by-\( m \) matrix \( A \).

- **lda**
  - The leading dimension of the array \( a \), \( lda \geq \max(1, m) \).

- **b**
  - Array, size \((ldb, n)\). Contains the \( m \)-by-\( n \) matrix \( B \).

- **ldb**
  - The leading dimension of the array \( b \), \( ldb \geq \max(1, m) \) for column-major layout; \( ldb \geq \max(1, n) \) for row-major layout.

- **ldc**
  - The leading dimension of the array \( c \), \( ldc \geq \max(1, m) \) for column-major layout; \( ldc \geq \max(1, n) \) for row-major layout.

**Output Parameters**

- **c**
  - Array, size \((ldc, n)\). Contains the \( m \)-by-\( n \) matrix \( C \).

**Return Values**

This function returns a value \( info \). If \( info = 0 \), the execution is successful. If \( info = -i \), parameter \( i \) had an illegal value.

**mkl_？tpack**

Copies a triangular/symmetric matrix or submatrix from standard full format to standard packed format.

**Syntax**

```c
lapack_int LAPACKE_mkl_stppack (int matrix_layout, char uplo, char trans, lapack_int n, float* ap, lapack_int i, lapack_int j, lapack_int rows, lapack_int cols, const float* a, lapack_int lda);

lapack_int LAPACKE_mkl_dtppack (int matrix_layout, char uplo, char trans, lapack_int n, double* ap, lapack_int i, lapack_int j, lapack_int rows, lapack_int cols, const double* a, lapack_int lda);

lapack_int LAPACKE_mkl_ctppack (int matrix_layout, char uplo, char trans, lapack_int n, MKL_Complex8* ap, lapack_int i, lapack_int j, lapack_int rows, lapack_int cols, const MKL_Complex8* a, lapack_int lda);
```
lapack_int LAPACKE_mkl_ztppack (int matrix_layout, char uplo, char trans, lapack_int n, MKL_Complex16* ap, lapack_int i, lapack_int j, lapack_int rows, lapack_int cols, const MKL_Complex16* a, lapack_int lda);

Include Files

• mkl.h

Description

The routine copies a triangular or symmetric matrix or its submatrix from standard full format to packed format

\[ AP_{i:i+\text{rows}-1, j:j+\text{cols}-1} := \text{op}(A) \]

Standard packed formats include:

• TP: triangular packed storage
• SP: symmetric indefinite packed storage
• HP: Hermitian indefinite packed storage
• PP: symmetric or Hermitian positive definite packed storage

Full formats include:

• GE: general
• TR: triangular
• SY: symmetric indefinite
• HE: Hermitian indefinite
• PO: symmetric or Hermitian positive definite

NOTE

Any elements of the copied submatrix rectangular outside of the triangular part of the matrix \( AP \) are skipped.

Input Parameters

\( uplo \)

Specifies whether the matrix \( AP \) is upper or lower triangular.

If \( uplo = 'U' \), \( AP \) is upper triangular.

If \( uplo = 'L' \), \( AP \) is lower triangular.

\( trans \)

Specifies whether or not the copied block of \( A \) is transposed or not.

If \( trans = 'N', \) no transpose: \( \text{op}(A) = A \).

If \( trans = 'T', \) transpose: \( \text{op}(A) = A^T \).

If \( trans = 'C, \) conjugate transpose: \( \text{op}(A) = A^H \). For real data this is the same as \( trans = 'T' \).

\( n \)

The order of the matrix \( AP; \) \( n \geq 0 \)

\( i, j \)

Coordinates of the left upper corner of the destination submatrix in \( AP \).

If \( uplo='U', \) \( 1 \leq i \leq j \leq n \).

If \( uplo='L', \) \( 1 \leq j \leq i \leq n \).

\( rows \)

Number of rows in the destination submatrix. \( 0 \leq \text{rows} \leq n - i + 1 \).
Number of columns in the destination submatrix. $0 \leq cols \leq n - j + 1$.

Pointer to the source submatrix.

Array $a$ contains the rows-by-cols submatrix stored as unpacked rows-by-columns if $trans = 'N'$, or unpacked columns-by-rows if $trans = 'T'$ or $trans = 'C'$.

The size of $a$ is

<table>
<thead>
<tr>
<th>matrix_layout</th>
<th>lda=cols</th>
<th>lda=rows</th>
</tr>
</thead>
<tbody>
<tr>
<td>LAPACK_COL_MAJOR</td>
<td></td>
<td></td>
</tr>
<tr>
<td>LAPACK_ROW_MAJOR</td>
<td>lda=rows</td>
<td>lda=cols</td>
</tr>
</tbody>
</table>

**NOTE**

If there are elements outside of the triangular part of $AP$, they are skipped and are not copied from $a$.

The leading dimension of the array $a$.

<table>
<thead>
<tr>
<th>matrix_layout</th>
<th>lda=cols</th>
<th>lda=max(1, cols)</th>
</tr>
</thead>
<tbody>
<tr>
<td>LAPACK_COL_MAJOR</td>
<td></td>
<td></td>
</tr>
<tr>
<td>LAPACK_ROW_MAJOR</td>
<td>lda=max(1, rows)</td>
<td></td>
</tr>
</tbody>
</table>

**Output Parameters**

Array of size at least $\max(1, n(n+1)/2)$. The array $ap$ contains either the upper or the lower triangular part of the matrix $AP$ (as specified by $uplo$) in packed storage (see Matrix Storage Schemes). The submatrix of $ap$ from row $i$ to row $i + rows - 1$ and column $j$ to column $j + cols - 1$ is overwritten with a copy of the source matrix.

**Return Values**

This function returns a value $info$. If $info=0$, the execution is successful. If $info = -i$, the $i$-th parameter had an illegal value.

**mkl_?tpunpack**

Copies a triangular/symmetric matrix or submatrix from standard packed format to full format.
Description
The routine copies a triangular or symmetric matrix or its submatrix from standard packed format to full format.

\[ A := \text{op}(\text{AP}_{i:i+\text{rows}-1, j:j+\text{cols}-1}) \]

Standard packed formats include:
- TP: triangular packed storage
- SP: symmetric indefinite packed storage
- HP: Hermitian indefinite packed storage
- PP: symmetric or Hermitian positive definite packed storage

Full formats include:
- GE: general
- TR: triangular
- SY: symmetric indefinite
- HE: Hermitian indefinite
- PO: symmetric or Hermitian positive definite

**NOTE**
Any elements of the copied submatrix rectangular outside of the triangular part of AP are skipped.

Input Parameters

**uplo**

Specifies whether matrix AP is upper or lower triangular.
- If \( \text{uplo} = 'U' \), AP is upper triangular.
- If \( \text{uplo} = 'L' \), AP is lower triangular.

**trans**

Specifies whether or not the copied block of AP is transposed.
- If \( \text{trans} = 'N' \), no transpose: \( \text{op}(\text{AP}) = \text{AP} \).
If \( \text{trans} = 'T' \), transpose: \( \text{op}(\text{AP}) = \text{AP}^T \).

If \( \text{trans} = 'C' \), conjugate transpose: \( \text{op}(\text{AP}) = \text{AP}^H \). For real data this is the same as \( \text{trans} = 'T' \).

The order of the matrix \( \text{AP} \); \( n \geq 0 \).

Array, size at least \( \max(1, n(n+1)/2) \). The array \( \text{ap} \) contains either the upper or the lower triangular part of the matrix \( \text{AP} \) (as specified by \( \text{uplo} \)) in packed storage (see Matrix Storage Schemes). It is the source for the submatrix of \( \text{AP} \) from row \( i \) to row \( i + \text{rows} - 1 \) and column \( j \) to column \( j + \text{cols} - 1 \) to be copied.

Coordinates of left upper corner of the submatrix in \( \text{AP} \) to copy.

If \( \text{uplo} = 'U' \), \( 1 \leq i \leq j \leq n \).

If \( \text{uplo} = 'L' \), \( 1 \leq j \leq i \leq n \).

Number of rows to copy. \( 0 \leq \text{rows} \leq n - i + 1 \).

Number of columns to copy. \( 0 \leq \text{cols} \leq n - j + 1 \).

The leading dimension of array \( \text{a} \).

| matrix_layout = LAPACK_COL_MAJOR | \( \text{lda} \geq \max(1, \text{rows}) \) | \( \text{lda} \geq \max(1, \text{cols}) \) |
| matrix_layout = LAPACK_ROW_MAJOR | \( \text{lda} \geq \max(1, \text{cols}) \) | \( \text{lda} \geq \max(1, \text{rows}) \) |

Output Parameters

**a**

Pointer to the destination matrix. On exit, array \( \text{a} \) is overwritten with a copy of the unpacked \( \text{rows-by-cols} \) submatrix of \( \text{ap} \) unpacked rows-by-columns if \( \text{trans} = 'N' \), or unpacked columns-by-rows if \( \text{trans} = 'T' \) or \( \text{trans} = 'C' \).

The size of \( \text{a} \) is

| matrix_layout = LAPACK_COL_MAJOR | \( \text{lda} \times \text{cols} \) | \( \text{lda} \times \text{rows} \) |
| matrix_layout = LAPACK_ROW_MAJOR | \( \text{lda} \times \text{rows} \) | \( \text{lda} \times \text{cols} \) |

**NOTE**

If there are elements outside of the triangular part of \( \text{ap} \) indicated by \( \text{uplo} \), they are skipped and are not copied to \( \text{a} \).
Return Values
This function returns a value info. If info=0, the execution is successful. If info = -i, the i-th parameter had an illegal value.

LAPACK Utility Functions and Routines
This section describes LAPACK utility functions and routines.

See Also
lsame Tests two characters for equality regardless of the case.
lsamen Tests two character strings for equality regardless of the case.
second/dsecnd Returns elapsed time in seconds. Use to estimate real time between two calls to this function.
xerbla Error handling function called by BLAS, LAPACK, Vector Math, and Vector Statistics functions.

ilaver
Returns the version of the LAPACK library.

Syntax
void LAPACKE_ilaver (lapack_int * vers_major, lapack_int * vers_minor, lapack_int * vers_patch);

Include Files
• mkl.h

Description
This routine returns the version of the LAPACK library.

Output Parameters

vers_major
Returns the major version of the LAPACK library.

vers_minor
Returns the minor version from the major version of the LAPACK library.

vers_patch
Returns the patch version from the minor version of the LAPACK library.

?lamch
Determines machine parameters for floating-point arithmetic.

Syntax
float LAPACKE_slamch (char cmach);
double LAPACKE_dlamch (char cmach);

Include Files
• mkl.h

Description
The function \texttt{?lamch} determines single precision and double precision machine parameters.

**Input Parameters**

- \texttt{cmach}

  Specifies the value to be returned by \texttt{?lamch}:
  - \texttt{eps} = \texttt{e} or \texttt{E}, \texttt{val} = \texttt{eps}
  - \texttt{sfmin} = \texttt{s} or \texttt{s}, \texttt{val} = \texttt{sfmin}
  - \texttt{base} = \texttt{b} or \texttt{B}, \texttt{val} = \texttt{base}
  - \texttt{eps*base} = \texttt{p} or \texttt{P}, \texttt{val} = \texttt{eps*base}
  - \texttt{t} = \texttt{n} or \texttt{n}, \texttt{val} = \texttt{t}
  - \texttt{rnd} = \texttt{r} or \texttt{R}, \texttt{val} = \texttt{rnd}
  - \texttt{emin} = \texttt{m} or \texttt{M}, \texttt{val} = \texttt{emin}
  - \texttt{rmin} = \texttt{u} or \texttt{U}, \texttt{val} = \texttt{rmin}
  - \texttt{rmax} = \texttt{l} or \texttt{L}, \texttt{val} = \texttt{rmax}

  where
  - \texttt{eps} = relative machine precision;
  - \texttt{sfmin} = safe minimum, such that \(1/sfmin\) does not overflow;
  - \texttt{base} = base of the machine;
  - \texttt{prec} = \texttt{eps*base};
  - \texttt{t} = number of (base) digits in the mantissa;
  - \texttt{rnd} = 1.0 when rounding occurs in addition, 0.0 otherwise;
  - \texttt{emin} = minimum exponent before (gradual) underflow;
  - \texttt{rmin} = \texttt{underflow\_threshold} - \texttt{base}^{\texttt{emin}-1};
  - \texttt{emax} = largest exponent before overflow;
  - \texttt{rmax} = \texttt{overflow\_threshold} - (\texttt{base}^{\texttt{emax}})(1-\texttt{eps}).

**NOTE**

You can use a character string for \texttt{cmach} instead of a single character in order to make your code more readable. The first character of the string determines the value to be returned. For example, \texttt{'Precision'} is interpreted as \texttt{'p'}.

**Output Parameters**

- \texttt{val}

  Value returned by the function.

**LAPACK Test Functions and Routines**

This section describes LAPACK test functions and routines.
?lagge
Generates a general m-by-n matrix.

Syntax

```
lapack_int LAPACKE_slagge (int matrix_layout, lapack_int m, lapack_int n, lapack_int kl, lapack_int ku, const float * d, float * a, lapack_int lda, lapack_int * iseed);
lapack_int LAPACKE_dlagge (int matrix_layout, lapack_int m, lapack_int n, lapack_int kl, lapack_int ku, const double * d, double * a, lapack_int lda, lapack_int * iseed);
lapack_int LAPACKE_clagge (int matrix_layout, lapack_int m, lapack_int n, lapack_int kl, lapack_int ku, const float * d, lapack_complex_float * a, lapack_int lda, lapack_int * iseed);
lapack_int LAPACKE_zlagge (int matrix_layout, lapack_int m, lapack_int n, lapack_int kl, lapack_int ku, const double * d, lapack_complex_double * a, lapack_int lda, lapack_int * iseed);
```

Include Files

- mkl.h

Description

The routine generates a general m-by-n matrix A, by pre- and post- multiplying a real diagonal matrix D with random matrices U and V:

\[ A := U \cdot D \cdot V, \]

where U and V are orthogonal for real flavors and unitary for complex flavors. The lower and upper bandwidths may then be reduced to kl and ku by additional orthogonal transformations.

Input Parameters

- \( m \)  
The number of rows of the matrix A (\( m \geq 0 \)).

- \( n \)  
The number of columns of the matrix A (\( n \geq 0 \)).

- \( kl \)  
The number of nonzero subdiagonals within the band of A (\( 0 \leq kl \leq m-1 \)).

- \( ku \)  
The number of nonzero superdiagonals within the band of A (\( 0 \leq ku \leq n-1 \)).

- \( d \)  
The array d with the dimension of \( \min(m, n) \) contains the diagonal elements of the diagonal matrix D.

- \( lda \)  
The leading dimension of the array a \( (lda \geq m) \) for column major layout and \( (lda \geq n) \) for row major layout.

- \( iseed \)  
The array iseed with the dimension of 4 contains the seed of the random number generator. The elements must be between 0 and 4095 and iseed must be odd.
Output Parameters

- **a**
  The array $a$ with size at least $\max(1, lda*n)$ for column major layout and $\max(1, lda*m)$ for row major layout contains the generated $m$-by-$n$ matrix $A$.

- **iseed**
  The array $iseed$ contains the updated seed on exit.

Return Values

This function returns a value $info$.

If $info = 0$, the execution is successful.

If $info < 0$, the $i$-th parameter had an illegal value.

If $info = -1011$, memory allocation error occurred.

?!laghe

**Generates a complex Hermitian matrix.**

Syntax

```c
lapack_int LAPACKE_claghe (int matrix_layout, lapack_int n, lapack_int k, const float * d, lapack_complex_float * a, lapack_int lda, lapack_int * iseed);

lapack_int LAPACKE_zlaghe (int matrix_layout, lapack_int n, lapack_int k, const double * d, lapack_complex_double * a, lapack_int lda, lapack_int * iseed);
```

Include Files

- mkl.h

Description

The routine generates a complex Hermitian matrix $A$, by pre- and post- multiplying a real diagonal matrix $D$ with random unitary matrix:

$$A := U*D*U^\text{H}$$

The semi-bandwidth may then be reduced to $k$ by additional unitary transformations.

**Input Parameters**

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **n**
  The order of the matrix $A$ ($n \geq 0$).

- **k**
  The number of nonzero subdiagonals within the band of $A$ ($0 \leq k \leq n-1$).

- **d**
  The array $d$ with the dimension of $(n)$ contains the diagonal elements of the diagonal matrix $D$.

- **lda**
  The leading dimension of the array $a$ ($lda \geq n$).

- **iseed**
  The array $iseed$ with the dimension of 4 contains the seed of the random number generator. The elements must be between 0 and 4095 and $iseed[3]$ must be odd.
Output Parameters

\(a\)

The array \(a\) of size at least \(\max(1, lda \times n)\) contains the generated \(n\)-by-\(n\) Hermitian matrix \(D\).

\(iseed\)

The array \(iseed\) contains the updated seed on exit.

Return Values

This function returns a value \(info\).

If \(info = 0\), the execution is successful.

If \(info < 0\), the \(i\)-th parameter had an illegal value.

If \(info = -1011\), memory allocation error occurred.

lagsy

Generates a symmetric matrix by pre- and post-multiplying a real diagonal matrix with a random unitary matrix.

Syntax

\[
\text{lapack_int LAPACKE_slagsy (int matrix_layout, lapack_int n, lapack_int k, const float * d, float * a, lapack_int lda, lapack_int * iseed);}\\
\text{lapack_int LAPACKE_dlagsy (int matrix_layout, lapack_int n, lapack_int k, const double * d, double * a, lapack_int lda, lapack_int * iseed);}\\
\text{lapack_int LAPACKE_clagsy (int matrix_layout, lapack_int n, lapack_int k, const float * d, lapack_complex_float * a, lapack_int lda, lapack_int * iseed);}\\
\text{lapack_int LAPACKE_zlagsy (int matrix_layout, lapack_int n, lapack_int k, const double * d, lapack_complex_double * a, lapack_int lda, lapack_int * iseed);}
\]

Include Files

- mkl.h

Description

The \(\text{lagsy}\) routine generates a symmetric matrix \(A\) by pre- and post-multiplying a real diagonal matrix \(D\) with a random matrix \(U\):

\[
A := U \ast D \ast U^T,
\]

where \(U\) is orthogonal for real flavors and unitary for complex flavors. The semi-bandwidth may then be reduced to \(k\) by additional unitary transformations.

Input Parameters

\(n\)

The order of the matrix \(A\) \((n \geq 0)\).

\(k\)

The number of nonzero subdiagonals within the band of \(A\) \((0 \leq k \leq n - 1)\).

\(d\)

The array \(d\) with the dimension of \(n\) contains the diagonal elements of the diagonal matrix \(D\).

\(lda\)

The leading dimension of the array \(a\) \((lda \geq n)\).
The array `iseed` with the dimension of 4 contains the seed of the random number generator. The elements must be between 0 and 4095 and `iseed[3]` must be odd.

Output Parameters

- **a**: The array of size \(\max(1, lda \times n)\) contains the generated symmetric \(n\)-by-\(n\) matrix \(D\).
- **iseed**: The array `iseed` contains the updated seed on exit.

Return Values

This function returns a value `info`.

- If `info = 0`, the execution is successful.
- If `info < 0`, the `i`-th parameter had an illegal value.
- If `info = -1011`, memory allocation error occurred.

### latms

*Generates a general \(m\)-by-\(n\) matrix with specific singular values.*

**Syntax**

```c
lapack_int LAPACKE_slatms (int matrix_layout, lapack_int m, lapack_int n, char dist, lapack_int * iseed, char sym, float * d, lapack_int mode, float cond, float dmax, lapack_int kl, lapack_int ku, char pack, float * a, lapack_int lda);
```

```c
lapack_int LAPACKE_dlatms (int matrix_layout, lapack_int m, lapack_int n, char dist, lapack_int * iseed, char sym, double * d, lapack_int mode, double cond, double dmax, lapack_int kl, lapack_int ku, char pack, double * a, lapack_int lda);
```

```c
lapack_int LAPACKE_clatms (int matrix_layout, lapack_int m, lapack_int n, char dist, lapack_int * iseed, char sym, float * d, lapack_int mode, float cond, float dmax, lapack_int kl, lapack_int ku, char pack, lapack_complex_float * a, lapack_int lda);
```

```c
lapack_int LAPACKE_zlatms (int matrix_layout, lapack_int m, lapack_int n, char dist, lapack_int * iseed, char sym, double * d, lapack_int mode, double cond, double dmax, lapack_int kl, lapack_int ku, char pack, lapack_complex_double * a, lapack_int lda);
```

**Include Files**

- mkl.h

**Description**

The `latms` routine generates random matrices with specified singular values, or symmetric/Hermitian matrices with specified eigenvalues for testing LAPACK programs.

It applies this sequence of operations:

1. Set the diagonal to \(d\), where \(d\) is input or computed according to `mode`, `cond`, `dmax`, and `sym` as described in Input Parameters.
2. Generate a matrix with the appropriate band structure, by one of two methods:
Method A

1. Generate a dense $m$-by-$n$ matrix by multiplying $d$ on the left and the right by random unitary matrices, then:
2. Reduce the bandwidth according to $k_l$ and $k_u$, using Householder transformations.

Method B:

Convert the bandwidth-0 (i.e., diagonal) matrix to a bandwidth-1 matrix using Givens rotations, "chasing" out-of-band elements back, much as in QR; then convert the bandwidth-1 to a bandwidth-2 matrix, etc.

Note that for reasonably small bandwidths (relative to $m$ and $n$) this requires less storage, as a dense matrix is not generated. Also, for symmetric or Hermitian matrices, only one triangle is generated.

Method A is chosen if the bandwidth is a large fraction of the order of the matrix, and $lda$ is at least $m$ (so a dense matrix can be stored.) Method B is chosen if the bandwidth is small (less than $(1/2)*n$ for symmetric or Hermitian or less than $0.3*n+m$ for nonsymmetric), or $lda$ is less than $m$ and not less than the bandwidth.

Pack the matrix if desired, using one of the methods specified by the pack parameter.

If Method B is chosen and band format is specified, then the matrix is generated in the band format and no repacking is necessary.

**Input Parameters**

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **m**
  The number of rows of the matrix $A$ ($m \geq 0$).

- **n**
  The number of columns of the matrix $A$ ($n \geq 0$).

- **dist**
  Specifies the type of distribution to be used to generate the random singular values or eigenvalues:
  - 'U': uniform distribution (0, 1)
  - 'S': symmetric uniform distribution (-1, 1)
  - 'N': normal distribution (0, 1)

- **iseed**
  Array with size 4.

  Specifies the seed of the random number generator. Values should lie between 0 and 4095 inclusive, and $iseed[3]$ should be odd. The random number generator uses a linear congruential sequence limited to small integers, and so should produce machine independent random numbers. The values of the array are modified, and can be used in the next call to ?latms to continue the same random number sequence.

- **sym**
  If $sym='S'$ or 'H', the generated matrix is symmetric or Hermitian, with eigenvalues specified by $d$, $cond$, $mode$, and $dmax$; they can be positive, negative, or zero.

  If $sym='P'$, the generated matrix is symmetric or Hermitian, with eigenvalues (which are singular, non-negative values) specified by $d$, $cond$, $mode$, and $dmax$. 

If `sym='N', the generated matrix is nonsymmetric, with singular, non-negative values specified by `d, `cond, `mode, and `dmax.

`d
Array, size `(MIN(`m, `n))
This array is used to specify the singular values or eigenvalues of `A (see the description of `sym). If `mode=0, then `d is assumed to contain the eigenvalues or singular values, otherwise elements of `d are computed according to `mode, `cond, and `dmax.

`mode
Describes how the singular/eigenvalues are specified.
- `mode = 0: use `d as input
- `mode = 1: set `d[0] = 1 and `d[1:`n - 1] = 1.0/`cond
- `mode = 2: set `d[0:`n - 2] = 1 and `d[`n - 1] = 1.0/`cond
- `mode = 3: set `d[i] = `cond/(i+1)
- `mode = 4: set `d[i] = 1 - i/(`n - 1)*((1 - 1/`cond)
- `mode = 5: set elements of `d to random numbers in the range (1/`cond, 1) such that their logarithms are uniformly distributed.
- `mode = 6: set elements of `d to random numbers from same distribution as the rest of the matrix.

`mode < 0 has the same meaning as ABS(`mode), except that the order of the elements of `d is reversed. Thus, if `mode is positive, `d has entries ranging from 1 to 1/`cond, if negative, from 1/`cond to 1.

If `sym='S' or 'H', and `mode is not 0, 6, nor -6, then the elements of `d are also given a random sign (multiplied by +1 or -1).

`cond
Used in setting `d as described for the `mode parameter. If used, `cond≥ 1.

`dmax
If `mode is not -6, 0 nor 6, the contents of `d, as computed according to `mode and `cond, are scaled by `dmax / max(abs(`d[i-1])); thus, the maximum absolute eigenvalue or singular value (the norm) is abs(`dmax).

**NOTE**
`dmax need not be positive: if `dmax is negative (or zero), `d will be scaled by a negative number (or zero).

`kl
Specifies the lower bandwidth of the matrix. For example, `kl=0 implies upper triangular, `kl=1 implies upper Hessenberg, and `kl being at least `m - 1 means that the matrix has full lower bandwidth. `kl must equal `ku if the matrix is symmetric or Hermitian.

`ku
Specifies the upper bandwidth of the matrix. For example, `ku=0 implies lower triangular, `ku=1 implies lower Hessenberg, and `ku being at least `n - 1 means that the matrix has full upper bandwidth. `kl must equal `ku if the matrix is symmetric or Hermitian.

`pack
Specifies packing of matrix:
- 'N': no packing
- 'U': zero out all subdiagonal entries (if symmetric or Hermitian)
- 'L': zero out all superdiagonal entries (if symmetric or Hermitian)
• 'B': store the lower triangle in band storage scheme (only if matrix symmetric, Hermitian, or lower triangular)
• 'Q': store the upper triangle in band storage scheme (only if matrix symmetric, Hermitian, or upper triangular)
• 'Z': store the entire matrix in band storage scheme (pivoting can be provided for by using this option to store $A$ in the trailing rows of the allocated storage)

Using these options, the various LAPACK packed and banded storage schemes can be obtained:

<table>
<thead>
<tr>
<th>Storage Type</th>

</tbody>
</table>

If two calls to `?latms` differ only in the `pack` parameter, they generate mathematically equivalent matrices.

`lda` specifies the first dimension of $a$ as declared in the calling program.

If `pack='N', 'U', 'L', 'C', or 'R'`, then `lda` must be at least $m$ for column major or at least $n$ for row major.

If `pack='B' or 'Q'`, then `lda` must be at least $\text{MIN}(kl, m - 1)$ (which is equal to $\text{MIN}(ku, n - 1)$).

If `pack='Z'`, `lda` must be large enough to hold the packed array: $\text{MIN}( ku, n - 1) + \text{MIN}( kl, m - 1) + 1$.

**Output Parameters**

`iseed` contains the updated seed.

The array `d` contains the updated seed.

**NOTE**

The array `d` is not modified if `mode = 0`.

`a` is an array of size `lda` by $n$.

The array $a$ contains the generated $m$-by-$n$ matrix $A$. 
a is first generated in full (unpacked) form, and then packed, if so specified by pack. Thus, the first m elements of the first n columns are always modified. If pack specifies a packed or banded storage scheme, all lda elements of the first n columns are modified; the elements of the array which do not correspond to elements of the generated matrix are set to zero.

Return Values
This function returns a value info.
If info = 0, the execution is successful.
If info < 0, the i-th parameter had an illegal value.
If info = -1011, memory allocation error occurred.
If info = 2, cannot scale to dmax (maximum singular value is 0).
If info = 3, error return from lagge, ?laghe, or lagsy.

ScaLAPACK Routines

Intel® Math Kernel Library implements routines from the ScaLAPACK package for distributed-memory architectures. Routines are supported for both real and complex dense and band matrices to perform the tasks of solving systems of linear equations, solving linear least-squares problems, eigenvalue and singular value problems, as well as performing a number of related computational tasks.

Intel® MKL ScaLAPACK routines are written in FORTRAN 77 with exception of a few utility routines written in C to exploit the IEEE arithmetic. All routines are available in all precision types: single precision, double precision, complex, and double complex precision. See the mkl_scalapack.h header file for C declarations of ScaLAPACK routines.

NOTE
ScaLAPACK routines are provided only for Intel® 64 or Intel® Many Integrated Core architectures.

See descriptions of ScaLAPACK computational routines that perform distinct computational tasks, as well as driver routines for solving standard types of problems in one call. Additionally, Intel® Math Kernel Library implements ScaLAPACK Auxiliary Routines, Utility Functions and Routines, and Matrix Redistribution/Copy Routines. The library includes routines for both real and complex data.

The <install_directory>/examples/scalapackf directory contains sample code demonstrating the use of ScaLAPACK routines.

Generally, ScaLAPACK runs on a network of computers using MPI as a message-passing layer and a set of prebuilt communication subprograms (BLACS), as well as a set of BLAS optimized for the target architecture. Intel® MKL version of ScaLAPACK is optimized for Intel® processors. For the detailed system and environment requirements, see Intel® MKL Release Notes and Intel® MKL Developer Guide.

For full reference on ScaLAPACK routines and related information, see [SLUG].

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Overview of ScaLAPACK Routines

The model of the computing environment for ScaLAPACK is represented as a one-dimensional array of processes (for operations on band or tridiagonal matrices) or also a two-dimensional process grid (for operations on dense matrices). To use ScaLAPACK, all global matrices or vectors should be distributed on this array or grid prior to calling the ScaLAPACK routines.

ScaLAPACK is closely tied to other components, including BLAS, BLACS, LAPACK, and PBLAS.
ScaLAPACK Array Descriptors

ScaLAPACK uses two-dimensional block-cyclic data distribution as a layout for dense matrix computations. This distribution provides good work balance between available processors, and also allows use of BLAS Level 3 routines for optimal local computations. Information about the data distribution that is required to establish the mapping between each global matrix and its corresponding process and memory location is contained in the array called the array descriptor associated with each global matrix. The size of the array descriptor is denoted as $dlen_\_$. 

Let $A$ be a two-dimensional block cyclicly distributed matrix with the array descriptor array $desca$. The meaning of each array descriptor element depends on the type of the matrix $A$. The tables "Array descriptor for dense matrices" and "Array descriptor for narrow-band and tridiagonal matrices" describe the meaning of each element for the different types of matrices.

</tr>
</tbody>
</table>

Not applicable: Reserved for future use. | 6 |

Similar notations are used for different matrices. For example: llb_a is the leading dimension of the local matrix storing the local blocks of the distributed matrix B and dtype_z is the type of the global matrix Z.

The number of rows and columns of a global dense matrix that a particular process in a grid receives after data distributing is denoted by LOC_r() and LOC_c(), respectively. To compute these numbers, you can use the ScALAPACK tool routine numroc.

After the block-cyclic distribution of global data is done, you may choose to perform an operation on a submatrix sub(A) of the global matrix A defined by the following 6 values (for dense matrices):

- m The number of rows of sub(A)
- n The number of columns of sub(A)
- a A pointer to the local matrix containing the entire global matrix A
- ia The row index of sub(A) in the global matrix A
- ja The column index of sub(A) in the global matrix A
**Optimization Notice**

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. ---

**Naming Conventions for ScaLAPACK Routines**

For each routine introduced in this chapter, you can use the ScaLAPACK name. The naming convention for ScaLAPACK routines is similar to that used for LAPACK routines. A general rule is that each routine name in ScaLAPACK, which has an LAPACK equivalent, is simply the LAPACK name prefixed by initial letter p. **ScaLAPACK names** have the structure p?yyzzz or p?yyzz, which is described below.

The initial letter p is a distinctive prefix of ScaLAPACK routines and is present in each such routine.

The second symbol ? indicates the data type:

- **s**: real, single precision
- **d**: real, double precision
- **c**: complex, single precision
- **z**: complex, double precision

The second and third letters yy indicate the matrix type as:

- **ge**: general
- **gb**: general band
- **gg**: a pair of general matrices (for a generalized problem)
- **dt**: general tridiagonal (diagonally dominant-like)
- **db**: general band (diagonally dominant-like)
- **po**: symmetric or Hermitian positive-definite
- **pb**: symmetric or Hermitian positive-definite band
- **pt**: symmetric or Hermitian positive-definite tridiagonal
- **sy**: symmetric
- **st**: symmetric tridiagonal (real)
- **he**: Hermitian
- **or**: orthogonal
- **tr**: triangular (or quasi-triangular)
- **tz**: trapezoidal

The array descriptor for the global matrix A
For computational routines, the last three letters **zzz** indicate the computation performed and have the same meaning as for LAPACK routines.

For driver routines, the last two letters **zz** or three letters **zzz** have the following meaning:

- **sv**: a *simple* driver for solving a linear system
- **svx**: an *expert* driver for solving a linear system
- **ls**: a driver for solving a linear least squares problem
- **ev**: a simple driver for solving a symmetric eigenvalue problem
- **evd**: a simple driver for solving an eigenvalue problem using a divide and conquer algorithm
- **evx**: an expert driver for solving a symmetric eigenvalue problem
- **svd**: a driver for computing a singular value decomposition
- **gvx**: an expert driver for solving a generalized symmetric definite eigenvalue problem

*Simple* driver here means that the driver just solves the general problem, whereas an *expert* driver is more versatile and can also optionally perform some related computations (such, for example, as refining the solution and computing error bounds after the linear system is solved).

**ScaLAPACK Computational Routines**

In the sections that follow, the descriptions of ScaLAPACK computational routines are given. These routines perform distinct computational tasks that can be used for:

- Solving Systems of Linear Equations
- Orthogonal Factorizations and LLS Problems
- Symmetric Eigenproblems
- Nonsymmetric Eigenproblems
- Singular Value Decomposition
- Generalized Symmetric-Definite Eigenproblems

See also the respective driver routines.

**Systems of Linear Equations: ScaLAPACK Computational Routines**

ScaLAPACK supports routines for the systems of equations with the following types of matrices:

- general
- general banded
- general diagonally dominant-like banded (including general tridiagonal)
- symmetric or Hermitian positive-definite
- symmetric or Hermitian positive-definite banded
- symmetric or Hermitian positive-definite tridiagonal

A *diagonally dominant-like* matrix is defined as a matrix for which it is known in advance that pivoting is not required in the LU factorization of this matrix.

For the above matrix types, the library includes routines for performing the following computations: *factoring* the matrix; *equilibrating* the matrix; *solving* a system of linear equations; *estimating the condition number* of a matrix; *refining* the solution of linear equations and computing its error bounds; *inverting* the matrix. Note that for some of the listed matrix types only part of the computational routines are provided (for example, routines that refine the solution are not provided for band or tridiagonal matrices). See Table “Computational Routines for Systems of Linear Equations” for full list of available routines.
To solve a particular problem, you can either call two or more computational routines or call a corresponding driver routine that combines several tasks in one call. Thus, to solve a system of linear equations with a general matrix, you can first call `p?getrf` (LU factorization) and then `p?getrs` (computing the solution). Then, you might wish to call `p?gerfs` to refine the solution and get the error bounds. Alternatively, you can just use the driver routine `p?gesvx` which performs all these tasks in one call.

Table "Computational Routines for Systems of Linear Equations" lists the ScaLAPACK computational routines for factorizing, equilibrating, and inverting matrices, estimating their condition numbers, solving systems of equations with real matrices, refining the solution, and estimating its error.

**Matrix Factorization: ScaLAPACK Computational Routines**

This section describes the ScaLAPACK routines for matrix factorization. The following factorizations are supported:

- LU factorization of general matrices
- LU factorization of diagonally dominant-like matrices
- Cholesky factorization of real symmetric or complex Hermitian positive-definite matrices

You can compute the factorizations using full and band storage of matrices.

`p?getrf`

*Computes the LU factorization of a general m-by-n distributed matrix.*

**Syntax**

```c
void psgetrf (MKL_INT *m, MKL_INT *n, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_INT *ipiv, MKL_INT *info);
void pdgetrf (MKL_INT *m, MKL_INT *n, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_INT *ipiv, MKL_INT *info);
void pcgetrf (MKL_INT *m, MKL_INT *n, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_INT *ipiv, MKL_INT *info);
void pzgetrf (MKL_INT *m, MKL_INT *n, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_INT *ipiv, MKL_INT *info);
```
Include Files

- mkl_scalapack.h

Description

The `pgetrf` function forms the LU factorization of a general \( m \)-by-\( n \) distributed matrix \( \text{sub}(A) = A(\text{ia} : \text{ia + m - 1}, \text{ja} : \text{ja + n - 1}) \) as

\[
A = P \cdot L \cdot U
\]

where \( P \) is a permutation matrix, \( L \) is lower triangular with unit diagonal elements (lower trapezoidal if \( m > n \)) and \( U \) is upper triangular (upper trapezoidal if \( m < n \)). \( L \) and \( U \) are stored in \( \text{sub}(A) \).

The function uses partial pivoting, with row interchanges.

**NOTE**

This function supports the Progress Routine feature. See `mkl_progress` for details.

Input Parameters

- \( m \) (global) The number of rows in the distributed matrix \( \text{sub}(A) \); \( m \geq 0 \).
- \( n \) (global) The number of columns in the distributed matrix \( \text{sub}(A) \); \( n \geq 0 \).
- \( a \) (local) Pointer into the local memory to an array of local size \( \text{lld}_a \cdot \text{LOCc}(\text{ja} + n - 1) \).
  Contains the local pieces of the distributed matrix \( \text{sub}(A) \) to be factored.
- \( \text{ia}, \text{ja} \) (global) The row and column indices in the global matrix \( A \) indicating the first row and the first column of the matrix \( \text{sub}(A) \), respectively.
- \( \text{desca} \) (global and local) array of size \( \text{dlen}_a \). The array descriptor for the distributed matrix \( A \).

Output Parameters

- \( a \) Overwritten by local pieces of the factors \( L \) and \( U \) from the factorization \( A = P \cdot L \cdot U \). The unit diagonal elements of \( L \) are not stored.
- \( \text{ipiv} \) (local) Array of size \( \text{LOCr}(\text{m}_a) + \text{mb}_a \).
  Contains the pivoting information: local row \( i \) was interchanged with global row \( \text{ipiv}[i-1] \). This array is tied to the distributed matrix \( A \).
- \( \text{info} \) (global)
  If \( \text{info} = 0 \), the execution is successful.
  \( \text{info} < 0 \): if the \( i \)-th argument is an array and the \( j \)-th entry, indexed \( j - 1 \), had an illegal value, then \( \text{info} = -(i \times 100 + j) \); if the \( i \)-th argument is a scalar and had an illegal value, then \( \text{info} = -i \).
  If \( \text{info} = i > 0 \), \( u_{\text{ia}+i}, \text{ja}+j-1 \) is 0. The factorization has been completed, but the factor \( U \) is exactly singular. Division by zero will occur if you use the factor \( U \) for solving a system of linear equations.

**p?gbtrf**

Computes the LU factorization of a general n-by-n banded distributed matrix.

**Syntax**

```c
void psgbtrf (MKL_INT *n, MKL_INT *bwl, MKL_INT *bwu, float *a, MKL_INT *ja,
MKL_INT *desca, MKL_INT *ipiv, float *af, MKL_INT *laf, float *work, MKL_INT
*lwork, MKL_INT *info);
void pdgbtrf (MKL_INT *n, MKL_INT *bwl, MKL_INT *bwu, double *a, MKL_INT *ja,
MKL_INT *desca, MKL_INT *ipiv, double *af, MKL_INT *laf, double *work, MKL_INT
*lwork, MKL_INT *info);
void pcgbtrf (MKL_INT *n, MKL_INT *bwl, MKL_INT *bwu, MKL_Complex8 *a, MKL_INT
*ja, MKL_INT *desca, MKL_INT *ipiv, MKL_Complex8 *af, MKL_INT *laf, MKL_Complex8
*work, MKL_INT *lwork, MKL_INT *info);
void pzgbtrf (MKL_INT *n, MKL_INT *bwl, MKL_INT *bwu, MKL_Complex16 *a, MKL_INT
*ja, MKL_INT *desca, MKL_INT *ipiv, MKL_Complex16 *af, MKL_INT *laf, MKL_Complex16
*work, MKL_INT *lwork, MKL_INT *info);
```

**Include Files**

- mkl_scalapack.h

**Description**

The **p?gbtrf** function computes the LU factorization of a general n-by-n real/complex banded distributed matrix \(A(1:n, ja:ja+n-1)\) using partial pivoting with row interchanges.

The resulting factorization is not the same factorization as returned from the LAPACK function ?gbtrf. Additional permutations are performed on the matrix for the sake of parallelism.

The factorization has the form

\[A(1:n, ja:ja+n-1) = P \cdot L \cdot U \cdot Q\]

where \(P\) and \(Q\) are permutation matrices, and \(L\) and \(U\) are banded lower and upper triangular matrices, respectively. The matrix \(Q\) represents reordering of columns for the sake of parallelism, while \(P\) represents reordering of rows for numerical stability using classic partial pivoting.

**Optimization Notice**

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804
**Input Parameters**

\( n \)  
(global) The number of rows and columns in the distributed submatrix \( A(1:n, ja:ja+n-1); n \geq 0 \).

\( bwl \)  
(global) The number of sub-diagonals within the band of \( A \)  
( \( 0 \leq bwl \leq n-1 \)).

\( bwu \)  
(global) The number of super-diagonals within the band of \( A \)  
( \( 0 \leq bwu \leq n-1 \)).

\( a \)  
(local)  
Pointer into the local memory to an array of local size \( lld_a \* \text{LOCc}(ja+n-1) \) where \( lld_a \geq 2 * bwl + 2 * bwu + 1 \).

Contains the local pieces of the \( n \)-by-\( n \) distributed banded matrix \( A(1:n, ja:ja+n-1) \) to be factored.

\( ja \)  
(global) The index in the global matrix \( A \) indicating the start of the matrix to be operated on (which may be either all of \( A \) or a submatrix of \( A \)).

\( \text{desca} \)  
(global and local) array of size \( dlen_\)_. The array descriptor for the distributed matrix \( A \).

If \( dtype_a = 501 \), then \( dlen_ \geq 7 \); else if \( dtype_a = 1 \), then \( dlen_ \geq 9 \).

\( laf \)  
(local) The size of the array \( af \).

Must be \( laf \geq (nb_a+ bwu) * (bwu+bwl) + 6 * (bwu+bwl) * (bwl+2 * bwu) \).

If \( laf \) is not large enough, an error code will be returned and the minimum acceptable size will be returned in \( af[0] \).

\( \text{work} \)  
(local) Same type as \( a \). Workspace array of size \( lwork \).

\( lwork \)  
(local or global) The size of the \( \text{work} \) array (\( lwork \geq 1 \)). If \( lwork \) is too small, the minimal acceptable size will be returned in \( \text{work}[0] \) and an error code is returned.

**Output Parameters**

\( a \)  
On exit, this array contains details of the factorization. Note that additional permutations are performed on the matrix, so that the factors returned are different from those returned by \( \text{LAPACK} \).

\( \text{ipiv} \)  
(local) array.

The size of \( \text{ipiv} \) must be \( \geq nb_a \).

Contains pivot indices for local factorizations. Note that you should not alter the contents of this array between factorization and solve.

\( af \)  
(local)  
Array of size \( laf \).
Auxiliary fill-in space. The fill-in space is created in a call to the factorization function \( p?gbtrf \) and is stored in \( af \).

Note that if a linear system is to be solved using \( p?gbtrs \) after the factorization function, \( af \) must not be altered after the factorization.

On exit, \( work[0] \) contains the minimum value of \( lwork \) required.

\( info \) (global)

If \( info=0 \), the execution is successful.

\( info < 0 \):

If the \( i \)-th argument is an array and the \( j \)-th entry, indexed \( j-1 \), had an illegal value, then \( info = -(i*100+j) \); if the \( i \)-th argument is a scalar and had an illegal value, then \( info = -i \).

\( info > 0 \):

If \( info = k \leq \text{NPROCS} \), the submatrix stored on processor \( info \) and factored locally was not nonsingular, and the factorization was not completed.

If \( info = k > \text{NPROCS} \), the submatrix stored on processor \( info-\text{NPROCS} \) representing interactions with other processors was not nonsingular, and the factorization was not completed.

**See Also**

\( p?dbtrf \)

*Computes the LU factorization of a \( n \)-by-\( n \) diagonally dominant-like banded distributed matrix.*

**Syntax**

```c
void psdbtrf (MKL_INT *n, MKL_INT *bwl, MKL_INT *bwu, float *a, MKL_INT *ja, MKL_INT *desca, float *af, MKL_INT *laf, float *work, MKL_INT *lwork, MKL_INT *info);
void pddbtrf (MKL_INT *n, MKL_INT *bwl, MKL_INT *bwu, double *a, MKL_INT *ja, MKL_INT *desca, double *af, MKL_INT *laf, double *work, MKL_INT *lwork, MKL_INT *info);
void pcdbtrf (MKL_INT *n, MKL_INT *bwl, MKL_INT *bwu, MKL_Complex8 *a, MKL_INT *ja, MKL_INT *desca, MKL_Complex8 *af, MKL_INT *laf, MKL_Complex8 *work, MKL_INT *lwork, MKL_INT *info);
void pzdbtrf (MKL_INT *n, MKL_INT *bwl, MKL_INT *bwu, MKL_Complex16 *a, MKL_INT *ja, MKL_INT *desca, MKL_Complex16 *af, MKL_INT *laf, MKL_Complex16 *work, MKL_INT *lwork, MKL_INT *info);
```

**Include Files**

- `mkl_scalapack.h`

**Description**

The \( p?dbtrf \) function computes the LU factorization of a \( n \)-by-\( n \) real/complex diagonally dominant-like banded distributed matrix \( A(1:n, ja:ja+n-1) \) without pivoting.
**NOTE**
A matrix is called *diagonally dominant-like* if pivoting is not required for LU to be numerically stable.

Note that the resulting factorization is not the same factorization as returned from LAPACK. Additional permutations are performed on the matrix for the sake of parallelism.

**Optimization Notice**

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Notice revision #20110804

**Input Parameters**

- **n**
  (global) The number of rows and columns in the distributed submatrix $A(1:n, ja:ja+n-1)$; $n \geq 0$.
- **bwl**
  (global) The number of sub-diagonals within the band of $A$
  $(0 \leq bwl \leq n-1)$.
- **bwu**
  (global) The number of super-diagonals within the band of $A$
  $(0 \leq bwu \leq n-1)$.
- **a**
  (local)
  Pointer into the local memory to an array of local size $lld_a \ast LOCc(ja+n-1)$.
  Contains the local pieces of the $n$-by-$n$ distributed banded matrix $A(1:n, ja:ja+n-1)$ to be factored.
- **ja**
  (global) The index in the global matrix $A$ indicating the start of the matrix to be operated on (which may be either all of $A$ or a submatrix of $A$).
- **desca**
  (global and local) array of size $dlen_\_$. The array descriptor for the distributed matrix $A$.
  If $dtype_a = 501$, then $dlen_\geq 7$;
  else if $dtype_a = 1$, then $dlen_\geq 9$.
- **laf**
  (local) The size of the array $af$.
  Must be $laf_{\geq NB \ast (bwl+bwu)+6 \ast (\max(bwl,bwu))^2}$.
  If $laf$ is not large enough, an error code will be returned and the minimum acceptable size will be returned in $af[0]$.
- **work**
  (local) Workspace array of size $lwork$. 
lwork

(local or global) The size of the work array, must be \( lwork \geq (\max(bwl, bwu))^2 \). If \( lwork \) is too small, the minimal acceptable size will be returned in \( \text{work}[0] \) and an error code is returned.

Output Parameters

a

On exit, this array contains details of the factorization. Note that additional permutations are performed on the matrix, so that the factors returned are different from those returned by LAPACK.

af

(local)

Array of size \( \text{laf} \).

Auxiliary fill-in space. The fill-in space is created in a call to the factorization function \( \text{p?dbtrf} \) and is stored in \( \text{af} \).

Note that if a linear system is to be solved using \( \text{p?dbtrs} \) after the factorization function, \( \text{af} \) must not be altered after the factorization.

work[0]

On exit, \( \text{work}[0] \) contains the minimum value of \( lwork \) required for optimum performance.

info

(global)

If \( info=0 \), the execution is successful.

\( info < 0 \):

If the \( i \)-th argument is an array and the \( j \)-th entry, indexed \( j - 1 \), had an illegal value, then \( info = -(i*100+j) \); if the \( i \)-th argument is a scalar and had an illegal value, then \( info = -i \).

\( info > 0 \):

If \( info = k \leq NPROCS \), the submatrix stored on processor \( info \) and factored locally was not diagonally dominant-like, and the factorization was not completed.

If \( info = k > NPROCS \), the submatrix stored on processor \( info-NPROCS \) representing interactions with other processors was not nonsingular, and the factorization was not completed.

Notice revision #20110804

Input Parameters

\( n \)
(global) The number of rows and columns to be operated on, that is, the order of the distributed submatrix \( A(1:n, ja:ja+n-1) \) \((n \geq 0)\).

\( dl, d, du \)
(local)
Pointers to the local arrays of size \( nb_a \) each.

On entry, the array \( dl \) contains the local part of the global vector storing the subdiagonal elements of the matrix. Globally, \( dl[0] \) is not referenced, and \( dl \) must be aligned with \( d \).

On entry, the array \( d \) contains the local part of the global vector storing the diagonal elements of the matrix.

On entry, the array \( du \) contains the local part of the global vector storing the super-diagonal elements of the matrix. \( du[n-1] \) is not referenced, and \( du \) must be aligned with \( d \).

\( ja \)
(global) The index in the global matrix \( A \) indicating the start of the matrix to be operated on (which may be either all of \( A \) or a submatrix of \( A \)).

\( desca \)
(global and local) array of size \( dlen_\). The array descriptor for the distributed matrix \( A \).

If \( dtype_a = 501 \), then \( dlen \geq 7 \);
else if $dtype_a = 1$, then $dlen \geq 9$.

$laf$ (local) The size of the array $af$.

Must be $laf \geq 2*(NB+2)$.

If $laf$ is not large enough, an error code will be returned and the minimum acceptable size will be returned in $af[0]$.

$work$ (local) Same type as $d$. Workspace array of size $lwork$.

$lwork$ (local or global) The size of the $work$ array, must be at least $lwork \geq 8*NFCOL$.

Output Parameters

$dl, d, du$ On exit, overwritten by the information containing the factors of the matrix.

$af$ (local) Array of size $laf$.

Auxiliary fill-in space. The fill-in space is created in a call to the factorization function $p?dttrf$ and is stored in $af$.

Note that if a linear system is to be solved using $p?dttrs$ after the factorization function, $af$ must not be altered.

$work[0]$ On exit, $work[0]$ contains the minimum value of $lwork$ required for optimum performance.

$info$ (global) If $info=0$, the execution is successful.

$info < 0$: If the $i$-th argument is an array and the $j$-th entry, indexed $j - 1$, had an illegal value, then $info = -(i*100+j)$; if the $i$-th argument is a scalar and had an illegal value, then $info = -i$.

$info > 0$: If $info = k \leq NPROCS$, the submatrix stored on processor $info$ and factored locally was not diagonally dominant-like, and the factorization was not completed.

If $info = k > NPROCS$, the submatrix stored on processor $info-NPROCS$ representing interactions with other processors was not nonsingular, and the factorization was not completed.

$p?potrf$ Computes the Cholesky factorization of a symmetric (Hermitian) positive-definite distributed matrix.

Syntax

```c
void pspotrf (char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
```
void pdpotrf (char *uplo, MKL_INT *n, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_INT *info);
void pcpotrf (char *uplo, MKL_INT *n, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_INT *info);
void pzpotrf (char *uplo, MKL_INT *n, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_INT *info);

Include Files
• mkl_scalapack.h

Description
The p?potrf function computes the Cholesky factorization of a real symmetric or complex Hermitian positive-definite distributed n-by-n matrix A(ia:ia+n-1, ja:ja+n-1), denoted below as sub(A).

The factorization has the form
sub(A) = U^H*U if uplo='U', or
sub(A) = L*L^H if uplo='L'

where L is a lower triangular matrix and U is upper triangular.

Input Parameters

uplo (global) Indicates whether the upper or lower triangular part of sub(A) is stored. Must be 'U' or 'L'.
If uplo = 'U', the array a stores the upper triangular part of the matrix sub(A) that is factored as U^H*U.
If uplo = 'L', the array a stores the lower triangular part of the matrix sub(A) that is factored as L*L^H.

n (global) The order of the distributed matrix sub(A) (n≥0).

a (local) Pointer into the local memory to an array of size lld_a*LOCc(ja+n-1). On entry, this array contains the local pieces of the n-by-n symmetric/Hermitian distributed matrix sub(A) to be factored. Depending on uplo, the array a contains either the upper or the lower triangular part of the matrix sub(A) (see uplo).

ia, ja (global) The row and column indices in the global matrix A indicating the first row and the first column of the matrix sub(A), respectively.

desca (global and local) array of size dlen_. The array descriptor for the distributed matrix A.

Output Parameters

a The upper or lower triangular part of a is overwritten by the Cholesky factor U or L, as specified by uplo.
info (global) .
If $info=0$, the execution is successful; 

$info < 0$: if the $i$-th argument is an array, and the $j$-th entry, indexed $j-1$, had an illegal value, then $info = -(i\times100+j)$; if the $i$-th argument is a scalar and had an illegal value, then $info = -i$. 

If $info = k > 0$, the leading minor of order $k$, $A(ia:ia+k-1, ja:ja+k-1)$, is not positive-definite, and the factorization could not be completed.

See Also
Overview for details of ScaLAPACK array descriptor structures and related notations.

**p?pbtrf**
Computes the Cholesky factorization of a symmetric (Hermitian) positive-definite banded distributed matrix.

**Syntax**
void pspbtrf (char *uplo, MKL_INT *n, MKL_INT *bw, float *a, MKL_INT *ja, MKL_INT *desca, float *af, MKL_INT *laf, float *work, MKL_INT *lwork, MKL_INT *info);
void pdpbtrf (char *uplo, MKL_INT *n, MKL_INT *bw, double *a, MKL_INT *ja, MKL_INT *desca, double *af, MKL_INT *laf, double *work, MKL_INT *lwork, MKL_INT *info);
void pcpbtrf (char *uplo, MKL_INT *n, MKL_INT *bw, MKL_Complex8 *a, MKL_INT *ja, MKL_INT *desca, MKL_Complex8 *af, MKL_INT *laf, MKL_Complex8 *work, MKL_INT *lwork, MKL_INT *info);

**Include Files**
- mkl_scalapack.h

**Description**
The p?pbtrf function computes the Cholesky factorization of an $n$-by-$n$ real symmetric or complex Hermitian positive-definite banded distributed matrix $A(1:n, ja:ja+n-1)$.

The resulting factorization is not the same factorization as returned from LAPACK. Additional permutations are performed on the matrix for the sake of parallelism.

The factorization has the form:

$A(1:n, ja:ja+n-1) = P*U^H*U*P^T$, if uplo='U', or $A(1:n, ja:ja+n-1) = P*L^H*L*P^T$, if uplo='L',

where $P$ is a permutation matrix and $U$ and $L$ are banded upper and lower triangular matrices, respectively.
Input Parameters

**uplo**
(global) Must be 'U' or 'L'.
If uplo = 'U', upper triangle of A(1:n, ja:ja+n-1) is stored;
If uplo = 'L', lower triangle of A(1:n, ja:ja+n-1) is stored.

**n**
(global) The order of the distributed submatrix A(1:n, ja:ja+n-1).
(n≥0).

**bw**
(global) The number of superdiagonals of the distributed matrix if uplo = 'U', or
the number of subdiagonals if uplo = 'L' (bw≥0).

**a**
(local)
Pointer into the local memory to an array of size lld_a*LOCc(ja+n-1).
On entry, this array contains the local pieces of the upper or lower triangle
of the symmetric/Hermitian band distributed matrix A(1:n, ja:ja+n-1) to be factored.

**ja**
(global) The index in the global matrix A indicating the start of the matrix to be operated on (which may be either all of A or a submatrix of A).

**desca**
(global and local) array of size dlen_. The array descriptor for the
distributed matrix A.
If dtype_a = 501, then dlen_ ≥ 7;
else if dtype_a = 1, then dlen_ ≥ 9.

**laf**
(local) The size of the array af.
Must be laf ≥ (NB+2*bw)*bw.
If laf is not large enough, an error code will be returned and the minimum acceptable size will be returned in af[0].

**work**
(local) Workspace array of size lwork.

**lwork**
(local or global) The size of the work array, must be lwork≥bw^2.

Output Parameters

**a**
On exit, if info=0, contains the permuted triangular factor U or L from the
Cholesky factorization of the band matrix A(1:n, ja:ja+n-1), as specified by uplo.

**af**
(local)
Array of size \( laf \). Auxiliary fill-in space. The fill-in space is created in a call to the factorization function \( \text{p}\text{pbtrf} \) and stored in \( af \). Note that if a linear system is to be solved using \( \text{p}\text{pbtrs} \) after the factorization function, \( af \) must not be altered.

\[
\text{work}[0]
\]

On exit, \( \text{work}[0] \) contains the minimum value of \( lwork \) required for optimum performance.

\[
\text{info}
\]

(global)

If \( \text{info}=0 \), the execution is successful.

\[
\text{info}<0:
\]

If the \( i \)-th argument is an array and the \( j \)-th entry, indexed \( j-1 \), had an illegal value, then \( \text{info} = -(i*100+j) \); if the \( i \)-th argument is a scalar and had an illegal value, then \( \text{info} = -i \).

\[
\text{info}>0:
\]

If \( \text{info} = k \leq \text{NPROCS} \), the submatrix stored on processor \( \text{info} \) and factored locally was not positive definite, and the factorization was not completed.

If \( \text{info} = k > \text{NPROCS} \), the submatrix stored on processor \( \text{info}-\text{NPROCS} \) representing interactions with other processors was not nonsingular, and the factorization was not completed.

\end{align*}
\]

\textbf{Include Files}

- mkl_scalapack.h

\textbf{Description}

The \( \text{p}\text{pttrf} \) function computes the Cholesky factorization of an \( n \)-by-\( n \) real symmetric or complex hermitian positive-definite tridiagonal distributed matrix \( A(1:n, ja:ja+n-1) \).
The resulting factorization is not the same factorization as returned from LAPACK. Additional permutations are performed on the matrix for the sake of parallelism.

The factorization has the form:

\[ A(1:n, ja:ja+n-1) = P*L*D*L^H*P^T, \] or

\[ A(1:n, ja:ja+n-1) = P*U^H*D*U*P^T, \]

where \( P \) is a permutation matrix, and \( U \) and \( L \) are tridiagonal upper and lower triangular matrices, respectively.

### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

### Input Parameters

- **n** (global) The order of the distributed submatrix \( A(1:n, ja:ja+n-1) \) (\( n \geq 0 \)).

- **d, e** (local)

  Pointers into the local memory to arrays of size \( nb_a \) each.

  On entry, the array \( d \) contains the local part of the global vector storing the main diagonal of the distributed matrix \( A \).

  On entry, the array \( e \) contains the local part of the global vector storing the upper diagonal of the distributed matrix \( A \).

- **ja** (global) The index in the global matrix \( A \) indicating the start of the matrix to be operated on (which may be either all of \( A \) or a submatrix of \( A \)).

- **desca** (global and local) array of size \( dlen_\). The array descriptor for the distributed matrix \( A \).

  If \( dtype_a = 501 \), then \( dlen \geq 7 \);

  else if \( dtype_a = 1 \), then \( dlen \geq 9 \).

- **laf** (local) The size of the array \( af \).

  Must be \( laf \geq nb_a + 2 \).

  If \( laf \) is not large enough, an error code will be returned and the minimum acceptable size will be returned in \( af[0] \).

- **work** (local) Workspace array of size \( lwork \).

- **lwork** (local or global) The size of the \( work \) array, must be at least \( lwork \geq 8*NPCOL \).
Output Parameters

\( d, e \)

On exit, overwritten by the details of the factorization.

\( af \)

Array of size \( \text{laf} \).

Auxiliary fill-in space. The fill-in space is created in a call to the factorization function \( \text{p?pttrf} \) and stored in \( af \).

Note that if a linear system is to be solved using \( \text{p?pttrs} \) after the factorization function, \( af \) must not be altered.

\( \text{work}[0] \)

On exit, \( \text{work}[0] \) contains the minimum value of \( \text{lwork} \) required for optimum performance.

\( \text{info} \)

If \( \text{info}=0 \), the execution is successful.

\( \text{info} < 0 \):

If the \( i \)-th argument is an array and the \( j \)-th entry, indexed \( j - 1 \), had an illegal value, then \( \text{info} = -(i*100+j) \); if the \( i \)-th argument is a scalar and had an illegal value, then \( \text{info} = -i \).

\( \text{info} > 0 \):

If \( \text{info} = k \leq \text{NPROCS} \), the submatrix stored on processor \( \text{info} \) and factored locally was not positive definite, and the factorization was not completed.

If \( \text{info} = k > \text{NPROCS} \), the submatrix stored on processor \( \text{info}-\text{NPROCS} \) representing interactions with other processors was not nonsingular, and the factorization was not completed.

Solving Systems of Linear Equations: ScaLAPACK Computational Routines

This section describes the ScaLAPACK routines for solving systems of linear equations. Before calling most of these routines, you need to factorize the matrix of your system of equations (see Routines for Matrix Factorization in this chapter). However, the factorization is not necessary if your system of equations has a triangular matrix.

\( \text{p?getrs} \)

Solves a system of distributed linear equations with a general square matrix, using the LU factorization computed by \( \text{p?getrf} \).

Syntax

void psgtrs (char *trans, MKL_INT *n, MKL_INT *nrhs, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_INT *ipiv, float *b, MKL_INT *ib, MKL_INT *jb, MKL_INT *descb, MKL_INT *info);

void pdgetrs (char *trans, MKL_INT *n, MKL_INT *nrhs, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_INT *ipiv, double *b, MKL_INT *ib, MKL_INT *jb, MKL_INT *descb, MKL_INT *info);
void pcgetrs (char *trans, MKL_INT *n, MKL_INT *nrhs, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_INT *ipiv, MKL_Complex8 *b, MKL_INT *ib, MKL_INT *jb, MKL_INT *info);

void pzgetrs (char *trans, MKL_INT *n, MKL_INT *nrhs, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_INT *ipiv, MKL_Complex16 *b, MKL_INT *ib, MKL_INT *jb, MKL_INT *descb, MKL_INT *info);

Include Files

- mkl_scalapack.h

Description

The p?getrs function solves a system of distributed linear equations with a general \( n \)-by-\( n \) distributed matrix \( \text{sub}(A) = A(\text{id}_a:\text{id}_a+n-1, \text{id}_b:\text{id}_b+n-1) \) using the \( LU \) factorization computed by p?getrf.

The system has one of the following forms specified by \( \text{trans} \):

- \( \text{sub}(A) \times X = \text{sub}(B) \) (no transpose),
- \( \text{sub}(A)^{T} \times X = \text{sub}(B) \) (transpose),
- \( \text{sub}(A)^{H} \times X = \text{sub}(B) \) (conjugate transpose),

where \( \text{sub}(B) = B(\text{id}_b:ib+n-1, jb:jb+nrhs-1) \).

Before calling this function, you must call p?getrf to compute the \( LU \) factorization of \( \text{sub}(A) \).

Input Parameters

- \( \text{trans} \) (global) Must be 'N' or 'T' or 'C'.
  - Indicates the form of the equations:
    - If \( \text{trans} = 'N' \), then \( \text{sub}(A) \times X = \text{sub}(B) \) is solved for \( X \).
    - If \( \text{trans} = 'T' \), then \( \text{sub}(A)^{T} \times X = \text{sub}(B) \) is solved for \( X \).
    - If \( \text{trans} = 'C' \), then \( \text{sub}(A)^{H} \times X = \text{sub}(B) \) is solved for \( X \).

- \( n \) (global) The number of linear equations; the order of the matrix \( \text{sub}(A) \) \( (n \geq 0) \).

- \( nrhs \) (global) The number of right hand sides; the number of columns of the distributed matrix \( \text{sub}(B) \) \( (nrhs \geq 0) \).

- \( a, b \) (local)
  - Pointers into the local memory to arrays of local sizes \( lld_a \times \text{LOC}(ja+n-1) \) and \( lld_b \times \text{LOC}(jb+nrhs-1) \), respectively.
  - On entry, the array \( a \) contains the local pieces of the factors \( L \) and \( U \) from the factorization \( \text{sub}(A) = P \times L \times U \); the unit diagonal elements of \( L \) are not stored. On entry, the array \( b \) contains the right hand sides \( \text{sub}(B) \).

- \( ia, ja \) (global) The row and column indices in the global matrix \( A \) indicating the first row and the first column of the matrix \( \text{sub}(A) \), respectively.

- \( \text{desca} \) (global and local) array of size \( dlen_\_ \). The array descriptor for the distributed matrix \( A \).
**ipiv**

(local) Array of size of \( \text{LOCr}(m, a) + mb_a \). Contains the pivoting information: local row \( i \) of the matrix was interchanged with the global row \( ipiv[i-1] \).

This array is tied to the distributed matrix \( A \).

**ib, jb**

(global) The row and column indices in the global matrix \( B \) indicating the first row and the first column of the matrix \( \text{sub}(B) \), respectively.

**descb**

(global and local) array of size \( dlen_ \). The array descriptor for the distributed matrix \( B \).

**Output Parameters**

**b**

On exit, overwritten by the solution distributed matrix \( X \).

**info**

If \( info=0 \), the execution is successful. \( info < 0 \):

If the \( i \)-th argument is an array and the \( j \)-th entry, indexed \( j - 1 \), had an illegal value, then \( info = -(i*100+j) \); if the \( i \)-th argument is a scalar and had an illegal value, then \( info = -i \).

**p\?gbtrs**

Solves a system of distributed linear equations with a general band matrix, using the LU factorization computed by \( p\?gbtrf \).

**Syntax**

```c
void psgbtrs (char *trans, MKL_INT *n, MKL_INT *bwl, MKL_INT *bwu, MKL_INT *nrhs, float *a, MKL_INT *ja, MKL_INT *desca, MKL_INT *ipiv, float *b, MKL_INT *ib, MKL_INT *descb, float *af, MKL_INT *laf, float *work, MKL_INT *lwork, MKL_INT *info);

void pdgbtrs (char *trans, MKL_INT *n, MKL_INT *bwl, MKL_INT *bwu, MKL_INT *nrhs, double *a, MKL_INT *ja, MKL_INT *desca, MKL_INT *ipiv, double *b, MKL_INT *ib, MKL_INT *descb, double *af, MKL_INT *laf, double *work, MKL_INT *lwork, MKL_INT *info);

void pcgbtrs (char *trans, MKL_INT *n, MKL_INT *bwl, MKL_INT *bwu, MKL_INT *nrhs, MKL_Complex8 *a, MKL_INT *ja, MKL_INT *desca, MKL_INT *ipiv, MKL_Complex8 *b, MKL_INT *ib, MKL_INT *descb, MKL_Complex8 *af, MKL_INT *laf, MKL_Complex8 *work, MKL_INT *lwork, MKL_INT *info);

void pzgbtrs (char *trans, MKL_INT *n, MKL_INT *bwl, MKL_INT *bwu, MKL_INT *nrhs, MKL_Complex16 *a, MKL_INT *ja, MKL_INT *desca, MKL_INT *ipiv, MKL_Complex16 *b, MKL_INT *ib, MKL_INT *descb, MKL_Complex16 *af, MKL_INT *laf, MKL_Complex16 *work, MKL_INT *lwork, MKL_INT *info);
```

**Include Files**

- mkl_scalapack.h
Description
The \texttt{p?gbtrs} function solves a system of distributed linear equations with a general band distributed matrix \(\text{sub}(A) = A(1:n, ja:ja+n-1)\) using the \(LU\) factorization computed by \texttt{p?gbtrf}.

The system has one of the following forms specified by \texttt{trans}:
\[ \text{sub}(A) \cdot X = \text{sub}(B) \] (no transpose),
\[ \text{sub}(A)^T \cdot X = \text{sub}(B) \] (transpose),
\[ \text{sub}(A)^H \cdot X = \text{sub}(B) \] (conjugate transpose),
where \(\text{sub}(B) = B(ib:ib+n-1, 1:nrhs)\).

Before calling this function, you must call \texttt{p?gbtrf} to compute the \(LU\) factorization of \(\text{sub}(A)\).

Input Parameters

- \texttt{trans} (global) Must be 'N' or 'T' or 'C'.
  Indicates the form of the equations:
  - If \(\text{trans} = 'N'\), then \(\text{sub}(A) \cdot X = \text{sub}(B)\) is solved for \(X\).
  - If \(\text{trans} = 'T'\), then \(\text{sub}(A)^T \cdot X = \text{sub}(B)\) is solved for \(X\).
  - If \(\text{trans} = 'C'\), then \(\text{sub}(A)^H \cdot X = \text{sub}(B)\) is solved for \(X\).

- \(n\) (global) The number of linear equations; the order of the distributed matrix \(\text{sub}(A)\) \((n \geq 0)\).

- \(bwl\) (global) The number of sub-diagonals within the band of \(A\) \((0 \leq bwl \leq n-1)\).

- \(bwu\) (global) The number of super-diagonals within the band of \(A\) \((0 \leq bwu \leq n-1)\).

- \(nrhs\) (global) The number of right hand sides; the number of columns of the distributed matrix \(\text{sub}(B)\) \((nrhs \geq 0)\).

- \(a, b\) (local)
  Pointers into the local memory to arrays of local sizes \(lld_a \cdot \text{LOCc}(ja+n-1)\) and \(lld_b \cdot \text{LOCc}(nrhs)\), respectively.
  The array \(a\) contains details of the \(LU\) factorization of the distributed band matrix \(A\).
  On entry, the array \(b\) contains the local pieces of the right hand sides \(B(ib:ib+n-1, 1:nrhs)\).

- \(ja\) (global) The index in the global matrix \(A\) indicating the start of the matrix to be operated on (which may be either all of \(A\) or a submatrix of \(A\)).

- \(desca\) (global and local) array of size \(dlen_\_\). The array descriptor for the distributed matrix \(A\).
  - If \(\text{dtype}_a = 501\), then \(dlen \geq 7\);
  - else if \(\text{dtype}_a = 1\), then \(dlen \geq 9\).

- \(ib\) (global) The index in the global matrix \(A\) indicating the start of the matrix to be operated on (which may be either all of \(A\) or a submatrix of \(A\)).
descb  (global and local) array of size dlen_. The array descriptor for the
distributed matrix A.
If dtype_b = 502, then dlen ≥ 7;
else if dtype_b = 1, then dlen ≥ 9.

laf  (local) The size of the array af.
Must be laf≥nb_a*(bwl+bwu)+6*(bwl+bwu)*(bwl+2*bwu).
If laf is not large enough, an error code will be returned and the minimum
acceptable size will be returned in af[0].

work  (local) Same type as a. Workspace array of size lwork.

lwork  (local or global) The size of the work array, must be at least
lwork≥nrhs*(nb_a+2*bwl+4*bwu).

Output Parameters

ipiv  (local) array.
The size of ipiv must be ≥nb_a.
Contains pivot indices for local factorizations. Note that you should not alter
the contents of this array between factorization and solve.

b  On exit, overwritten by the local pieces of the solution distributed matrix X.

af  (local)
Array of size laf.
Auxiliary Fill-in space. The fill-in space is created in a call to the
factorization function p?gbtrf and is stored in af.
Note that if a linear system is to be solved using p?gbtrs after the
factorization function, af must not be altered after the factorization.

work[0]  On exit, work[0] contains the minimum value of lwork required for
optimum performance.

info  If info=0, the execution is successful.
info < 0:
If the i-th argument is an array and the j-th entry, indexed j - 1, had an
illegal value, then info = -(i*100+j); if the i-th argument is a scalar and
had an illegal value, then info = -i.

Description

The `p?dbtrs` function solves for \( X \) one of the systems of equations:

\[
\text{sub}(A)X = \text{sub}(B),
\]

\[
(\text{sub}(A))^T X = \text{sub}(B),
\]

or

\[
(\text{sub}(A))^H X = \text{sub}(B),
\]

where \( \text{sub}(A) = A(1:n, ja:ja+n-1) \) is a diagonally dominant-like banded distributed matrix, and \( \text{sub}(B) \) denotes the distributed matrix \( B(ib:ib+n-1, 1:nrhs) \).

This function uses the \( LU \) factorization computed by `p?dbtrf`.

Input Parameters

- **trans**
  - (global) Must be 'N' or 'T' or 'C'.
  - Indicates the form of the equations:
    - If `trans = 'N'`, then \( \text{sub}(A)X = \text{sub}(B) \) is solved for \( X \).
    - If `trans = 'T'`, then \( (\text{sub}(A))^T X = \text{sub}(B) \) is solved for \( X \).
    - If `trans = 'C'`, then \( (\text{sub}(A))^H X = \text{sub}(B) \) is solved for \( X \).

- **n**
  - (global) The order of the distributed matrix \( \text{sub}(A) \) (\( n \geq 0 \)).

- **bwl**
  - (global) The number of subdiagonals within the band of \( A \)
    - \( 0 \leq bwl \leq n-1 \).

- **bwu**
  - (global) The number of superdiagonals within the band of \( A \)
    - \( 0 \leq bwu \leq n-1 \).

- **nrhs**
  - (global) The number of right hand sides; the number of columns of the distributed matrix \( \text{sub}(B) \) (\( nrhs \geq 0 \)).
### a, b

Pointers into the local memory to arrays of local sizes \( lld_a \times LOCc(ja+n-1) \) and \( lld_b \times LOCc(nrhs) \), respectively.

On entry, the array \( a \) contains details of the LU factorization of the band matrix \( A \), as computed by \( p\text{?dbtrf} \).

On entry, the array \( b \) contains the local pieces of the right hand side distributed matrix sub\( (B) \).

### ja

The index in the global matrix \( A \) indicating the start of the matrix to be operated on (which may be either all of \( A \) or a submatrix of \( A \)).

### desca

Array descriptor for the distributed matrix \( A \).

If \( dtype_a = 501 \), then \( dlen \geq 7 \); otherwise if \( dtype_a = 1 \), then \( dlen \geq 9 \).

### ib

The row index in the global matrix \( B \) indicating the first row of the matrix to be operated on (which may be either all of \( B \) or a submatrix of \( B \)).

### descb

Array descriptor for the distributed matrix \( B \).

If \( dtype_b = 502 \), then \( dlen \geq 7 \); otherwise if \( dtype_b = 1 \), then \( dlen \geq 9 \).

### af, work

Arrays of size \( laf \) and \( lwork \), respectively. The array \( af \) contains auxiliary fill-in space. The fill-in space is created in a call to the factorization function \( p\text{?dbtrf} \) and is stored in \( af \).

The array \( work \) is a workspace array.

### laf

The size of the array \( af \).

Must be \( laf \geq NB \times (bwl+bwu)+6 \times (\max(bwl,bwu))^2 \).

If \( laf \) is not large enough, an error code will be returned and the minimum acceptable size will be returned in \( af[0] \).

### lwork

The size of the array \( work \), must be at least \( lwork \geq (\max(bwl,bwu))^2 \).

### Output Parameters

### b

On exit, this array contains the local pieces of the solution distributed matrix \( X \).

### work[0]

On exit, \( work[0] \) contains the minimum value of \( lwork \) required for optimum performance.

### info

If \( info=0 \), the execution is successful. \( info < 0 \):
If the $i$-th argument is an array and the $j$-th entry, indexed $j - 1$, had an illegal value, then $info = -(i\times100+j)$; if the $i$-th argument is a scalar and had an illegal value, then $info = -i$.

**p?dttrs**
Solves a system of linear equations with a diagonally dominant-like tridiagonal distributed matrix using the factorization computed by p?dttrf.

**Syntax**

```c
void psdttrs (char *trans , MKL_INT *n , MKL_INT *nrhs , float *dl , float *d , float *du , MKL_INT *ja , MKL_INT *desca , float *b , MKL_INT *ib , MKL_INT *descb , float *af , MKL_INT *laf , float *work , MKL_INT *lwork , MKL_INT *info );
void pddttrs (char *trans , MKL_INT *n , MKL_INT *nrhs , double *dl , double *d , double *du , MKL_INT *ja , MKL_INT *desca , double *b , MKL_INT *ib , MKL_INT *descb , double *af , MKL_INT *laf , double *work , MKL_INT *lwork , MKL_INT *info );
void pcdttrs (char *trans , MKL_INT *n , MKL_INT *nrhs , MKL_Complex8 *dl , MKL_Complex8 *d , MKL_Complex8 *du , MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *b , MKL_INT *ib , MKL_INT *descb , MKL_Complex8 *af , MKL_INT *laf , MKL_Complex8 *work , MKL_INT *lwork , MKL_INT *info );
void pzdttrs (char *trans , MKL_INT *n , MKL_INT *nrhs , MKL_Complex16 *dl , MKL_Complex16 *d , MKL_Complex16 *du , MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *b , MKL_INT *ib , MKL_INT *descb , MKL_Complex16 *af , MKL_INT *laf , MKL_Complex16 *work , MKL_INT *lwork , MKL_INT *info );
```

**Include Files**

- mkl_scalapack.h

**Description**
The p?dttrs function solves for $X$ one of the systems of equations:

$\text{sub}(A)X = \text{sub}(B)$,

$(\text{sub}(A))^T X = \text{sub}(B)$, or

$(\text{sub}(A))^H X = \text{sub}(B)$,

where $\text{sub}(A) = A(1:n, ja:ja+n-1)$ is a diagonally dominant-like tridiagonal distributed matrix, and $\text{sub}(B)$ denotes the distributed matrix $B(ib:ib+n-1, 1:nrhs)$.

This function uses the LU factorization computed by p?dttrf.

**Input Parameters**

`trans` (global) Must be 'N' or 'T' or 'C'.

Indicates the form of the equations:

If $trans = 'N$', then $\text{sub}(A)X = \text{sub}(B)$ is solved for $X$.

If $trans = 'T$', then $(\text{sub}(A))^T X = \text{sub}(B)$ is solved for $X$. 

1260
If $trans = 'C'$, then $(\text{sub}(A))^H X = \text{sub}(B)$ is solved for $X$.

$n$

(global) The order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$).

$nrhs$

(global) The number of right hand sides; the number of columns of the distributed matrix $\text{sub}(B)$ ($nrhs \geq 0$).

$dl, d, du$

(local)

Pointers to the local arrays of size $nb_a$ each.

On entry, these arrays contain details of the factorization. Globally, $dl[0]$ and $du[n-1]$ are not referenced; $dl$ and $du$ must be aligned with $d$.

$ja$

(global) The index in the global matrix $A$ indicating the start of the matrix to be operated on (which may be either all of $A$ or a submatrix of $A$).

$desca$

(global and local) array of size $dlen_\_$. The array descriptor for the distributed matrix $A$.

If $\text{dtype}_a = 501$ or $\text{dtype}_a = 502$, then $dlen_\_ \geq 7$;

else if $\text{dtype}_a = 1$, then $dlen_\_ \geq 9$.

$b$

(local) Same type as $d$.

Pointer into the local memory to an array of local size $lld_b*LOCc(nrhs)$

On entry, the array $b$ contains the local pieces of the $n$-by-$nrhs$ right hand side distributed matrix $\text{sub}(B)$.

$ib$

(global) The row index in the global matrix $B$ indicating the first row of the matrix to be operated on (which may be either all of $B$ or a submatrix of $B$).

$descb$

(global and local) array of size $dlen_\_$. The array descriptor for the distributed matrix $B$.

If $\text{dtype}_b = 502$, then $dlen_\_ \geq 7$;

else if $\text{dtype}_b = 1$, then $dlen_\_ \geq 9$.

$af, work$

(local)

Arrays of size $laf$ and $lwork$, respectively.

The array $af$ contains auxiliary fill-in space. The fill-in space is created in a call to the factorization function p\texttt{dttrf} and is stored in $af$. If a linear system is to be solved using p\texttt{dttrs} after the factorization function, $af$ must not be altered.

The array $work$ is a workspace array.

$laf$

(local) The size of the array $af$.

Must be $laf \geq NB*(bwl+bwu)+6*(bwl+bwu)* (bw1+2*bwu)$.

If $laf$ is not large enough, an error code will be returned and the minimum acceptable size will be returned in $af[0]$.

$lwork$

(local or global) The size of the array $work$, must be at least $lwork \geq 10*NPCOL+4*nrhs$. 
Output Parameters

- **b**: On exit, this array contains the local pieces of the solution distributed matrix X.
- **work[0]**: On exit, work[0] contains the minimum value of lwork required for optimum performance.
- **info**: If info=0, the execution is successful. info < 0:
  - If the i-th argument is an array and the j-th entry, indexed j-1, had an illegal value, then info = -(i*100+j); if the i-th argument is a scalar and had an illegal value, then info = -i.

**p?potrs**
Solves a system of linear equations with a Cholesky-factored symmetric/Hermitian distributed positive-definite matrix.

Syntax

```c
void pspotrs (char *uplo , MKL_INT *n , MKL_INT *nrhs , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb , MKL_INT *info );
void pdpotrs (char *uplo , MKL_INT *n , MKL_INT *nrhs , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb , MKL_INT *info );
void pcpotrs (char *uplo , MKL_INT *n , MKL_INT *nrhs , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb , MKL_INT *info );
void pzpotrs (char *uplo , MKL_INT *n , MKL_INT *nrhs , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The p?potrs function solves for X a system of distributed linear equations in the form:

$$\text{sub}(A)*X = \text{sub}(B)$$

where \( \text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1) \) is an \( n \)-by-\( n \) real symmetric or complex Hermitian positive definite distributed matrix, and \( \text{sub}(B) \) denotes the distributed matrix \( B(ib:ib+n-1, jb:jb+nrhs-1) \).

This function uses Cholesky factorization

- \( \text{sub}(A) = U^H*U \), or \( \text{sub}(A) = L*L^H \)

computed by p?potrf.
Input Parameters

**uplo**

(global) Must be 'U' or 'L'.

If **uplo** = 'U', upper triangle of sub($A$) is stored;

If **uplo** = 'L', lower triangle of sub($A$) is stored.

**n**

(global) The order of the distributed matrix sub($A$) ($n \geq 0$).

**nrhs**

(global) The number of right hand sides; the number of columns of the distributed matrix sub($B$) ($nrhs \geq 0$).

**a, b**

(local)

Pointers into the local memory to arrays of local sizes

$lidi_a*\text{LOCc}(ja+n-1)$ and $lidi_b*\text{LOCc}(jb+nrhs-1)$, respectively.

The array $a$ contains the factors $L$ or $U$ from the Cholesky factorization sub($A$) = $L*L^H$ or sub($A$) = $U^H*U$, as computed by $p?potrf$.

On entry, the array $b$ contains the local pieces of the right hand sides sub($B$).

**ia, ja**

(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the matrix sub($A$), respectively.

**desca**

(global and local) array of size $dlen_\_$. The array descriptor for the distributed matrix $A$.

**ib, jb**

(global) The row and column indices in the global matrix $B$ indicating the first row and the first column of the matrix sub($B$), respectively.

**descb**

(local) array of size $dlen_\_$. The array descriptor for the distributed matrix $B$.

Output Parameters

**b**

Overwritten by the local pieces of the solution matrix $X$.

**info**

If info=0, the execution is successful.

info < 0: if the $i$-th argument is an array and the $j$-th entry, indexed $j - 1$, had an illegal value, then info = $-(i*100+j)$; if the $i$-th argument is a scalar and had an illegal value, then info = $-i$.

Description
The p?pbtrs function solves for $X$ a system of distributed linear equations in the form:

$$\text{sub}(A)X = \text{sub}(B),$$

where $\text{sub}(A) = A(1:n, ja:ja+n-1)$ is an $n$-by-$n$ real symmetric or complex Hermitian positive definite distributed band matrix, and $\text{sub}(B)$ denotes the distributed matrix $B(ib:ib+n-1, 1:nrhs)$.

This function uses Cholesky factorization

$$\text{sub}(A) = P*U^H*U*P^T,$$

computed by p?pbtrf.

Input Parameters

- **uplo**
  
  (global) Must be 'U' or 'L'.
  
  If uplo = 'U', upper triangle of sub$(A)$ is stored;
  
  If uplo = 'L', lower triangle of sub$(A)$ is stored.

- **n**
  
  (global) The order of the distributed matrix sub$(A)$ ($n \geq 0$).

- **bw**
  
  (global) The number of superdiagonals of the distributed matrix if uplo = 'U', or the number of subdiagonals if uplo = 'L' ($bw \geq 0$).

- **nrhs**
  
  (global) The number of right hand sides; the number of columns of the distributed matrix sub$(B)$ ($nrhs \geq 0$).

- **a, b**
  
  (local)
  
  Pointers into the local memory to arrays of local sizes $lld_a*LOCc(ja+n-1)$ and $lld_b*LOCc(nrhs-1)$, respectively.
  
  The array $a$ contains the permuted triangular factor $U$ or $L$ from the Cholesky factorization $\text{sub}(A) = P*U^H*U*P^T$, or $\text{sub}(A) = P*L^H*P^T$ of the band matrix $A$, as returned by p?pbtrf.
  
  On entry, the array $b$ contains the local pieces of the $n$-by-$nrhs$ right hand side distributed matrix sub$(B)$.

- **ja**
  
  (global) The index in the global matrix $A$ indicating the start of the matrix to be operated on (which may be either all of $A$ or a submatrix of $A$).
(global and local) array of size $dlen_\_$. The array descriptor for the distributed matrix $A$.

If $dtype\_a = 501$, then $dlen \geq 7$;
else if $dtype\_a = 1$, then $dlen \geq 9$.

$ib$ (global) The row index in the global matrix $B$ indicating the first row of the matrix sub($B$).

$descb$ (global and local) array of size $dlen\_$. The array descriptor for the distributed matrix $B$.

If $dtype\_b = 502$, then $dlen \geq 7$;
else if $dtype\_b = 1$, then $dlen \geq 9$.

$af$, $work$ (local) Arrays, same type as $a$.

The array $af$ is of size $laf$. It contains auxiliary fill-in space. The fill-in space is created in a call to the factorization function $p\?dbtrf$ and is stored in $af$.

The array $work$ is a workspace array of size $lwork$.

$laf$ (local) The size of the array $af$.

Must be $laf\geq nrhs\times bw$.

If $laf$ is not large enough, an error code will be returned and the minimum acceptable size will be returned in $af[0]$.

$lwork$ (local or global) The size of the array $work$, must be at least $lwork\geq bw^2$.

**Output Parameters**

$b$ On exit, if $info=0$, this array contains the local pieces of the $n$-by-$nrhs$ solution distributed matrix $X$.

$work[0]$ On exit, $work[0]$ contains the minimum value of $lwork$ required for optimum performance.

$info$ If $info=0$, the execution is successful.

$info < 0$:

If the $i$-th argument is an array and the $j$-th entry, indexed $j - 1$, had an illegal value, then $info = -(i\times100+j)$; if the $i$-th argument is a scalar and had an illegal value, then $info = -i$.

```

Include Files
- mkl_scalapack.h

Description
The `p?pttrs` function solves for $X$ a system of distributed linear equations in the form:

$$\text{sub}(A) \cdot X = \text{sub}(B),$$

where $\text{sub}(A) = A(1:n, ja:ja+n-1)$ is an $n$-by-$n$ real symmetric or complex Hermitian positive definite tridiagonal distributed matrix, and $\text{sub}(B)$ denotes the distributed matrix $B(ib:ib+n-1, 1:nrhs)$.

This function uses the factorization $\text{sub}(A) = P \cdot L \cdot D \cdot L^T \cdot P^T$, or $\text{sub}(A) = P \cdot U^H \cdot D \cdot U \cdot P^T$ computed by `p?pttrf`.

Input Parameters
- **uplo** (global, used in complex flavors only)
  Must be `'U'` or `'L'`.
  - If `uplo = 'U'`, upper triangle of sub$(A)$ is stored;
  - If `uplo = 'L'`, lower triangle of sub$(A)$ is stored.
- **n** (global) The order of the distributed matrix sub$(A)$ ($n \geq 0$).
- **nrhs** (global) The number of right hand sides; the number of columns of the distributed matrix sub$(B)$ ($nrhs \geq 0$).
- **d, e** (local)
  Pointers into the local memory to arrays of size $nb_a$ each.
  These arrays contain details of the factorization as returned by `p?pttrf`.
- **ja** (global) The index in the global matrix $A$ indicating the start of the matrix to be operated on (which may be either all of $A$ or a submatrix of $A$).
desca

(global and local) array of size dlen_. The array descriptor for the distributed matrix A.

If dtype_a = 501 or dtype_a = 502, then dlen ≥ 7;
else if dtype_a = 1, then dlen ≥ 9.

b

(local) Same type as d, e.

Pointer into the local memory to an array of local size lld_b*LOCc(nrhs).

On entry, the array b contains the local pieces of the n-by-nrhs right hand side distributed matrix sub(B).

ib

(global) The row index in the global matrix B indicating the first row of the matrix to be operated on (which may be either all of B or a submatrix of B).

descb

(global and local) array of size dlen_. The array descriptor for the distributed matrix B.

If dtype_b = 502, then dlen ≥ 7;
else if dtype_b = 1, then dlen ≥ 9.

af, work

Arrays of size laf and (lwork), respectively. The array af contains auxiliary fill-in space. The fill-in space is created in a call to the factorization function p?pttrf and is stored in af.

The array work is a workspace array.

laf

(local) The size of the array af.

Must be laf≥nb_a+2.

If laf is not large enough, an error code is returned and the minimum acceptable size will be returned in af[0].

lwork

(local or global) The size of the array work, must be at least

lwork ≥ (10+2*min(100,nrhs))*NPCOL+4*nrhs.

Output Parameters

b

On exit, this array contains the local pieces of the solution distributed matrix X.

work[0])

On exit, work[0] contains the minimum value of lwork required for optimum performance.

info

If info=0, the execution is successful.

info < 0:

if the i-th argument is an array and the j-th entry, indexed j - 1, had an illegal value, then info = -(i*100+j); if the i-th argument is a scalar and had an illegal value, then info = -i.

Include Files

• mkl_scalapack.h

Description

The p?trtrsfunction solves for X one of the following systems of linear equations:

sub(A)*X = sub(B),
(sub(A))T*X = sub(B), or
(sub(A))H*X = sub(B),

where sub(A) = A(ia:ia+n-1, ja:ja+n-1) is a triangular distributed matrix of order n, and sub(B) denotes the distributed matrix B(ib:ib+n-1, jb:jb+nrhs-1).

A check is made to verify that sub(A) is nonsingular.

Input Parameters

uplo  
(global) Must be 'U' or 'L'.
Indicates whether sub(A) is upper or lower triangular:
If uplo = 'U', then sub(A) is upper triangular.
If uplo = 'L', then sub(A) is lower triangular.

trans  
(global) Must be 'N' or 'T' or 'C'.
Indicates the form of the equations:
If trans = 'N', then sub(A)*X = sub(B) is solved for X.
If trans = 'T', then sub(A)T*X = sub(B) is solved for X.
If trans = 'C', then sub(A)H*X = sub(B) is solved for X.

diag  
(global) Must be 'N' or 'U'.
If diag = 'N', then sub(A) is not a unit triangular matrix.
If \( \text{diag} = 'U' \), then \( \text{sub}(A) \) is unit triangular.

\( n \)  
(global) The order of the distributed matrix \( \text{sub}(A) \) \((n \geq 0)\).

\( \text{nrhs} \)  
(global) The number of right-hand sides; i.e., the number of columns of the distributed matrix \( \text{sub}(B) \) \((\text{nrhs} \geq 0)\).

\( a, b \)  
(local)  
Pointers into the local memory to arrays of local sizes \( \text{lld}_a * \text{LOCc}(ja+n-1) \) and \( \text{lld}_b * \text{LOCc}(jb+\text{nrhs}-1) \), respectively.

The array \( a \) contains the local pieces of the distributed triangular matrix \( \text{sub}(A) \).

If \( \text{uplo} = 'U' \), the leading \( n \)-by-\( n \) upper triangular part of \( \text{sub}(A) \) contains the upper triangular matrix, and the strictly lower triangular part of \( \text{sub}(A) \) is not referenced.

If \( \text{uplo} = 'L' \), the leading \( n \)-by-\( n \) lower triangular part of \( \text{sub}(A) \) contains the lower triangular matrix, and the strictly upper triangular part of \( \text{sub}(A) \) is not referenced.

If \( \text{diag} = 'U' \), the diagonal elements of \( \text{sub}(A) \) are also not referenced and are assumed to be 1.

On entry, the array \( b \) contains the local pieces of the right hand side distributed matrix \( \text{sub}(B) \).

\( ia, ja \)  
(global) The row and column indices in the global matrix \( A \) indicating the first row and the first column of the matrix \( \text{sub}(A) \), respectively.

\( \text{desca} \)  
(global and local) array of size \( \text{dlen}_a \). The array descriptor for the distributed matrix \( A \).

\( ib, jb \)  
(global) The row and column indices in the global matrix \( B \) indicating the first row and the first column of the matrix \( \text{sub}(B) \), respectively.

\( \text{descb} \)  
(global and local) array of size \( \text{dlen}_b \). The array descriptor for the distributed matrix \( B \).

**Output Parameters**

\( b \)  
On exit, if \( \text{info}=0 \), \( \text{sub}(B) \) is overwritten by the solution matrix \( X \).

\( \text{info} \)  
If \( \text{info}=0 \), the execution is successful.

\( \text{info} < 0 \):  
if the \( i \)-th argument is an array and the \( j \)-th entry, indexed \( j - 1 \), had an illegal value, then \( \text{info} = -(i*100+j) \); if the \( i \)-th argument is a scalar and had an illegal value, then \( \text{info} = -i \).

\( \text{info} > 0 \):  
if \( \text{info} = i \), the \( i \)-th diagonal element of \( \text{sub}(A) \) is zero, indicating that the submatrix is singular and the solutions \( X \) have not been computed.

Estimating the Condition Number: ScaLAPACK Computational Routines

This section describes the ScaLAPACK routines for estimating the condition number of a matrix. The condition number is used for analyzing the errors in the solution of a system of linear equations. Since the condition number may be arbitrarily large when the matrix is nearly singular, the routines actually compute the reciprocal condition number.

**p?gecon**

Estimates the reciprocal of the condition number of a general distributed matrix in either the 1-norm or the infinity-norm.

**Syntax**

```c
void psgecon (char *norm, MKL_INT *n, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *anorm, float *rcond, float *work, MKL_INT *iwork, MKL_INT *iwork, MKL_INT *info);

void pdgecon (char *norm, MKL_INT *n, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *anorm, double *rcond, double *work, MKL_INT *iwork, MKL_INT *iwork, MKL_INT *info);

void pcgecon (char *norm, MKL_INT *n, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *anorm, float *rcond, MKL_Complex8 *work, MKL_INT *iwork, float *rwork, MKL_INT *iwork, MKL_INT *info);

void pzgecon (char *norm, MKL_INT *n, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *anorm, double *rcond, MKL_Complex16 *work, MKL_INT *iwork, double *rwork, MKL_INT *iwork, MKL_INT *info);
```

**Include Files**

- mkl_scalapack.h

**Description**

The p?gecon function estimates the reciprocal of the condition number of a general distributed real/complex matrix \( \text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1) \) in either the 1-norm or infinity-norm, using the LU factorization computed by p?getrf.

An estimate is obtained for \( \|\text{sub}(A)^{-1}\| \), and the reciprocal of the condition number is computed as

\[
\text{rcond} = \frac{1}{\|\text{sub}(A)\| \times \|\text{sub}(A)^{-1}\|}
\]

**Input Parameters**

- **norm**
  (global) Must be '1' or 'O' or 'I'.
  Specifies whether the 1-norm condition number or the infinity-norm condition number is required.
  If \( \text{norm} = '1' \) or '0', then the 1-norm is used;
  If \( \text{norm} = 'I' \), then the infinity-norm is used.

- **n**
  (global) The order of the distributed matrix \( \text{sub}(A) \) \((n \geq 0)\).
a
 (local)
 Pointer into the local memory to an array of size lld_a*LOCc(ja+n-1).

The array a contains the local pieces of the factors L and U from the
factorization sub(A) = P*L*U; the unit diagonal elements of L are not
stored.

ia, ja
 (global) The row and column indices in the global matrix A indicating the
first row and the first column of the matrix sub(A), respectively.

desca
 (global and local) array of size dlen_. The array descriptor for the
distributed matrix A.

anorm
 (global)
 If norm = '1' or 'O', the 1-norm of the original distributed matrix sub(A);
If norm = 'I', the infinity-norm of the original distributed matrix sub(A).

work
 (local)
 The array work of size lwork is a workspace array.

lwork
 (local or global) The size of the array work.
 For real flavors:
 lwork must be at least
 lwork\geq 2*LOCr(n+mod(ia-1,mb_a))+2*LOCc(n+mod(ja-1,nb_a))
 +\max(2, \max(nb_a*\max(1,iceil(NPROW-1, NPCOL))), LOCc(n
 +mod(ja-1,nb_a)) + nb_a*\max(1,iceil(NPCOL-1, NPROW))).

 For complex flavors:
 lwork must be at least
 lwork\geq 2*LOCr(n+mod(ia-1,mb_a))+\max(2,
 max(nb_a*iceil(NPROW-1, NPCOL), LOCc(n+mod(ja-1,nb_a)) +
 nb_a*iceil(NPCOL-1, NPROW))).

LOCr and LOCc values can be computed using the ScaLAPACK tool function
numroc; NPROW and NPCOL can be determined by calling the function
blacs_gridinfo.

NOTE
 iceil(x,y) is the ceiling of x/y, and mod(x,y) is the integer
 remainder remainder of x/y.

iwork
 (local) Workspace array of size liwork. Used in real flavors only.

liwork
 (local or global) The size of the array iwork; used in real flavors only. Must
be at least
 liwork\geq LOCr(n+mod(ia-1,mb_a)).

rwork
 (local)
 Workspace array of size lrwork. Used in complex flavors only.
lrwork  
(local or global) The size of the array rwork; used in complex flavors only. 
Must be at least 
\[ lrwork \geq \max(1, 2*\text{LOCc}(n+\text{mod}(ja-1, nb_a))). \]

**Output Parameters**

rcond  
(global) 
The reciprocal of the condition number of the distributed matrix sub(A). See 
Description.

work[0]  
On exit, work[0] contains the minimum value of lwork required for 
optimum performance.

iwork[0]  
On exit, iwork[0] contains the minimum value of liwork required for 
optimum performance (for real flavors).

rwork[0]  
On exit, rwork[0] contains the minimum value of lrwork required for 
optimum performance (for complex flavors).

info  
(global) If info=0, the execution is successful. 
info < 0: 
If the i-th argument is an array and the j-th entry, indexed j - 1, had an 
illegal value, then info = -(i*100+j); if the i-th argument is a scalar and 
had an illegal value, then info = -i.

**See Also**

**Overview** for details of ScaLAPACK array descriptor structures and related notations.

**p?pocon**

Estimates the reciprocal of the condition number (in 
the 1 - norm) of a symmetric / Hermitian positive-
definite distributed matrix.

**Syntax**

```c
void pspocon (char *uplo, MKL_INT *n, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *
desca, float *anorm, float *rcond, float *work, MKL_INT *lwork, MKL_INT *iwork,
MKL_INT *info);
void pdpocon (char *uplo, MKL_INT *n, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *
desca, double *anorm, double *rcond, double *work, MKL_INT *lwork, MKL_INT *
iwork, MKL_INT *iwork, MKL_INT *info);
void pcpocon (char *uplo, MKL_INT *n, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja,
MKL_INT *desca, float *anorm, float *rcond, MKL_Complex8 *work, MKL_INT *
lwork, float *rwork, MKL_INT *lrwork, MKL_INT *info);
void pzpocon (char *uplo, MKL_INT *n, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja,
MKL_INT *desca, double *anorm, double *rcond, MKL_Complex16 *work, MKL_INT *
lwork, double *rwork, MKL_INT *lrwork, MKL_INT *info);
```

**Include Files**

- mkl_scalapack.h
Description

The `p?pocon` function estimates the reciprocal of the condition number (in the 1 - norm) of a real symmetric or complex Hermitian positive definite distributed matrix `sub(A) = A(ia:ia+n-1, ja:ja+n-1)`, using the Cholesky factorization `sub(A) = U^H*U` or `sub(A) = L*L^H` computed by `p?potrf`.

An estimate is obtained for `||sub(A)^{-1}||`, and the reciprocal of the condition number is computed as

$$rcond = \frac{1}{\|\text{Sub}(A)\| \times \|\text{Sub}(A)^{-1}\|}$$

Input Parameters

**uplo**

(global) Must be `'U'` or `'L'`.

Specifies whether the factor stored in `sub(A)` is upper or lower triangular.

If `uplo = 'U'`, `sub(A)` stores the upper triangular factor `U` of the Cholesky factorization `sub(A) = U^H*U`.

If `uplo = 'L'`, `sub(A)` stores the lower triangular factor `L` of the Cholesky factorization `sub(A) = L*L^H`.

**n**

(global) The order of the distributed matrix `sub(A)` (n\geq0).

**a**

(local)

Pointer into the local memory to an array of size `lld_a*LOCc(ja+n-1)`.

The array `a` contains the local pieces of the factors `L` or `U` from the Cholesky factorization `sub(A) = U^H*U`, or `sub(A) = L*L^H`, as computed by `p?potrf`.

**ia, ja**

(global) The row and column indices in the global matrix `A` indicating the first row and the first column of the matrix `sub(A)`, respectively.

**desca**

(global and local) array of size `dlen_`. The array descriptor for the distributed matrix `A`.

**anorm**

(global)

The 1-norm of the symmetric/Hermitian distributed matrix `sub(A)`.

**work**

(local)

The array `work` of size `lwork` is a workspace array.

**lwork**

(local or global) The size of the array `work`.

*For real flavors:*

`lwork` must be at least

$$lwork \geq 2*\text{LOCr}(n+\text{mod}(ia-1,mb_a))+2*\text{LOCc}(n+\text{mod}(ja-1,nb_a)) + \text{max}(2, \text{max}(nb_a*\text{iceil}(\text{NPROW}-1, \text{NPCOL}), \text{LOCc}(n+\text{mod}(ja-1,nb_a))+nb_a*\text{iceil}(\text{NPCOL}-1, \text{NPROW})))$$

*For complex flavors:*

`lwork` must be at least

$$lwork \geq 2*\text{LOCr}(n+\text{mod}(ia-1,mb_a))+2*\text{LOCr}(n+\text{mod}(ja-1,nb_a)) + \text{max}(2, \text{max}(nb_a*\text{iceil}(\text{NPROW}-1, \text{NPCOL}), \text{LOCr}(n+\text{mod}(ja-1,nb_a))+nb_a*\text{iceil}(\text{NPCOL}-1, \text{NPROW})))$$
\[ lwork \geq 2 \cdot \text{LOCr}(n + \text{mod}(ia - 1, mb_a)) + \text{max}(2, \text{max}(nb_a \cdot \text{max}(1, \text{ceil}(\text{NPROW} - 1, \text{NPCOL})), \text{LOCc}(n + \text{mod}(ja - 1, nb_a)) + nb_a \cdot \text{max}(1, \text{ceil}(\text{NPCOL} - 1, \text{NPROW})))) \].

If \( lwork = -1 \), then \( lwork \) is a global input and a workspace query is assumed. The routine only calculates the minimum and optimal size for all work arrays. Each value is returned in the first entry of the corresponding work array, and no error message is issued by \text{p}x\text{erbla}.

**NOTE**

\( \text{ceil}(x, y) \) is the ceiling of \( x/y \), and \( \text{mod}(x, y) \) is the integer remainder of \( x/y \).

\( iwork \) (local) Workspace array of size \( liwork \). Used in real flavors only.

\( liwork \) (local or global) The size of the array \( lwork \); used in real flavors only. Must be at least \( liwork \geq \text{LOCr}(n + \text{mod}(ia - 1, mb_a)) \).

If \( liwork = -1 \), then \( liwork \) is a global input and a workspace query is assumed. The routine only calculates the minimum and optimal size for all work arrays. Each value is returned in the first entry of the corresponding work array, and no error message is issued by \text{p}x\text{erbla}.

\( rwork \) (local)

Workspace array of size \( lrwork \). Used in complex flavors only.

\( lrwork \) (local or global) The size of the array \( rwork \); used in complex flavors only. Must be at least \( lrwork \geq 2 \cdot \text{LOCc}(n + \text{mod}(ja - 1, nb_a)) \).

If \( lrwork = -1 \), then \( lrwork \) is a global input and a workspace query is assumed. The routine only calculates the minimum and optimal size for all work arrays. Each value is returned in the first entry of the corresponding work array, and no error message is issued by \text{p}x\text{erbla}.

**Output Parameters**

\( rcond \) (global)

The reciprocal of the condition number of the distributed matrix sub(\( A \)).

\( \text{work}[0] \) On exit, \( \text{work}[0] \) contains the minimum value of \( lwork \) required for optimum performance.

\( \text{iwork}[0] \) On exit, \( \text{iwork}[0] \) contains the minimum value of \( liwork \) required for optimum performance (for real flavors).

\( \text{rwork}[0] \) On exit, \( \text{rwork}[0] \) contains the minimum value of \( lrwork \) required for optimum performance (for complex flavors).

\( info \) (global) If \( info = 0 \), the execution is successful.

\( info < 0: \)

If the \( i \)-th argument is an array and the \( j \)-th entry, indexed \( j - 1 \), had an illegal value, then \( info = -(i\times100+j) \); if the \( i \)-th argument is a scalar and had an illegal value, then \( info = -i \).
See Also
Overview for details of ScaLAPACK array descriptor structures and related notations.

\textbf{p?trcon}

Estimates the reciprocal of the condition number of a triangular distributed matrix in either 1-norm or infinity-norm.

**Syntax**

```c
void pstrcon(char *norm, char *uplo, char *diag, MKL_INT *n, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *rcond, float *work, MKL_INT *lwork, MKL_INT *iwork, MKL_INT *info);

void pdtrcon(char *norm, char *uplo, char *diag, MKL_INT *n, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *rcond, double *work, MKL_INT *lwork, MKL_INT *iwork, MKL_INT *info);

void pctrcon(char *norm, char *uplo, char *diag, MKL_INT *n, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *rcond, MKL_Complex8 *work, MKL_INT *lwork, float *rwork, MKL_INT *iwork, MKL_INT *info);

void pztrcon(char *norm, char *uplo, char *diag, MKL_INT *n, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *rcond, MKL_Complex16 *work, MKL_INT *lwork, double *rwork, MKL_INT *iwork, MKL_INT *info);
```

**Include Files**

- mkl_scalapack.h

**Description**

The \textbf{p?trcon} function estimates the reciprocal of the condition number of a triangular distributed matrix

\[ \text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1), \]

in either the 1-norm or the infinity-norm.

The norm of \text{sub}(A) is computed and an estimate is obtained for \( \| \text{sub}(A)^{-1} \| \), then the reciprocal of the condition number is computed as

\[ rcond = \frac{1}{\| \text{sub}(A) \| \times \| \text{sub}(A)^{-1} \|} \]

**Input Parameters**

\textbf{norm} (global) Must be 'I' or 'O' or 'I'.

Specifies whether the 1-norm condition number or the infinity-norm condition number is required.

If \text{norm} = '1' or 'O', then the 1-norm is used;

If \text{norm} = 'I', then the infinity-norm is used.

\textbf{uplo} (global) Must be 'U' or 'L'.

If \text{uplo} = 'U', \text{sub}(A) is upper triangular. If \text{uplo} = 'L', \text{sub}(A) is lower triangular.

\textbf{diag} (global) Must be 'N' or 'U'.
If $\text{diag} = 'N'$, sub($A$) is non-unit triangular. If $\text{diag} = 'U'$, sub($A$) is unit triangular.

$n$ (global) The order of the distributed matrix sub($A$), ($n \geq 0$).

$a$ (local) Pointer into the local memory to an array of size $\text{lld}_a \ast \text{LOCc}(ja+n-1)$.

The array $a$ contains the local pieces of the triangular distributed matrix sub($A$).

If $\text{uplo} = 'U'$, the leading $n$-by-$n$ upper triangular part of this distributed matrix contains the upper triangular matrix, and its strictly lower triangular part is not referenced.

If $\text{uplo} = 'L'$, the leading $n$-by-$n$ lower triangular part of this distributed matrix contains the lower triangular matrix, and its strictly upper triangular part is not referenced.

If $\text{diag} = 'U'$, the diagonal elements of sub($A$) are also not referenced and are assumed to be 1.

$ia, ja$ (global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the matrix sub($A$), respectively.

$\text{desca}$ (global and local) array of size $\text{dlen}_\_$. The array descriptor for the distributed matrix $A$.

$\text{work}$ (local) The array $\text{work}$ of size $\text{lwork}$ is a workspace array.

$lwork$ (local or global) The size of the array $\text{work}$.

For real flavors:

$lwork$ must be at least

$$lwork \geq 2 \ast \text{LOCr}(n+\text{mod}(ia-1,mb_a))+\text{LOCc}(n+\text{mod}(ja-1,nb_a))+\max(2,\max(\text{nb}_a\ast\max(1,\text{iceil}(\text{NPROW}-1,\text{NPCOL})),\text{LOCc}(n+\text{mod}(ja-1,nb_a))+\text{nb}_a\ast\max(1,\text{iceil}(\text{NPCOL}-1,\text{NPROW})))).$$

For complex flavors:

$lwork$ must be at least

$$lwork \geq 2 \ast \text{LOCr}(n+\text{mod}(ia-1,mb_a))+\max(2,\max(\text{nb}_a\ast\text{iceil}(\text{NPROW}-1,\text{NPCOL}),\text{LOCc}(n+\text{mod}(ja-1,nb_a))+\text{nb}_a\ast\text{iceil}(\text{NPCOL}-1,\text{NPROW}))).$$

**NOTE**

$\text{iceil}(x,y)$ is the ceiling of $x/y$, and $\text{mod}(x,y)$ is the integer remainder of $x/y$.

$iwork$ (local) Workspace array of size $\text{liwork}$. Used in real flavors only.

$\text{liwork}$ (local or global) The size of the array $\text{iwork}$; used in real flavors only. Must be at least
liwork $\geq$ LOCr($n$+$\text{mod}(ia-1,mb_a)$).

**rwork**

(local)
Workspace array of size lrwork. Used in complex flavors only.

**lrwork**

(local or global) The size of the array rwork; used in complex flavors only. Must be at least

lrwork $\geq$ LOCc($n$+$\text{mod}(ja-1,nb_a)$).

**Output Parameters**

**rcond**

(global)
The reciprocal of the condition number of the distributed matrix sub($A$).

**work[0]**

On exit, work[0] contains the minimum value of lwork required for optimum performance.

**iwork[0]**

On exit, iwork[0] contains the minimum value of liwork required for optimum performance (for real flavors).

**rwork[0]**

On exit, rwork[0] contains the minimum value of lrwork required for optimum performance (for complex flavors).

**info**

(global) If info=0, the execution is successful.

info $<$ 0:
If the $i$-th argument is an array and the $j$-th entry, indexed $j$ - 1, had an illegal value, then info = -(i$\times$100$+$j); if the $i$-th argument is a scalar and had an illegal value, then info = -$i$.

### Refining the Solution and Estimating Its Error: ScaLAPACK Computational Routines

This section describes the ScaLAPACK routines for refining the computed solution of a system of linear equations and estimating the solution error. You can call these routines after factorizing the matrix of the system of equations and computing the solution (see Routines for Matrix Factorization and Solving Systems of Linear Equations).

**p?gerfs**

Improves the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution.

**Syntax**

void p?gerfs (char *trans , MKL_INT *n , MKL_INT *nrhs , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *af , MKL_INT *iaf , MKL_INT *jaf , MKL_INT *descf , MKL_INT *ipiv , float *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , float *ferr , float *berr , float *work , MKL_INT *lwork , MKL_INT *iwork , MKL_INT *liwork , MKL_INT *info );
Include Files

- mkl_scalapack.h

Description

The `pdgerfs` function improves the computed solution to one of the systems of linear equations

\[
\text{sub}(A) \cdot \text{sub}(X) = \text{sub}(B),
\]

\[
\text{sub}(A)^T \cdot \text{sub}(X) = \text{sub}(B), \text{ or }
\]

\[
\text{sub}(A)^H \cdot \text{sub}(X) = \text{sub}(B)
\]

and provides error bounds and backward error estimates for the solution.

Here \( \text{sub}(A) = A(\text{ia:ia}+n-1, \text{ja:ja}+n-1) \), \( \text{sub}(B) = B(\text{ib:ib}+n-1, \text{jb:jb}+\text{nrhs}-1) \), and \( \text{sub}(X) = X(\text{ix:ix}+n-1, \text{ix:xj}+\text{nrhs}-1) \).

Input Parameters

- `trans` (global) Must be 'N' or 'T' or 'C'.
  
  Specifies the form of the system of equations:
  
  If `trans = 'N'`, the system has the form \( \text{sub}(A) \cdot \text{sub}(X) = \text{sub}(B) \) (No transpose);
  
  If `trans = 'T'`, the system has the form \( \text{sub}(A)^T \cdot \text{sub}(X) = \text{sub}(B) \) (Transpose);
  
  If `trans = 'C'`, the system has the form \( \text{sub}(A)^H \cdot \text{sub}(X) = \text{sub}(B) \) (Conjugate transpose).

- `n` (global) The order of the distributed matrix \( \text{sub}(A) \) (\( n \geq 0 \)).

- `nrhs` (global) The number of right-hand sides, i.e., the number of columns of the matrices \( \text{sub}(B) \) and \( \text{sub}(X) \) (\( \text{nrhs} \geq 0 \)).

- `a, af, b, x` (local)

  Pointers into the local memory to arrays of local sizes

  \( a: \text{ld}_a \cdot \text{LOCc}(\text{ja}+n-1), \)
\[ af: \text{lld}_af * \text{LOCc}(jaf+n-1), \]
\[ b: \text{lld}_b * \text{LOCc}(jb+nrhs-1), \]
\[ x: \text{lld}_x * \text{LOCc}(jx+nrhs-1). \]

The array \( a \) contains the local pieces of the distributed matrix \( \text{sub}(A) \).

The array \( af \) contains the local pieces of the distributed factors of the matrix \( \text{sub}(A) = P*L*U \) as computed by \( \text{pgetrf} \).

The array \( b \) contains the local pieces of the distributed matrix of right hand sides \( \text{sub}(B) \).

On entry, the array \( x \) contains the local pieces of the distributed solution matrix \( \text{sub}(X) \).

\( ia, ja \) (global) The row and column indices in the global matrix \( A \) indicating the first row and the first column of the matrix \( \text{sub}(A) \), respectively.

\( desca \) (global and local) array of size \( dlen_\)_. The array descriptor for the distributed matrix \( A \).

\( iaf, jaf \) (global) The row and column indices in the global matrix \( AF \) indicating the first row and the first column of the matrix \( \text{sub}(AF) \), respectively.

\( descaf \) (global and local) array of size \( dlen_\)_. The array descriptor for the distributed matrix \( AF \).

\( ib, jb \) (global) The row and column indices in the global matrix \( B \) indicating the first row and the first column of the matrix \( \text{sub}(B) \), respectively.

\( descb \) (global and local) array of size \( dlen_\)_. The array descriptor for the distributed matrix \( B \).

\( ix, jx \) (global) The row and column indices in the global matrix \( X \) indicating the first row and the first column of the matrix \( \text{sub}(X) \), respectively.

\( descx \) (global and local) array of size \( dlen_\)_. The array descriptor for the distributed matrix \( X \).

\( ipiv \) (local)

Array of size \( \text{LOCr}(m_af) + mb_af \).

This array contains pivoting information as computed by \( \text{pgetrf} \). If \( ipiv[i]=j \), then the local row \( i+1 \) was swapped with the global row \( j \) where \( i=0, \ldots, \text{LOCr}(m_af) + mb_af-1 \).

This array is tied to the distributed matrix \( A \).

\( work \) (local)

The array \( work \) of size \( lwork \) is a workspace array.

\( lwork \) (local or global) The size of the array \( work \).

For real flavors:

\( lwork \) must be at least

\( lwork \geq 3*\text{LOCr}(n+\text{mod}(ia-1,mb_a)) \)

For complex flavors:
`lwork` must be at least
\[ lwork \geq 2 \times \text{LOCr}(n + \text{mod}(ia-1, mb_a)) \]

**NOTE**

\[ \text{mod}(x, y) \] is the integer remainder of \( x/y \).

- `iwork` (local) Workspace array, size `liwork`. Used in real flavors only.
- `liwork` (local or global) The size of the array `lwork`; used in real flavors only. Must be at least
\[ liwork \geq \text{LOCr}(n + \text{mod}(ib-1, mb_b)) \]
- `rwork` (local)
  Workspace array, size `lrwork`. Used in complex flavors only.
- `lrwork` (local or global) The size of the array `rwork`; used in complex flavors only. Must be at least
\[ lrwork \geq \text{LOCr}(n + \text{mod}(ib-1, mb_b)) \]

**Output Parameters**

- `x`
  Arrays of size `LOCc(jb+nrhs-1)` each.
  On exit, contains the improved solution vectors.

- `ferr, berr`
  The array `ferr` contains the estimated forward error bound for each solution vector of sub(\(X\)).
  If XTRUE is the true solution corresponding to sub(\(X\)), `ferr` is an estimated upper bound for the magnitude of the largest element in (sub(\(X\)) - XTRUE) divided by the magnitude of the largest element in sub(\(X\)). The estimate is as reliable as the estimate for `rcond`, and is almost always a slight overestimate of the true error.
  This array is tied to the distributed matrix \(X\).

  The array `berr` contains the component-wise relative backward error of each solution vector (that is, the smallest relative change in any entry of sub(\(A\)) or sub(\(B\)) that makes sub(\(X\)) an exact solution). This array is tied to the distributed matrix \(X\).

- `work[0]`
  On exit, `work[0]` contains the minimum value of `lwork` required for optimum performance.

- `iwork[0]`
  On exit, `iwork[0]` contains the minimum value of `liwork` required for optimum performance (for real flavors).

- `rwork[0]`
  On exit, `rwork[0]` contains the minimum value of `lrwork` required for optimum performance (for complex flavors).

- `info`
  (global) If `info=0`, the execution is successful.

  - `info < 0`:
    If the \(i\)-th argument is an array and the \(j\)-th entry, indexed \( j - 1 \), had an illegal value, then `info = -(i*100+j)`; if the \(i\)-th argument is a scalar and had an illegal value, then `info = -i`.

**Description**

The p?porfs function improves the computed solution to the system of linear equations

\[
\text{sub}(A)*\text{sub}(X) = \text{sub}(B),
\]

where \( \text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1) \) is a real symmetric or complex Hermitian positive definite distributed matrix and

\[
\text{sub}(B) = B(ib:ib+n-1, jb:jb+nrhs-1),
\]

\[
\text{sub}(X) = X(ix:ix+n-1, jx:jx+nrhs-1)
\]

are right-hand side and solution submatrices, respectively. This function also provides error bounds and backward error estimates for the solution.

**Input Parameters**

- **uplo**
  (global) Must be 'U' or 'L'.

---

*ScaLAPACK Routines* 4

1281
Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix sub(A) is stored.

If uplo = 'U', sub(A) is upper triangular. If uplo = 'L', sub(A) is lower triangular.

\( n \) (global) The order of the distributed matrix sub(A) \( (n \geq 0) \).

\( nrhs \) (global) The number of right-hand sides, i.e., the number of columns of the matrices sub(B) and sub(X) \( (nrhs \geq 0) \).

\( a, af, b, x \) (local)

Pointers into the local memory to arrays of local sizes

- \( a: lld_a \times LOCc(ja+n-1) \),
- \( af: lld_{af} \times LOCc(jaf+n-1) \),
- \( b: lld_b \times LOCc(jb+nrhs-1) \),
- \( x: lld_x \times LOCc(jx+nrhs-1) \).

The array \( a \) contains the local pieces of the \( n \)-by-\( n \) symmetric/Hermitian distributed matrix sub(A).

If uplo = 'U', the leading \( n \)-by-\( n \) upper triangular part of sub(A) contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced.

If uplo = 'L', the leading \( n \)-by-\( n \) lower triangular part of sub(A) contains the lower triangular part of the distributed matrix, and its strictly upper triangular part is not referenced.

The array \( af \) contains the factors \( L \) or \( U \) from the Cholesky factorization sub(A) = \( L^H \times L \) or sub(A) = \( U \times U^H \), as computed by \( p?potrf \).

On entry, the array \( b \) contains the local pieces of the distributed matrix of right hand sides sub(B).

On entry, the array \( x \) contains the local pieces of the solution vectors sub(X).

\( ia, ja \) (global) The row and column indices in the global matrix A indicating the first row and the first column of the matrix sub(A), respectively.

\( desca \) (global and local) array of size \( dlen_\). The array descriptor for the distributed matrix A.

\( iaf, jaf \) (global) The row and column indices in the global matrix AF indicating the first row and the first column of the matrix sub(AF), respectively.

\( descaf \) (global and local) array of size \( dlen_\). The array descriptor for the distributed matrix AF.

\( ib, jb \) (global) The row and column indices in the global matrix B indicating the first row and the first column of the matrix sub(B), respectively.

\( descb \) (global and local) array of size \( dlen_\). The array descriptor for the distributed matrix B.

\( ix, jx \) (global) The row and column indices in the global matrix X indicating the first row and the first column of the matrix sub(X), respectively.
(global and local) array of size dlen_. The array descriptor for the distributed matrix X.

(work (local)
The array work of size lwork is a workspace array.

(lwork (local) The size of the array work.

For real flavors:
lwork must be at least
lwork \geq 3*LOCr(n+\text{mod}(ia-1,mb_a))

For complex flavors:
lwork must be at least
lwork \geq 2*LOCr(n+\text{mod}(ia-1,mb_a))

NOTE
\text{mod}(x,y) is the integer remainder of x/y.

(iwork (local) Workspace array of size liwork. Used in real flavors only.

(liwork (local or global) The size of the array iwork; used in real flavors only. Must be at least
liwork \geq \text{LOCr}(n+\text{mod}(ib-1,mb_b)).

(rwork (local)
Workspace array of size lrwork. Used in complex flavors only.

(lrwork (local or global) The size of the array rwork; used in complex flavors only. Must be at least lrwork \geq \text{LOCr}(n+\text{mod}(ib-1,mb_b)).

Output Parameters

x

On exit, contains the improved solution vectors.

Arrays of size LOCc(jb+nrhs-1) each.

The array ferr contains the estimated forward error bound for each solution vector of sub(X).

If XTRUE is the true solution corresponding to sub(X), ferr is an estimated upper bound for the magnitude of the largest element in (sub(X) - XTRUE) divided by the magnitude of the largest element in sub(X). The estimate is as reliable as the estimate for rcond, and is almost always a slight overestimate of the true error.

This array is tied to the distributed matrix X.

The array berr contains the component-wise relative backward error of each solution vector (that is, the smallest relative change in any entry of sub(A) or sub(B) that makes sub(X) an exact solution). This array is tied to the distributed matrix X.
On exit, `work[0]` contains the minimum value of `lwork` required for optimum performance.

On exit, `iwork[0]` contains the minimum value of `liwork` required for optimum performance (for real flavors).

On exit, `rwork[0]` contains the minimum value of `lrwork` required for optimum performance (for complex flavors).

(info) If `info=0`, the execution is successful.

If the `i`-th argument is an array and the `j`-th entry, indexed `j-1`, had an illegal value, then `info = -(i*100+j)`; if the `i`-th argument is a scalar and had an illegal value, then `info = -i`.

Overview for details of ScaLAPACK array descriptor structures and related notations.

**p?trrfs**
Provides error bounds and backward error estimates for the solution to a system of linear equations with a distributed triangular coefficient matrix.

**Syntax**

```c
void pstrrfs (char *uplo, char *trans, char *diag, MKL_INT *n, MKL_INT *nrhs, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *b, MKL_INT *ib, MKL_INT *jb, MKL_INT *descb, float *x, MKL_INT *ix, MKL_INT *jx, MKL_INT *descx, float *ferr, float *berr, float *work, MKL_INT *lwork, MKL_INT *iwork, MKL_INT *info);

void pdtrrfs (char *uplo, char *trans, char *diag, MKL_INT *n, MKL_INT *nrhs, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *b, MKL_INT *ib, MKL_INT *jb, MKL_INT *descb, double *x, MKL_INT *ix, MKL_INT *jx, MKL_INT *descx, double *ferr, double *berr, double *work, MKL_INT *lwork, MKL_INT *iwork, MKL_INT *liwork, MKL_INT *info);

void pctrrfs (char *uplo, char *trans, char *diag, MKL_INT *n, MKL_INT *nrhs, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_Complex8 *b, MKL_INT *ib, MKL_INT *jb, MKL_INT *descb, MKL_Complex8 *x, MKL_INT *ix, MKL_INT *jx, MKL_INT *descx, float *ferr, float *berr, MKL_Complex8 *work, MKL_INT *lwork, float *rwork, MKL_INT *lrwork, MKL_INT *info);

void pztrrfs (char *uplo, char *trans, char *diag, MKL_INT *n, MKL_INT *nrhs, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_Complex16 *b, MKL_INT *ib, MKL_INT *jb, MKL_INT *descb, MKL_Complex16 *x, MKL_INT *ix, MKL_INT *jx, MKL_INT *descx, double *ferr, double *berr, MKL_Complex16 *work, MKL_INT *lwork, double *rwork, MKL_INT *lrwork, MKL_INT *info);
```

**Include Files**
- mkl_scalapack.h

**Description**
The `p?trrfs` function provides error bounds and backward error estimates for the solution to one of the systems of linear equations.
\( \text{sub}(A)*\text{sub}(X) = \text{sub}(B), \)
\( \text{sub}(A)^T*\text{sub}(X) = \text{sub}(B), \) or
\( \text{sub}(A)^H*\text{sub}(X) = \text{sub}(B), \)
where \( \text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1) \) is a triangular matrix,
\( \text{sub}(B) = B(ib:ib+n-1, jb:jb+\text{nrhs}-1), \) and
\( \text{sub}(X) = X(ix:ix+n-1, jx:jx+\text{nrhs}-1). \)

The solution matrix \( X \) must be computed by \texttt{p?trtrs} or some other means before entering this function. The function \texttt{p?trrfs} does not do iterative refinement because doing so cannot improve the backward error.

**Input Parameters**

- **uplo**
  
  (global) Must be 'U' or 'L'.
  
  If \( \text{uplo} = 'U' \), \( \text{sub}(A) \) is upper triangular. If \( \text{uplo} = 'L' \), \( \text{sub}(A) \) is lower triangular.

- **trans**
  
  (global) Must be 'N' or 'T' or 'C'.
  
  Specifies the form of the system of equations:
  
  If \( \text{trans} = 'N' \), the system has the form \( \text{sub}(A)*\text{sub}(X) = \text{sub}(B) \) (No transpose);
  
  If \( \text{trans} = 'T' \), the system has the form \( \text{sub}(A)^T*\text{sub}(X) = \text{sub}(B) \) (Transpose);
  
  If \( \text{trans} = 'C' \), the system has the form \( \text{sub}(A)^H*\text{sub}(X) = \text{sub}(B) \) (Conjugate transpose).

- **diag**
  
  Must be 'N' or 'U'.
  
  If \( \text{diag} = 'N' \), then \( \text{sub}(A) \) is non-unit triangular.
  
  If \( \text{diag} = 'U' \), then \( \text{sub}(A) \) is unit triangular.

- **n**
  
  (global) The order of the distributed matrix \( \text{sub}(A) \) \((n\geq0)\).

- **nrhs**
  
  (global) The number of right-hand sides, that is, the number of columns of the matrices \( \text{sub}(B) \) and \( \text{sub}(X) \) \((\text{nrhs}\geq0)\).

- **a, b, x**
  
  (local)
  
  Pointers into the local memory to arrays of local sizes
  
  \( a: \text{lld}_a * \text{LOCc}(ja+n-1), \)
  
  \( b: \text{lld}_b * \text{LOCc}(jb+\text{nrhs}-1), \)
  
  \( x: \text{lld}_x * \text{LOCc}(jx+\text{nrhs}-1). \)

  The array \( a \) contains the local pieces of the original triangular distributed matrix \( \text{sub}(A) \).
  
  If \( \text{uplo} = 'U' \), the leading \( n \)-by-\( n \) upper triangular part of \( \text{sub}(A) \) contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced.

  If \( \text{uplo} = 'L' \), the leading \( n \)-by-\( n \) lower triangular part of \( \text{sub}(A) \) contains the lower triangular part of the distributed matrix, and its strictly upper triangular part is not referenced.
If diag = 'U', the diagonal elements of sub(A) are also not referenced and are assumed to be 1.

On entry, the array b contains the local pieces of the distributed matrix of right hand sides sub(B).

On entry, the array x contains the local pieces of the solution vectors sub(X).

ia, ja (global) The row and column indices in the global matrix A indicating the first row and the first column of the matrix sub(A), respectively.

desca (global and local) array of size dlen_. The array descriptor for the distributed matrix A.

ib, jb (global) The row and column indices in the global matrix B indicating the first row and the first column of the matrix sub(B), respectively.

descb (global and local) array of size dlen_. The array descriptor for the distributed matrix B.

ix, jx (global) The row and column indices in the global matrix X indicating the first row and the first column of the matrix sub(X), respectively.

descx (global and local) array of size dlen_. The array descriptor for the distributed matrix X.

work (local) The array work of size lwork is a workspace array.

lwork (local) The size of the array work.

For real flavors:

lwork must be at least \( lwork \geq 3 \cdot \text{LOCr}(n + \text{mod}(ia-1, mb_a)) \)

For complex flavors:

lwork must be at least

\( lwork \geq 2 \cdot \text{LOCr}(n + \text{mod}(ia-1, mb_a)) \)

---

**NOTE**

\( \text{mod}(x, y) \) is the integer remainder of \( x/y \).

---

iwork (local) Workspace array of size liwork. Used in real flavors only.

liwork (local or global) The size of the array lwork; used in real flavors only. Must be at least

\( liwork \geq \text{LOCr}(n + \text{mod}(ib-1, mb_b)) \).

rwork (local) Workspace array of size lrwork. Used in complex flavors only.

lrwork (local or global) The size of the array rwork; used in complex flavors only. Must be at least \( lrwork \geq \text{LOCr}(n + \text{mod}(ib-1, mb_b)) \).
Output Parameters

**ferr, berr**  
Arrays of size $\text{LOCc}(jb+nrhs-1)$ each.  
The array *ferr* contains the estimated forward error bound for each  
solution vector of $\text{sub}(X)$.  
If $X_{\text{TRUE}}$ is the true solution corresponding to $\text{sub}(X)$, *ferr* is an estimated  
upper bound for the magnitude of the largest element in $(\text{sub}(X) - X_{\text{TRUE}})$  
divided by the magnitude of the largest element in $\text{sub}(X)$. The estimate is  
as reliable as the estimate for $rcond$, and is almost always a slight  
overestimate of the true error.  
This array is tied to the distributed matrix $X$.  
The array *berr* contains the component-wise relative backward error of  
each solution vector (that is, the smallest relative change in any entry of  
$\text{sub}(A)$ or $\text{sub}(B)$ that makes $\text{sub}(X)$ an exact solution). This array is tied to  
the distributed matrix $X$.

**work[0]**  
On exit, *work[0]* contains the minimum value of *lwork* required for  
optimum performance.

**iwork[0]**  
On exit, *iwork[0]* contains the minimum value of *liwork* required for  
optimum performance (for real flavors).

**rwork[0]**  
On exit, *rwork[0]* contains the minimum value of *lrwork* required for  
optimum performance (for complex flavors).

**info**  
(global) If info=0, the execution is successful.  
info < 0:  
If the $i$-th argument is an array and the $j$-th entry, indexed $j-1$, had an  
illegal value, then info = $-(i*100+j)$; if the $i$-th argument is a scalar and  
had an illegal value, then info = $-i$.

See Also  
Overview  for details of ScaLAPACK array descriptor structures and related notations.

Matrix Inversion: ScaLAPACK Computational Routines

This sections describes ScaLAPACK routines that compute the inverse of a matrix based on the previously  
obtained factorization. Note that it is not recommended to solve a system of equations $Ax = b$ by first  
computing $A^{-1}$ and then forming the matrix-vector product $x = A^{-1}b$. Call a solver routine instead (see  
Solving Systems of Linear Equations); this is more efficient and more accurate.

**p?getri**  
*Computes the inverse of a LU-factored distributed matrix.*

**Syntax**

```c
void psgetri (MKL_INT *n, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca,  
MKL_INT *ipiv, float *work, MKL_INT *lwork, MKL_INT *iwork, MKL_INT *liwork,  
MKL_INT *info );
```
void pdgetri (MKL_INT *n, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_INT *ipiv, double *work, MKL_INT *lwork, MKL_INT *iwork, MKL_INT *liwork, MKL_INT *info);

void pcgetri (MKL_INT *n, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_INT *ipiv, MKL_Complex8 *work, MKL_INT *iwork, MKL_INT *liwork, MKL_INT *info);

void pzgetri (MKL_INT *n, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_INT *ipiv, MKL_Complex16 *work, MKL_INT *lwork, MKL_INT *iwork, MKL_INT *liwork, MKL_INT *info);

Include Files
- mkl_scalapack.h

Description
The p?getri function computes the inverse of a general distributed matrix sub(A) = A(ia:ia+n-1, ja:ja+n-1) using the LU factorization computed by p?getrf. This method inverts U and then computes the inverse of sub(A) by solving the system

\[ \text{inv}(\text{sub}(A)) \times L = \text{inv}(U) \]

for \( \text{inv}(\text{sub}(A)) \).

Input Parameters

\[ n \]
(global) The number of rows and columns to be operated on, that is, the order of the distributed matrix sub(A) \((n \geq 0)\).

\[ a \]
(local)
Pointer into the local memory to an array of local size \( lld_a \times LOCc(ja+n-1) \).

On entry, the array \( a \) contains the local pieces of the \( L \) and \( U \) obtained by the factorization sub(A) = \( P \times L \times U \) computed by p?getrf.

\[ ia, ja \]
(global) The row and column indices in the global matrix \( A \) indicating the first row and the first column of the matrix sub(A), respectively.

\[ desca \]
(global and local) array of size \( dlen_\). The array descriptor for the distributed matrix \( A \).

\[ work \]
(local)
The array \( work \) of size \( lwork \) is a workspace array.

\[ lwork \]
(local) The size of the array \( work \). \( lwork \) must be at least \( lwork \geq LOCr(n + \text{mod}(ia-1,mb_a)) \times nb_a \).

NOTE
\( \text{mod}(x,y) \) is the integer remainder of \( x/y \).

The array \( work \) is used to keep at most an entire column block of sub(A).

\[ iwork \]
(local) Workspace array used for physically transposing the pivots, size \( liwork \).

\[ liwork \]
(local or global) The size of the array \( iwork \).
The minimal value $liwork$ of is determined by the following code:

```plaintext
if NPROW == NPCOL then
    liwork = LOCc(n_a + mod(ja-1,nb_a))+ nb_a
else
    liwork = LOCc(n_a + mod(ja-1,nb_a)) +
    max(ceil(ceil(LOCr(m_a)/mb_a)/(lcm/NPROW)),nb_a)
end if
```

where $lcm$ is the least common multiple of process rows and columns ($NPROW$ and $NPCOL$).

**Output Parameters**

- $ipiv$ (local)
  - Array of size $LOCr(m_a)+ mb_a$.
  - This array contains the pivoting information.
  - If $ipiv[i]=j$, then the local row $i+1$ was swapped with the global row $j$ where $i=0, \ldots, LOCr(m_a) + mb_a-1$.
  - This array is tied to the distributed matrix $A$.

- $work[0]$
  - On exit, $work[0]$ contains the minimum value of $lwork$ required for optimum performance.

- $iwork[0]$
  - On exit, $iwork[0]$ contains the minimum value of $liwork$ required for optimum performance.

- $info$ (global)
  - If $info=0$, the execution is successful.
  - $info < 0$:
    - If the $i$-th argument is an array and the $j$-th entry, indexed $j-1$, had an illegal value, then $info = -(i*100+j)$; if the $i$-th argument is a scalar and had an illegal value, then $info = -i$.
  - $info > 0$:
    - If $info = i$, the matrix element $U(i,i)$ is exactly zero. The factorization has been completed, but the factor $U$ is exactly singular, and division by zero will occur if it is used to solve a system of equations.

**See Also**

**p?potri**

*Computes the inverse of a symmetric/Hermitian positive definite distributed matrix.*

**Syntax**

```c
void pspotri (char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
```
void pdpotri (char *uplo , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info);
void pcpotri (char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *info);
void pzpotri (char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info);

Include Files

• mkl_scalapack.h

Description

The p?potrf function computes the inverse of a real symmetric or complex Hermitian positive definite distributed matrix \( A = sub(A) = A(ia:ia+n-1, ja:ja+n-1) \) using the Cholesky factorization \( sub(A) = U^H \cdot U \) or \( sub(A) = L \cdot L^H \) computed by p?potrf.

Input Parameters

uplo (global) Must be 'U' or 'L'.
 Specifies whether the upper or lower triangular part of the symmetric/ Hermitian matrix \( sub(A) \) is stored.

If \( uplo = 'U' \), upper triangle of \( sub(A) \) is stored. If \( uplo = 'L' \), lower triangle of \( sub(A) \) is stored.

n (global) The number of rows and columns to be operated on, that is, the order of the distributed matrix \( sub(A) \) \( (n \geq 0) \).

a (local)
 Pointer into the local memory to an array of local size \( lld_a \cdot LOCc(ja+n-1) \).
 On entry, the array \( a \) contains the local pieces of the triangular factor \( U \) or \( L \) from the Cholesky factorization \( sub(A) = U^H \cdot U \), or \( sub(A) = L \cdot L^H \), as computed by p?potrf.

ia, ja (global) The row and column indices in the global matrix \( A \) indicating the first row and the first column of the matrix \( sub(A) \), respectively.

desca (global and local) array of size \( dlen_ \). The array descriptor for the distributed matrix \( A \).

Output Parameters

a On exit, overwritten by the local pieces of the upper or lower triangle of the (symmetric/Hermitian) inverse of \( sub(A) \).

info (global) If \( info=0 \), the execution is successful.

\( info < 0 \):
If the \( i \)-th argument is an array and the \( j \)-th entry, indexed \( j - 1 \), had an illegal value, then \( info = -(i \cdot 100 + j) \); if the \( i \)-th argument is a scalar and had an illegal value, then \( info = -i \).

\( info > 0 \):
If info = i, the element (i, i) of the factor U or L is zero, and the inverse could not be computed.

p?trtri
Computes the inverse of a triangular distributed matrix.

Syntax
void pstrtri (char *uplo , char *diag , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
void pdtrtri (char *uplo , char *diag , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
void pctrtri (char *uplo , char *diag , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
void pztrtri (char *uplo , char *diag , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );

Include Files
• mkl_scalapack.h

Description
The p?trtri function computes the inverse of a real or complex upper or lower triangular distributed matrix
sub(A) = A(ia:ia+n-1, ja:ja+n-1).

Input Parameters
uplo (global) Must be 'U' or 'L'.
   Specifies whether the distributed matrix sub(A) is upper or lower triangular.
   If uplo = 'U', sub(A) is upper triangular.
   If uplo = 'L', sub(A) is lower triangular.

diag
   Must be 'N' or 'U'.
   Specifies whether or not the distributed matrix sub(A) is unit triangular.
   If diag = 'N', then sub(A) is non-unit triangular.
   If diag = 'U', then sub(A) is unit triangular.

n (global) The number of rows and columns to be operated on, that is, the order of the distributed matrix sub(A) (n≥0).

a (local)
   Pointer into the local memory to an array of local size ld_a*LOCc(ja+n-1).
   The array a contains the local pieces of the triangular distributed matrix sub(A).
If uplo = 'U', the leading n-by-n upper triangular part of sub(A) contains the upper triangular matrix to be inverted, and the strictly lower triangular part of sub(A) is not referenced.

If uplo = 'L', the leading n-by-n lower triangular part of sub(A) contains the lower triangular matrix, and the strictly upper triangular part of sub(A) is not referenced.

ia, ja
(global) The row and column indices in the global matrix A indicating the first row and the first column of the matrix sub(A), respectively.

desca
(global and local) array of size dlen_. The array descriptor for the distributed matrix A.

Output Parameters

a
On exit, overwritten by the (triangular) inverse of the original matrix.

info
(global) If info=0, the execution is successful.

info < 0:
If the i-th argument is an array and the j-th entry, indexed j - 1, had an illegal value, then info = -(i*100+j); if the i-th argument is a scalar and had an illegal value, then info = -i.

info > 0:
If info = k, the matrix element A(ia+k-1, ja+k-1) is exactly zero. The triangular matrix sub(A) is singular and its inverse cannot be computed.

Matrix Equilibration: ScaLAPACK Computational Routines

ScaLAPACK routines described in this section are used to compute scaling factors needed to equilibrate a matrix. Note that these routines do not actually scale the matrices.

p?geequ
Computes row and column scaling factors intended to equilibrate a general rectangular distributed matrix and reduce its condition number.

Syntax

void psgeequ (MKL_INT *m, MKL_INT *n, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *r, float *c, float *rowcnd, float *colcnd, float *amax, MKL_INT *info);
void pdgeequ (MKL_INT *m, MKL_INT *n, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *r, double *c, double *rowcnd, double *colcnd, double *amax, MKL_INT *info);
void pcgeequ (MKL_INT *m, MKL_INT *n, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *r, float *c, float *rowcnd, float *colcnd, float *amax, MKL_INT *info);
void pzgeequ (MKL_INT *m, MKL_INT *n, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *r, double *c, double *rowcnd, double *colcnd, double *amax, MKL_INT *info);

Include Files

- mkl_scalapack.h

Description

The p?geequ function computes row and column scalings intended to equilibrate an \( m \)-by-\( n \) distributed matrix \( \text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1) \) and reduce its condition number. The output array \( r \) returns the row scale factors \( r_i \), and the array \( c \) returns the column scale factors \( c_j \). These factors are chosen to try to make the largest element in each row and column of the matrix \( B \) with elements \( b_{ij} = r_i a_{ij} c_j \) have absolute value 1.

\( r_i \) and \( c_j \) are restricted to be between \( SMLNUM = \text{smallest safe number} \) and \( BIGNUM = \text{largest safe number} \). Use of these scaling factors is not guaranteed to reduce the condition number of \( \text{sub}(A) \) but works well in practice.

\( SMLNUM \) and \( BIGNUM \) are parameters representing machine precision. You can use the ?lamch routines to compute them. For example, compute single precision values of \( SMLNUM \) and \( BIGNUM \) as follows:

\[
\begin{align*}
SMLNUM &= \text{slamch ('s')} \\
BIGNUM &= 1 / SMLNUM
\end{align*}
\]

The auxiliary function p?laqge uses scaling factors computed by p?geequ to scale a general rectangular matrix.

Input Parameters

- \( m \) (global) The number of rows to be operated on, that is, the number of rows of the distributed matrix \( \text{sub}(A) \) (\( m \geq 0 \)).
- \( n \) (global) The number of columns to be operated on, that is, the number of columns of the distributed matrix \( \text{sub}(A) \) (\( n \geq 0 \)).
- \( a \) (local)
  Pointer into the local memory to an array of local size \( lld_a \times \text{LOCc}(ja+n-1) \).
  The array \( a \) contains the local pieces of the \( m \)-by-\( n \) distributed matrix whose equilibration factors are to be computed.
- \( ia, ja \) (global) The row and column indices in the global matrix \( A \) indicating the first row and the first column of the matrix \( \text{sub}(A) \), respectively.
- \( \text{desca} \) (global and local) array of size \( dlen_\_ \). The array descriptor for the distributed matrix \( A \).

Output Parameters

- \( r, c \) (local)
  Arrays of sizes \( \text{LOCr}(m_a) \) and \( \text{LOCc}(n_a) \), respectively.
  If \( info = 0 \), or \( info > ia+m-1 \), \( r[i] \) contain the row scale factors for \( \text{sub}(A) \) for \( ia-1 \leq i < ia+m-1 \). \( r \) is aligned with the distributed matrix \( A \), and replicated across every process column. \( r \) is tied to the distributed matrix \( A \).
If $info = 0$, $c[i]$ contain the column scale factors for $sub(A)$ for $ja-1 \leq i < ja+n-1$. $c$ is aligned with the distributed matrix $A$, and replicated down every process row. $c$ is tied to the distributed matrix $A$.

$\text{rowcnd, colcnd}$ (global)

If $info = 0$ or $info > ia+m-1$, $\text{rowcnd}$ contains the ratio of the smallest $r_i$ to the largest $r_i$ ($ia \leq i \leq ia+m-1$). If $\text{rowcnd} \geq 0.1$ and $amax$ is neither too large nor too small, it is not worth scaling by $r_i$.

If $info = 0$, $\text{colcnd}$ contains the ratio of the smallest $c_j$ to the largest $c_j$ ($ja \leq j \leq ja+n-1$).

If $\text{colcnd} \geq 0.1$, it is not worth scaling by $c_j$.

$\text{amax}$ (global)

Absolute value of the largest matrix element. If $amax$ is very close to overflow or very close to underflow, the matrix should be scaled.

$\text{info}$ (global) If $info = 0$, the execution is successful.

$\text{info} < 0$:

If the $i$-th argument is an array and the $j$-th entry, indexed $j-1$, had an illegal value, then $info = -(i*100+j)$; if the $i$-th argument is a scalar and had an illegal value, then $info = -i$.

$\text{info} > 0$:

If $info = i$ and

$I \leq m$, the $i$-th row of the distributed matrix $sub(A)$ is exactly zero;

$I > m$, the $(i - m)$-th column of the distributed matrix $sub(A)$ is exactly zero.

**See Also**

**Overview** for details of ScaLAPACK array descriptor structures and related notations.

**p？poequ**

Computes row and column scaling factors intended to equilibrate a symmetric (Hermitian) positive definite distributed matrix and reduce its condition number.

**Syntax**

void pspoequ (MKL_INT *n, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *sr, float *sc, float *scond, float *amax, MKL_INT *info);

void pdpoequ (MKL_INT *n, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *sr, double *sc, double *scond, double *amax, MKL_INT *info);

void pcpoequ (MKL_INT *n, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *sr, float *sc, float *scond, float *amax, MKL_INT *info);

void pzpoequ (MKL_INT *n, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *sr, double *sc, double *scond, double *amax, MKL_INT *info);
Include Files

- mkl_scalapack.h

Description

The \( \texttt{p?poequ} \) function computes row and column scalings intended to equilibrate a real symmetric or complex Hermitian positive definite distributed matrix \( \text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1) \) and reduce its condition number (with respect to the two-norm). The output arrays \( \text{sr} \) and \( \text{sc} \) return the row and column scale factors:

\[
S(i) = \frac{1}{\sqrt{a_{i,i}}}
\]

These factors are chosen so that the scaled distributed matrix \( B \) with elements \( b_{ij} = s(i) * a_{ij} * s(j) \) has ones on the diagonal. This choice of \( \text{sr} \) and \( \text{sc} \) puts the condition number of \( B \) within a factor \( n \) of the smallest possible condition number over all possible diagonal scalings.

The auxiliary function \( \texttt{p?laqsy} \) uses scaling factors computed by \( \texttt{p?geequ} \) to scale a general rectangular matrix.

Input Parameters

- \( n \) (global) The number of rows and columns to be operated on, that is, the order of the distributed matrix \( \text{sub}(A) \) \((n \geq 0)\).
- \( a \) (local) Pointer into the local memory to an array of local size \( \text{lld}_{a} \ast \text{LOCc}(ja+n-1) \).
  The array \( a \) contains the \( n \)-by-\( n \) symmetric/Hermitian positive definite distributed matrix \( \text{sub}(A) \) whose scaling factors are to be computed. Only the diagonal elements of \( \text{sub}(A) \) are referenced.
- \( ia, ja \) (global) The row and column indices in the global matrix \( A \) indicating the first row and the first column of the matrix \( \text{sub}(A) \), respectively.
- \( \text{desca} \) (global and local) array of size \( \text{dlen}_\_ \). The array descriptor for the distributed matrix \( A \).

Output Parameters

- \( \text{sr}, \text{sc} \) (local) Arrays of sizes \( \text{LOCr}(m_\_) \) and \( \text{LOCc}(n_\_) \), respectively.
  If \( \text{info} = 0 \), the array \( \text{sr}(ia:ia+n-1) \) contains the row scale factors for \( \text{sub}(A) \). \( \text{sr} \) is aligned with the distributed matrix \( A \), and replicated across every process column. \( \text{sr} \) is tied to the distributed matrix \( A \).
  If \( \text{info} = 0 \), the array \( \text{sc}(ja:ja+n-1) \) contains the column scale factors for \( \text{sub}(A) \). \( \text{sc} \) is aligned with the distributed matrix \( A \), and replicated down every process row. \( \text{sc} \) is tied to the distributed matrix \( A \).
- \( \text{scond} \) (global)
If \( info = 0 \), \( scond \) contains the ratio of the smallest \( sr[i] \) (or \( sc[j] \)) to the largest \( sr[i] \) (or \( sc[j] \)), with
\[
1 \leq i < ia+n-1 \quad \text{and} \quad 1 \leq j < ja+n-1.
\]

If \( scond \geq 0.1 \) and \( amax \) is neither too large nor too small, it is not worth scaling by \( sr \) (or \( sc \)).

\( amax \)

Absolute value of the largest matrix element. If \( amax \) is very close to overflow or very close to underflow, the matrix should be scaled.

\( info \)

If \( info = 0 \), the execution is successful.

\( info < 0 \):

If the \( i \)-th argument is an array and the \( j \)-th entry, indexed \( j-1 \), had an illegal value, then \( info = -(i*100+j) \); if the \( i \)-th argument is a scalar and had an illegal value, then \( info = -i \).

\( info > 0 \):

If \( info = k \), the \( k \)-th diagonal entry of \( sub(A) \) is nonpositive.

Orthogonal Factorizations: ScaLAPACK Computational Routines

This section describes the ScaLAPACK routines for the QR(RQ) and LQ(QL) factorization of matrices. Routines for the RZ factorization as well as for generalized QR and RQ factorizations are also included. For the mathematical definition of the factorizations, see the respective LAPACK sections or refer to [SLUG].

Table "Computational Routines for Orthogonal Factorizations" lists ScaLAPACK routines that perform orthogonal factorization of matrices.

**p?geqrf**

*Computes the QR factorization of a general m-by-n matrix.*

**Syntax**

```c
void pgeqrf (MKL_INT *m, MKL_INT *n, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *tau, float *work, MKL_INT *lwork, MKL_INT *info);
void dgeqrf (MKL_INT *m, MKL_INT *n, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *tau, double *work, MKL_INT *lwork, MKL_INT *info);
void cgeqrf (MKL_INT *m, MKL_INT *n, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_Complex8 *tau, MKL_Complex8 *work, MKL_INT *lwork, MKL_INT *info);
void zgeqrf (MKL_INT *m, MKL_INT *n, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_Complex16 *tau, MKL_Complex16 *work, MKL_INT *lwork, MKL_INT *info);
```

**Include Files**

- mkl_scalapack.h

**Description**

The `p?geqrf` function forms the QR factorization of a general \( m \)-by-\( n \) distributed matrix \( \text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1) \) as \( A=Q*R \).

**Input Parameters**

- \( m \) (global) The number of rows in the distributed matrix \( \text{sub}(A) \); \( (m \geq 0) \).
- \( n \) (global) The number of columns in the distributed matrix \( \text{sub}(A) \); \( (n \geq 0) \).
- \( \text{a} \) (local) Pointer into the local memory to an array of local size \( lld_a*\text{LOCc}(ja+n-1) \).
- \( \text{ia, ja} \) Contains the local pieces of the distributed matrix \( \text{sub}(A) \) to be factored.
- (global) The row and column indices in the global matrix \( A \) indicating the first row and the first column of the submatrix \( A(ia:ia+m-1, ja:ja+n-1) \), respectively.
(global and local) array of size dlen_. The array descriptor for the distributed matrix A

(local).

Workspace array of size lwork.

(local or global) size of work, must be at least lwork≥nb_a * (mp0+mq0+nb_a), where

irow = indxg2p(ia, mb_a, MYROW, rsrca, NPROW),
irow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW),
irow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW),
mp0 = numroc(m+iroff, mb_a, MYROW, iarow, NPROW),
ir0 = numroc(n+icoff, nb_a, MYCOL, iacol, NPCOL), and numroc,
indxg2p are ScalAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function blacs_gridinfo.

If lwork = -1, then lwork is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

The elements on and above the diagonal of sub(A) contain the min(m,n)-by-n upper trapezoidal matrix R (R is upper triangular if m≥n); the elements below the diagonal, with the array tau, represent the orthogonal/unitary matrix Q as a product of elementary reflectors (see Application Notes below).

Array of size LOCc(ja+min(m,n)-1).

Contains the scalar factor of elementary reflectors. tau is tied to the distributed matrix A.

On exit, work[0] contains the minimum value of lwork required for optimum performance.

= 0, the execution is successful.

< 0, if the i-th argument is an array and the j-th entry, indexed j - 1, had an illegal value, then info = -(i*100+j); if the i-th argument is a scalar and had an illegal value, then info = -i.

Application Notes

The matrix Q is represented as a product of elementary reflectors

Q = H(ja)*H(ja+1)*...*H(ja+k-1),

where k = min(m,n).

Each H(i) has the form
\[ H(i) = I - \tau v^* v \]

where \( \tau \) is a real/complex scalar, and \( v \) is a real/complex vector with \( v(1:i-1) = 0 \) and \( v(i) = 1; v(i+1:m) \) is stored on exit in \( A(ia+i:ia+m-1, ja+i-1) \), and \( \tau \) in \( \tau[ja+i-2] \).

**See Also**
Overview for details of ScaLAPACK array descriptor structures and related notations.

**p?geqpf**
Computes the QR factorization of a general \( m \)-by-\( n \) matrix with pivoting.

**Syntax**

void psgeqpf (MKL_INT *m, MKL_INT *n, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_INT *ipiv, float *tau, float *work, MKL_INT *lwork, MKL_INT *info);
void pdgeqpf (MKL_INT *m, MKL_INT *n, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_INT *ipiv, double *tau, double *work, MKL_INT *lwork, MKL_INT *info);
void pcgeqpf (MKL_INT *m, MKL_INT *n, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_INT *ipiv, MKL_Complex8 *tau, MKL_Complex8 *work, MKL_INT *lwork, float *rwork, MKL_INT *lrwork, MKL_INT *info);
void pzgeqpf (MKL_INT *m, MKL_INT *n, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_INT *ipiv, MKL_Complex16 *tau, MKL_Complex16 *work, MKL_INT *lwork, double *rwork, MKL_INT *lrwork, MKL_INT *info);

**Include Files**

- mkl_scalapack.h

**Description**
The p?geqpf function forms the QR factorization with column pivoting of a general \( m \)-by-\( n \) distributed matrix \( \text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1) \) as \( \text{sub}(A)*P = Q*R \).

**Input Parameters**

- \( m \) (global) The number of rows in the matrix \( \text{sub}(A) \) \( (m \geq 0) \).
- \( n \) (global) The number of columns in the matrix \( \text{sub}(A) \) \( (n \geq 0) \).
- \( a \) (local)
  Pointer into the local memory to an array of local size \( lld_a*\text{LOCc}(ja+n-1) \). Contains the local pieces of the distributed matrix \( \text{sub}(A) \) to be factored.
- \( ia, ja \) (global) The row and column indices in the global matrix \( A \) indicating the first row and the first column of the submatrix \( A(ia:ia+m-1, ja:ja+n-1) \), respectively.
- \( \text{desca} \) (global and local) array of size \( dlen_. \) The array descriptor for the distributed matrix \( A \).
- \( \text{work} \) (local)
  Workspace array of size \( \text{lwork} \).
(local or global) size of work, must be at least

For real flavors:
\[ lwork \geq \max(3, mp_0 + nq_0) + \text{LOCc } (ja+n-1) + nq_0. \]

For complex flavors:
\[ lwork \geq \max(3, mp_0 + nq_0). \]

Here
\[ iroff = \text{mod}(ia-1, mb_a), \quad icoff = \text{mod}(ja-1, nb_a), \]
\[ iarow = \text{indxg2p}(ia, mb_a, \text{MYROW}, rsrc_a, \text{NPROW}), \]
\[ iacol = \text{indxg2p}(ja, nb_a, \text{MYCOL}, csrc_a, \text{NPCOL}), \]
\[ mp_0 = \text{numroc}(m+iroff, mb_a, \text{MYROW}, iarow, \text{NPROW}), \]
\[ nq_0 = \text{numroc}(n+icooff, nb_a, \text{MYCOL}, iacol, \text{NPCOL}), \]
\[ \text{LOCc } (ja+n-1) = \text{numroc}(ja+n-1, nb_a, \text{MYCOL}, csrc_a, \text{NPCOL}), \]
\[ \text{and numroc, indxg2p are ScaLAPACK tool functions.} \]

You can determine MYROW, MYCOL, NPROW and NPCOL by calling the blacs_gridinfo function.

If \( lwork = -1 \), then \( lwork \) is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pXerbla.

Workspace array of size \( lrwork \) (complex flavors only).

( local or global) size of \( rwork \) (complex flavors only). The value of \( lrwork \) must be at least
\[ lwork \geq \text{LOCc } (ja+n-1) + nq_0. \]

Here
\[ iroff = \text{mod}(ia-1, mb_a), \quad icoff = \text{mod}(ja-1, nb_a), \]
\[ iarow = \text{indxg2p}(ia, mb_a, \text{MYROW}, rsrc_a, \text{NPROW}), \]
\[ iacol = \text{indxg2p}(ja, nb_a, \text{MYCOL}, csrc_a, \text{NPCOL}), \]
\[ mp_0 = \text{numroc}(m+iroff, mb_a, \text{MYROW}, iarow, \text{NPROW}), \]
\[ nq_0 = \text{numroc}(n+icooff, nb_a, \text{MYCOL}, iacol, \text{NPCOL}), \]
\[ \text{LOCc } (ja+n-1) = \text{numroc}(ja+n-1, nb_a, \text{MYCOL}, csrc_a, \text{NPCOL}), \]
\[ \text{and numroc, indxg2p are ScaLAPACK tool functions.} \]

You can determine MYROW, MYCOL, NPROW and NPCOL by calling the blacs_gridinfo function.

If \( lrwork = -1 \), then \( lrwork \) is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pXerbla.
Output Parameters

The elements on and above the diagonal of \( \text{sub}(A) \) contain the \( \min(m,n) \)-by-\( n \) upper trapezoidal matrix \( R \) (\( R \) is upper triangular if \( m \geq n \)); the elements below the diagonal, with the array \( \text{tau} \), represent the orthogonal/unitary matrix \( Q \) as a product of elementary reflectors (see Application Notes below).

\( \text{ipiv} \)

(local) Array of size \( \text{LOCc}(ja+n-1) \).

\( \text{ipiv}[i] = k \), the local \((i+1)\)-th column of \( \text{sub}(A)*P \) was the global \( k \)-th column of \( \text{sub}(A) \) \((0 \leq i < \text{LOCc}(ja+n-1)) \). \( \text{ipiv} \) is tied to the distributed matrix \( A \).

\( \text{tau} \)

(local)

Array of size \( \text{LOCc}(ja+\min(m, n)-1) \).

Contains the scalar factor \( \text{tau} \) of elementary reflectors. \( \text{tau} \) is tied to the distributed matrix \( A \).

\( \text{work}[0] \)

On exit, \( \text{work}[0] \) contains the minimum value of \( lwork \) required for optimum performance.

\( \text{rwork}[0] \)

On exit, \( \text{rwork}[0] \) contains the minimum value of \( lrwork \) required for optimum performance.

\( \text{info} \)

(global)

\( = 0 \), the execution is successful.

\( < 0 \), if the \( i \)-th argument is an array and the \( j \)-th entry, indexed \( j - 1 \), had an illegal value, then \( \text{info} = -(i*100+j) \); if the \( i \)-th argument is a scalar and had an illegal value, then \( \text{info} = -i \).

Application Notes

The matrix \( Q \) is represented as a product of elementary reflectors

\[ Q = H(1)*H(2)*...*H(k) \]

where \( k = \min(m,n) \).

Each \( H(i) \) has the form

\[ H = I - \tau \cdot v \cdot v' \]

where \( \tau \) is a real/complex scalar, and \( v \) is a real/complex vector with \( v(1:i-1) = 0 \) and \( v(i) = 1 \); \( v(i+1:m) \) is stored on exit in \( A(ia+i:ia+m-1, ja+i-1) \).

The matrix \( P \) is represented in \( \text{ipiv} \) as follows: if \( \text{ipiv}[j] = i \) then the \((j+1)\)-th column of \( P \) is the \( i \)-th canonical unit vector \((0 \leq j < \text{LOCc}(ja+n-1)) \).

\texttt{porgqr}

Generates the orthogonal matrix \( Q \) of the QR factorization formed by \texttt{pgeqrf}.
Syntax

```c
void psorgqr (MKL_INT *m, MKL_INT *n, MKL_INT *k, float *a, MKL_INT *ia, MKL_INT *desca, float *tau, float *work, MKL_INT *lwork, MKL_INT *info);
void pdorgqr (MKL_INT *m, MKL_INT *n, MKL_INT *k, double *a, MKL_INT *ia, MKL_INT *desca, double *tau, double *work, MKL_INT *lwork, MKL_INT *info);
```

Include Files
- mkl_scalapack.h

Description
The `p?orgqr` function generates the whole or part of \( m \)-by-\( n \) real distributed matrix \( Q \) denoting \( A(ia:ia+m-1, ja:ja+n-1) \) with orthonormal columns, which is defined as the first \( n \) columns of a product of \( k \) elementary reflectors of order \( m \) \( Q = H(1)*H(2)*...*H(k) \) as returned by `p?geqrf`.

Input Parameters
- \( m \) (global) The number of rows in the matrix sub(\( Q \)) \((m \geq 0)\).
- \( n \) (global) The number of columns in the matrix sub(\( Q \)) \((n \geq 0)\).
- \( k \) (global) The number of elementary reflectors whose product defines the matrix \( Q(n \geq k \geq 0) \).
- \( a \) (local) Pointer into the local memory to an array of local size \( ld_a*LOCc(ja+n-1) \). The \( j \)-th column of the matrix stored in \( a \) must contain the vector that defines the elementary reflector \( H(j), ja \leq j \leq ja+k-1 \), as returned by `p?geqrf` in the \( k \) columns of its distributed matrix argument \( A(ia:* \), ja:ja+k-1).\)
- \( ia, ja \) (global) The row and column indices in the global matrix \( A \) indicating the first row and the first column of the submatrix \( A(ia:ia+m-1, ja:ja+n-1) \), respectively.
- \( desca \) (global and local) array of size \( dlen_\). The array descriptor for the distributed matrix \( A \).
- \( tau \) (local) Array of size \( LOCc(ja+k-1) \). Contains the scalar factor \( tau[j] \) of elementary reflectors \( H(j+1) \) as returned by `p?geqrf` \( 0 \leq j < LOCc(ja+k-1) \). \( tau \) is tied to the distributed matrix \( A \).
- \( work \) (local) Workspace array of size of \( lwork \).
- \( lwork \) (local or global) size of \( work \). Must be at least \( lwork \geq nb_a*(nqa0 + mpa0 + nb_a) \), where...
irow = indxg2p(ia, mb_a, MYROW, rsra, NPROW),
ja = indxg2p(ja, nb_a, MYCOL, csra, NPCOL),
mpa0 = numroc(m+irow, mb_a, MYROW, iarow, NPROW),
nqa0 = numroc(n+ja, nb_a, MYCOL, iacol, NPCOL);
indxg2p and numroc are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function blacs_gridinfo.

If lwork = -1, then lwork is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

a
Contains the local pieces of the m-by-n distributed matrix Q.

work[0]
On exit, [0] contains the minimum value of lwork required for optimum performance.

info
(global)
= 0: the execution is successful.
< 0: if the i-th argument is an array and the j-th entry, indexed j - 1, had an illegal value, then info = -(i*100+j); if the i-th argument is a scalar and had an illegal value, then info = -i.

pzungqr
Generates the complex unitary matrix Q of the QR factorization formed by p?geqr.

Syntax
void pcungqr (MKL_INT *m, MKL_INT *n, MKL_INT *k, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_Complex8 *tau, MKL_Complex8 *work, MKL_INT *lwork, MKL_INT *info );
void pzungqr (MKL_INT *m, MKL_INT *n, MKL_INT *k, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_Complex16 *tau, MKL_Complex16 *work, MKL_INT *lwork, MKL_INT *info );

Include Files
• mkl_scalapack.h

Description
This function generates the whole or part of m-by-n complex distributed matrix Q denoting A(ia:ia+m-1, ja:ja+n-1) with orthonormal columns, which is defined as the first n columns of a product of k elementary reflectors of order m

$$Q = H(1)*H(2)*...*H(k)$$
as returned by `p?geqrf`.

**Input Parameters**

- **m** (global) The number of rows in the matrix sub(Q); \(m \geq 0\).
- **n** (global) The number of columns in the matrix sub(Q) \(m \geq n \geq 0\).
- **k** (global) The number of elementary reflectors whose product defines the matrix Q \(n \geq k \geq 0\).
- **a** (local) Pointer into the local memory to an array of size \(lld_a \times \text{LOCc}(ja+n-1)\). The \(j\)-th column of the matrix stored in \(a\) must contain the vector that defines the elementary reflector \(H(j)\), \(ja \leq j \leq ja + k - 1\), as returned by `p?geqrf` in the \(k\) columns of its distributed matrix argument \(A(ia:*, ja:ja+k-1)\).
- **ia, ja** (global) The row and column indices in the global matrix \(A\) indicating the first row and the first column of the submatrix \(A\), respectively.
- **desca** (global and local) array of size \(dlen_\_\). The array descriptor for the distributed matrix \(A\).
- **tau** (local) Array of size \(\text{LOCc}(ja+k-1)\). Contains the scalar factor \(\tau[j]\) of elementary reflectors \(H(j+1)\) as returned by `p?geqrf` \(0 \leq j < \text{LOCc}(ja+k-1)\). \(\tau\) is tied to the distributed matrix \(A\).
- **work** (local) Workspace array of size of \(lwork\).
- **lwork** (local or global) size of \(work\), must be at least \(lwork \geq nb_a \times (nqa0 + mpa0 + nb_a)\), where
- \(\text{ipoffa} = \text{mod}(ia-1, mb_a)\),
- \(\text{icoffa} = \text{mod}(ja-1, nb_a)\),
- \(\text{iarow} = \text{indxg2p}(ia, mb_a, \text{MYROW}, \text{rsra}, \text{NPROW})\),
- \(\text{iacol} = \text{indxg2p}(ja, nb_a, \text{MYCOL}, \text{csra}, \text{NPCOL})\),
- \(mpa0 = \text{numroc}(m+i\text{ipoffa}, mb_a, \text{MYROW}, \text{iarow}, \text{NPROW})\),
- \(nqa0 = \text{numroc}(n+i\text{icoffa}, nb_a, \text{MYCOL}, \text{iacol}, \text{NPCOL})\)

`indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

If \(lwork = -1\), then \(lwork\) is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pXerbla`.

**Output Parameters**

- **a** Contains the local pieces of the \(m\)-by-\(n\) distributed matrix \(Q\).
work[0]

On exit work[0] contains the minimum value of lwork required for optimum performance.

info

(global)

= 0: the execution is successful.

< 0: if the i-th argument is an array and the j-th entry, indexed j - 1, had an illegal value, then info = -(i*100+j); if the i-th argument is a scalar and had an illegal value, then info = -i.

p?ormqr

Multiplies a general matrix by the orthogonal matrix Q of the QR factorization formed by p?geqrf.

Syntax

void psormqr (char *side, char *trans, MKL_INT *m, MKL_INT *n, MKL_INT *k, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *tau, float *c, MKL_INT *ic, MKL_INT *jc, MKL_INT *descc, float *work, MKL_INT *lwork, MKL_INT *info);

void pdormqr (char *side, char *trans, MKL_INT *m, MKL_INT *n, MKL_INT *k, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *tau, double *c, MKL_INT *ic, MKL_INT *jc, MKL_INT *descc, double *work, MKL_INT *lwork, MKL_INT *info);

Include Files

• mkl_scalapack.h

Description

The p?ormqr function overwrites the general real m-by-n distributed matrix sub (C) = C(ic:ic+m-1,ja:ja+n-1) with

\[
\begin{align*}
\text{side} &= 'L' & \quad & \text{side} &= 'R' \\
\text{trans} &= 'N': & Q*\text{sub}(C) & \quad & \text{sub}(C)*Q \\
\text{trans} &= 'T': & Q^T*\text{sub}(C) & \quad & \text{sub}(C)*Q^T
\end{align*}
\]

where Q is a real orthogonal distributed matrix defined as the product of k elementary reflectors

\[Q = H(1)H(2)...H(k)\]

as returned by p?geqrf. Q is of order m if side = 'L' and of order n if side = 'R'.

Input Parameters

side

(global)

='L': Q or Q^T is applied from the left.

='R': Q or Q^T is applied from the right.

trans

(global)

='N', no transpose, Q is applied.

='T', transpose, Q^T is applied.
(global) The number of rows in the distributed matrix sub(C) \((m \geq 0)\).

\(n\) (global) The number of columns in the distributed matrix sub(C) \((n \geq 0)\).

\(k\) (global) The number of elementary reflectors whose product defines the matrix \(Q\). Constraints:

If \(side = 'L'\), \(m \geq k \geq 0\)

If \(side = 'R'\), \(n \geq k \geq 0\).

\(a\) (local)

Pointer into the local memory to an array of size \(lld_a*LOCc(ja+n-1)\). The \(j\)-th column of the matrix stored in \(a\) must contain the vector that defines the elementary reflector \(H(j)\), \(ja \leq j \leq ja+k-1\), as returned by \(p?geqrf\) in the \(k\) columns of its distributed matrix argument \(A(ia:*, ja:ja+k-1)\). \(A(ia:*, ja:ja+k-1)\) is modified by the function but restored on exit.

If \(side = 'L'\), \(lld_a \geq \max(1, LOCr(ia+m-1))\)

If \(side = 'R'\), \(lld_a \geq \max(1, LOCr(ia+n-1))\)

\(ia, ja\) (global) The row and column indices in the global matrix \(A\) indicating the first row and the first column of the submatrix \(A\), respectively.

\(desca\) (global and local) array of size \(dlen_\). The array descriptor for the distributed matrix \(A\).

\(tau\) (local)

Array of size \(LOCc(ja+k-1)\).

Contains the scalar factor \(tau[j]\) of elementary reflectors \(H(j+1)\) as returned by \(p?geqrf\) \((0 \leq j < LOCc(ja+k-1))\). \(tau\) is tied to the distributed matrix \(A\).

\(c\) (local)

Pointer into the local memory to an array of local size \(lld_c*LOCc(jc+n-1)\).

Contains the local pieces of the distributed matrix sub(C) to be factored.

\(ic, jc\) (global) The row and column indices in the global matrix \(C\) indicating the first row and the first column of the matrix sub(C), respectively.

\(desc\) (global and local) array of size \(dlen_\). The array descriptor for the distributed matrix \(C\).

\(work\) (local)

Workspace array of size of \(lwork\).

\(lwork\) (local or global) size of \(work\), must be at least:

if \(side = 'L'\),

\[lwork \geq \max((nb_a*(nb_a-1))/2, (nqc0+mpc0)*nb_a) + nb_a*nb_a\]

else if \(side = 'R'\),

\[lwork \geq \max((nb_a*(nb_a-1))/2, (nqc0+\max(npa0+\text{numroc}(\text{numroc}(n+icoffc, nb_a, 0, 0, NPCOL), nb_a, 0, 0, lcmq), mpc0))*nb_a) + nb_a*nb_a\]
end if 
where

\[ \text{lcmq} = \frac{\text{lcm}}{\text{NPCOL}} \quad \text{with} \quad \text{lcm} = \text{ilcm} (\text{NPROW}, \text{NPCOL}), \]
\[ \text{iroffa} = \text{mod}(\text{ia}-1, \text{mb}_a), \]
\[ \text{icoffa} = \text{mod}(\text{ja}-1, \text{nb}_a), \]
\[ \text{iarow} = \text{indxg2p}(\text{ia}, \text{mb}_a, \text{MYROW}, \text{rsrc}_a, \text{NPROW}), \]
\[ \text{npa0} = \text{numroc}(\text{n}+\text{iroffa}, \text{mb}_a, \text{MYROW}, \text{iarow}, \text{NPROW}), \]
\[ \text{iroffc} = \text{mod}(\text{ic}-1, \text{mb}_c), \]
\[ \text{icoffc} = \text{mod}(\text{jc}-1, \text{nb}_c), \]
\[ \text{icrow} = \text{indxg2p}(\text{ic}, \text{mb}_c, \text{MYROW}, \text{rsrc}_c, \text{NPROW}), \]
\[ \text{iccol} = \text{indxg2p}(\text{jc}, \text{nb}_c, \text{MYCOL}, \text{csrc}_c, \text{NPCOL}), \]
\[ \text{mpc0} = \text{numroc}(\text{m}+\text{iroffc}, \text{mb}_c, \text{MYROW}, \text{icrow}, \text{NPCOL}), \]
\[ \text{nqc0} = \text{numroc}(\text{n}+\text{icoffc}, \text{nb}_c, \text{MYCOL}, \text{iccol}, \text{NPCOL}), \]
\[ \text{ilcm}, \text{indxg2p} \quad \text{and} \quad \text{numroc} \quad \text{are ScaLAPACK tool functions}; \quad \text{MYROW}, \text{MYCOL}, \]
\[ \text{NPROW} \quad \text{and} \quad \text{NPCOL} \quad \text{can be determined by calling the function} \]
\[ \text{blacs_gridinfo}. \]

If \( \text{lwork} = -1 \), then \( \text{lwork} \) is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by \text{pxerbla}.

\section*{Output Parameters}

\subsection*{c}
Overwritten by the product \( Q\*\text{sub}(C) \), or \( Q^T\*\text{sub}(C) \), or \( \text{sub}(C)*Q^T \), or \( \text{sub}(C)*Q \).

\subsection*{work[0]}
On exit \( \text{work[0]} \) contains the minimum value of \( \text{lwork} \) required for optimum performance.

\subsection*{info}
\begin{itemize}
  \item \( \text{info} = 0 \): the execution is successful.
  \item \( \text{info} < 0 \): if the \( i \)-th argument is an array and the \( j \)-th entry, indexed \( j - 1 \), had an illegal value, then \( \text{info} = -(i\*100+j) \); if the \( i \)-th argument is a scalar and had an illegal value, then \( \text{info} = -i \).

• mkl_scalapack.h

Description
This function overwrites the general complex m-by-n distributed matrix sub(C) = C(ic:ic+m-1,ic:ic+n-1)
with

side = 'L': Q or QH is applied from the left.
side = 'R': Q or QH is applied from the right.

trans = 'N': Q*sub(C)
trans = 'C': QH*sub(C)

where Q is a complex unitary distributed matrix defined as the product of k elementary reflectors
Q = H(1)H(2)...H(k) as returned by p?geqr3. Q is of order m if side = 'L' and of order n if side = 'R'.

Input Parameters

side
(global)
= 'L': Q or QH is applied from the left.
= 'R': Q or QH is applied from the right.

trans
(global)
= 'N', no transpose, Q is applied.
= 'C', conjugate transpose, QH is applied.

m
(global) The number of rows in the distributed matrix sub(C) (m≥0).

n
(global) The number of columns in the distributed matrix sub(C) (n≥0).

k
(global) The number of elementary reflectors whose product defines the matrix Q. Constraints:
If side = 'L', m≥k≥0
If side = 'R', n≥k≥0.

a
(local)
Pointer into the local memory to an array of size llda*locC(ja+k-1). The j-th column of the matrix stored in a must contain the vector that defines the elementary reflector H(j), ja≤j≤ja+k-1, as returned by p?geqr3 in the k columns of its distributed matrix argument A(ia:*, ja:ja+k-1). A(ia:*, ja:ja+k-1) is modified by the function but restored on exit.
If $side = 'L'$, $lld_a \geq \max(1, \text{LOCr}(ia+m-1))$

If $side = 'R'$, $lld_a \geq \max(1, \text{LOCr}(ia+n-1))$

$ia, ja$ (global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the submatrix $A$, respectively.

$desca$ (global and local) array of size $dlen_\_$. The array descriptor for the distributed matrix $A$.

$tau$ (local)
Array of size $\text{LOCc}(ja+k-1)$.
Contains the scalar factor $\tau[j]$ of elementary reflectors $H(j+1)$ as returned by $\text{p?geqr2}$ ($0 \leq j < \text{LOCc}(ja+k-1)$). $\tau$ is tied to the distributed matrix $A$.

c (local)
Pointer into the local memory to an array of local size $lld_c*\text{LOCc}(jc+n-1)$.
Contains the local pieces of the distributed matrix sub($C$) to be factored.

$ic, jc$ (global) The row and column indices in the global matrix $C$ indicating the first row and the first column of the submatrix $C$, respectively.

$descc$ (global and local) array of size $dlen_\_$. The array descriptor for the distributed matrix $C$.

$work$ (local)
Workspace array of size of $lwork$.

$lwork$ (local or global) size of $work$, must be at least:
If $side = 'L'$,
$$lwork \geq \max\left(\frac{nb_a*(nb_a-1)}{2}, (nqc0 + mpc0)*nb_a + nb_a*nb_a\right)$$
else if $side = 'R'$,
$$lwork \geq \max\left(\frac{nb_a*(nb_a-1)}{2}, (nqc0 + \max(npa0 + \text{numroc}(\text{numroc}(n+iroffa, mb_a, 0, 0, \text{NPCOL}, nb_a, 0, 0, \text{lcmq}), mpc0)))*nb_a + nb_a*nb_a\right)$$
end if

where
$$\text{lcmq} = \text{lcm}/\text{NPCOL} \text{ with lcm = ilcm (NPROW, NPCOL)},$$
iroffa = mod($ia-1, mb_a$),
icoffa = mod($ja-1, nb_a$),
$$iarow = \text{indxg2p}(ia, mb_a, \text{MYROW}, \text{rsrc}_a, \text{NPROW}),$$
npa0 = $\text{numroc}(n+iroffa, mb_a, \text{MYROW}, iarow, \text{NPROW})$,
iroffc = mod($ic-1, mb_c$),
icoffc = mod($jc-1, nb_c$),
icrow = $\text{indxg2p}(ic, mb_c, \text{MYROW}, \text{rsrc}_c, \text{NPROW})$,
iccol = $\text{indxg2p}(jc, nb_c, \text{MYCOL}, \text{csrc}_c, \text{NPCOL})$. 
mpc0 = numroc(m+iroffc, mb_c, MYROW, icrow, NPROW),
nqc0 = numroc(n+icoffc, nb_c, MYCOL, iccol, NPCOL),

ilcm, indxg2p and numroc are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function blacs_gridinfo.

If lwork = -1, then lwork is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

c
Overwritten by the product Q*sub(C), or Q^H*sub(C), or sub(C)*Q^H, or sub(C)*Q.

work[0]
On exit work[0] contains the minimum value of lwork required for optimum performance.

info
(global)
= 0: the execution is successful.
< 0: if the i-th argument is an array and the j-th entry, indexed j - 1, had an illegal value, then info = -(i*100+j); if the i-th argument is a scalar and had an illegal value, then info = -i.

Include Files

• mkl_scalapack.h

Description

The p?gelqf function computes the LQ factorization of a real/complex distributed m-by-n matrix sub(A) = A(ia:ia+m-1,ja:ja+n-1) = L*Q.
Input Parameters

\( m \) (global) The number of rows in the distributed submatrix \( \text{sub}(A) \) \((m \geq 0)\).

\( n \) (global) The number of columns in the distributed submatrix \( \text{sub}(A) \) \((n \geq 0)\).

\( a \) (local)

Pointer into the local memory to an array of local size \( \text{lld}_a \cdot \text{LOCc}(ja+n-1) \).

Contains the local pieces of the distributed matrix \( \text{sub}(A) \) to be factored.

\( ia, ja \) (global) The row and column indices in the global array \( A \) indicating the first row and the first column of the submatrix \( A(ia:ia+m-1,ja:ja+n-1) \), respectively.

\( \text{desca} \) (global and local) array of size \( dlen_\). The array descriptor for the distributed matrix \( A \).

\( \text{work} \) (local)

Workspace array of size of \( lwork \).

\( lwork \) (local or global) size of \( \text{work} \), must be at least \( lwork \geq mb_a \cdot (mp0 + nq0 + mb_a) \), where

\[
\begin{align*}
     & iroff = \text{mod}(ia-1, mb_a), \\
     & icoff = \text{mod}(ja-1, nb_a), \\
     & iarow = \text{indxg2p}(ia, mb_a, \text{MYROW}, \text{rsrc_a}, \text{NPROW}), \\
     & iacol = \text{indxg2p}(ja, nb_a, \text{MYCOL}, \text{csrc_a}, \text{NPCOL}), \\
     & mp0 = \text{numroc}(m+iroff, mb_a, \text{MYROW}, iarow, \text{NPROW}), \\
     & nq0 = \text{numroc}(n+icoff, nb_a, \text{MYCOL}, iacol, \text{NPCOL})
\end{align*}
\]

\text{indxg2p} \text{ and } \text{numroc} \text{ are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function blacs_gridinfo.}

**NOTE**

\( \text{mod}(x,y) \) is the integer remainder of \( x/y \).

If \( lwork = -1 \), then \( lwork \) is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by \text{pxerbla}.

Output Parameters

\( a \)

The elements on and below the diagonal of \( \text{sub}(A) \) contain the \( m \)-by-\( \min(m,n) \) lower trapezoidal matrix \( L \) (\( L \) is lower trapezoidal if \( m \leq n \)); the elements above the diagonal, with the array \( \tau \), represent the orthogonal/unitary matrix \( Q \) as a product of elementary reflectors (see Application Notes below).

\( \tau \) (local)
Array of size $\text{LOCr}(ia+\min(m,n)-1)$.

Contains the scalar factors of elementary reflectors. $\tau$ is tied to the distributed matrix $A$.

$\text{work}[0]$

On exit, $\text{work}[0]$ contains the minimum value of $l\text{work}$ required for optimum performance.

$info$

(global)

$= 0$: the execution is successful.

$< 0$: if the $i$-th argument is an array and the $j$-th entry, indexed $j - 1$, had an illegal value, then $info = -(i*100+j)$; if the $i$-th argument is a scalar and had an illegal value, then $info = -i$.

**Application Notes**

The matrix $Q$ is represented as a product of elementary reflectors

$$Q = H^{(ia+k-1)}*H^{(ia+k-2)}*...*H^{(ia)},$$

where $k = \min(m,n)$

Each $H(i)$ has the form

$$H(i) = I - \tau*V*V'$$

where $\tau$ is a real/complex scalar, and $V$ is a real/complex vector with $V(1:i-1) = 0$ and $V(i) = 1$; $V(i+1:n)$ is stored on exit in $A(ia+i-1,ja+i:ja+n-1)$, and $\tau$ in $\text{tau}[ia+i-2]$.

*Overview* for details of ScaLAPACK array descriptor structures and related notations.

**porglq**

Generates the real orthogonal matrix $Q$ of the $LQ$ factorization formed by $\text{pgelqf}$.

**Syntax**

```c
void psorglq (MKL_INT *m, MKL_INT *n, MKL_INT *k, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *tau, float *work, MKL_INT *lwork, MKL_INT *info);
void pdorglq (MKL_INT *m, MKL_INT *n, MKL_INT *k, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *tau, double *work, MKL_INT *lwork, MKL_INT *info);
```

**Include Files**

- mkl_scalapack.h

**Description**

The $\text{porglq}$ function generates the whole or part of $m$-by-$n$ real distributed matrix $Q$ denoting $A(ia:ia + m-1, ja:ja+n-1)$ with orthonormal rows, which is defined as the first $m$ rows of a product of $k$ elementary reflectors of order $n$

$$Q = H(k)*...*H(2)*H(1)$$

as returned by $\text{pgelqf}$.
Input Parameters

- \( m \) (global) The number of rows in the matrix sub(\( Q \)); \( m \geq 0 \).
- \( n \) (global) The number of columns in the matrix sub(\( Q \)); \( n \geq m \geq 0 \).
- \( k \) (global) The number of elementary reflectors whose product defines the matrix \( Q \); \( m \geq k \geq 0 \).
- \( a \) (local) Pointer into the local memory to an array of local size \( lld_a \cdot LOCc(ja+n-1) \).
  On entry, the \( i \)-th row of the matrix stored in \( a \) must contain the vector that defines the elementary reflector \( H(i) \), \( ia \leq i \leq ia+k-1 \), as returned by \( p?gelqf \) in the \( k \) rows of its distributed matrix argument \( A(ia:ia+k-1, ja:*) \).
- \( ia, ja \) (global) The row and column indices in the global matrix \( A \) indicating the first row and the first column of the submatrix \( A(ia:ia+m-1, ja:ja+n-1) \), respectively.
- \( desca \) (global and local) array of size \( dlen_\). The array descriptor for the distributed matrix \( A \).
- \( work \) (local) Workspace array of size of \( lwork \).
- \( lwork \) (local or global) size of \( work \), must be at least
  \[ lwork \geq mb_a \cdot (mpa0+nqa0+mb_a) \], where
  \[ iroffa = \text{mod}(ia-1, mb_a), \]
  \[ icoffa = \text{mod}(ja-1, nb_a), \]
  \[ iarow = \text{indxg2p}(ia, mb_a, MYROW, rsrch_a, NPROW), \]
  \[ iacol = \text{indxg2p}(ja, nb_a, MYCOL, csrch_a, NPCOL), \]
  \[ mpa0 = \text{numroc}(m+iroffa, mb_a, MYROW, iarow, NPROW), \]
  \[ nqa0 = \text{numroc}(n+icoffa, nb_a, MYCOL, iacol, NPCOL) \]

NOTE \( \text{mod}(x,y) \) is the integer remainder of \( x/y \).

\text{indxg2p} and \text{numroc} are ScaLAPACK tool functions; \( \text{MYROW}, \text{MYCOL}, \text{NPROW} \) and \( \text{NPCOL} \) can be determined by calling the function \text{blacs_gridinfo}.

If \( lwork = -1 \), then \( lwork \) is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by \text{pxerbla}.

Output Parameters

- \( a \) Contains the local pieces of the \( m \)-by-\( n \) distributed matrix \( Q \) to be factored.
- \( tau \) (local)
Array of size $\text{LOCr}(ia+k-1)$.

Contains the scalar factors $\tau[j]$ of elementary reflectors $H(j+1)$, $0 \leq j < \text{LOCr}(ia+k-1)$. $\tau$ is tied to the distributed matrix $A$.

$\text{work}[0]$

On exit, $\text{work}[0]$ contains the minimum value of $l\text{work}$ required for optimum performance.

$info$

(global)

$ = 0$: the execution is successful.

$ < 0$: if the $i$-th argument is an array and the $j$-th entry, indexed $j-1$, had an illegal value, then $info = -(i*100+j)$; if the $i$-th argument is a scalar and had an illegal value, then $info = -i$.

$p\text{?unglq}$

Generates the unitary matrix $Q$ of the LQ factorization formed by $p\text{?gelqf}$.

Syntax

void pcunglq (MKL_INT *m, MKL_INT *n, MKL_INT *k, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_Complex8 *tau, MKL_Complex8 *work, MKL_INT *lwork, MKL_INT *info);

void pzunglq (MKL_INT *m, MKL_INT *n, MKL_INT *k, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_Complex16 *tau, MKL_Complex16 *work, MKL_INT *lwork, MKL_INT *info);

Include Files

• mkl_scalapack.h

Description

This function generates the whole or part of $m$-by-$n$ complex distributed matrix $Q$ denoting $A(ia:ia+n-1,ja:ja+n-1)$ with orthonormal rows, which is defined as the first $m$ rows of a product of $k$ elementary reflectors of order $n$

$Q = (H(k))^H*...*(H(2))^H*(H(1))^H$ as returned by $p\text{?gelqf}$.

Input Parameters

$m$

(global) The number of rows in the matrix $\text{sub}(Q)$ ($m \geq 0$).

$n$

(global) The number of columns in the matrix $\text{sub}(Q)$ ($n \geq m \geq 0$).

$k$

(global) The number of elementary reflectors whose product defines the matrix $Q$ ($m \geq k \geq 0$).

$a$

(local)
Pointer into the local memory to an array of local size \( lld_a * \text{LOCc}(ja+n-1) \). On entry, the \( i \)-th row of the matrix stored in \( a \) must contain the vector that defines the elementary reflector \( H(i) \), \( ia \leq i \leq ia+k-1 \), as returned by \( \text{p?gelqf} \) in the \( k \) rows of its distributed matrix argument \( A(ia:ia+k-1, ja:*). \)

\( ia, ja \) (global) The row and column indices in the global matrix \( A \) indicating the first row and the first column of the submatrix \( A(ia:ia+m-1, ja:ja+n-1) \), respectively.

\( \text{desca} \) (global and local) array of size \( dlen_\). The array descriptor for the distributed matrix \( A \).

\( \text{tau} \) (local)

Array of size \( \text{LOCr}(ia+k-1) \).

Contains the scalar factors \( \text{tau}[j] \) of elementary reflectors \( H(j+1) \), \( 0 \leq j < \text{LOCr}(ia+k-1) \). \( \text{tau} \) is tied to the distributed matrix \( A \).

\( \text{work} \) (local)

Workspace array of size of \( lwork \).

\( lwork \) (local or global) size of \( \text{work} \), must be at least

\[ lwork \geq mb_a * (mpa0 + nqa0 + mb_a) \]

where

\[
\begin{align*}
iroff &= \text{mod}(ia-1, mb_a), \\
icoff &= \text{mod}(ja-1, nb_a), \\
ivarow &= \text{indxg2p}(ia, mb_a, \text{MYROW}, \text{rsrc}_a, \text{NPROW}), \\
ivicol &= \text{indxg2p}(ja, nb_a, \text{MYCOL}, \text{csrc}_a, \text{NPCOL}), \\
mpa0 &= \text{numroc}(m+iroff, mb_a, \text{MYROW}, iarrow, \text{NPROW}), \\
nqa0 &= \text{numroc}(n+icoff, nb_a, \text{MYCOL}, iacol, \text{NPCOL})
\end{align*}
\]

\( \text{indxg2p} \) and \( \text{numroc} \) are ScaLAPACK tool functions; \( \text{MYROW} \), \( \text{MYCOL} \), \( \text{NPROW} \) and \( \text{NPCOL} \) can be determined by calling the function \( \text{blacs_gridinfo} \).

**NOTE**

\( \text{mod}(x, y) \) is the integer remainder of \( x/y \).

If \( lwork = -1 \), then \( lwork \) is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by \( \text{pxerbla} \).

### Output Parameters

\( a \)

Contains the local pieces of the \( m \)-by-\( n \) distributed matrix \( Q \) to be factored.

On exit, \( \text{work}[0] \) contains the minimum value of \( lwork \) required for optimum performance.

\( \text{info} \)

(gLOBAL)

\( = 0 \): the execution is successful.
< 0: if the i-th argument is an array and the j-th entry, indexed j - 1, had
an illegal value, then info = -(i*100+j); if the i-th argument is a scalar
and had an illegal value, then info = -i.

p?ormlq
Multiplies a general matrix by the orthogonal matrix Q
of the LQ factorization formed by p?gelqf.

Syntax
void psormlq (char *side, char *trans, MKL_INT *m, MKL_INT *n, MKL_INT *k, float
*a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *tau, float *c, MKL_INT *ic,
MKL_INT *jc, MKL_INT *descc, float *work, MKL_INT *lwork, MKL_INT *info);

void pdormlq (char *side, char *trans, MKL_INT *m, MKL_INT *n, MKL_INT *k, double
*a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *tau, double *c, MKL_INT
*ic, MKL_INT *jc, MKL_INT *descc, double *work, MKL_INT *lwork, MKL_INT *info);

Include Files
• mkl_scalapack.h

Description
The p?ormlq function overwrites the general real m-by-n distributed matrix sub(C) = C(icc:ic+m-1,jc:jc
+n-1) with

side = 'L'
side = 'R'

trans = 'N': Q*sub(C) sub(C)*Q
trans = 'T': Q*T*sub(C) sub(C)*Q*T

where Q is a real orthogonal distributed matrix defined as the product of k elementary reflectors
Q = H(k)...H(2) H(1)
as returned by p?gelqf. Q is of order m if side = 'L' and of order n if side = 'R'.

Input Parameters
side (global)
= 'L': Q or Q*T is applied from the left.
= 'R': Q or Q*T is applied from the right.

trans (global)
= 'N', no transpose, Q is applied.
= 'T', transpose, Q*T is applied.

m (global) The number of rows in the distributed matrix sub(C) (m≥0).
n (global) The number of columns in the distributed matrix sub(C) (n≥0).
k (global) The number of elementary reflectors whose product defines the
matrix Q. Constraints:
If $side = 'L'$, $m \geq k \geq 0$

If $side = 'R'$, $n \geq k \geq 0$.

a (local)

Pointer into the local memory to an array of size $lld_a*\text{LOCc}(ja+m-1)$, if $side = 'L'$ and $lld_a*\text{LOCc}(ja+n-1)$, if $side = 'R'$. The $i$-th row of the matrix stored in $a$ must contain the vector that defines the elementary reflector $H(i)$, $ia \leq ia+k-1$, as returned by $p?gelqf$ in the $k$ rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$.

$A(ia:ia+k-1, ja:*)$ is modified by the function but restored on exit.

$ia, ja$ (global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the submatrix $A$, respectively.

desca (global and local) array of size $dlen_\text{a}$. The array descriptor for the distributed matrix $A$.

tau (local)

Array of size $\text{LOCc}(ja+k-1)$.

Contains the scalar factor $\tau[j]$ of elementary reflectors $H(j+1)$ as returned by $p?gelqf$ ($0 \leq j < \text{LOCc}(ja+k-1)$). $\tau$ is tied to the distributed matrix $A$.

c (local)

Pointer into the local memory to an array of local size $lld_c*\text{LOCc}(jc+n-1)$.

Contains the local pieces of the distributed matrix $\text{sub}(C)$ to be factored.

$ic, jc$ (global) The row and column indices in the global matrix $C$ indicating the first row and the first column of the submatrix $C$, respectively.

descc (global and local) array of size $dlen_\text{c}$. The array descriptor for the distributed matrix $C$.

work (local)

Workspace array of size of $lwork$.

$lwork$ (local or global) size of the array $work$; must be at least:

If $side = 'L'$,

$$lwork \geq \max((mb_a (mb_a-1))/2, (mpc0 + maxmqa0) + \text{numroc}(\text{numroc}(m + iroffc, mb_a, 0, 0, \text{NPROW}), mb_a, 0, 0, \text{lcmp}), nqc0) \times mb_a) + mb_a \times mb_a$$

else if $side = 'R'$,

$$lwork \geq \max((mb_a (mb_a-1))/2, (mpc0 + nqc0) \times mb_a + mb_a \times mb_a$$

end if

where

$$lcmp = \text{lcm}/\text{NPROW} \text{ with } \text{lcm} = \text{ilcm(\text{NPROW}, NPCOL)},$$

$$iroffa = \text{mod(ia-1, mb_a)},$$

$$icoffa = \text{mod(ja-1, mb_a)},$$
iacol = indxg2p(ja, nb_a, MYCOL, csr_a, NPCOL),
mqa0 = numroc(m+icoffa, nb_a, MYCOL, iacol, NPCOL),
iroffc = mod(ic-1, mb_c),
icoffc = mod(jc-1, nb_c),
icrow = indxg2p(ic, mb_c, MYROW, rsr_c, NPROW),
iccol = indxg2p(jc, nb_c, MYCOL, csr_c, NPCOL),
mpc0 = numroc(m+iroffc, mb_c, MYROW, icrow, NPROW),
nqc0 = numroc(n+icoffc, nb_c, MYCOL, iccol, NPCOL),

NOTE
mod(x,y) is the integer remainder of x/y.

Ilcm, indxg2p and numroc are ScALAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function blacs_gridinfo.

If lwork = -1, then lwork is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

c
Overwritten by the product Q*sub(C), or Q'*sub(C), or sub(C)*Q', or sub(C)*Q

work[0]
On exit work[0] contains the minimum value of lwork required for optimum performance.

info
(global)
= 0: the execution is successful.
< 0: if the i-th argument is an array and the j-th entry, indexed j - 1, had an illegal value, then info = -(i*100+j); if the i-th argument is a scalar and had an illegal value, then info = -i.

See Also
Overview for details of ScALAPACK array descriptor structures and related notations.

p?unmlq
Multiplies a general matrix by the unitary matrix Q of the LQ factorization formed by p?gelqf.

Syntax
void pcunmlq (char *side, char *trans, MKL_INT *m, MKL_INT *n, MKL_INT *k,
MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_Complex8 *tau,
MKL_Complex8 *c, MKL_INT *ic, MKL_INT *jc, MKL_INT *desc, MKL_Complex8 *work,
MKL_INT *lwork, MKL_INT *info );
void pzunmlq (char *side, char *trans, MKL_INT *m, MKL_INT *n, MKL_INT *k,
MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_Complex16 *tau,
MKL_Complex16 *c, MKL_INT *ic, MKL_INT *jc, MKL_INT *descc, MKL_Complex16 *work,
MKL_INT *lwork, MKL_INT *info);

Include Files
- mkl_scalapack.h

Description
This function overwrites the general complex m-by-n distributed matrix sub(C) = C(ic:ic+m-1,jc:jc+n-1)
with

side = 'L':
  trans = 'N':  Q*sub(C)
  trans = 'C':  QH*sub(C)
side = 'R':
  trans = 'N':  sub(C)*Q
  trans = 'C':  sub(C)*QH

where Q is a complex unitary distributed matrix defined as the product of k elementary reflectors
Q = H(k)' ... H(2)' H(1)'
as returned by p?gelqf. Q is of order m if side = 'L' and of order n if side = 'R'.

Input Parameters
side
  (global)
  = 'L': Q or QH is applied from the left.
  = 'R': Q or QH is applied from the right.

trans
  (global)
  = 'N', no transpose, Q is applied.
  = 'C', conjugate transpose, QH is applied.

m
  (global) The number of rows in the distributed matrix sub(C) (m≥0).

n
  (global) The number of columns in the distributed matrix sub(C) (n≥0).

k
  (global) The number of elementary reflectors whose product defines the
  matrix Q. Constraints:
  If side = 'L', m≥k≥0
  If side = 'R', n≥k≥0.

a
  (local)
  Pointer into the local memory to an array of size lld_a*LOCc(ja+m-1), if
  side = 'L' and lld_a*LOCc(ja+n-1), if side = 'R', where lld_a≥
  max(1, LOCr (ia+k-1)). The i-th column of the matrix stored in a
  must contain the vector that defines the elementary reflector H(i),
  ia≤i≤ia+k-1, as returned by p?gelqf in the k rows of its distributed matrix argument
  A(ia:ia+k-1, ja:()). A(ia:ia+k-1, ja:) is modified by the function but
  restored on exit.

ia, ja
  (global) The row and column indices in the global matrix A indicating the
  first row and the first column of the submatrix A, respectively.
desca (global and local) array of size dlen_. The array descriptor for the distributed matrix A.

tau (local)
Array of size LOCc(ia+k-1).
Contains the scalar factor $\tau[j]$ of elementary reflectors $H(j+1)$ as returned by $p?gelqf$ ($0 \leq j < LOCc(ia+k-1)$). tau is tied to the distributed matrix A.

c (local)
Pointer into the local memory to an array of local size $lld_c*LOCc(jc+n-1)$.
Contains the local pieces of the distributed matrix sub($C$) to be factored.

ic, jc (global) The row and column indices in the global matrix $C$ indicating the first row and the first column of the submatrix $C$, respectively.

desccc (global and local) array of size dlen_. The array descriptor for the distributed matrix $C$.

work (local)
Workspace array of size of lwork.

lwork (local or global) size of the array work; must be at least:
If $side = 'L'$,
$$lwork \geq \max((mb_a*(mb_a-1))/2, (mpc0 + maxmqa0) + \text{numroc}(\text{numroc}(m + iroffc, mb_a, 0, 0, \text{NPROW}), mb_a, 0, 0, lcmp), nqc0)*mb_a + mb_a*mb_a$$
else if $side = 'R'$,
$$lwork \geq \max((mb_a*(mb_a-1))/2, (mpc0 + nqc0)*mb_a + mb_a*mb_a$$
end if

where
$$lcmp = lcm/NPROW \text{ with } lcm = \text{lcm (NPROW, NPCOL)}$$
$$iroffa = \text{mod}(ia-1, mb_a)$$
$$icoffa = \text{mod}(ja-1, nb_a)$$
$$iacol = \text{indxg2p}(ja, nb_a, MYCOL, csrca_a, NPCOL)$$
$$mqa0 = \text{numroc}(m + icoffa, nb_a, MYCOL, iacol, NPCOL)$$
$$iroffc = \text{mod}(ic-1, mb_c)$$
$$icoffe = \text{mod}(jc-1, nb_c)$$
$$icrow = \text{indxg2p}(ic, mb_c, MYROW, rsrca_c, NPROW)$$
$$iccol = \text{indxg2p}(jc, nb_c, MYCOL, csrca_c, NPCOL)$$
$$mpc0 = \text{numroc}(m+iroffc, mb_c, MYROW, icrow, NPROW)$$
$$nqc0 = \text{numroc}(n+icoffe, nb_c, MYCOL, iccol, NPCOL)$$
NOTE

mod(x,y) is the integer remainder of x/y.

ilcm, indxg2p and numroc are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function blacs_gridinfo.

If lwork = -1, then lwork is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

c

Overwritten by the product Q*sub(C), or Q'*sub (C), or sub(C)*Q', or sub(C)*Q

work[0]

On exit work[0] contains the minimum value of lwork required for optimum performance.

info (global)

= 0: the execution is successful.
< 0: if the i-th argument is an array and the j-th entry, indexed j - 1, had an illegal value, then info = -(i*100+j); if the i-th argument is a scalar and had an illegal value, then info = -i.

See Also

Include Files

• mkl_scalapack.h
Description

The `pgeqlf` function forms the QL factorization of a real/complex distributed \( m \times n \) matrix \( \text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1) = Q^*L \).

Input Parameters

- \( m \) (global) The number of rows in the matrix \( \text{sub}(Q) \); \( m \geq 0 \).
- \( n \) (global) The number of columns in the matrix \( \text{sub}(Q) \); \( n \geq 0 \).
- \( a \) (local) Pointer into the local memory to an array of local size \( \text{lld}_a \times \text{LOCc}(ja+n-1) \). Contains the local pieces of the distributed matrix \( \text{sub}(A) \) to be factored.
- \( ia, ja \) (global) The row and column indices in the global matrix \( A \) indicating the first row and the first column of the submatrix \( A(ia:ia+m-1, ja:ja+n-1) \), respectively.
- \( \text{desca} \) (global and local) array of size \( dlen_\)_. The array descriptor for the distributed matrix \( A \).
- \( \text{work} \) (local) Workspace array of size of \( lwork \).
- \( lwork \) (local or global) size of \( \text{work} \), must be at least \( lwork \geq \text{nb}_a \times (mp0 + nq0 + \text{nb}_a) \), where
  - \( iroff = \text{mod}(ia-1, \text{mb}_a) \),
  - \( icoff = \text{mod}(ja-1, \text{nb}_a) \),
  - \( iarow = \text{indxg2p}(ia, \text{mb}_a, \text{MYROW}, \text{rsrc}_a, \text{NPROW}) \),
  - \( iacol = \text{indxg2p}(ja, \text{nb}_a, \text{MYCOL}, \text{csrc}_a, \text{NPCOL}) \),
  - \( mp0 = \text{numroc}(m+iroff, \text{mb}_a, \text{MYROW}, iarow, \text{NPROW}) \),
  - \( nq0 = \text{numroc}(n+icoff, \text{nb}_a, \text{MYCOL}, iacol, \text{NPCOL}) \).

**NOTE**

\( \text{mod}(x, y) \) is the integer remainder of \( x/y \).

\( \text{numroc} \) and \( \text{indxg2p} \) are ScaLAPACK tool functions; \( \text{MYROW}, \text{MYCOL}, \text{NPROW} \) and \( \text{NPCOL} \) can be determined by calling the function \( \text{blacs_gridinfo} \).

If \( lwork = -1 \), then \( lwork \) is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by \( \text{pxerbla} \).

Output Parameters

- \( a \) On exit, if \( m \geq n \), the lower triangle of the distributed submatrix \( A(ia+m-n:ia+m-1, ja:ja+n-1) \) contains the \( n \times n \) lower triangular matrix \( L \); if \( m \leq n \), the elements on and below the \( (n-m) \)-th superdiagonal contain the \( m \times n \)
lower trapezoidal matrix \( L \); the remaining elements, with the array \( \tau \), represent the orthogonal/unitary matrix \( Q \) as a product of elementary reflectors (see Application Notes below).

\[
\tau \\
\text{(local)}
\]

Array of size \( \text{LOCc}(ja+n-1) \).

Contains the scalar factors of elementary reflectors. \( \tau \) is tied to the distributed matrix \( A \).

\[
\text{work}[0]
\]

On exit, \( \text{work}[0] \) contains the minimum value of \( l_{\text{work}} \) required for optimum performance.

\[
\text{info}
\]

(global)

= 0: the execution is successful.

< 0: if the \( i \)-th argument is an array and the \( j \)-th entry, indexed \( j-1 \), had an illegal value, then \( \text{info} = -(i*100+j); \) if the \( i \)-th argument is a scalar and had an illegal value, then \( \text{info} = -i. \)

Application Notes
The matrix \( Q \) is represented as a product of elementary reflectors
\[
Q = H(ja+k-1)*...*H(ja+1)*H(ja)
\]
where \( k = \min(m,n) \)

Each \( H(i) \) has the form
\[
H(i) = I - \tau_{i}v_{i}v'_{i}
\]
where \( \tau \) is a real/complex scalar, and \( v \) is a real/complex vector with \( v(m-k+i+1:m) = 0 \) and \( v(m-k+i) = 1; v(1:m-k+i-1) \) is stored on exit in \( A(ia:ia+m-k+i-2, ja+n-k+i-1) \), and \( \tau \) in \( \tau[ja+n-k+i-2] \).

\[
p\text{orgql}
\]
Generates the orthogonal matrix \( Q \) of the QL factorization formed by \( p\text{geqlf} \).

Syntax
\[
\text{void psorgql (MKL_INT } *m, \text{ MKL_INT } *n, \text{ MKL_INT } *k, \text{ float } *a, \text{ MKL_INT } *ia, \text{ MKL_INT } *ja, \text{ MKL_INT } *desca, \text{ float } *tau, \text{ float } *work, \text{ MKL_INT } *lwork, \text{ MKL_INT } *info );
\]
\[
\text{void pdorgql (MKL_INT } *m, \text{ MKL_INT } *n, \text{ MKL_INT } *k, \text{ double } *a, \text{ MKL_INT } *ia, \text{ MKL_INT } *ja, \text{ MKL_INT } *desca, \text{ double } *tau, \text{ double } *work, \text{ MKL_INT } *lwork, \text{ MKL_INT } *info );
\]

Include Files
- mkl_scalapack.h

Description
The \( p\text{orgql} \) function generates the whole or part of \( m\)-by-\( n \) real distributed matrix \( Q \) denoting \( A(ia:ia+m-1, ja:ja+n-1) \) with orthonormal rows, which is defined as the first \( m \) rows of a product of \( k \) elementary reflectors of order \( n \)
\[
Q = H(k)*...*H(2)*H(1)
\]
Input Parameters

$m$  
(global) The number of rows in the matrix sub$(Q)$, $(m \geq 0)$.

$n$  
(global) The number of columns in the matrix sub$(Q)$, $(m \geq n \geq 0)$.

$k$  
(global) The number of elementary reflectors whose product defines the matrix $Q$, $(n \geq k \geq 0)$.

$a$  
(local)  
Pointer into the local memory to an array of local size $lld_a \times LOCc(ja+n-1)$. On entry, the $j$-th column of the matrix stored in $a$ must contain the vector that defines the elementary reflector $H(j), ja+n-k \leq j \leq ja+n-1$, as returned by $p?geqlf$ in the $k$ columns of its distributed matrix argument $A(ia:*, ja+n-k:ja+n-1)$.

$ia, ja$  
(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the submatrix $A(ia:ia+m-1, ja:ja+n-1)$, respectively.

$desca$  
(global and local) array of size $dlen_\_$. The array descriptor for the distributed matrix $A$.

$tau$  
(local)  
Array of size $LOCc(ja+n-1)$. Contains the scalar factors $\tau[j]$ of elementary reflectors $H(j+1), 0 \leq j < LOCr(ia+n-1)$. $tau$ is tied to the distributed matrix $A$.

$work$  
(local)  
Workspace array of size of $lwork$.

$lwork$  
(local or global) size of $work$, must be at least $lwork \geq nb_a \times (nqa0 + mpa0 + nb_a)$, where  

$$
iroffa = \text{mod}(ia-1, mb_a),
$$

$$
icoffa = \text{mod}(ja-1, nb_a),
$$

$$
iarow = \text{indxg2p}(ia, mb_a, MYROW, rsrc_a, NPROW),
$$

$$
iacol = \text{indxg2p}(ja, nb_a, MYCOL, csrc_a, NPCOL),
$$

$$
mpa0 = \text{numroc}(m+iroffa, mb_a, MYROW, iarow, NPROW),
$$

$$
nqa0 = \text{numroc}(n+icoffa, nb_a, MYCOL, iacol, NPCOL)
$$

NOTE

mod$(x, y)$ is the integer remainder of $x/y$.

indxg2p and numroc are ScALAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function blacs_gridinfo.
If \( lwork = -1 \), then \( lwork \) is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by \texttt{pxerbla}.

**Output Parameters**

\( a \)

Contains the local pieces of the \( m \)-by-\( n \) distributed matrix \( Q \) to be factored.

\( \text{work}[0] \)

On exit, \( \text{work}[0] \) contains the minimum value of \( lwork \) required for optimum performance.

\( \text{info} \) (global)

= 0: the execution is successful.

< 0: if the \( i \)-th argument is an array and the \( j \)-th entry, indexed \( j - 1 \), had an illegal value, then \( \text{info} = -(i\times100+j) \); if the \( i \)-th argument is a scalar and had an illegal value, then \( \text{info} = -i \).

**See Also**

\texttt{pzungql}

Generates the unitary matrix \( Q \) of the QL factorization formed by \texttt{p?geqlf}.

**Syntax**

```c
void pcungql (const MKL_INT *m , const MKL_INT *n , const MKL_INT *k , MKL_Complex8 *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca , const MKL_Complex8 *tau , MKL_Complex8 *work , const MKL_INT *lwork , MKL_INT *info );
void pzungql (const MKL_INT *m , const MKL_INT *n , const MKL_INT *k , MKL_Complex16 *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca , const MKL_Complex16 *tau , MKL_Complex16 *work , const MKL_INT *lwork , MKL_INT *info );
```

**Include Files**

- \texttt{mklscalapack.h}

**Description**

This function generates the whole or part of \( m \)-by-\( n \) complex distributed matrix \( Q \) denoting \( A(ia:ia+n-1,ja:ja+n-1) \) with orthonormal rows, which is defined as the first \( n \) columns of a product of \( k \) elementary reflectors of order \( m \)

\[ Q = (H(k))^{H}\star(H(2))^{H}\star(H(1))^{H} \]

as returned by \texttt{p?geqlf}.

**Input Parameters**

\( m \) (global) The number of rows in the matrix sub(\( Q \)) \( (m\geq0) \).

\( n \) (global) The number of columns in the matrix sub(\( Q \)) \( (n\geq0) \).

\( k \) (global) The number of elementary reflectors whose product defines the matrix \( Q \) \( (n\geq k \geq 0) \).
**Output Parameters**

- **a**
  
  Contains the local pieces of the \( m \)-by-\( n \) distributed matrix \( Q \) to be factored.

- **work[0]**

  On exit, `work[0]` contains the minimum value of `lwork` required for optimum performance.

- **info**

  (global)

  \( = 0 \): the execution is successful.
< 0: if the i-th argument is an array and the j-th entry, indexed \( j - 1 \), had an illegal value, then \( info = -(i*100+j) \); if the i-th argument is a scalar and had an illegal value, then \( info = -i \).

See Also
Overview for details of ScaLAPACK array descriptor structures and related notations.

\textbf{p?ormql}

Multiplies a general matrix by the orthogonal matrix \( Q \) of the QL factorization formed by \textbf{p?geqlf}.

\textbf{Syntax}

```c
void psormql (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *k , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *tau , float *c , MKL_INT *ic , MKL_INT *jc , MKL_INT *descc , float *work , MKL_INT *lwork , MKL_INT *info );
void pdormql (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *k , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *tau , double *c , MKL_INT *ic , MKL_INT *jc , MKL_INT *descc , double *work , MKL_INT *lwork , MKL_INT *info );
```

\textbf{Include Files}

- mkl_scalapack.h

\textbf{Description}

The \textbf{p?ormql} function overwrites the general real \( m \)-by-\( n \) distributed matrix \( sub(C) = C(ic:ic+m-1,jc:jc+n-1) \) with

\[
\begin{align*}
\text{side} = \text{'L'}: & \quad Q \text{ or } Q^T \text{ is applied from the left.} \\
\text{trans} = \text{'N'}: & \quad Q^*\text{sub}(C) \\
\text{trans} = \text{'T'}: & \quad Q^T*\text{sub}(C)
\end{align*}
\]

where \( Q \) is a real orthogonal distributed matrix defined as the product of \( k \) elementary reflectors

\[ Q = H(k)' \ldots H(2)' H(1)' \]

as returned by \textbf{p?geqlf}. \( Q \) is of order \( m \) if \text{side} = \text{'L'} and of order \( n \) if \text{side} = \text{'R'}.

\textbf{Input Parameters}

\textbf{side} (global)

- \text{'L'}: \( Q \) or \( Q^T \) is applied from the left.
- \text{'R'}: \( Q \) or \( Q^T \) is applied from the right.

\textbf{trans} (global)

- \text{'N'}: no transpose, \( Q \) is applied.
- \text{'T'}: transpose, \( Q^T \) is applied.

\textbf{m} (global) The number of rows in the distributed matrix \( \text{sub}(C) \), \((m \geq 0)\).

\textbf{n} (global) The number of columns in the distributed matrix \( \text{sub}(C) \), \((n \geq 0)\).

\textbf{k} (global) The number of elementary reflectors whose product defines the matrix \( Q \). Constraints:
If \( \text{side} = 'L' \), \( m \geq k \geq 0 \).

If \( \text{side} = 'R' \), \( n \geq k \geq 0 \).

\( a \)  
(local)

Pointer into the local memory to an array of size \( \text{lld}_a \times \text{LOCc}(ja+k-1) \). The \( j \)-th column of the matrix stored in \( a \) must contain the vector that defines the elementary reflector \( H(j) \), \( ja \leq j \leq ja+k-1 \), as returned by \( \text{p?gelqf} \) in the \( k \) columns of its distributed matrix argument \( A(ia:*, ja:ja+k-1) \). \( A(ia:*, ja:ja+k-1) \) is modified by the function but restored on exit.

If \( \text{side} = 'L' \), \( \text{lld}_a \geq \max(1, \text{LOCr}(ia+m-1)) \).
If \( \text{side} = 'R' \), \( \text{lld}_a \geq \max(1, \text{LOCr}(ia+n-1)) \).

\( \text{ia}, \text{ja} \)  
(global) The row and column indices in the global matrix \( A \) indicating the first row and the first column of the submatrix \( A \), respectively.

\( \text{desca} \)  
(global and local) array of size \( dlen_\text{c} \). The array descriptor for the distributed matrix \( A \).

\( \tau \)  
(local)

Array of size \( \text{LOCc}(ja+n-1) \).

Contains the scalar factor \( \tau[j] \) of elementary reflectors \( H(j+1) \) as returned by \( \text{p?geqlf} \) \( (0 \leq j < \text{LOCc}(ja+k-1)) \). \( \tau \) is tied to the distributed matrix \( A \).

\( c \)  
(local)

Pointer into the local memory to an array of local size \( \text{lld}_c \times \text{LOCc}(jc+n-1) \).

Contains the local pieces of the distributed matrix sub(\( C \)) to be factored.

\( \text{ic}, \text{jc} \)  
(global) The row and column indices in the global matrix \( C \) indicating the first row and the first column of the submatrix \( C \), respectively.

\( \text{descC} \)  
(global and local) array of size \( dlen_\text{c} \). The array descriptor for the distributed matrix \( C \).

\( \text{work} \)  
(local)

Workspace array of size of \( \text{lwork} \).

\( \text{lwork} \)  
(local or global) dimension of \( \text{work} \), must be at least:

If \( \text{side} = 'L' \),
\[ lwork \geq \max((\text{nb}_a \times (\text{nb}_a-1))/2, (\text{nqc}_0 + \text{mpc}_0) \times \text{nb}_a + \text{nb}_a \times \text{nb}_a) \]
else if \( \text{side} = 'R' \),
\[ lwork \geq \max((\text{nb}_a \times (\text{nb}_a-1))/2, (\text{nqc}_0 + \max(\text{npa}_0 + \text{numroc}(\text{numroc}(\text{npa}_0 + \text{icoffc}, \text{nb}_a, 0, 0, \text{NPCOL}), \text{nb}_a, 0, 0, \text{lcmq}), \text{mpc}_0) \times \text{nb}_a + \text{nb}_a \times \text{nb}_a) \]
end if

where

\( \text{lcmq} = \text{lcm}/\text{NPCOL} \) with \( \text{lcm} = \text{ilcm}(\text{NPROW}, \text{NPCOL}), \text{icoffc} = \text{mod}(\text{ia}-1, \text{mb}_a) \).
icoffa = mod(ja-1, nb_a),
iarow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW),
npa0= numroc(n + iroffa, mb_a, MYROW, iarow, NPROW),
iroffc = mod(ic-1, mb_c),
icoffc = mod(ic-1, mb_c),
icrow = indxg2p(ic, mb_c, MYROW, rsrc_c, NPROW),
iccol = indxg2p(jc, nb_c, MYCOL, csrc_c, NPCOL),
mpc0 = numroc(m+iroffc, mb_c, MYROW, icrow, NPROW),
nqc0 = numroc(n+icoffc, nb_c, MYCOL, iccol, NPCOL),

NOTE

\text{mod}(x,y) \text{ is the integer remainder of } x/y.

\text{lcm, indxg2p and numroc are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function blacs_gridinfo.}

If lwork = -1, then lwork is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

c

Overwritten by the product Q* sub(C), or Q’*sub (C), or sub(C)* Q’, or sub(C)* Q

work[0]

On exit work[0] contains the minimum value of lwork required for optimum performance.

info

(global)

= 0: the execution is successful.

< 0: if the i-th argument is an array and the j-th entry, indexed j - 1, had an illegal value, then info = -(i*100+j); if the i-th argument is a scalar and had an illegal value, then info = -i.

Include Files
• mkl_scalapack.h

Description
This function overwrites the general complex m-by-n distributed matrix sub(C) = C(ic:ic+m-1,jc:jc+n-1) with

\[
\begin{align*}
\text{side} = 'L': & \quad \text{Q or } Q^H \text{ is applied from the left.} \\
\text{side} = 'R': & \quad \text{Q or } Q^H \text{ is applied from the right.} \\
\text{trans} = 'N': & \quad Q\text{sub}(C) \\
\text{trans} = 'C': & \quad Q^H\text{sub}(C)
\end{align*}
\]

where Q is a complex unitary distributed matrix defined as the product of k elementary reflectors

\[
Q = H(k)' ... H(2)' H(1')
\]
as returned by p?geqlf. Q is of order m if side = 'L' and of order n if side = 'R'.

Input Parameters
side
(global)
= 'L': Q or Q^H is applied from the left.
= 'R': Q or Q^H is applied from the right.

trans
(global)
= 'N', no transpose, Q is applied.
= 'C', conjugate transpose, Q^H is applied.

m
(global) The number of rows in the distributed matrix sub(C) (\(m\geq0\)).

n
(global) The number of columns in the distributed matrix sub(C) (\(n\geq0\)).

k
(global) The number of elementary reflectors whose product defines the matrix Q. Constraints:
If side = 'L', \(m\geq k \geq 0\)
If side = 'R', \(n\geq k \geq 0\).

a
(local)
Pointer into the local memory to an array of size lld_a*LOCc(ja+k-1). The j-th column of the matrix stored in a must contain the vector that defines the elementary reflector H(j), \(ja\leq j \leq ja+k-1\), as returned by p?geqlf in the k columns of its distributed matrix argument A(ia:*, ja:ja+k-1). A(ia:*, ja:ja+k-1) is modified by the function but restored on exit.
If side = 'L', lld_a \geq \max(1, LOCr(ia+m-1)),
If side = 'R', lld_a \geq \max(1, LOCr(ia+n-1)).
(global) The row and column indices in the global matrix \( A \) indicating the first row and the first column of the submatrix \( A \), respectively.

desca

(global and local) array of size \( dlen_ \). The array descriptor for the distributed matrix \( A \).

tau

(local)

Array of size \( \text{LOCc}(\text{ia}+\text{n}-1) \).

Contains the scalar factor \( \tau[j] \) of elementary reflectors \( H(j+1) \) as returned by \( \text{p?geqlf} \) \((0 \leq j < \text{LOCc}(\text{ia}+\text{n}-1)) \). \( \tau \) is tied to the distributed matrix \( A \).

c

(local)

Pointer into the local memory to an array of local size \( \text{lld}_c*\text{LOCc}(\text{jc}+\text{n}-1) \).

Contains the local pieces of the distributed matrix sub\((C)\) to be factored.

ic, jc

(global) The row and column indices in the global matrix \( C \) indicating the first row and the first column of the submatrix \( C \), respectively.

descc

(global and local) array of size \( dlen_ \). The array descriptor for the distributed matrix \( C \).

work

Workspace array of size of \( \text{lwork} \).

lwork

(local or global) size of \( \text{work} \), must be at least:

If \( \text{side} = 'L', \)
\[
\text{lwork} \geq \max( (\text{nb}_a*(\text{nb}_a-1))/2, (\text{nqc}_0+\text{mpc}_0)*\text{nb}_a + \text{nb}_a*\text{nb}_a
\]

else if \( \text{side} = 'R', \)
\[
\text{lwork} \geq \max( (\text{nb}_a*(\text{nb}_a-1))/2, (\text{nqc}_0+\text{mpa}_0) + \text{numroc}(\text{numroc}(n+\text{ioccof}_c, \text{nb}_a, 0, 0, \text{NPCOL}), \text{nb}_a, 0, 0, \text{lcm}_q, \text{mpc}_0))*\text{nb}_a
\]
\[
+ \text{nb}_a*\text{nb}_a
\]

end if

where

\( \text{lcmp} = \text{lcm}/\text{NPCOL} \) with \( \text{lcm} = \text{lcm}(\text{NRW}, \text{NPCOL}), \)

\( \text{iroff}_a = \text{mod}(\text{ia}-1, \text{mb}_a), \)

\( \text{icoff}_a = \text{mod}(\text{ja}-1, \text{nb}_a), \)

\( \text{iarow} = \text{indxg2p}(\text{ia}, \text{mb}_a, \text{MYROW}, \text{rsrc}_a, \text{NRW}), \)

\( \text{mpa}_0 = \text{numroc}(n+\text{ioccof}_c, \text{nb}_a, 0, 0, \text{NPCOL}), \)

\( \text{iroff}_c = \text{mod}(\text{ic}-1, \text{mb}_c), \)

\( \text{icoff}_c = \text{mod}(\text{jc}-1, \text{nb}_c), \)

\( \text{icrow} = \text{indxg2p}(\text{ic}, \text{mb}_c, \text{MYROW}, \text{rsrc}_c, \text{NRW}), \)

\( \text{mpc}_0 = \text{numroc}(m+\text{iroff}_c, \text{mb}_c, \text{MYROW}, \text{icrow}, \text{NRW}), \)

\( \text{nqc}_0 = \text{numroc}(n+\text{iroff}_c, \text{nb}_c, \text{MYCOL}, \text{iccol}, \text{NPCOL}), \)
\[ \text{mod}(x, y) \text{ is the integer remainder of } x/y. \]

\[ \text{ilcm}, \text{indxg2p} \text{ and } \text{numroc} \text{ are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function blacs_gridinfo.} \]

\[ \text{NOTE} \]
\[ \text{mod}(x, y) \text{ is the integer remainder of } x/y. \]

If \( lwork = -1 \), then \( lwork \) is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by \( \text{pxerbla} \).

**Output Parameters**

\[ c \]
Overwritten by the product \( Q^* \) sub(\( C \)), or \( Q^* \) sub (\( C \)), or sub(\( C \))* \( Q \), or sub(\( C \))* \( Q^* \).

\[ \text{work}[0] \]
On exit \( \text{work}[0] \) contains the minimum value of \( lwork \) required for optimum performance.

\[ \text{info} \]
\( \) (global)
\[ = 0: \] the execution is successful.
\[ < 0: \] if the \( i \)-th argument is an array and the \( j \)-th entry, indexed \( j - 1 \), had an illegal value, then \( info = -(i*100+j) \); if the \( i \)-th argument is a scalar and had an illegal value, then \( info = -i \).

**See Also**

\]
Include Files

- mkl_scalapack.h

Description

The `pgerqf` function forms the QR factorization of a general \( m \)-by-\( n \) distributed matrix \( \text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1) \) as

\[ A = R \times Q \]

Input Parameters

- \( m \)
  (global) The number of rows in the distributed matrix \( \text{sub}(A) \); \( m \geq 0 \).

- \( n \)
  (global) The number of columns in the distributed matrix \( \text{sub}(A) \); \( n \geq 0 \).

- \( a \)
  (local)
  Pointer into the local memory to an array of local size \( lld_a \times \text{LOCc}(ja+n-1) \).
  Contains the local pieces of the distributed matrix \( \text{sub}(A) \) to be factored.

- \( ia, ja \)
  (global) The row and column indices in the global matrix \( A \) indicating the first row and the first column of the submatrix \( \text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1) \), respectively.

- \( \text{desca} \)
  (global and local) array of size \( dlen_\). The array descriptor for the distributed matrix \( A \).

- \( \text{work} \)
  (local)
  Workspace array of size \( lwork \).

- \( lwork \)
  (local or global) size of \( \text{work} \), must be at least

\[
\text{lwork} \geq \text{mb}_a \times (\text{mp}_0 + \text{nq}_0 + \text{mb}_a),
\]

where

\[
\text{iroff} = \text{mod}(ia-1, \text{mb}_a),
\]

\[
\text{icoff} = \text{mod}(ja-1, \text{nb}_a),
\]

\[
\text{iarow} = \text{indxg2p}(ia, \text{mb}_a, \text{MYROW}, \text{rsnc}_a, \text{NPROW}),
\]

\[
\text{iacol} = \text{indxg2p}(ja, \text{nb}_a, \text{MYCOL}, \text{csnc}_a, \text{NPCOL}),
\]

\[
\text{mp}_0 = \text{numroc}(m+\text{iroff}, \text{mb}_a, \text{MYROW}, \text{iarow}, \text{NPROW}),
\]

\[
\text{nq}_0 = \text{numroc}(n+\text{icoff}, \text{nb}_a, \text{MYCOL}, \text{iacol}, \text{NPCOL})
\]

and \text{numroc}, \text{indxg2p} are ScaLAPACK tool functions; \text{MYROW}, \text{MYCOL}, \text{NPROW} and \text{NPCOL} can be determined by calling the function \text{blacs_gridinfo}.

If \( lwork = -1 \), then \( lwork \) is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by \text{pxerbla}. 

\[ \text{mod}(x,y) \] is the integer remainder of \( x/y \). 

\[ nq0 = \text{numroc}(n+icoff, nb_a, MYCOL, iacol, NPCOL) \text{ and numroc, indxg2p are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function blacs_gridinfo.} \]

If \( lwork = -1 \), then \( lwork \) is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by \text{pxerbla}. 

\[ \text{mod}(x,y) \] is the integer remainder of \( x/y \). 

\[ nq0 = \text{numroc}(n+icoff, nb_a, MYCOL, iacol, NPCOL) \text{ and numroc, indxg2p are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function blacs_gridinfo.} \]
Output Parameters

On exit, if \( m \leq n \), the upper triangle of \( A(ia:ia+m-1, ja:ja+n-1) \) contains the \( m \)-by-\( m \) upper triangular matrix \( R \); if \( m > n \), the elements on and above the \( (m - n) \)-th subdiagonal contain the \( m \)-by-\( n \) upper trapezoidal matrix \( R \); the remaining elements, with the array \( \tau \), represent the orthogonal/unitary matrix \( Q \) as a product of elementary reflectors (see Application Notes below).

\( \tau \) (local)

Array of size \( \text{LOCr}(ia+m-1) \).

Contains the scalar factor of elementary reflectors. \( \tau \) is tied to the distributed matrix \( A \).

\( \text{work}[0] \)

On exit, \( \text{work}[0] \) contains the minimum value of \( lwork \) required for optimum performance.

\( \text{info} \) (global)

\( = 0 \), the execution is successful.

\( < 0 \), if the \( i \)-th argument is an array and the \( j \)-th entry, indexed \( j-1 \), had an illegal value, then \( \text{info} = -(i*100+j) \); if the \( i \)-th argument is a scalar and had an illegal value, then \( \text{info} = -i \).

Application Notes

The matrix \( Q \) is represented as a product of elementary reflectors
\[
Q = H(ia)H(ia+1)\ldots H(ia+k-1),
\]
where \( k = \min(m,n) \).

Each \( H(i) \) has the form
\[
H(i) = I - \tau \cdot v \cdot v^T
\]
where \( \tau \) is a real/complex scalar, and \( v \) is a real/complex vector with \( v(n-k+i+1:n) = 0 \) and \( v(n-k+i) = 1 \); \( v(1:n-k+i-1) \) is stored on exit in \( A(ia+m-k+i-1,ja:ja+n-k+i-2) \), and \( \tau \) in \( \tau[ia+m-k+i-2] \).

\texttt{p?orgrq}

Generates the orthogonal matrix \( Q \) of the RQ factorization formed by \texttt{p?gerqf}.

Syntax

\[
\text{void psorgrq (MKL_INT } \* m, \text{ MKL_INT } \* n, \text{ MKL_INT } \* k, \text{ float } \* a, \text{ MKL_INT } \* ia, \text{ MKL_INT } \* ja, \text{ MKL_INT } \* desca, \text{ float } \* \tau, \text{ float } \* \text{work, MKL_INT } \* lwork, \text{ MKL_INT } \* \text{info });}
\]
\[
\text{void pdorgrq (MKL_INT } \* m, \text{ MKL_INT } \* n, \text{ MKL_INT } \* k, \text{ double } \* a, \text{ MKL_INT } \* ia, \text{ MKL_INT } \* ja, \text{ MKL_INT } \* desca, \text{ double } \* \tau, \text{ double } \* \text{work, MKL_INT } \* \text{lwork, MKL_INT } \* \text{info });}
\]

Include Files

- \texttt{mkl_scalapack.h}
Description
The _?orgqr_ function generates the whole or part of _m_ by _n_ real distributed matrix _Q_ denoting _A__(ia:ia+m-1,ja:ja+n-1) with orthonormal rows that is defined as the last _m_ rows of a product of _k_ elementary reflectors of order _n_

\[ Q = H(1)^*H(2)^*...*H(k) \]

as returned by _?gerqf_.

Input Parameters

- **_m_** (global) The number of rows in the matrix sub(_Q_), \((m \geq 0)\).
- **_n_** (global) The number of columns in the matrix sub(_Q_), \((n \geq m \geq 0)\).
- **_k_** (global) The number of elementary reflectors whose product defines the matrix _Q_ \((m \geq k \geq 0)\).
- **_a_** (local) Pointer into the local memory to an array of local size \(lld_a*\text{LOCc}(ja+n-1)\). The _i_-th row of the matrix stored in _a_ must contain the vector that defines the elementary reflector _H_(\(i\)), \(ia \leq i \leq ia+m-1\), as returned by _?gerqf_ in the _k_ rows of its distributed matrix argument _A__(ia+m-k:ia+m-1,ja:*)
- **_ia, ja_** (global) The row and column indices in the global matrix _A_ indicating the first row and the first column of the submatrix _A_, respectively.
- **_desca_** (global and local) array of size \(dlen_\). The array descriptor for the distributed matrix _A_.
- **_tau_** (local) Array of size \(\text{LOCc}(ja+k-1)\).
  Contains the scalar factor _tau_[_] of elementary reflectors _H_(\(_i+1\)) as returned by _?gerqf_, \(0 \leq i < \text{LOCr}(ja+k-1)\). _tau_ is tied to the distributed matrix _A_.
- **_work_** (local) Workspace array of size of _lwork_.
- **_lwork_** (local or global) size of _work_, must be at least \(lwork \geq mb_a*(mpa0 + nqa0 + mb_a)\), where
  \( iroff_a = \text{mod}(ia-1, mb_a)\),
  \( icoff_a = \text{mod}(ja-1, nb_a)\),
  \( iarow = \text{indxg2p}(ia, mb_a, \text{MYROW}, rsrca, \text{NPROW})\),
  \( iacol = \text{indxg2p}(ja, nb_a, \text{MYCOL}, csrca, \text{NPCOL})\),
  \( mpa0 = \text{numroc}(m+iroff_a, mb_a, \text{MYROW}, iarow, \text{NPROW})\),
  \( nqa0 = \text{numroc}(n+icoff_a, nb_a, \text{MYCOL}, iacol, \text{NPCOL})\)

  _indxg2p_ and _numroc_ are ScaLAPACK tool functions; _MYROW_, _MYCOL_, _NPROW_ and _NPCOL_ can be determined by calling the function _blacs_gridinfo_.

_ScaLAPACK Routines_
NOTE

\( \text{mod}(x,y) \) is the integer remainder of \( x/y \).

If \( lwork = -1 \), then \( lwork \) is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by \text{pxerbla}.

Output Parameters

- \( a \) contains the local pieces of the \( m \)-by-\( n \) distributed matrix \( Q \).
- \( \text{work}[0] \) contains the minimum value of \( lwork \) required for optimum performance.
- \( \text{info} \) is an (global) output parameter.

\( \text{info} = 0 \) : the execution is successful.
\( < 0 \) : if the \( i \)-th argument is an array and the \( j \)-th entry, indexed \( j - 1 \), had an illegal value, then \( \text{info} = -(i*100+j) \); if the \( i \)-th argument is a scalar and had an illegal value, then \( \text{info} = -i \).

\text{p?ungrq}

Generates the unitary matrix \( Q \) of the RQ factorization formed by \text{p?gerqf}.

Syntax

void pcungrq (MKL_INT *m, MKL_INT *n, MKL_INT *k, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_Complex8 *tau, MKL_Complex8 *work, MKL_INT *lwork, MKL_INT *info);
void pzungrq (MKL_INT *m, MKL_INT *n, MKL_INT *k, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_Complex16 *tau, MKL_Complex16 *work, MKL_INT *lwork, MKL_INT *info);

Include Files
- mkl_scalapack.h

Description

This function generates the \( m \)-by-\( n \) complex distributed matrix \( Q \) denoting \( A(ia:ia+m-1,ja:ja+n-1) \) with orthonormal rows, which is defined as the last \( m \) rows of a product of \( k \) elementary reflectors of order \( n \)

\( Q = (H(1))^H* (H(2))^H * ... * (H(k))^H \) as returned by \text{p?gerqf}.

Input Parameters

- \( m \) (global) The number of rows in the matrix sub(\( Q \)); \( m \geq 0 \).
- \( n \) (global) The number of columns in the matrix sub(\( Q \)) \( n \geq m \geq 0 \).
The number of elementary reflectors whose product defines the matrix $Q$ ($m \geq k \geq 0$).

Pointer into the local memory to an array of size $lld_a*LOCc(ja+n-1)$. The $i$-th row of the matrix stored in $a$ must contain the vector that defines the elementary reflector $H(i)$, $ia+m-k \leq i \leq ia+m-1$, as returned by $p?gerqf$ in the $k$ rows of its distributed matrix argument $A(ia+m-k:ia+m-1, ja*)$.

The row and column indices in the global matrix $A$ indicating the first row and the first column of the submatrix $A$, respectively.

(global and local) array of size $dlen_\_$. The array descriptor for the distributed matrix $A$.

Array of size $LOCr(ia+m-1)$.

Contains the scalar factor $\tau[i]$ of elementary reflectors $H(i+1)$ as returned by $p?gerqf$, $0 \leq i < LOCr(ia+m-1)$. $\tau$ is tied to the distributed matrix $A$.

Workspace array of size of $lwork$.

(size of work, must be at least $lwork \geq mb_a*(mpa0 + nqa0+mb_a)$, where

\[
\begin{align*}
  iroff &= \text{mod}(ia-1, mb_a), \\
  icoff &= \text{mod}(ja-1, nb_a), \\
  iarow &= \text{indxg2p}(ia, mb_a, \text{MYROW}, \text{rsrc_a}, \text{NPROW}), \\
  iacol &= \text{indxg2p}(ja, nb_a, \text{MYCOL}, \text{csrc_a}, \text{NPCOL}), \\
  mpa0 &= \text{numroc}(m+iroff, mb_a, \text{MYROW}, iarow, \text{NPROW}), \\
  nqa0 &= \text{numroc}(n+icoff, nb_a, \text{MYCOL}, iacol, \text{NPCOL})
\end{align*}
\]

\[\text{mod}(x, y)\text{ is the integer remainder of } x/y.\]

indxg2p and numroc are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function blacs_gridinfo.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pzerbla.

### Output Parameters

Contains the local pieces of the $m$-by-$n$ distributed matrix $Q$.

On exit $work[0]$ contains the minimum value of $lwork$ required for optimum performance.
info (global)
= 0: the execution is successful.
< 0: if the i-th argument is an array and the j-th entry, indexed j - 1, had an illegal value, then info = -(i*100+j); if the i-th argument is a scalar and had an illegal value, then info = -i.

Overview for details of ScaLAPACK array descriptor structures and related notations.

pormr3
Applies an orthogonal distributed matrix to a general m-by-n distributed matrix.

Syntax
void psormr3 (const char* side, const char* trans, const MKL_INT* m, const MKL_INT* n, const MKL_INT* k, const MKL_INT* l, const float* a, const MKL_INT* ia, const MKL_INT* ja, const MKL_INT* desca, const float* tau, float* c, const MKL_INT* ic, const MKL_INT* jc, const MKL_INT* descc, float* work, const MKL_INT* lwork, MKL_INT* info);
void pdormr3 (const char* side, const char* trans, const MKL_INT* m, const MKL_INT* n, const MKL_INT* k, const MKL_INT* l, const double* a, const MKL_INT* ia, const MKL_INT* ja, const MKL_INT* desca, const double* tau, double* c, const MKL_INT* ic, const MKL_INT* jc, const MKL_INT* descc, double* work, const MKL_INT* lwork, MKL_INT* info);

Include Files
• mkl_scalapack.h

Description
pormr3 overwrites the general real m-by-n distributed matrix sub( C ) = C(ic:ic+m-1,jc:jc+n-1) with

<table>
<thead>
<tr>
<th>side = 'L'</th>
<th>side = 'R'</th>
</tr>
</thead>
<tbody>
<tr>
<td>trans = 'N'</td>
<td>Q * sub( C )</td>
</tr>
<tr>
<td>trans = 'T'</td>
<td>Q**T * sub( C )</td>
</tr>
</tbody>
</table>

where Q is a real orthogonal distributed matrix defined as the product of k elementary reflectors
Q = H(1) H(2) . . . H(k)
as returned by pztzrzf. Q is of order m if side = 'L' and of order n if side = 'R'.

Input Parameters
side (global)
= 'L': apply Q or Q**T from the Left;
= 'R': apply Q or Q**T from the Right.

trans (global)
= 'N': No transpose, apply Q;
= 'T': Transpose, apply \( Q^T \).

\( m \) (global)
The number of rows to be operated on i.e the number of rows of the distributed submatrix \( \text{sub}(C) \). \( m >= 0 \).

\( n \) (global)
The number of columns to be operated on i.e the number of columns of the distributed submatrix \( \text{sub}(C) \). \( n >= 0 \).

\( k \) (global)
The number of elementary reflectors whose product defines the matrix \( Q \).
If \( \text{side} = 'L' \), \( m >= k >= 0 \),
if \( \text{side} = 'R' \), \( n >= k >= 0 \).

\( l \) (global)
The columns of the distributed submatrix \( \text{sub}(A) \) containing the meaningful part of the Householder reflectors.
If \( \text{side} = 'L' \), \( m >= l >= 0 \),
if \( \text{side} = 'R' \), \( n >= l >= 0 \).

\( a \) (local)
Pointer into the local memory to an array of size \( \text{lld}_a \times \text{LOCc}(ja+m-1) \) if \( \text{side} = 'L' \), and \( \text{lld}_a \times \text{LOCc}(ja+n-1) \) if \( \text{side} = 'R' \), where \( \text{lld}_a \geq \text{MAX}(1,\text{LOCr}(ia+k-1)) \);
On entry, the \( i \)-th row must contain the vector which defines the elementary reflector \( H(i) \), \( ia <= i <= ia+k-1 \), as returned by \( \text{p?tzrzf} \) in the \( k \) rows of its distributed matrix argument \( A(ia:ia+k-1,ja:*). \)
\( A(ia:ia+k-1,ja:*)) \) is modified by the routine but restored on exit.

\( ia \) (global)
The row index in the global array \( a \) indicating the first row of \( \text{sub}(A) \).

\( ja \) (global)
The column index in the global array \( a \) indicating the first column of \( \text{sub}(A) \).

desca (global and local)
Array of size \( \text{dlen}_a \).
The array descriptor for the distributed matrix \( A \).

\( \tau \) (local)
Array, size \( \text{LOCc}(ia+k-1) \).
This array contains the scalar factors \( \tau(i) \) of the elementary reflectors \( H(i) \) as returned by \( \text{p?tzrzf} \). \( \tau \) is tied to the distributed matrix \( A \).

\( c \) (local)
Pointer into the local memory to an array of size \( \text{lld}_c \times \text{LOCc}(jc+n-1) \).
On entry, the local pieces of the distributed matrix $C$.

$(\text{global})$

The row index in the global array $c$ indicating the first row of $C$.

$(\text{global})$

The column index in the global array $c$ indicating the first column of $C$.

$(\text{global and local})$

Array of size $dlen_\_.$

The array descriptor for the distributed matrix $C$.

$(\text{local})$

Array, size $(lwork)$

$(\text{local})$

The size of the array $work$.

$lwork$ is local input and must be at least

If $side = 'L'$, $lwork >= MpC0 + \text{MAX}(\text{MAX}(1, NqC0 \text{, numroc($numroc(m + IROFFC, mb_a, 0, 0, NPROW), mb_a, 0, 0, NqC0))})$;

If $side = 'R'$, $lwork >= NqC0 + \text{MAX}(1, MpC0)$;

where $LCMP = LCM / NPROW$

$LCM = ilcm(NPROW, NPCOL)$,

$IROFFC = \text{MOD}(ic-1, mb_c)$,

$ICOFFC = \text{MOD}(jc-1, nb_c)$,

$ICROW = \text{indxg2p}(ic, mb_c, MYROW, rsrcc_c, NPROW)$,

$ICCOL = \text{indxg2p}(jc, nb_c, MYCOL, csrcc_c, NPCOL)$,

$MpC0 = \text{numroc}(m+IROFFC, mb_c, MYROW, ICROW, NPROW)$,

$NqC0 = \text{numroc}(n+ICOFFC, nb_c, MYCOL, ICCOL, NPCOL)$,

$lclm$, $\text{indxg2p}$, and $\text{numroc}$ are ScaLAPACK tool functions;

$MYROW$, $MYCOL$, $NPROW$ and $NPCOL$ can be determined by calling the subroutine $\text{blacs_gridinfo}$.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by $\text{pxerbla}$.

**Output Parameters**

$c$

On exit, $\text{sub}(C)$ is overwritten by $Q*\text{sub}(C)$ or $Q^*\text{sub}(C)$ or $\text{sub}(C)*Q$ or $\text{sub}(C)^*Q$.

$work$

On exit, $work[0]$ returns the minimal and optimal $lwork$.

$info$

$(\text{local})$
= 0: successful exit
< 0: If the $i$-th argument is an array and the $j$-th entry had an illegal value, then $info = -(i*100+j)$, if the $i$-th argument is a scalar and had an illegal value, then $info = -i$.

**Application Notes**

**Alignment requirements**

The distributed submatrices $A(ia:\ast, ja:\ast)$ and $C(ic:ic+m-1, jc:jc+n-1)$ must verify some alignment properties, namely the following expressions should be true:

- If $side = 'L$',
  \[ nb_a = mb_c \text{ AND ICOFFA} = IROFFC \]

- If $side = 'R$',
  \[ nb_a = nb_c \text{ AND ICOFFA} = ICOFFC \text{ AND IACOL} = ICCOL \]

**p?unmr3**

Applies an orthogonal distributed matrix to a general $m$-by-$n$ distributed matrix.

**Syntax**

```c
void pcunmr3 (const char* side, const char* trans, const MKL_INT* m, const MKL_INT* n, const MKL_INT* k, const MKL_INT* l, const MKL_Complex8* a, const MKL_INT* ia, const MKL_INT* ja, const MKL_INT* desca, const MKL_Complex8* tau, MKL_Complex8* c, const MKL_INT* ic, const MKL_INT* jc, const MKL_INT* descc, MKL_Complex8* work, const MKL_INT* lwork, MKL_INT* info);

void pzunmr3 (const char* side, const char* trans, const MKL_INT* m, const MKL_INT* n, const MKL_INT* k, const MKL_INT* l, const MKL_Complex16* a, const MKL_INT* ia, const MKL_INT* ja, const MKL_INT* desca, const MKL_Complex16* tau, MKL_Complex16* c, const MKL_INT* ic, const MKL_INT* jc, const MKL_INT* descc, MKL_Complex16* work, const MKL_INT* lwork, MKL_INT* info);
```

**Include Files**

- mkl_scalapack.h

**Description**

p?unmr3 overwrites the general complex $m$-by-$n$ distributed matrix $\text{sub}( C ) = C(ic:ic+m-1, jc:jc+n-1)$ with

- $side = 'L'$
  \[ trans = 'N': Q * \text{sub}( C ) \]
  \[ trans = 'C': Q^H * \text{sub}( C ) \]

- $side = 'R'$
  \[ trans = 'N': \text{sub}( C ) * Q \]
  \[ trans = 'C': \text{sub}( C ) * Q^H \]

where $Q$ is a complex unitary distributed matrix defined as the product of $k$ elementary reflectors

$Q = H(1)' H(2)' \ldots H(k)'$

as returned by p?tzrzf. $Q$ is of order $m$ if $side = 'L$' and of order $n$ if $side = 'R$'.

**Input Parameters**

- $side$ (global)
  - $'L$': apply $Q$ or $Q^H$ from the Left;
= 'R': apply $Q$ or $Q^H$ from the Right.

$trans$
    (global)
  = 'N': No transpose, apply $Q$;
  = 'C': Conjugate transpose, apply $Q^H$.

$m$
    (global)
  The number of rows to be operated on i.e the number of rows of the
distributed submatrix sub$(C)$. $m \geq 0$.

$n$
    (global)
  The number of columns to be operated on i.e the number of columns of the
distributed submatrix sub$(C)$. $n \geq 0$.

$k$
    (global)
  The number of elementary reflectors whose product defines the matrix $Q$.
  If $side = 'L', m \geq k \geq 0$, if $side = 'R', n \geq k \geq 0$.

$l$
    (global)
  The columns of the distributed submatrix sub$(A)$ containing the
meaningful part of the Householder reflectors.
  If $side = 'L', m \geq l \geq 0$, if $side = 'R', n \geq l \geq 0$.

$a$
    (local)
  Pointer into the local memory to an array of size $lld_a*LOCc(ja+m-1)$ if
$side='L'$, and $lld_a*LOCc(ja+n-1)$ if $side='R'$, where $lld_a \geq$
MAX(1,LOCr($ia+k-1$));
  On entry, the $i$-th row must contain the vector which defines the elementary
reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by $p?tzrzf$ in the $k$
rows of its distributed matrix argument $A(ia:ia+k-1,ja:*)$.
  $A(ia:ia+k-1,ja:*)$ is modified by the routine but restored on exit.

$ia$
    (global)
  The row index in the global array $a$ indicating the first row of sub$(A)$.

$ja$
    (global)
  The column index in the global array $a$ indicating the first column of
sub$(A)$.

$desca$
    (global and local)
  Array of size $dlen_-$.
  The array descriptor for the distributed matrix $A$.

$tau$
    (local)
  Array, size LOCc($ia+k-1$).
  This array contains the scalar factors $tau(i)$ of the elementary reflectors
$H(i)$ as returned by $p?tzrzf$. $tau$ is tied to the distributed matrix $A$.

$c$
    (local)
Pointer into the local memory to an array of size $lld_c*LOCc(jc+n-1)$.

On entry, the local pieces of the distributed matrix sub(C).

$ic$ (global)

The row index in the global array $c$ indicating the first row of sub(C).

$jc$ (global)

The column index in the global array $c$ indicating the first column of sub(C).

$descC$ (global and local)

Array of size $dlen_-$.

The array descriptor for the distributed matrix $C$.

$work$ (local)

Array, size ($lwork$)

On exit, $work(1)$ returns the minimal and optimal $lwork$.

$lwork$ (local or global)

The size of the array $work$.

$lwork$ is local input and must be at least

If $side = 'L'$, $lwork >= MpC0 + MAX( MAX( 1, NqC0 ), numroc( numroc( m +IROFFC, mb_a, 0, 0, NPROW ), mb_a, 0, 0, LCMP ) );$

if $side = 'R'$, $lwork >= NqC0 + MAX( 1, MpC0 );$

where LCMP = LCM / NPROW with LCM = ICLM( NPROW, NPCOL ),

IROFFC = MOD( ic-1, MB_C ), ICOFFC = MOD( jc-1, nb_c ),

ICROW = indxg2p( ic, MB_C, MYROW, rsrc_c, NPROW ),

ICCOL = indxg2p( jc, nb_c, MYCOL, csrc_c, NPCOL ),

$MpC0 = numroc( m+IROFFC, MB_C, MYROW, ICROW, NPROW )$,

$NqC0 = numroc( n+ICOFFC, nb_c, MYCOL, ICCOL, NPCOL )$,

$lcm$, $indxg2p$, and $numroc$ are ScaLAPACK tool functions;

$MYROW$, $MYCOL$, $NPROW$ and $NPCOL$ can be determined by calling the subroutine $blacs_gridinfo$.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by $pxerbla$.

**Output Parameters**

$c$

On exit, sub(C) is overwritten by $Q*sub(C)$ or $Q'*sub(C)$ or sub(C)*$Q'$ or sub(C)*$Q$.

$work$ (local)

Array, size ($lwork$)
On exit, work[0] returns the minimal and optimal lwork.

info
   = 0: successful exit
   < 0: If the i-th argument is an array and the j-th entry had an illegal value, then info = -(i*100+j), if the i-th argument is a scalar and had an illegal value, then info = -i.

Application Notes
Alignment requirements
The distributed submatrices A(ia:*, ja:*) and C(ic:ic+m-1, jc:jc+n-1) must verify some alignment properties, namely the following expressions should be true:
If side = 'L', ( nb_a = MB_C and ICOFFA = IROFFC )
If side = 'R', ( nb_a = nb_c and ICOFFA = ICOFFC and IACOL = ICCOL )

pormrq
Multiplies a general matrix by the orthogonal matrix Q of the RQ factorization formed by pgerqf.

Syntax
void psormrq (char *side, char *trans, MKL_INT *m, MKL_INT *n, MKL_INT *k, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *tau, float *c, MKL_INT *ic, MKL_INT *jc, MKL_INT *descc, float *work, MKL_INT *lwork, MKL_INT *info);
void pdormrq (char *side, char *trans, MKL_INT *m, MKL_INT *n, MKL_INT *k, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *tau, double *c, MKL_INT *ic, MKL_INT *jc, MKL_INT *descc, double *work, MKL_INT *lwork, MKL_INT *info);

Include Files
- mkl_scalapack.h

Description
The pormrq function overwrites the general real m-by-n distributed matrix sub (C) = C(ic:ic+m-1, jc:jc+n-1) with

side = 'L':
trans = 'N': Q*sub(C)  side = 'R'
trans = 'T': Q^T*sub(C)

side = 'R':
trans = 'N': sub(C)*Q^T
trans = 'T': sub(C)*Q

where Q is a real orthogonal distributed matrix defined as the product of k elementary reflectors
Q = H(1) H(2)... H(k)

as returned by pgerqf. Q is of order m if side = 'L' and of order n if side = 'R'.

Input Parameters
side
   (global)
   = 'L': Q or Q^T is applied from the left.
   = 'R': Q or Q^T is applied from the right.
trans (global) = 'N', no transpose, Q is applied.
= 'T', transpose, QT is applied.

m (global) The number of rows in the distributed matrix sub(C) (m ≥ 0).

n (global) The number of columns in the distributed matrix sub(C) (n ≥ 0).

k (global) The number of elementary reflectors whose product defines the
        matrix Q. Constraints:
        If side = 'L', m ≥ k ≥ 0
        If side = 'R', n ≥ k ≥ 0.

a (local) Pointer into the local memory to an array of size lld_a*LOCc(ja+m-1) if
        side = 'L', and lld_a*LOCc(ja+n-1) if side = 'R'.
        The i-th row of the matrix stored in a must contain the vector that defines
        the elementary reflector H(i), ia ≤ i ≤ ia+k-1, as returned by p?gerqf in the
        k rows of its distributed matrix argument A(ia:ia+k-1, ja:ja). A(ia:ia
        +k-1, ja:* ) is modified by the function but restored on exit.

ia, ja (global) The row and column indices in the global matrix A indicating the
        first row and the first column of the submatrix A, respectively.

desca (global and local) array of size dlen_. The array descriptor for the
        distributed matrix A.

tau (local) Array of size LOCc(ja+k-1).
        Contains the scalar factor tau[i] of elementary reflectors H(i+1) as
        returned by p?gerqf (0 ≤ i < LOCc(ja+k-1)). tau is tied to the distributed
        matrix A.

c (local) Pointer into the local memory to an array of local size lld_c*LOCc(jc+n-1).
        Contains the local pieces of the distributed matrix sub(C) to be factored.

ic, jc (global) The row and column indices in the global matrix C indicating the
        first row and the first column of the matrix sub(C), respectively.

desccc (global and local) array of size dlen_. The array descriptor for the
        distributed matrix C.

work (local) Workspace array of size of lwork.
lwork (local or global) size of work, must be at least:
        If side = 'L',
        lwork ≥ max((mb_a*(mb_a-1))/2, (mpc0 + max(mqa0 +
        numroc(numroc(n+iroffc, mb_a, 0, 0, NPROW), mb_a, 0, 0,
        lcmp), nqc0))*mb_a) + mb_a*mb_a

4 ScaLAPACK Routines
else if side = 'R',
    lwork ≥ max((mb_a*(mb_a-1)) / 2, (mpc0 + nqc0)*mb_a + mb_a*mb_a)
end if

where

lcmp = lcm/NPROW with lcm = ilcm (NPROW, NPCOL),
iroffa = mod(ia-1, mb_a),
icoffa = mod(ja-1, nb_a),
iacol = indxg2p(ja, nb_a, MYCOL, csnc_a, NPCOL),
mqa0 = numroc(n+icoffa, nb_a, MYCOL, iacol, NPCOL),
irrofc = mod(ic-1, mb_c),
icoffc = mod(jc-1, nb_c),
icrow = indxg2p(ic, mb_c, MYROW, rsnc_c, NPROW),
iccol = indxg2p(jc, nb_c, MYCOL, csnc_c, NPCOL),
mpc0 = numroc(m+irrofc, mb_c, MYROW, icrow, NPROW),
nqc0 = numroc(n+icoffc, nb_c, MYCOL, iccol, NPCOL),

**NOTE**

mod(x, y) is the integer remainder of x/y.

ilcm, indxg2p and numroc are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function blacs_gridinfo.

If lwork = -1, then lwork is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

c
Overwritten by the product Q* sub(C), or Q'*sub (C), or sub(C)* Q', or sub(C)* Q

work[0]
On exit work[0] contains the minimum value of lwork required for optimum performance.

info
(global)
= 0: the execution is successful.
< 0: if the i-th argument is an array and the j-th entry, indexed j - 1, had an illegal value, then info = -(i*100+j); if the i-th argument is a scalar and had an illegal value, then info = -i.

Include Files
• mkl_scalapack.h

Description
The p?tzrzf function reduces the m-by-n (m ≤ n) real/complex upper trapezoidal matrix sub(A)= A(ia:ia+m-1, ja:ja+n-1) to upper triangular form by means of orthogonal/unitary transformations. The upper trapezoidal matrix A is factored as
A = (R 0)*Z,
where Z is an n-by-n orthogonal/unitary matrix and R is an m-by-m upper triangular matrix.

Input Parameters

m
(global) The number of rows in the matrix sub(A); (m≥0).

n
(global) The number of columns in the matrix sub(A) (n≥0).

a
(local)
Pointer into the local memory to an array of size lld_a*LOCc(ja+n-1).
Contains the local pieces of the m-by-n distributed matrix sub (A) to be factored.

ia, ja
(global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A, respectively.

desca
(global and local) array of size dlen_. The array descriptor for the distributed matrix A.

work
(local)
Workspace array of size of lwork.

lwork
(local or global) size of work, must be at least
lwork≥mb_a*(mp0+nq0+mb_a), where

\[ iroff = \text{mod}(ia-1, mb_a), \]
\[ icoff = \text{mod}(ja-1, nb_a), \]
\[ iarow = \text{indxg2p}(ia, mb_a, MYROW, rsrc_a, NPROW), \]
\[ iacol = \text{indxg2p}(ja, nb_a, MYCOL, csrc_a, NPCOL), \]
\[ mp0 = \text{numroc}(m+iroff, mb_a, MYROW, iarow, NPROW), \]
\[ nq0 = \text{numroc}(n+icoff, nb_a, MYCOL, iacol, NPCOL) \]

NOTE
mod(x,y) is the integer remainder of x/y.

indxg2p and numroc are ScalAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function blacs_gridinfo.
If \texttt{lwork} = -1, then \texttt{lwork} is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by \texttt{pxerbla}.

**Output Parameters**

\texttt{a}  
On exit, the leading \(m\)-by-\(m\) upper triangular part of sub(\(A\)) contains the upper triangular matrix \(R\), and elements \(m+1\) to \(n\) of the first \(m\) rows of sub (\(A\)), with the array \(\texttt{tau}\), represent the orthogonal/unitary matrix \(Z\) as a product of \(m\) elementary reflectors.

\texttt{work[0]}  
On exit \texttt{work[0]} contains the minimum value of \texttt{lwork} required for optimum performance.

\texttt{tau}  
(Array of size \texttt{LOCr}(\texttt{ia}+\texttt{m}-1).  
Contains the scalar factor of elementary reflectors. \texttt{tau} is tied to the distributed matrix \(A\).

\texttt{info}  
(global)  
= 0: the execution is successful.  
< 0:if the \(i\)-th argument is an array and the \(j\)-th entry, indexed \(j-1\), had an illegal value, then \texttt{info} = -(\(i\)*100+\(j\)); if the \(i\)-th argument is a scalar and had an illegal value, then \texttt{info} = -\(i\).

**Application Notes**

The factorization is obtained by the Householder’s method. The \(k\)-th transformation matrix, \(Z(k)\), which is or whose conjugate transpose is used to introduce zeros into the \((m - k +1)\)-th row of sub(\(A\)), is given in the form

\[
Z(k) = \begin{bmatrix}
  i & 0 \\
  0 & T(k)
\end{bmatrix}
\]

where

\[
T(k) = i - \texttt{tau} \cdot u(k) \cdot u(k)',
\]

\[
u(k) = \begin{bmatrix}
  1 \\
  0 \\
  z(k)
\end{bmatrix}
\]

\texttt{tau} is a scalar and \(Z(k)\) is an \((n - m)\) element vector. \texttt{tau} and \(Z(k)\) are chosen to annihilate the elements of the \(k\)-th row of sub(\(A\)). The scalar \texttt{tau} is returned in the \(k\)-th element of \texttt{tau}, indexed \(k-1\), and the vector \(u(k)\) in the \(k\)-th row of sub(\(A\)), such that the elements of \(Z(k)\) are in \(a(k, m + 1), \ldots, a(k, n)\). The elements of \(R\) are returned in the upper triangular part of sub(\(A\)). \(Z\) is given by

\[
Z = Z(1) \times Z(2) \times \ldots \times Z(m).
\]

**Description**
This function overwrites the general real $m$-by-$n$ distributed matrix $\text{sub}(C) = C(\text{ic}:\text{ic}+m-1,\text{jc}:\text{jc}+n-1)$ with

- $\text{side} = \text{'L'}$: $Q$ or $Q^T$ is applied from the left.
- $\text{side} = \text{'R'}$: $Q$ or $Q^T$ is applied from the right.

- $\text{trans} = \text{'N'}$: no transpose, $Q$ is applied.
- $\text{trans} = \text{'T'}$: transpose, $Q^T$ is applied.

where $Q$ is a real orthogonal distributed matrix defined as the product of $k$ elementary reflectors $Q = H(1) H(2) \ldots H(k)$ as returned by p?tzrzf. $Q$ is of order $m$ if $\text{side} = \text{'L'}$ and of order $n$ if $\text{side} = \text{'R'}$.

**Input Parameters**
- **side** (global)
  - $\text{side} = \text{'L'}$: $Q$ or $Q^T$ is applied from the left.
  - $\text{side} = \text{'R'}$: $Q$ or $Q^T$ is applied from the right.
- **trans** (global)
  - $\text{trans} = \text{'N'}$: no transpose, $Q$ is applied.
  - $\text{trans} = \text{'T'}$: transpose, $Q^T$ is applied.
- **m** (global) The number of rows in the distributed matrix $\text{sub}(C)$ ($m \geq 0$).
- **n** (global) The number of columns in the distributed matrix $\text{sub}(C)$ ($n \geq 0$).
- **k** (global) The number of elementary reflectors whose product defines the matrix $Q$. Constraints:
  - If $\text{side} = \text{'L'}$, $m \geq k \geq 0$
If \( \text{side} = 'R' \), \( n \geq k \geq 0 \).

The columns of the distributed matrix sub(\( A \)) containing the meaningful part of the Householder reflectors.

If \( \text{side} = 'L' \), \( m \geq 1 \geq 0 \)

If \( \text{side} = 'R' \), \( n \geq 1 \geq 0 \).

\( a \) (local)

Pointer into the local memory to an array of size \( \text{lld}_a \* \text{LOCc}(ja+m-1) \) if \( \text{side} = 'L' \), and \( \text{lld}_a \* \text{LOCc}(ja+n-1) \) if \( \text{side} = 'R' \), where \( \text{lld}_a \geq \max(1, \text{LOCr}(ia+k-1)) \).

The \( i \)-th row of the matrix stored in \( a \) must contain the vector that defines the elementary reflector \( H(i) \), \( ia \leq i \leq ia+k-1 \), as returned by \text{p?tzrzf} in the \( k \) rows of its distributed matrix argument \( A(ia:ia+k-1, ja:*) \). \( A(ia:ia+k-1, ja:*) \) is modified by the function but restored on exit.

\( ia, ja \) (global) The row and column indices in the global matrix \( A \) indicating the first row and the first column of the submatrix \( A \), respectively.

\( \text{desca} \) (global and local) array of size \( \text{dlen}_a \). The array descriptor for the distributed matrix \( A \).

\( \tau \) (local)

Array of size \( \text{LOCc}(ia+k-1) \).

Contains the scalar factor \( \tau[i] \) of elementary reflectors \( H(i+1) \) as returned by \text{p?tzrzf} \( (0 \leq i < \text{LOCc}(ia+k-1)) \). \( \tau \) is tied to the distributed matrix \( A \).

\( c \) (local)

Pointer into the local memory to an array of local size \( \text{lld}_c \* \text{LOCc}(jc+n-1) \).

Contains the local pieces of the distributed matrix sub(\( C \)) to be factored.

\( ic, jc \) (global) The row and column indices in the global matrix \( C \) indicating the first row and the first column of the submatrix \( C \), respectively.

\( \text{descC} \) (global and local) array of size \( \text{dlen}_c \). The array descriptor for the distributed matrix \( C \).

\( \text{work} \) (local)

Workspace array of size of \( \text{lwork} \).

\( \text{lwork} \) (local or global) size of \( \text{work} \), must be at least:

If \( \text{side} = 'L' \),

\[ \text{lwork} \geq \max( \frac{(\text{mb}_a \* (\text{mb}_a-1))}{2}, (\text{mpc}_0 + \max(\text{mqa}_0 + \text{numroc}(\text{numroc}(n+ioffc, \text{mb}_a, 0, 0, \text{NPROW}), \text{mb}_a, 0, 0, \text{lcmp}), \text{nqc}_0) \* \text{mb}_a) + \text{mb}_a \* \text{mb}_a \) \]

else if \( \text{side} = 'R' \),

\[ \text{lwork} \geq \max( \frac{(\text{mb}_a \* (\text{mb}_a-1))}{2}, (\text{mpc}_0 + \text{nqc}_0) \* \text{mb}_a) + \text{mb}_a \* \text{mb}_a \) \]
end if

where

\[ lcmp = \text{lcm}/\text{NPROW} \text{ with } \text{lcm} = \text{ilcm} (\text{NPROW}, \text{NPCOL}), \]
\[ \text{iroffa} = \text{mod}(\text{ia}-1, \text{mb}_a), \text{icoffa} = \text{mod}(\text{ja}-1, \text{nb}_a), \]
\[ \text{iacol} = \text{indxg2p}(\text{ja}, \text{nb}_a, \text{MYCOL}, \text{csrc}_a, \text{NPCOL}), \]
\[ \text{mqa0} = \text{numroc}(\text{n}+\text{icoffa}, \text{nb}_a, \text{MYCOL}, \text{iacol}, \text{NPCOL}), \]
\[ \text{iroffc} = \text{mod}(\text{ic}-1, \text{mb}_c), \]
\[ \text{icoffc} = \text{mod}(\text{jc}-1, \text{nb}_c), \]
\[ \text{iacon} = \text{indxg2p}(\text{ja}, \text{nb}_a, \text{MYCOL}, \text{csrc}_a, \text{NPCOL}), \]
\[ \text{mpc0} = \text{numroc}(\text{m}+\text{iroffc}, \text{mb}_c, \text{MYROW}, \text{icrow}, \text{NPROW}), \]
\[ \text{nqc0} = \text{numroc}(\text{n}+\text{icoffc}, \text{nb}_c, \text{MYCOL}, \text{iccol}, \text{NPCOL}), \]

**NOTE**

\[ \text{mod}(x,y) \text{ is the integer remainder of } x/y. \]

\text{ilcm}, \text{indxg2p} \text{ and } \text{numroc} \text{ are ScaLAPACK tool functions; } \text{MYROW}, \text{MYCOL}, \text{NPROW} \text{ and } \text{NPCOL} \text{ can be determined by calling the function } \text{blacs_gridinfo}. \]

If \text{lwork} = -1, then \text{lwork} is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by \text{pxerbla}.

**Output Parameters**

\text{c}

Overwritten by the product \( Q*\text{sub}(C) \), or \( Q^\ast*\text{sub}(C) \), or \( \text{sub}(C)*Q^\ast \), or \( \text{sub}(C)*Q \)

\text{work[0]}

On exit \text{work[0]} contains the minimum value of \text{lwork} required for optimum performance.

\text{info}

(global)

\[ = 0: \text{the execution is successful.} \]
\[ < 0: \text{if the } i\text{-th argument is an array and the } j\text{-th entry, indexed } j - 1, \text{ had an illegal value, then } \text{info} = -(i*100+j); \text{ if the } i\text{-th argument is a scalar and had an illegal value, then } \text{info} = -i. \]

**See Also**

```

Include Files

- mkl_scalapack.h

Description

This function overwrites the general complex m-by-n distributed matrix

\[
\text{sub}(C) = C(i\text{c}:i\text{c}+m-1,j\text{c}:j\text{c}+n-1)
\]

with

\[
\begin{align*}
\text{side} = 'L' & \quad \text{side} = 'R' \\
\text{trans} = 'N' : & \quad Q*\text{sub}(C) & \quad \text{sub}(C)*Q \\
\text{trans} = 'C' : & \quad Q^H*\text{sub}(C) & \quad \text{sub}(C)*Q^H
\end{align*}
\]

where \(Q\) is a complex unitary distributed matrix defined as the product of \(k\) elementary reflectors

\(Q = H(1)' H(2)'... H(k)\)

as returned by pctzrzf/pztzrzf. \(Q\) is of order \(m\) if \text{side} = 'L' and of order \(n\) if \text{side} = 'R'.

Input Parameters

- \text{side} (global)
  - 'L': Q or \(Q^H\) is applied from the left.
  - 'R': Q or \(Q^H\) is applied from the right.

- \text{trans} (global)
  - 'N', no transpose, Q is applied.
  - 'C', conjugate transpose, \(Q^H\) is applied.

- \text{m} (global) The number of rows in the distributed matrix \(\text{sub}(C)\), \((m \geq 0)\).

- \text{n} (global) The number of columns in the distributed matrix \(\text{sub}(C)\), \((n \geq 0)\).

- \text{k} (global) The number of elementary reflectors whose product defines the matrix \(Q\). Constraints:
  - If \text{side} = 'L', \(m \geq k \geq 0\)
  - If \text{side} = 'R', \(n \geq k \geq 0\).

- \text{l} (global) The columns of the distributed matrix \(\text{sub}(A)\) containing the meaningful part of the Householder reflectors.
  - If \text{side} = 'L', \(m \geq l \geq 0\)
  - If \text{side} = 'R', \(n \geq l \geq 0\).
Pointer into the local memory to an array of size \( lld_a*\text{LOCc}(ja+m-1) \) if \( \text{side} = 'L' \), and \( lld_a*\text{LOCc}(ja+n-1) \) if \( \text{side} = 'R' \), where \( lld_a \geq \text{max}(1, \text{LOCr}(ja+k-1)) \). The \( i \)-th row of the matrix stored in \( a \) must contain the vector that defines the elementary reflector \( H(i) \), \( ia \leq i \leq ia+k-1 \), as returned by \( \text{p?gerqf} \) in the \( k \) rows of its distributed matrix argument \( A(ia:ia+k-1, ja:*) \). \( A(ia:ia+k-1, ja:*) \) is modified by the function but restored on exit.

**ia, ja**

The row and column indices in the global matrix \( A \) indicating the first row and the first column of the submatrix \( A \), respectively.

**desca**

Array of size \( \text{LOCc}(ia+k-1) \).

Contains the scalar factor \( \tau[i] \) of elementary reflectors \( H(i+1) \) as returned by \( \text{p?gerqf} \) \( (0 \leq i < \text{LOCc}(ia+k-1)) \). \( \tau \) is tied to the distributed matrix \( A \).

**c**

Pointer into the local memory to an array of local size \( lld_c*\text{LOCc}(jc+n-1) \).

Contains the local pieces of the distributed matrix sub(\( C \)) to be factored.

**ic, jc**

The row and column indices in the global matrix \( C \) indicating the first row and the first column of the submatrix \( C \), respectively.

**dexec**

Array of size \( \text{dlen}_c \). The array descriptor for the distributed matrix \( C \).

**work**

Workspace array of size \( lwork \).

**lwork**

Size of \( \text{work} \), must be at least:

If \( \text{side} = 'L' \),

\[
lwork \geq \max\left(\frac{(mb_a*(mb_a-1))}{2}, \frac{(mpc0+\text{max}(mqa0+\text{numroc}(\text{numroc}(n+iwoffc, mb_a, 0, 0, \text{NPROW}), mb_a, 0, 0, lcmp), nqc0))*mb_a}{mb_a} + mb_a*mb_a\right)
\]

else if \( \text{side} = 'R' \),

\[
lwork \geq \max\left(\frac{(mb_a*(mb_a-1))}{2}, \frac{(mpc0+nqc0)*mb_a}{mb_a} + mb_a*mb_a\right)
\]

end if

where

\[
lcmp = \text{lcm}/\text{NPROW} \text{ with lcm = ilcm(\text{NPROW}, \text{NPCOL})},
\]

\[
iwoffc = \text{mod}(ia-1, mb_a),
\]

\[
\text{icoffa} = \text{mod}(ja-1, nb_a),
\]

\[
\text{iacol} = \text{indxg2p}(ja, nb_a, \text{MYCOL}, \text{csrc}_a, \text{NPCOL}),
\]

\[
mqa0 = \text{numroc}(m+icoffa, nb_a, \text{MYCOL}, \text{iacol}, \text{NPCOL}),
\]

\[
\text{mpc0} = \text{numroc}(n+iwoffc, mb_a, 0, 0, \text{NPROW}),
\]

\[
\text{nqc0} = \text{numroc}(n+iwoffc, mb_a, 0, 0, lcmp).
\]
iroffc = mod(ic-1, mb_c),
icoffc = mod(jc-1, nb_c),
icrow = indxg2p(ic, mb_c, MYROW, rsrc_c, NPROW),
iccol = indxg2p(jc, nb_c, MYCOL, csrc_c, NPCOL),
mpc0 = numroc(m+iroffc, mb_c, MYROW, icrow, NPROW),
nqc0 = numroc(n+icoffc, nb_c, MYCOL, iccol, NPCOL),

**NOTE**

mod(x, y) is the integer remainder of x/y.

ilcm, indxg2p and numroc are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function blacs_gridinfo.

If lwork = -1, then lwork is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

### Output Parameters

**c**

Overwritten by the product $Q^* \text{sub}(C)$, or $Q^* \text{sub}(C)$, or $\text{sub}(C)*Q'$, or $\text{sub}(C)*Q$

**work[0]**

On exit work[0] contains the minimum value of lwork required for optimum performance.

**info**

(global)

= 0: the execution is successful.

< 0: if the i-th argument is an array and the j-th entry, indexed $j-1$, had an illegal value, then info = -$i*100+j$; if the i-th argument is a scalar and had an illegal value, then info = -$i$.

### See Also

**p?ggqr**

Computes the generalized QR factorization.

### Syntax

void psggqrf (MKL_INT *n, MKL_INT *m, MKL_INT *p, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *tauA, float *b, MKL_INT *ib, MKL_INT *jb, MKL_INT *descb, float *tauB, float *work, MKL_INT *lwork, MKL_INT *info);

void pdggqr (MKL_INT *n, MKL_INT *m, MKL_INT *p, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *tauA, double *b, MKL_INT *ib, MKL_INT *jb, MKL_INT *descb, double *tauB, double *work, MKL_INT *lwork, MKL_INT *info);
void pcgqr (MKL_INT *n, MKL_INT *m, MKL_INT *p, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_Complex8 *tau, MKL_Complex8 *b, MKL_INT *ib, MKL_INT *jb, MKL_INT *descb, MKL_Complex8 *taub, MKL_Complex8 *work, MKL_INT *iwork, MKL_INT *info);
void pzgqr (MKL_INT *n, MKL_INT *m, MKL_INT *p, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_Complex16 *tau, MKL_Complex16 *b, MKL_INT *ib, MKL_INT *jb, MKL_INT *descb, MKL_Complex16 *taub, MKL_Complex16 *work, MKL_INT *iwork, MKL_INT *info);

Include Files
- mkl_scalapack.h

Description
The p?gqr function forms the generalized QR factorization of an \(n\)-by-\(m\) matrix

\[
\text{sub}(A) = A(ia:ia+n-1, ja:ja+m-1)
\]

and an \(n\)-by-\(p\) matrix

\[
\text{sub}(B) = B(ib:ib+n-1, jb:jb+p-1)
\]

as

\[
\text{sub}(A) = Q*R, \text{sub}(B) = Q*T*Z,
\]

where \(Q\) is an \(n\)-by-\(n\) orthogonal/unitary matrix, \(Z\) is a \(p\)-by-\(p\) orthogonal/unitary matrix, and \(R\) and \(T\) assume one of the forms:

If \(n \geq m\)

\[
R = \begin{pmatrix} R_{11} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{pmatrix}
\]

where \(R_{11}\) is upper triangular, and

\[
T = \begin{pmatrix} \mathbf{0} & T_{12} \\ \mathbf{0} & \mathbf{0} \end{pmatrix} n, \text{ if } n \leq p,
\]

\[
T = \begin{pmatrix} T_{11} & \mathbf{0} \\ T_{21} & \mathbf{0} \end{pmatrix} \begin{pmatrix} \mathbf{0} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{pmatrix} n - p, \text{ if } n > p,
\]

where \(T_{12}\) or \(T_{21}\) is an upper triangular matrix.
In particular, if sub\((B)\) is square and nonsingular, the GQR factorization of sub\((A)\) and sub\((B)\) implicitly gives the QR factorization of \(\text{inv}(\text{sub}(B)) \ast \text{sub}(A)\):

\[
\text{inv}(\text{sub}(B)) \ast \text{sub}(A) = Z^H \ast (\text{inv}(T) \ast R)
\]

**Input Parameters**

\(n\)

(global) The number of rows in the distributed matrices sub\((A)\) and sub\((B)\) \((n \geq 0)\).

\(m\)

(global) The number of columns in the distributed matrix sub\((A)\) \((m \geq 0)\).

\(p\)

The number of columns in the distributed matrix sub\((B)\) \((p \geq 0)\).

\(a\)

(local)

Pointer into the local memory to an array of size \(lld_a \ast \text{LOCc}(ja+m-1)\).

Contains the local pieces of the \(n\)-by-\(m\) matrix sub\((A)\) to be factored.

\(ia, ja\)

(global) The row and column indices in the global matrix \(A\) indicating the first row and the first column of the submatrix \(A\), respectively.

\(desca\)

(global and local) array of size \(dlen_\). The array descriptor for the distributed matrix \(A\).

\(b\)

(local)

Pointer into the local memory to an array of size \(lld_b \ast \text{LOCc}(jb+p-1)\).

Contains the local pieces of the \(n\)-by-\(p\) matrix sub\((B)\) to be factored.

\(ib, jb\)

(global) The row and column indices in the global matrix \(B\) indicating the first row and the first column of the submatrix \(B\), respectively.

\(descb\)

(global and local) array of size \(dlen_\). The array descriptor for the distributed matrix \(B\).

\(work\)

(local)

Workspace array of size of \(lwork\).

\(lwork\)

(local or global) Sze of \(work\), must be at least

\[
\text{lwork} \geq \max\left(nb_a \ast (npa0+ma0+nb_a), \max((nb_a \ast (nb_a-1))/2, (pqb0+npb0) \ast nb_a) + nb_a \ast nb_a, mb_b \ast (npb0+pqb0+mb_b)\right),
\]

where

\[
\begin{align*}
\text{iroffa} &= \text{mod}(ia-1, mb_A), \\
\text{icoffa} &= \text{mod}(ja-1, nb_a), \\
\text{iarow} &= \text{indxg2p}(ia, mb_a, \text{MYROW}, \text{rsrc}_a, \text{NPROW}), \\
\text{iacol} &= \text{indxg2p}(ja, nb_a, \text{MYCOL}, \text{csrc}_a, \text{NPCOL}), \\
\text{npa0} &= \text{numroc} (n+\text{iroffa}, mb_a, \text{MYROW}, \text{iarow}, \text{NPROW}), \\
\text{ma0} &= \text{numroc} (m+\text{icoffa}, nb_a, \text{MYCOL}, \text{iacol}, \text{NPCOL}) \\
\text{iroffb} &= \text{mod}(ib-1, mb_b), \\
\text{icoffb} &= \text{mod}(jb-1, nb_b), \\
\text{ibrow} &= \text{indxg2p}(ib, mb_b, \text{MYROW}, \text{rsrc}_b, \text{NPROW}),
\end{align*}
\]
ibcol = indxg2p(jb, nb_b, MYCOL, csrc_b, NPCOL),
npb0 = numroc (n+iroffa, mb_b, MYROW, Ibrow, NPROW),
pqb0 = numroc(m+icoffb, nb_b, MYCOL, ibcol, NPCOL)

NOTE
\mod(x,y) \text{ is the integer remainder of } x/y.

and numroc, indxg2p are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function blacs_gridinfo.

If lwork = -1, then lwork is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pzerbla.

Output Parameters

\textbf{a}

On exit, the elements on and above the diagonal of sub (A) contain the min(n, m)-by-m upper trapezoidal matrix \( R \) (\( R \) is upper triangular if \( n \geq m \)); the elements below the diagonal, with the array \( \text{taua} \), represent the orthogonal/unitary matrix \( Q \) as a product of \( \min(n, m) \) elementary reflectors. (See Application Notes below).

\textbf{taua}, \textbf{taub}

Arrays of size \( \text{LOCc}(ja+\min(n,m)-1) \) for \( \text{taua} \) and \( \text{LOCr}(ib+n-1) \) for \( \text{taub} \).

The array \( \text{taua} \) contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix \( Q \). \( \text{taua} \) is tied to the distributed matrix \( A \). (See Application Notes below).

The array \( \text{taub} \) contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix \( Z \). \( \text{taub} \) is tied to the distributed matrix \( B \). (See Application Notes below).

\textbf{work[0]}

On exit \( \text{work[0]} \) contains the minimum value of \( lwork \) required for optimum performance.

\textbf{info}

(global)

\( = 0: \) the execution is successful.

\( < 0: \) if the \( i \)-th argument is an array and the \( j \)-th entry, indexed \( j - 1 \), had an illegal value, then \( \text{info} = -(i*100+j) \); if the \( i \)-th argument is a scalar and had an illegal value, then \( \text{info} = -i \).

Application Notes

The matrix \( Q \) is represented as a product of elementary reflectors

\[ Q = H(ja)*H(ja+1)*...*H(ja+k-1), \]

where \( k = \min(n,m) \).

Each \( H(i) \) has the form

\[ H(i) = i - \text{taua}^*v*v' \]
where \( \tau_a \) is a real/complex scalar, and \( v \) is a real/complex vector with \( v(1:i-1) = 0 \) and \( v(i) = 1 \); \( v(i+1:n) \) is stored on exit in \( A(ia:i+a+n-1, ja:i-1) \), and \( \tau_a \) in \( \tau_a[ja+i-2] \). To form \( Q \) explicitly, use ScaLAPACK function \( \text{p?orgqr/p?unqr} \). To use \( Q \) to update another matrix, use ScaLAPACK function \( \text{p?ormqr/p?unmqr} \).

The matrix \( Z \) is represented as a product of elementary reflectors
\[
Z = H(ib)^*H(ib+1)^*...*H(ib+k-1), \text{ where } k = \min(n,p).
\]

Each \( H(i) \) has the form
\[
H(i) = I - \tau_a^* v' v
\]
where \( \tau_a \) is a real/complex scalar, and \( v \) is a real/complex vector with \( v(p-k+i+1:p) = 0 \) and \( v(p-k+i) = 1 \); \( v(1:p-k+i-1) \) is stored on exit in \( B(ib+n-k+i-1, jb:jb+p-k+i-2) \), and \( \tau_a \) in \( \tau_a[ib+n-k+i-2] \). To form \( Z \) explicitly, use ScaLAPACK function \( \text{p?orgqr/p?unqr} \). To use \( Z \) to update another matrix, use ScaLAPACK function \( \text{p?ormqr/p?unmqr} \).

**See Also**

Overview for details of ScaLAPACK array descriptor structures and related notations.

**p?ggrqf**

Computes the generalized RQ factorization.

**Syntax**

```c
void psggrqf (MKL_INT *m, MKL_INT *n, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *tauaf, float *b, MKL_INT *ib, MKL_INT *jb, MKL_INT *descb, float *tauab, float *work, MKL_INT *lwork, MKL_INT *info);

```

**Include Files**

- mkl_scalapack.h

**Description**

The \( \text{p?ggrqf} \) function forms the generalized RQ factorization of an \( m \)-by-\( n \) matrix \( \text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1) \) and a \( p \)-by-\( n \) matrix \( \text{sub}(B) = B(ib:ib+p-1, jb:jb+n-1) \):

\[
\text{sub}(A) = R^*Q, \quad \text{sub}(B) = Z^*T^*Q,
\]

where \( Q \) is an \( n \)-by-\( n \) orthogonal/unitary matrix, \( Z \) is a \( p \)-by-\( p \) orthogonal/unitary matrix, and \( R \) and \( T \) assume one of the forms:

\[
R = \begin{cases} 
0 & R_{12} \\
R_{12} & \end{cases}, \text{ if } m \leq n,
\]

\[
R_{12} = \begin{pmatrix} R_{11} & R_{12} \\
R_{21} & R_{22} \end{pmatrix}, \text{ if } m > n,
\]

\[
T = \begin{cases} 
I & T_{22} \\
T_{21} & \end{cases}, \text{ if } n \leq p,
\]

\[
T_{21} = \begin{pmatrix} T_{211} & T_{212} \\
T_{11} & T_{12} \end{pmatrix}, \text{ if } n > p.
\]
or
\[
R = \begin{pmatrix}
R_{11} & m - n \\
R_{12} & n
\end{pmatrix}, \quad \text{if } m > n
\]
where \(R_{11}\) or \(R_{21}\) is upper triangular, and
\[
T = \begin{pmatrix}
T_{11} & n \\
0 & p - n
\end{pmatrix}, \quad \text{if } p \geq n
\]
or
\[
T = p \begin{pmatrix}
T_{11} & T_{12} \\
0 & n - p
\end{pmatrix}, \quad \text{if } p < n,
\]
where \(T_{11}\) is upper triangular.

In particular, if \(\text{sub}(B)\) is square and nonsingular, the GRQ factorization of \(\text{sub}(A)\) and \(\text{sub}(B)\) implicitly gives the RQ factorization of \(\text{sub}(A)^* \text{inv}(\text{sub}(B))\):
\[
\text{sub}(A)^* \text{inv}(\text{sub}(B)) = (R^* \text{inv}(T))^* Z^\prime
\]
where \(\text{inv}(\text{sub}(B))\) denotes the inverse of the matrix \(\text{sub}(B)\), and \(Z^\prime\) denotes the transpose (conjugate transpose) of matrix \(Z\).

**Input Parameters**

- \(m\) (global) The number of rows in the distributed matrices \(\text{sub}(A)\) \((m \geq 0)\).
- \(p\) The number of rows in the distributed matrix \(\text{sub}(B)\) \((p \geq 0)\).
- \(n\) (global) The number of columns in the distributed matrices \(\text{sub}(A)\) and \(\text{sub}(B)\) \((n \geq 0)\).
- \(a\) (local)
  Pointer into the local memory to an array of size \(lld_a * \text{LOCc}(ja+n-1)\).
  Contains the local pieces of the \(m\)-by-\(n\) distributed matrix \(\text{sub}(A)\) to be factored.
- \(ia, ja\) (global) The row and column indices in the global matrix \(A\) indicating the first row and the first column of the submatrix \(A\), respectively.
- \(desca\) (global and local) array of size \(dlen_\). The array descriptor for the distributed matrix \(A\).
- \(b\) (local)
  Pointer into the local memory to an array of size \(lld_b * \text{LOCc}(jb+n-1)\).
  Contains the local pieces of the \(p\)-by-\(n\) matrix \(\text{sub}(B)\) to be factored.
(global) The row and column indices in the global matrix $B$ indicating the first row and the first column of the submatrix $B$, respectively.

(descb) array of size dlen_. The array descriptor for the distributed matrix $B$.

(work) Workspace array of size of lwork.

(lwork) Size of work, must be at least 
\[
\text{lwork} \geq \max(\text{mb}_a*\text{mp}_a + \text{nqa}_a + \text{mb}_a, \text{mb}_a*\text{pp}_b + \text{nqb}_b + \text{nb}_b),
\]
where
\[
\text{iroffa} = \text{mod}(\text{ia} - 1, \text{mb}_A),
\]
\[
\text{icoffa} = \text{mod}(\text{ja} - 1, \text{nb}_A),
\]
\[
\text{iarow} = \text{indxg2p}(\text{ia}, \text{mb}_A, \text{MYROW}, \text{rsrc}_A, \text{NPROW}),
\]
\[
\text{iacol} = \text{indxg2p}(\text{ja}, \text{nb}_A, \text{MYCOL}, \text{csrc}_A, \text{NPCOL}),
\]
\[
\text{mp}_a = \text{numroc}(\text{m} + \text{iroffa}, \text{mb}_A, \text{MYROW}, \text{iarow}, \text{NPROW}),
\]
\[
\text{nqa}_a = \text{numroc}(\text{m} + \text{icoffa}, \text{nb}_A, \text{MYCOL}, \text{iacol}, \text{NPCOL})
\]
\[
\text{iroffb} = \text{mod}(\text{ib} - 1, \text{mb}_B),
\]
\[
\text{icoffb} = \text{mod}(\text{jb} - 1, \text{nb}_B),
\]
\[
\text{ibrow} = \text{indxg2p}(\text{ib}, \text{mb}_B, \text{MYROW}, \text{rsrc}_B, \text{NPROW}),
\]
\[
\text{ibcol} = \text{indxg2p}(\text{jb}, \text{nb}_B, \text{MYCOL}, \text{csrc}_B, \text{NPCOL}),
\]
\[
\text{pp}_b = \text{numroc}(\text{p} + \text{iroffb}, \text{mb}_B, \text{MYROW}, \text{ibrow}, \text{NPROW}),
\]
\[
\text{nqb}_b = \text{numroc}(\text{n} + \text{icoffb}, \text{nb}_B, \text{MYCOL}, \text{ibcol}, \text{NPCOL})
\]

NOTE 
\[
\text{mod}(x, y) \text{ is the integer remainder of } x/y.
\]

and \text{numroc}, \text{indxg2p} are ScaLAPACK tool functions; \text{MYROW}, \text{MYCOL}, \text{NPROW} and \text{NPCOL} can be determined by calling the function \text{blacs_gridinfo}.

If \text{lwork} = -1, then \text{lwork} is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by \text{pxerbla}.

Output Parameters

(a) On exit, if $m \leq n$, the upper triangle of $A(ia:ia+m-1, ja+n-m:ja+n-1)$ contains the $m$-by-$m$ upper triangular matrix $R$; if $m \geq n$, the elements on and above the $(m-n)$-th subdiagonal contain the $m$-by-$n$ upper trapezoidal matrix $R$; the remaining elements, with the array \text{taua}, represent the orthogonal/unitary matrix $Q$ as a product of $\min(n,m)$ elementary reflectors (see Application Notes below).

(taua, taub) (local)
Arrays of size \( \text{LOCr}(ia+m-1) \) for \( \text{taua} \) and \( \text{LOCc}(jb+\min(p,n)-1) \) for \( \text{taub} \).

The array \( \text{taua} \) contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix \( Q \). \( \text{taua} \) is tied to the distributed matrix \( A \). (See Application Notes below).

The array \( \text{taub} \) contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix \( Z \). \( \text{taub} \) is tied to the distributed matrix \( B \). (See Application Notes below).

\( \text{work}[0] \)

On exit \( \text{work}[0] \) contains the minimum value of \( l\text{work} \) required for optimum performance.

\( \text{info} \)

\( \text{(global)} \)

\( = 0 \): the execution is successful.

\(< 0 \): if the \( i \)-th argument is an array and the \( j \)-th entry, indexed \( j - 1 \), had an illegal value, then \( \text{info} = -(i\times100+j) \); if the \( i \)-th argument is a scalar and had an illegal value, then \( \text{info} = -i \).

Application Notes

The matrix \( Q \) is represented as a product of elementary reflectors

\[ Q = H(ia)H(ia+1)\ldots H(ia+k-1), \]

where \( k = \min(m,n) \).

Each \( H(i) \) has the form

\[ H(i) = i - \text{taua}v^*v' \]

where \( \text{taua} \) is a real/complex scalar, and \( v \) is a real/complex vector with \( v(n-k+i+1:n) = 0 \) and \( v(n-k+i) = 1 \); \( v(1:n-k+i-1) \) is stored on exit in \( A(ia+m-k+i-1, ja:ja+n-k+i-2) \), and \( \text{taua} \) in \( \text{taua}[ia+m-k+i-2] \). To form \( Q \) explicitly, use ScaLAPACK function \( \text{p?orgqr/p?ungqr} \). To use \( Q \) to update another matrix, use ScaLAPACK function \( \text{p?ormqr/p?unmqr} \).

The matrix \( Z \) is represented as a product of elementary reflectors

\[ Z = H(jb)H(jb+1)\ldots H(jb+k-1), \]

where \( k = \min(p,n) \).

Each \( H(i) \) has the form

\[ H(i) = i - \text{taub}v^*v' \]

where \( \text{taub} \) is a real/complex scalar, and \( v \) is a real/complex vector with \( v(1:i-1) = 0 \) and \( v(i) = 1 \); \( v(i+1:p) \) is stored on exit in \( B(ib+i:ib+p-1,jb+i-1) \), and \( \text{taub} \) in \( \text{taub}[jb+i-2] \). To form \( Z \) explicitly, use ScaLAPACK function \( \text{p?orgqr/p?ungqr} \). To use \( Z \) to update another matrix, use ScaLAPACK function \( \text{p?ormqr/p?unmqr} \).

Symmetric Eigenvalue Problems: ScaLAPACK Computational Routines

To solve a symmetric eigenproblem with ScaLAPACK, you usually need to reduce the matrix to real tridiagonal form \( T \) and then find the eigenvalues and eigenvectors of the tridiagonal matrix \( T \). ScaLAPACK includes routines for reducing the matrix to a tridiagonal form by an orthogonal (or unitary) similarity transformation \( A = QQT^T \) as well as for solving tridiagonal symmetric eigenvalue problems. These routines are listed in Table “Computational Routines for Solving Symmetric Eigenproblems”.
There are different routines for symmetric eigenproblems, depending on whether you need eigenvalues only or eigenvectors as well, and on the algorithm used (either the QTQ algorithm, or bisection followed by inverse iteration).

* This routine is described as part of auxiliary ScaLAPACK routines.

#### p?syngst

*Reduces a complex Hermitian-definite generalized eigenproblem to standard form.*

### Syntax

```c
void pssyngst (const MKL_INT* ibtype, const char* uplo, const MKL_INT* n, float* a, const MKL_INT* ia, const MKL_INT* ja, const MKL_INT* desca, const float* b, const MKL_INT* ib, const MKL_INT* jb, const MKL_INT* descb, float* scale, float* work, const MKL_INT* lwork, MKL_INT* info);

void pdsyngst (const MKL_INT* ibtype, const char* uplo, const MKL_INT* n, double* a, const MKL_INT* ia, const MKL_INT* ja, const MKL_INT* desca, const double* b, const MKL_INT* ib, const MKL_INT* jb, const MKL_INT* descb, double* scale, double* work, const MKL_INT* lwork, MKL_INT* info);
```

### Include Files

- mkl_scalapack.h

### Description

p?syngst *reduces a complex Hermitian-definite generalized eigenproblem to standard form.*

p?syngst *performs the same function as p?hegst, but is based on rank 2K updates, which are faster and more scalable than triangular solves (the basis of p?syngst).*

p?syngst *calls p?hegst when uplo='U', hence p?hegst provides improved performance only when uplo='L', ibtype=1.*

p?syngst *also calls p?hegst when insufficient workspace is provided, hence p?syngst provides improved performance only when lwork >= 2 * NPO * NB + NQO * NB + NB * NB.*

In the following sub($A$) denotes $A(ia:ia+n-1,ja:ja+n-1)$ and sub($B$) denotes $B(ib:ib+n-1,jb:jb+n-1)$.

If $ibtype = 1$, the problem is sub($A$)*$x = \lambda$*sub($B$)*$x$, and sub($A$) is overwritten by inv($U^H$)*sub($A$)*$x$ or inv($L$)*sub($A$)*$x$.

If $ibtype = 2$ or $3$, the problem is sub($A$)*sub($B$)*$x = \lambda$*sub($B$)*$x$ or sub($B$)*sub($A$)*$x = \lambda$*sub($A$)*$x$, and sub($A$) is overwritten by $U$*sub($A$)*$U^H$ or $L^H$*sub($A$)*$L$. 

1365
sub( B ) must have been previously factorized as $U^H U$ or $L^*L^H$ by p?potrf.

### Input Parameters

- **ibtype**
  - (global)
  - $= 1$: compute $\text{inv}(U^H)\text{sub}(A)\text{inv}(U)$ or $\text{inv}(L)\text{sub}(A)\text{inv}(L^H)$;
  - $= 2$ or $3$: compute $U\text{sub}(A)U^H$ or $L^*\text{sub}(A)L$.

- **uplo**
  - (global)
  - $= 'U'$: Upper triangle of sub( A ) is stored and sub( B ) is factored as $U^H U$;
  - $= 'L'$: Lower triangle of sub( A ) is stored and sub( B ) is factored as $L^*L^H$.

- **n**
  - (global)
  - The order of the matrices sub( A ) and sub( B ). $n \geq 0$.

- **a**
  - (local)
  - Pointer into the local memory to an array of size $\text{lld}_a\text{LOC}(ja+n-1)$.
  - On entry, this array contains the local pieces of the $n$-by-$n$ Hermitian distributed matrix sub( A ). If $\text{uplo} = 'U'$, the leading $n$-by-$n$ upper triangular part of sub( A ) contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If $\text{uplo} = 'L'$, the leading $n$-by-$n$ lower triangular part of sub( A ) contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced.

- **ia**
  - (global)
  - A's global row index, which points to the beginning of the submatrix which is to be operated on.

- **ja**
  - (global)
  - A's global column index, which points to the beginning of the submatrix which is to be operated on.

- **desca**
  - (global and local)
  - Array of size $\text{dien}_\_$. The array descriptor for the distributed matrix A.

- **b**
  - (local)
  - Pointer into the local memory to an array of size $\text{lld}_b\text{LOC}(jb+n-1)$.
  - On entry, this array contains the local pieces of the triangular factor from the Cholesky factorization of sub( B ), as returned by p?potrf.

- **ib**
  - (global)
  - B's global row index, which points to the beginning of the submatrix which is to be operated on.

- **jb**
  - (global)
  - B's global column index, which points to the beginning of the submatrix which is to be operated on.

- **descb**
  - (global and local)
The array descriptor for the distributed matrix $B$.

(work)

Array, size (lwork)

(lwork)

The size of the array work.

lwork is local input and must be at least $lwork \geq \text{MAX}( \text{NB} \times (\text{NP0} + 1), 3 \times \text{NB} )$

When $\text{ibtype} = 1$ and $\text{uplo} = 'L'$, \text{p?syngst} provides improved performance when $lwork \geq 2 \times \text{NP0} \times \text{NB} + \text{NQ0} \times \text{NB} + \text{NB} \times \text{NB}$,

where $\text{NB} = \text{mb}_a = \text{nb}_a$,

$\text{NP0} = \text{numroc}( n, \text{NB}, 0, 0, \text{NPROW} )$,

$\text{NQ0} = \text{numroc}( n, \text{NB}, 0, 0, \text{NPROW} )$,

\text{numroc} is a ScaLAPACK tool functions

MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine blacs_gridinfo.

If $lwork = -1$, then lwork is global input and a workspace query is assumed; the routine only calculates the optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by \text{pxerbla}.

Output Parameters

\text{a}

On exit, if $\text{info} = 0$, the transformed matrix, stored in the same format as sub( $A$ ).

(scale)

Amount by which the eigenvalues should be scaled to compensate for the scaling performed in this routine. At present, scale is always returned as 1.0, it is returned here to allow for future enhancement.

(work)

Array, size (lwork)

On exit, work[0] returns the minimal and optimal lwork.

(info)

= 0: successful exit

< 0: If the $i$-th argument is an array and the $j$-th entry had an illegal value, then $\text{info} = -(i*100+j)$, if the $i$-th argument is a scalar and had an illegal value, then $\text{info} = -i$.

p?syntrd

\textit{Reduces a real symmetric matrix to symmetric tridiagonal form.}
Syntax

```c
void pssytrd (const char* uplo, const MKL_INT* n, float* a, const MKL_INT* ia, const MKL_INT* ja, const MKL_INT* desca, float* d, float* e, float* tau, float* work, const MKL_INT* lwork, MKL_INT* info);

void pdsytrd (const char* uplo, const MKL_INT* n, double* a, const MKL_INT* ia, const MKL_INT* ja, const MKL_INT* desca, double* d, double* e, double* tau, double* work, const MKL_INT* lwork, MKL_INT* info);
```

Include Files

- mkl_scalapack.h

Description

`p?syntrd` is a prototype version of `p?sytrd` which uses tailored codes (either the serial, `?sytrd`, or the parallel code, `p?syttrd`) when the workspace provided by the user is adequate.

`p?syntrd` reduces a real symmetric matrix `sub(A)` to symmetric tridiagonal form `T` by an orthogonal similarity transformation:

\[ Q' \cdot sub(A) \cdot Q = T, \]

where `sub(A) = A(ia:ia+n-1, ja:ja+n-1)`.

Features

`p?syntrd` is faster than `p?sytrd` on almost all matrices, particularly small ones (i.e. `n < 500 * sqrt(P)`), provided that enough workspace is available to use the tailored codes.

The tailored codes provide performance that is essentially independent of the input data layout.

The tailored codes place no restrictions on `ia`, `ja`, `MB` or `NB`. At present, `ia`, `ja`, `MB` and `NB` are restricted to those values allowed by `p?hetrd` to keep the interface simple (see the Application Notes section for more information about the restrictions).

Input Parameters

**uplo**

(global)

Specifies whether the upper or lower triangular part of the symmetric matrix `sub(A)` is stored:

- `='U'`: Upper triangular
- `='L'`: Lower triangular

**n**

(global)

The number of rows and columns to be operated on, i.e. the order of the distributed submatrix `sub(A)`, `n >= 0`.

**a**

(local)

Pointer into the local memory to an array of size `lda*LOCc(ja+n-1)`. On entry, this array contains the local pieces of the symmetric distributed matrix `sub(A)`. If `uplo = 'U'`, the leading `n`-by-`n` upper triangular part of `sub(A)` contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If `uplo = 'L'`, the leading `n`-by-`n` lower triangular part of `sub(A)` contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced.

**ia**

(global)
The row index in the global array $a$ indicating the first row of sub($A$).

$ja$ (global)

The column index in the global array $a$ indicating the first column of sub($A$).

desca (global and local)

Array of size $dlen_-$.

The array descriptor for the distributed matrix $A$.

work (local)

Array, size ($lwork$)

$lwork$ (local or global)

The size of the array $work$.

$lwork$ is local input and must be at least $lwork \geq \text{MAX( NB \times ( NP + 1 ), 3 \times NB )}$

For optimal performance, greater workspace is needed, i.e.

$lwork \geq 2 \times ( ANB +1 ) \times ( 4 \times NPS +2 ) + ( NPS + 4 ) \times NPS$

$ANB = \text{pjlaenv}( ICTXT, 3, 'p?sytrd', 'L', 0, 0, 0, 0 )$

$ICTXT = \text{desca}( \text{ctxt}_- )$

$SQNPC = \text{INT( sqrt( REAL( NPROW \times NPCOL ) ) )}$

$numroc$ is a ScaLAPACK tool function.

$\text{pjlaenv}$ is a ScaLAPACK environmental inquiry function.

$NPROW$ and $NPCOL$ can be determined by calling the subroutine $\text{blacs_gridinfo}$.

### Output Parameters

$a$

On exit, if $\text{uplo} = 'U'$, the diagonal and first superdiagonal of sub($A$) are overwritten by the corresponding elements of the tridiagonal matrix $T$, and the elements above the first superdiagonal, with the array $\tau$, represent the orthogonal matrix $Q$ as a product of elementary reflectors; if $\text{uplo} = 'L'$, the diagonal and first subdiagonal of sub($A$) are overwritten by the corresponding elements of the tridiagonal matrix $T$, and the elements below the first subdiagonal, with the array $\tau$, represent the orthogonal matrix $Q$ as a product of elementary reflectors. See Further Details.

$d$ (local)

Array, size LOCc$(ja+n-1)$

The diagonal elements of the tridiagonal matrix $T$: $d(i) = A(i,i)$. $d$ is tied to the distributed matrix $A$.

$e$ (local)

Array, size LOCc$(ja+n-1)$ if $\text{uplo} = 'U'$, LOCc$(ja+n-2)$ otherwise.
The off-diagonal elements of the tridiagonal matrix $T$: $e(i) = A(i,i+1)$ if $uplo = 'U'$, $e(i) = A(i+1,i)$ if $uplo = 'L'$. $e$ is tied to the distributed matrix $A$.

$tau$

(local)

Array, size $\text{LOCc}(ja+n-1)$.

This array contains the scalar factors $tau$ of the elementary reflectors. $tau$ is tied to the distributed matrix $A$.

$work$

(local)

Array, size $(lwork)$

On exit, $work[0]$ returns the optimal $lwork$.

$info$

(global)

$= 0$: successful exit

$< 0$: If the $i$-th argument is an array and the $j$-th entry had an illegal value, then $info = -(i*100+j)$, if the $i$-th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

If $uplo = 'U'$, the matrix $Q$ is represented as a product of elementary reflectors $Q = H(n-1) . . . H(2) H(1)$.

Each $H(i)$ has the form

$$H(i) = I - \tau \cdot v \cdot v'$$

where $\tau$ is a complex scalar, and $v$ is a complex vector with $v(i+1:n) = 0$ and $v(i) = 1$; $v(1:i-1)$ is stored in $A(ia:ia+i-2, ja+i)$, and $\tau$ in $\tau(ja+i-1)$.

If $uplo = 'L'$, the matrix $Q$ is represented as a product of elementary reflectors $Q = H(1) H(2) . . . H(n-1)$.

Each $H(i)$ has the form

$$H(i) = I - \tau \cdot v \cdot v'$$

where $\tau$ is a complex scalar, and $v$ is a complex vector with $v(1:i) = 0$ and $v(i+1) = 1$; $v(i+2:n)$ is stored on exit in $A(ia+i+1:ia+n-1, ja+i-1)$, and $\tau$ in $\tau(ja+i-1)$.

The contents of $\text{sub}( A )$ on exit are illustrated by the following examples with $n = 5$:

if $uplo = 'U'$:

$$\begin{bmatrix}
  d & e & v_2 & v_3 & v_4 \\
  d & e & v_3 & v_4 \\
  d & e & v_3 \\
  d & e \\
  d
\end{bmatrix}$$

if $uplo = 'L'$:

$$\begin{bmatrix}
  d \\
  e & d \\
  v_1 & e & d \\
  v_1 & v_2 & e & d \\
  v_1 & v_2 & v_3 & e & d
\end{bmatrix}$$
where $d$ and $e$ denote diagonal and off-diagonal elements of $T$, and $v_l$ denotes an element of the vector defining $H(l)$.

**Alignment requirements**

The distributed submatrix sub$(A)$ must verify some alignment properties, namely the following expression should be true:

\[
( mb_a = nb_a \text{ and } IROFFA = ICOFFA \text{ and } IROFFA = 0 ) \text{ with } IROFFA = \text{mod}( ia-1, mb_a ), \text{ and } ICOFFA = \text{mod}( ja-1, nb_a ).
\]

$p?sytrd$

*Reduces a symmetric matrix to real symmetric tridiagonal form by an orthogonal similarity transformation.*

**Syntax**

```c
void pssytrd (char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *d , float *e , float *tau , float *work , MKL_INT *lwork , MKL_INT *info );
void pdsytrd (char *uplo , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *d , double *e , double *tau , double *work , MKL_INT *lwork , MKL_INT *info );
```

**Include Files**

- mkl_scalapack.h

**Description**

The $p?sytrd$ function reduces a real symmetric matrix sub$(A)$ to symmetric tridiagonal form $T$ by an orthogonal similarity transformation:

\[ Q^* \text{sub}(A) Q = T, \]

where sub$(A) = A(ia:ia+n-1,ja:ja+n-1)$.

**Input Parameters**

- **uplo**
  
  (global)
  
  Specifies whether the upper or lower triangular part of the symmetric matrix sub$(A)$ is stored:
  
  If $uplo = 'U'$, upper triangular
  
  If $uplo = 'L'$, lower triangular

- **n**
  
  (global) The order of the distributed matrix sub$(A)$ ($n \geq 0$).

- **a**
  
  (local)
  
  Pointer into the local memory to an array of size $lld_a*\text{LOCc}(ja+n-1)$. On entry, this array contains the local pieces of the symmetric distributed matrix sub$(A)$.
  
  If $uplo = 'U'$, the leading $n$-by-$n$ upper triangular part of sub$(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced.
If \( uplo = 'L' \), the leading \( n \)-by-\( n \) lower triangular part of \( sub(A) \) contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced. See Application Notes below.

\( ia, ja \) (global) The row and column indices in the global matrix \( A \) indicating the first row and the first column of the submatrix \( A \), respectively.

\( desca \) (global and local) array of size \( dlen_\_ \). The array descriptor for the distributed matrix \( A \).

\( work \) (local) Workspace array of size \( lwork \).

\( lwork \) (local or global) size of \( work \), must be at least:

\[
lwork \geq \max(NB\cdot(np +1), 3\cdot NB),
\]

where \( NB = mb_\_a = nb_\_a \),

\[
np = \text{numroc}(n, NB, MYROW, iarow, NPROW),
\]

\[
 iarow = \text{indxg2p}(ia, NB, MYROW, rsrca_\_, NPROW).
\]

\( \text{indxg2p} \) and \( \text{numroc} \) are ScaLAPACK tool functions; \( MYROW, MYCOL, NPROW \) and \( NPCOL \) can be determined by calling the function \( \text{blacs_gridinfo} \).

If \( lwork = -1 \), then \( lwork \) is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by \( \text{p}x\text{erbla} \).

**Output Parameters**

\( a \)

On exit, if \( uplo = 'U' \), the diagonal and first superdiagonal of \( sub(A) \) are overwritten by the corresponding elements of the tridiagonal matrix \( T \), and the elements above the first superdiagonal, with the array \( tau \), represent the orthogonal matrix \( Q \) as a product of elementary reflectors; if \( uplo = 'L' \), the diagonal and first subdiagonal of \( sub(A) \) are overwritten by the corresponding elements of the tridiagonal matrix \( T \), and the elements below the first subdiagonal, with the array \( tau \), represent the orthogonal matrix \( Q \) as a product of elementary reflectors. See Application Notes below.

\( d \) (local)

Arrays of size \( \text{LOCc}(ja+n-1) \). The diagonal elements of the tridiagonal matrix \( T \):

\[
d[i] = A(i+1,i+1), \ 0 \leq i < \text{LOCc}(ja+n-1).
\]

\( d \) is tied to the distributed matrix \( A \).

\( e \) (local)

Arrays of size \( \text{LOCc}(ja+n-1) \) if \( uplo = 'U' \), \( \text{LOCc}(ja+n-2) \) otherwise.

The off-diagonal elements of the tridiagonal matrix \( T \):

\[
e[i] = A(i+1,i+2), \ 0 \leq i < \text{LOCc}(ja+n-1) \text{ if } uplo = 'U',
\]

\[
e[i] = A(i+2,i+1) \text{ if } uplo = 'L'.
\]

\( e \) is tied to the distributed matrix \( A \).
tau

(local)

Arrays of size $\text{LOCc}(ja+n-1)$. This array contains the scalar factors of the
elementary reflectors. $\text{tau}$ is tied to the distributed matrix $A$.

work[0]

On exit $\text{work}[0]$ contains the minimum value of $lwork$ required for
optimum performance.

info

(global)

= 0: the execution is successful.

< 0: if the $i$-th argument is an array and the $j$-th entry, indexed $j-1$, had
an illegal value, then $\text{info} = -(i*100+j)$; if the $i$-th argument is a scalar
and had an illegal value, then $\text{info} = -i$.

Application Notes

If $\text{uplo} = 'U'$, the matrix $Q$ is represented as a product of elementary reflectors

$Q = H(n-1)... H(2) H(1)$.

Each $H(i)$ has the form

$H(i) = i - \text{tau} \times v \times v'$,

where $\text{tau}$ is a real scalar, and $v$ is a real vector with $v(i+1:n) = 0$ and $v(i) = 1$; $v(1:i-1)$ is stored on exit in $A(ia:ia+i-2, ja+i)$, and $\text{tau}$ in $\text{tau}[ja+i-2]$.

If $\text{uplo} = 'L'$, the matrix $Q$ is represented as a product of elementary reflectors

$Q = H(1) H(2)... H(n-1)$.

Each $H(i)$ has the form

$H(i) = i - \text{tau} \times v \times v'$,

where $\text{tau}$ is a real scalar, and $v$ is a real vector with $v(1:i) = 0$ and $v(i+1) = 1$; $v(i+2:n)$ is stored on exit in $A(ia+i+1:ia+n-1, ja+i-1)$, and $\text{tau}$ in $\text{tau}[ja+i-2]$.

The contents of sub($A$) on exit are illustrated by the following examples with $n = 5$:

If $\text{uplo} = 'U'$:

\[
\begin{bmatrix}
  d & e & v2 & v3 & v4 \\
  d & e & v3 & v4 \\
  d & e & v4 \\
  d & e \\
  d
\end{bmatrix}
\]

If $\text{uplo} = 'L'$:
where \( d \) and \( e \) denote diagonal and off-diagonal elements of \( T \), and \( v_i \) denotes an element of the vector defining \( H(i) \).

**See Also**

*Overview* for details of ScaLAPACK array descriptor structures and related notations.

**p?ormtr**

*Multiplying a general matrix by the orthogonal transformation matrix from a reduction to tridiagonal form determined by p?sytrd.*

**Syntax**

```c
void psormtr (char *side, char *uplo, char *trans, MKL_INT *m, MKL_INT *n, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *tau, float *c, MKL_INT *ic, MKL_INT *jc, MKL_INT *descc, float *work, MKL_INT *lwork, MKL_INT *info);
void pdormtr (char *side, char *uplo, char *trans, MKL_INT *m, MKL_INT *n, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *tau, double *c, MKL_INT *ic, MKL_INT *jc, MKL_INT *descc, double *work, MKL_INT *lwork, MKL_INT *info);
```

**Include Files**

- mkl_scalapack.h

**Description**

This function overwrites the general real distributed \( m \)-by-\( n \) matrix \( sub(C) = C(ic:ic+m-1,jc:jc+n-1) \) with

- \( side = 'L' \) : \( Q^T \) or \( Q \) is applied from the left.
- \( side = 'R' \) : \( Q^T \) or \( Q \) is applied from the right.

where \( Q \) is a real orthogonal distributed matrix of order \( nq \), with \( nq = m \) if \( side = 'L' \) and \( nq = n \) if \( side = 'R' \).

\( Q \) is defined as the product of \( nq \) elementary reflectors, as returned by \( p?sytrd \).

If \( uplo = 'U' \), \( Q = H(nq-1)... H(2) \) \( H(1) \);
If \( uplo = 'L' \), \( Q = H(1) H(2)... H(nq-1) \).

**Input Parameters**

- \( side \) = \( 'L' \) : \( Q \) or \( Q^T \) is applied from the left.
- \( 'R' \) : \( Q \) or \( Q^T \) is applied from the right.
trans
(global)
= 'N', no transpose, Q is applied.
= 'T', transpose, QT is applied.

uplo
(global)
= 'U': Upper triangle of A(ia:*, ja:*) contains elementary reflectors
from p?sytrd;
= 'L': Lower triangle of A(ia:*, ja:*) contains elementary reflectors
from p?sytrd

m
(global) The number of rows in the distributed matrix sub(C) (m≥0).

n
(global) The number of columns in the distributed matrix sub(C) (n≥0).

a
(local)
Pointer into the local memory to an array of size lld_a*LOCc(ja+m-1) if
side = 'L', and lld_a*LOCc(ja+n-1) if side = 'R'.
Contains the vectors that define the elementary reflectors, as returned by
p?sytrd.
If side='L', lld_a ≥ max(1,LOCr(ia+m-1));
If side = 'R', lld_a ≥ max(1, LOCr(ia+n-1)).

ia, ja
(global) The row and column indices in the global matrix A indicating the
first row and the first column of the submatrix A, respectively.
desca
(global and local) array of size dlen_. The array descriptor for the
distributed matrix A.
tau
(local)
Array of size of itau where
if side = 'L' and uplo = 'U', itau = LOCC(m_a),
if side = 'L' and uplo = 'L', itau = LOCC(ja+m-2),
if side = 'R' and uplo = 'U', itau = LOCC(n_a),
if side = 'R' and uplo = 'L', itau = LOCC(ja+n-2).

tau[i] must contain the scalar factor of the elementary reflector H(i+1), as
returned by p?sytrd (0 ≤ i < itau). tau is tied to the distributed matrix A.

c
(local)
Pointer into the local memory to an array of size lld_c*LOCc(jc+n-1).
Contains the local pieces of the distributed matrix sub (C).

ic, jc
(global) The row and column indices in the global matrix C indicating the
first row and the first column of the submatrix C, respectively.
desccc
(global and local) array of size dlen_. The array descriptor for the
distributed matrix C.
work
(local)
Workspace array of size lwork.
lwork

(local or global) size of work, must be at least:

if uplo = 'U',
    iaa = ia; jaa = ja+1, icc = ic; jcc = jc;
else uplo = 'L',
    iaa = ia+1, jaa = ja;
If side = 'L',
    icc = ic+1; jcc = jc;
else icc = ic; jcc = jc+1;
end if
end if
If side = 'L',
    mi= m-1; ni= n
    lwork ≥ max((nb_a*(nb_a-1))/2, (nqc0 + mpc0)*nb_a) + nb_a*nb_a
else
If side = 'R',
    mi= m; mi = n-1;
    lwork≥max((nb_a*(nb_a-1))/2, (nqc0 + max(npa0+numroc(numroc(ni+icoffc, nb_a, 0, 0, NCOL), nb_a, 0, 0, lcmq), mpc0)))*nb_a) + nb_a*nb_a
end if

where lcmq = lcm/NPCOL with lcm = ilcm(NPROW, NCOL),
iroffa = mod(iaa-1, mb_a),
icoffa = mod(jaa-1, nb_a),
iarow = indxg2p(iaa, mb_a, MYROW, rsrc_a, NPROW),
npa0 = numroc(ni+iroffa, mb_a, MYROW, iarow, NPROW),
iroffc = mod(icc-1, mb_c),
icoffc = mod(jcc-1, nb_c),
icrow = indxg2p(icc, mb_c, MYROW, rsrcc, NPROW),
iccol = indxg2p(jcc, nb_c, MYCOL, csrcc, NCOL),
mpc0 = numroc(mi+iroffc, mb_c, MYROW, icrow, NPROW),
nqc0 = numroc(ni+icoffc, nb_c, MYCOL, iccol, NCOL),

NOTE

mod(x,y) is the integer remainder of x/y.

NOTE
mod(x,y) is the integer remainder of x/y.
ilcm, indxg2p and numroc are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function blacs_gridinfo. If lwork = -1, then lwork is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

**Output Parameters**

- **c**: Overwritten by the product Q*sub(C), or Q'*sub(C), or sub(C)*Q', or sub(C)*Q.
- **work[0]**: On exit work[0] contains the minimum value of lwork required for optimum performance.
- **info** (global)
  - = 0: the execution is successful.
  - < 0: if the i-th argument is an array and the j-th entry, indexed j - 1, had an illegal value, then info = -(i*100+j); if the i-th argument is a scalar and had an illegal value, then info = -i.

**See Also**

Overview for details of ScaLAPACK array descriptor structures and related notations.

**p?hengst**

Reduces a complex Hermitian-definite generalized eigenproblem to standard form.

**Syntax**

```c
void pchengst (const MKL_INT* ibtype, const char* uplo, const MKL_INT* n, MKL_Complex8* a, const MKL_INT* ia, const MKL_INT* ja, const MKL_INT* desca, const MKL_Complex8* b, const MKL_INT* ib, const MKL_INT* jb, const MKL_INT* descb, float* scale, MKL_Complex8* work, const MKL_INT* lwork, MKL_INT* info);
void pzhengst (const MKL_INT* ibtype, const char* uplo, const MKL_INT* n, MKL_Complex16* a, const MKL_INT* ia, const MKL_INT* ja, const MKL_INT* desca, const MKL_Complex16* b, const MKL_INT* ib, const MKL_INT* jb, const MKL_INT* descb, double* scale, MKL_Complex16* work, const MKL_INT* lwork, MKL_INT* info);
```

**Include Files**

- mkl_scalapack.h

**Description**

p?hengst reduces a complex Hermitian-definite generalized eigenproblem to standard form.

p?hengst performs the same function as p?hegst, but is based on rank 2K updates, which are faster and more scalable than triangular solves (the basis of p?hengst).

p?hengst also calls p?hegst when insufficient workspace is provided, hence p?hengst provides improved performance only when lwork is sufficient (as described in the parameter descriptions).
In the following sub( A ) denotes the submatrix A( ia:ia+n-1, ja:ja+n-1 ) and sub( B ) denotes the submatrix B( ib:ib+n-1, jb:jb+n-1 ).

If ibtype = 1, the problem is sub( A )*x = lambda*sub( B )*x, and sub( A ) is overwritten by inv(U)*sub( A )*inv(U) or inv(L)*sub( A )*inv(L).

If ibtype = 2 or 3, the problem is sub( A )*sub( B )*x = lambda*x or sub( B )*sub( A )*x = lambda*x, and sub( A ) is overwritten by U*sub( A )*U or L*sub( A )*L.

sub( B ) must have been previously factorized as U*U or L*L by p?potrf.

Input Parameters

ibtype (global)
1: compute inv(U)*sub( A )*inv(U) or inv(L)*sub( A )*inv(L);
2 or 3: compute U*sub( A )*U or L*sub( A )*L.

uplo (global)
'U': Upper triangle of sub( A ) is stored and sub( B ) is factored as U*U;
'L': Lower triangle of sub( A ) is stored and sub( B ) is factored as L*L.

n (global)
The order of the matrices sub( A ) and sub( B ). n >= 0.

a (local)
Pointer into the local memory to an array of size lld_a*LOCc(ja+n-1).

On entry, this array contains the local pieces of the n-by-n Hermitian distributed matrix sub( A ). If uplo = 'U', the leading n-by-n upper triangular part of sub( A ) contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If uplo = 'L', the leading n-by-n lower triangular part of sub( A ) contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced.

ia (global)
Global row index of matrix A, which points to the beginning of the submatrix on which to operate.

ja (global)
Global column index of matrix A, which points to the beginning of the submatrix on which to operate.

desca (global and local)
Array of size dlen_.
The array descriptor for the distributed matrix A.

b (local)
Pointer into the local memory to an array of size lld_b*LOCc(jb+n-1).

ib (global)
Global row index of matrix B, which points to the beginning of the submatrix on which to operate.
jb

(global)
Global column index of matrix B, which points to the beginning of the submatrix on which to operate.

descb

(global and local)
Array of size dlen_

The array descriptor for the distributed matrix B.

work

(local)
Array, size (lwork)

On exit, work(1) returns the minimal and optimal lwork.

lwork

(local)
The size of the array work.

lwork is local input and must be at least lwork >= MAX( NB * ( NP0 +1 ), 3 * NB ).

When ibtype = 1 and uplo = 'L', p?hentnd provides improved performance when lwork >= 2 * NP0 * NB + NQ0 * NB + NB * NB, where NB = mb_a = nb_a, NP0 = numroc( n, NB, 0, 0, NPROW ), NQ0 = numroc( n, NB, 0, 0, NPROW ), and numroc is a ScaLAPACK tool function.

MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine blacs_gridinfo.

If lwork = -1, then lwork is global input and a workspace query is assumed; the routine only calculates the optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

a

On exit, if info = 0, the transformed matrix, stored in the same format as sub( A ).

scale

(global)
Amount by which the eigenvalues should be scaled to compensate for the scaling performed in this routine.

scale is always returned as 1.0.

work

On exit, work[0] returns the minimal and optimal lwork.

info

(global)

= 0: successful exit
< 0: If the i-th argument is an array and the j-entry had an illegal value, then info = -(i*100+j), if the i-th argument is a scalar and had an illegal value, then info = -i.

p?hentrd

Reduces a complex Hermitian matrix to Hermitian tridiagonal form.
Syntax

void pchentrd (const char* uplo, const MKL_INT* n, MKL_Complex8* a, const MKL_INT* ia, const MKL_INT* ja, const MKL_INT* desca, float* d, float* e, MKL_Complex8* tau, MKL_Complex8* work, const MKL_INT* lwork, float* rwork, const MKL_INT* lrwork, MKL_INT* info);

void pzhentrd (const char* uplo, const MKL_INT* n, MKL_Complex16* a, const MKL_INT* ia, const MKL_INT* ja, const MKL_INT* desca, double* d, double* e, MKL_Complex16* tau, MKL_Complex16* work, const MKL_INT* lwork, double* rwork, const MKL_INT* lrwork, MKL_INT* info);

Include Files

• mkl_scalapack.h

Description

p?hentrd is a prototype version of p?hetrd which uses tailored codes (either the serial, ?hetrd, or the parallel code, p?hettrd) when adequate workspace is provided.

p?hentrd reduces a complex Hermitian matrix sub( A ) to Hermitian tridiagonal form T by an unitary similarity transformation:

Q^* * sub( A ) * Q = T, where sub( A ) = A(ia:ia+n-1,ja:ja+n-1).

p?hentrd is faster than p?hetrd on almost all matrices, particularly small ones (i.e. n < 500 * sqrt(P) ), provided that enough workspace is available to use the tailored codes.

The tailored codes provide performance that is essentially independent of the input data layout.

The tailored codes place no restrictions on ia, ja, MB or NB. At present, ia, ja, MB and NB are restricted to those values allowed by p?hetrd to keep the interface simple (see the Application Notes section for more information about the restrictions).

Input Parameters

uplo (global)

Specifies whether the upper or lower triangular part of the Hermitian matrix sub( A ) is stored:

= 'U': Upper triangular

= 'L': Lower triangular

n (global)

The number of rows and columns to be operated on, i.e. the order of the distributed submatrix sub( A ). n >= 0.

a (local)

Pointer into the local memory to an array of size lld_a*LOCc(ja+n-1).

On entry, this array contains the local pieces of the Hermitian distributed matrix sub( A ). If uplo = 'U', the leading n-by-n upper triangular part of sub( A ) contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If uplo = 'L', the leading n-by-n lower triangular part of sub( A ) contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced.

ia (global)
The row index in the global array $a$ indicating the first row of $\text{sub}(A)$.

$ja$ (global)

The column index in the global array $a$ indicating the first column of $\text{sub}(A)$.

$desca$ (global and local)

Array of size $\text{dlen}_\text{a}$.

The array descriptor for the distributed matrix $A$.

$work$ (local)

Array, size (lwork)

$lwork$ (local or global)

The size of the array $work$.

$lwork$ is local input and must be at least $lwork \geq \text{MAX}( \text{NB} \times (\text{NP} + 1), 3 \times \text{NB} )$.

For optimal performance, greater workspace is needed:

$lwork \geq 2 \times (\text{ANB}+1) \times (4 \times \text{NPS}+2) + (\text{NPS}+4) \times \text{NPS}$

$\text{ANB} = \text{pjlaenv}( \text{ICTXT}, 3, 'p?hettrd', 'L', 0, 0, 0, 0 )$

$\text{ICTXT} = \text{desca}( \text{ctxt}_\text{a} )$

$\text{SQNPC} = \text{INT}( \sqrt{\text{REAL}(\text{NPROW} \times \text{NPCOL})}) )$

$\text{NPS} = \text{MAX}( \text{numroc}( n, 1, 0, 0, \text{SQNPC}), 2 \times \text{ANB} )$

numroc is a ScaLAPACK tool function.

pjlaenv is a ScaLAPACK environmental inquiry function.

$\text{NPROW}$ and $\text{NPCOL}$ can be determined by calling the subroutine blacs_gridinfo.

$rwork$ (local)

Array, size (lrwork)

$lrwork$ (local or global)

The size of the array $rwork$.

$lrwork$ is local input and must be at least $lrwork \geq 1$.

For optimal performance, greater workspace is needed, i.e. $lrwork \geq \text{MAX}(2 \times n)$

Output Parameters

$a$

Output on exit, if $\text{uplo} = 'U'$, the diagonal and first superdiagonal of $\text{sub}(A)$ are overwritten by the corresponding elements of the tridiagonal matrix $T$, and the elements above the first superdiagonal, with the array $\text{tau}$, represent the unitary matrix $Q$ as a product of elementary reflectors; if $\text{uplo} = 'L'$, the diagonal and first subdiagonal of $\text{sub}(A)$ are overwritten by the corresponding elements of the tridiagonal...
matrix $T$, and the elements below the first subdiagonal, with the array $	au$, represent the unitary matrix $Q$ as a product of elementary reflectors. See Application Notes.

d
(local)
Array, size $\text{LOCc}(ja+n-1)$

The diagonal elements of the tridiagonal matrix $T$: $d[i-1] = A(i,i)$. $d$ is tied to the distributed matrix $A$.

e
(local)
Array, size $\text{LOCc}(ja+n-1)$ if $\text{uplo} = 'U'$, $\text{LOCc}(ja+n-2)$ otherwise.

The off-diagonal elements of the tridiagonal matrix $T$: $e[i-1] = A(i,i+1)$ if $\text{uplo} = 'U'$, $e[i-1] = A(i+1,i)$ if $\text{uplo} = 'L'$. $e$ is tied to the distributed matrix $A$.

$\tau$
(local)
Array, size $\text{LOCc}(ja+n-1)$.

This array contains the scalar factors $\tau$ of the elementary reflectors. $\tau$ is tied to the distributed matrix $A$.

work
On exit, $\text{work}[0]$ returns the optimal $lwork$.

rwork
On exit, $\text{rwork}[0]$ returns the optimal $lrwork$.

info
(global)

$= 0$: successful exit

$< 0$: If the $i$-th argument is an array and the $j$-th entry had an illegal value, then $\text{info} = -(i*100+j)$, if the $i$-th argument is a scalar and had an illegal value, then $\text{info} = -i$.

Application Notes

If $\text{uplo} = 'U'$, the matrix $Q$ is represented as a product of elementary reflectors

$$ Q = H(n-1) \ldots H(2) H(1). $$

Each $H(i)$ has the form

$$ H(i) = I - \tau \cdot v \cdot v', $$

where $\tau$ is a complex scalar, and $v$ is a complex vector with $v(i+1:n) = 0$ and $v(i) = 1$; $v(1:i-1)$ is stored on exit in $A(ia:ia+i-2,ja+i)$, and $\tau$ in $\tau(ja+i-1)$.

If $\text{uplo} = 'L'$, the matrix $Q$ is represented as a product of elementary reflectors

$$ Q = H(1) H(2) \ldots H(n-1). $$

Each $H(i)$ has the form

$$ H(i) = I - \tau \cdot v \cdot v', $$

where $\tau$ is a complex scalar, and $v$ is a complex vector with $v(1:i) = 0$ and $v(i+1) = 1$; $v(i+2:n)$ is stored on exit in $A(ia+i+1:ia+n-1,ja+i-1)$, and $\tau$ in $\tau(ja+i-1)$.

The contents of sub($A$) on exit are illustrated by the following examples with $n = 5$:

if $\text{uplo} = 'U'$:
where \( d \) and \( e \) denote diagonal and off-diagonal elements of \( T \), and \( vi \) denotes an element of the vector defining \( H(i) \).

**Alignment requirements**

The distributed submatrix \( \text{sub}(A) \) must verify some alignment properties, namely the following expression should be true:

\[
(mb_{-a} = nb_{-a} \text{ and } IROFFA = ICOFFA \text{ and } IROFFA = 0) \text{ with } IROFFA = \text{mod}(ia-1, mb_{-a}), \text{ and ICOFFA = mod}(ja-1, nb_{-a}).
\]

**p?hetrd**

*Reduces a Hermitian matrix to Hermitian tridiagonal form by a unitary similarity transformation.*

**Syntax**

```c
void pchetrd (char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *d , float *e , MKL_Complex8 *tau , MKL_Complex8 *work , MKL_INT *lwork , MKL_INT *info );
void pzhetrd (char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *d , double *e , MKL_Complex16 *tau , MKL_Complex16 *work , MKL_INT *lwork , MKL_INT *info );
```

**Include Files**

- mkl_scalapack.h

**Description**

The p?hetrd function reduces a complex Hermitian matrix \( \text{sub}(A) \) to Hermitian tridiagonal form \( T \) by a unitary similarity transformation:

\[
Q^{*}\text{sub}(A)^{*}Q = T
\]

where \( \text{sub}(A) = A(ia:ia+n-1,ja:ja+n-1) \).

**Input Parameters**

- \( uplo \) (global)

  Specifies whether the upper or lower triangular part of the Hermitian matrix \( \text{sub}(A) \) is stored:

  If \( uplo = 'U' \), upper triangular
If uplo = 'L', lower triangular

\( n \)  
(global) The order of the distributed matrix sub(\( A \)) (\( n \geq 0 \)).

\( a \)  
(local)
Pointer into the local memory to an array of size \( lld_a \ast \text{LOCc}(ja+n-1) \). On entry, this array contains the local pieces of the Hermitian distributed matrix sub(\( A \)).

If uplo = 'U', the leading \( n \)-by-\( n \) upper triangular part of sub(\( A \)) contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced.

If uplo = 'L', the leading \( n \)-by-\( n \) lower triangular part of sub(\( A \)) contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced. (see Application Notes below).

\( ia, ja \)  
(global) The row and column indices in the global matrix \( A \) indicating the first row and the first column of the submatrix \( A \), respectively.

\( desca \)  
(global and local) array of size \( dlen_\). The array descriptor for the distributed matrix \( A \).

\( work \)  
(local)
Workspace array of size \( lwork \).

\( lwork \)  
(local or global) size of \( work \), must be at least:
\[ lwork \geq \max(NB\ast(np +1), 3\ast NB) \]

where \( NB = mb_a = nb_a \),
\( np = \text{numroc}(n, NB, MYROW, iarow, NPROW) \),
\( iarow = \text{indxg2p}(ia, NB, MYROW, rsrca, NPROW) \).

\text{indxg2p} and \text{numroc} are \text{ScaLAPACK} tool functions; \text{MYROW}, MYCOL, NPROW and NPCOL can be determined by calling the function \text{blacs_gridinfo}.

If \( lwork = -1 \), then \( lwork \) is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by \text{pxerbla}.

**Output Parameters**

\( a \)  
On exit,
If uplo = 'U', the diagonal and first superdiagonal of sub(\( A \)) are overwritten by the corresponding elements of the tridiagonal matrix \( T \), and the elements above the first superdiagonal, with the array \( tau \), represent the unitary matrix \( Q \) as a product of elementary reflectors; if uplo = 'L', the diagonal and first subdiagonal of sub(\( A \)) are overwritten by the corresponding elements of the tridiagonal matrix \( T \), and the elements below the first subdiagonal, with the array \( tau \), represent the unitary matrix \( Q \) as a product of elementary reflectors (see Application Notes below).

\( d \)  
(local)
Arrays of size $\text{LOC}(ja+n-1)$. The diagonal elements of the tridiagonal matrix $T$:
\[ d[i] = A(i+1,i+1), \quad 0 \leq i < \text{LOC}(ja+n-1). \]
$d$ is tied to the distributed matrix $A$.

$e$

(local)

Arrays of size $\text{LOC}(ja+n-1)$ if $\text{uplo} = 'U'$; $\text{LOC}(ja+n-2)$ otherwise. The off-diagonal elements of the tridiagonal matrix $T$:
\[ e[i] = A(i+1,i+2), \quad 0 \leq i < \text{LOC}(ja+n-1) \]
for $\text{uplo} = 'U'$,
\[ e[i] = A(i+2,i+1) \]
otherwise. $e$ is tied to the distributed matrix $A$.

$\tau$

(local)

Array of size $\text{LOC}(ja+n-1)$. This array contains the scalar factors of the elementary reflectors. $\tau$ is tied to the distributed matrix $A$.

$\text{work}[0]$

On exit $\text{work}[0]$ contains the minimum value of $l\text{work}$ required for optimum performance.

$info$

(global)

$= 0$: the execution is successful.

$< 0$: if the $i$-th argument is an array and the $j$-th entry, indexed $j - 1$, had an illegal value, then $info = -(i*100+j)$; if the $i$-th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

If $\text{uplo} = 'U'$, the matrix $Q$ is represented as a product of elementary reflectors
\[ Q = H(n-1)*...*H(2)*H(1). \]
Each $H(i)$ has the form
\[ H(i) = i - \tau*v*v', \]
where $\tau$ is a complex scalar, and $v$ is a complex vector with $v(i+1:n) = 0$ and $v(i) = 1$; $v(1:i-1)$ is stored on exit in $A(ia:ia+i-2, ja+i)$, and $\tau$ in $\tau[ja+i-2]$.

If $\text{uplo} = 'L'$, the matrix $Q$ is represented as a product of elementary reflectors
\[ Q = H(1)*H(2)*...*H(n-1). \]
Each $H(i)$ has the form
\[ H(i) = i - \tau*v*v', \]
where $\tau$ is a complex scalar, and $v$ is a complex vector with $v(1:i) = 0$ and $v(i+1) = 1$; $v(i+2:n)$ is stored on exit in $A(ia+i+1:ia+n-1, ja+i-1)$, and $\tau$ in $\tau[ja+i-2]$.

The contents of sub($A$) on exit are illustrated by the following examples with $n = 5$:

If $\text{uplo} = 'U'$:
If \texttt{uplo} = 'L':

\[
\begin{bmatrix}
  d & e & v_2 & v_3 & v_4 \\
  & d & e & v_3 & v_4 \\
  & & d & e & v_4 \\
  & & & d & e \\
\end{bmatrix}
\]

where \(d\) and \(e\) denote diagonal and off-diagonal elements of \(T\), and \(v_i\) denotes an element of the vector defining \(H(i)\).

Overview for details of ScaLAPACK array descriptor structures and related notations.

**p?unmtr**

*Multiplies a general matrix by the unitary transformation matrix from a reduction to tridiagonal form determined by p?hetrd.*

**Syntax**

```c
void pcunmtr (char *side, char *uplo, char *trans, MKL_INT *m, MKL_INT *n, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_Complex8 *tau, MKL_Complex8 *c, MKL_INT *ic, MKL_INT *jc, MKL_INT *descc, MKL_Complex8 *work, MKL_INT *lwork, MKL_INT *info);
void pzunmtr (char *side, char *uplo, char *trans, MKL_INT *m, MKL_INT *n, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_Complex16 *tau, MKL_Complex16 *c, MKL_INT *ic, MKL_INT *jc, MKL_INT *descc, MKL_Complex16 *work, MKL_INT *lwork, MKL_INT *info);
```

**Include Files**

- mkl_scalapack.h

**Description**

This function overwrites the general complex distributed \(m\)-by-\(n\) matrix \(\text{sub}(C) = C(ic:ic+m-1,jc:jc+n-1)\) with

- \(side = 'L'\): \(Q\text{sub}(C)\)
- \(side = 'R'\): \(\text{sub}(C)Q\)
trans = 'C': Q^H*sub(C) sub(C)*Q^H

where Q is a complex unitary distributed matrix of order nq, with nq = m if side = 'L' and nq = n if side = 'R'.

Q is defined as the product of nq-1 elementary reflectors, as returned by p?hetrd.

If uplo = 'U', Q = H(nq-1)...H(2) H(1);
If uplo = 'L', Q = H(1) H(2)...H(nq-1).

Input Parameters

side (global)
= 'L': Q or Q^H is applied from the left.
= 'R': Q or Q^H is applied from the right.

trans (global)
= 'N', no transpose, Q is applied.
= 'C', conjugate transpose, Q^H is applied.

uplo (global)
= 'U': Upper triangle of A(ia:*, ja:*) contains elementary reflectors from p?hetrd;
= 'L': Lower triangle of A(ia:*, ja:) contains elementary reflectors from p?hetrd

m (global) The number of rows in the distributed matrix sub(C) (m≥0).

n (global) The number of columns in the distributed matrix sub(C) (n≥0).

a (local)
Pointer into the local memory to an array of size lld_a*LOCc(ja+m-1) if side = 'L', and lld_a*LOCc(ja+m-1) if side = 'R'.

Contains the vectors which define the elementary reflectors, as returned by p?hetrd.

If side='L', lld_a ≥ max(1,LOCr(ia+m-1));
If side = 'R', lld_a ≥ max(1,LOCr(ia+n-1)).

ia, ja (global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A, respectively.

desca (global and local) array of size dlen_. The array descriptor for the distributed matrix A.

tau (local)
Array of size of ltau where
If side = 'L' and uplo = 'U', ltau = LOCc(m_a),
if side = 'L' and uplo = 'L', ltau = LOCc(ja+m-2),
if side = 'R' and uplo = 'U', ltau = LOCc(n_a),
if side = 'R' and uplo = 'L', ltau = LOCc(ja+n-2).
$\tau[i]$ must contain the scalar factor of the elementary reflector $H(i+1)$, as returned by $p\text{hetrd}$ ($0 \leq i < \ell\tau$). $\tau$ is tied to the distributed matrix $A$.

declaration(c)
Pointer into the local memory to an array of size $lld_c*\text{LOCc}(jc+n-1)$.
Contains the local pieces of the distributed matrix sub $(C)$.

declaration(ic, jc)
(global) The row and column indices in the global matrix $C$ indicating the first row and the first column of the submatrix $C$, respectively.

declaration(desc)
(global and local) array of size $dlen_\text{.}$ The array descriptor for the distributed matrix $C$.

declaration(work)
(local)
Workspace array of size $lwork$.

declaration(lwork)
(local or global) size of $work$, must be at least:
If $\text{uplo} = 'U'$,
\begin{align*}
    iaa &= ia; jaa = ja+1, icc = ic; jcc = jc;
    \text{else } \text{uplo} &= 'L',
    iaa &= ia+1, jaa = ja;
    \text{If } \text{side} &= 'L',
    icc &= ic+1; jcc = jc;
    \text{else } icc &= ic; jcc = jc+1;
\end{align*}
end if
end if
If $\text{side} = 'L'$,
\begin{align*}
    mi &= m-1; ni = n;
    lwork &\geq \max((nb_a*(nb_a-1))/2, (nqc0 + mpc0)*nb_a) + nb_a*nb_a
    \text{else}
    lwork &\geq \max((nb_a*(nb_a-1))/2, (nqc0 + 
        \max(npa0+\text{numroc}(\text{numroc}(ni+\text{icoffc}, nb_a, 0, 0, \text{NPCOL}), nb_a, 0, 0, 1\text{lcmq}), mpc0))*nb_a) + nb_a*nb_a
    \end{align*}
end if
If $\text{side} = 'R'$,
\begin{align*}
    mi &= m; mi = n-1;
    lwork &\geq \max((nb_a*(nb_a-1))/2, (nqc0 + 
        \max(npa0+\text{numroc}(\text{numroc}(ni+\text{icoffc}, nb_a, 0, 0, \text{NPCOL}), nb_a, 0, 0, 1\text{lcmq}), mpc0))*nb_a) + nb_a*nb_a
    \end{align*}
end if
where $1\text{cmq} = \text{lcm}/\text{NPCOL}$ with $1\text{cm} = \text{ilcm}(\text{NPROW}, \text{NPCOL})$
\begin{align*}
    \text{irow} &= \text{indxg2p}(iaa, mb_a, \text{MYROW}, rsr\text{c}_a, \text{NPROW}),
    npa0 &= \text{numroc}(ni+\text{icoffa}, mb_a, \text{MYROW}, \text{irow}, \text{NPROW}),
    \text{iroffc} &= \text{mod}(\text{iccc}-1, \text{mb}_c),
\end{align*}
\( \text{icoffe} = \text{mod}(jcc - 1, \ nb_c), \)
\( \text{icrow} = \text{indxg2p}(icc, \ mb_c, \ MYROW, \ rsr_c_c, \ NPROW), \)
\( \text{iccol} = \text{indxg2p}(jcc, \ nb_c, \ MYCOL, \ csr_c_c, \ NPCOL), \)
\( \text{mpc0} = \text{numroc}(mi + iroffc, \ mb_c, \ MYROW, \ icrow, \ NPROW), \)
\( \text{nqc0} = \text{numroc}(ni + icoffc, \ nb_c, \ MYCOL, \ iccol, \ NPCOL), \)

**NOTE**

\( \text{mod}(x, y) \) is the integer remainder of \( x/y \).

\( \text{ilcm}, \ \text{indxg2p} \) and \( \text{numroc} \) are ScaLAPACK tool functions; \( \text{MYROW}, \ \text{MYCOL}, \ \text{NPROW} \) and \( \text{NPCOL} \) can be determined by calling the function \( \text{blacs_gridinfo} \). If \( \text{lwork} = -1 \), then \( \text{lwork} \) is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by \( \text{pxerbla} \).

**Output Parameters**

- \( c \)
  - Overwritten by the product \( Q \times \text{sub}(C), \) or \( Q' \times \text{sub}(C), \) or \( \text{sub}(C) \times Q', \) or \( \text{sub}(C) \times Q. \)
  - \( \text{work}[0] \)
    - On exit \( \text{work}[0] \) contains the minimum value of \( \text{lwork} \) required for optimum performance.
  - \( \text{info} \)
    - (global)
      - \( = 0: \) the execution is successful.
      - \( < 0: \) if the \( i \)-th argument is an array and the \( j \)-th entry, indexed \( j - 1, \) had an illegal value, then \( \text{info} = -(i \times 100 + j); \) if the \( i \)-th argument is a scalar and had an illegal value, then \( \text{info} = -i. \)

**See Also**

**p?stebz**

*Computes the eigenvalues of a symmetric tridiagonal matrix by bisection.*

**Syntax**

```c
void psstebz (MKL_INT *ictxt, char *range, char *order, MKL_INT *n, float *vl, float *vu, MKL_INT *il, MKL_INT *iu, float *abstol, float *d, float *e, MKL_INT *m, MKL_INT *nsplit, float *w, MKL_INT *iblock, MKL_INT *isplit, float *work, MKL_INT *lwork, MKL_INT *iwork, MKL_INT *info);
void pdstebz (MKL_INT *ictxt, char *range, char *order, MKL_INT *n, double *vl, double *vu, MKL_INT *il, MKL_INT *iu, double *abstol, double *d, double *e, MKL_INT *m, MKL_INT *nsplit, double *w, MKL_INT *iblock, MKL_INT *isplit, double *work, MKL_INT *lwork, MKL_INT *iwork, MKL_INT *info);
```
Include Files

- mkl_scalapack.h

Description

The \texttt{p?stebz} function computes the eigenvalues of a symmetric tridiagonal matrix in parallel. These may be all eigenvalues, all eigenvalues in the interval \([vl, vu]\), or the eigenvalues \(il\) through \(iu\). A static partitioning of work is done at the beginning of \texttt{p?stebz} which results in all processes finding an (almost) equal number of eigenvalues.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

\begin{itemize}
  \item \texttt{ictxt} (global) The BLACS context handle.
  \item \texttt{range} (global) Must be \texttt{'A'} or \texttt{'V'} or \texttt{'I'}.
    \begin{itemize}
      \item If \texttt{range = 'A'}, the function computes all eigenvalues.
      \item If \texttt{range = 'V'}, the function computes eigenvalues in the interval \([vl, vu]\).
      \item If \texttt{range = 'I'}, the function computes eigenvalues \(il\) through \(iu\).
    \end{itemize}
  \item \texttt{order} (global) Must be \texttt{'B'} or \texttt{'E'}.
    \begin{itemize}
      \item If \texttt{order = 'B'}, the eigenvalues are to be ordered from smallest to largest within each split-off block.
      \item If \texttt{order = 'E'}, the eigenvalues for the entire matrix are to be ordered from smallest to largest.
    \end{itemize}
  \item \texttt{n} (global) The order of the tridiagonal matrix \(T(n \geq 0)\).
  \item \texttt{vl, vu} (global)
    \begin{itemize}
      \item If \texttt{range = 'V'}, the function computes the lower and the upper bounds for the eigenvalues on the interval \([l, u]\).
      \item If \texttt{range = 'A' or 'I'}, \(vl\) and \(vu\) are not referenced.
    \end{itemize}
  \item \texttt{il, iu} (global)
    \begin{itemize}
      \item Constraint: \(1 \leq il \leq iu \leq n\).
      \item If \texttt{range = 'I'}, the index of the smallest eigenvalue is returned for \(il\) and of the largest eigenvalue for \(iu\) (assuming that the eigenvalues are in ascending order) must be returned.
    \end{itemize}
\end{itemize}
If range = 'A' or 'V', il and iu are not referenced.

abstol

The absolute tolerance to which each eigenvalue is required. An eigenvalue (or cluster) is considered to have converged if it lies in an interval of width abstol. If abstol≤0, then the tolerance is taken as ulp||T||, where ulp is the machine precision, and ||T|| means the 1-norm of T.

Eigenvalues will be computed most accurately when abstol is set to the underflow threshold slamch('U'), not 0. Note that if eigenvectors are desired later by inverse iteration (p?stein), abstol should be set to 2*p?lamch('S').

d

Array of size n.

Contains n diagonal elements of the tridiagonal matrix T. To avoid overflow, the matrix must be scaled so that its largest entry is no greater than overflow^{1/2} * underflow^{1/4} in absolute value, and for greatest accuracy, it should not be much smaller than that.

e

Array of size n - 1.

Contains (n-1) off-diagonal elements of the tridiagonal matrix T. To avoid overflow, the matrix must be scaled so that its largest entry is no greater than overflow^{1/2} * underflow^{1/4} in absolute value, and for greatest accuracy, it should not be much smaller than that.

work

Array of size max(5n, 7). This is a workspace array.

lwork

(local) The size of the work array must be ≥ max(5n, 7).

If lwork = -1, then lwork is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

iwork

(local) Array of size max(4n, 14). This is a workspace array.

liwork

(local) The size of the iwork array must ≥max(4n, 14, NPROCS).

If liwork = -1, then liwork is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

m

(global) The actual number of eigenvalues found. 0≤m≤n

nsplit

(global) The number of diagonal blocks detected in T. 1≤nsplit≤n

w

(global)
Array of size \( n \). On exit, the first \( m \) elements of \( w \) contain the eigenvalues on all processes.

\( iblock \) (global)

Array of size \( n \). At each row/column \( j \) where \( e[j-1] \) is zero or small, the matrix \( T \) is considered to split into a block diagonal matrix. On exit \( iblock[i] \) specifies which block (from 1 to the number of blocks) the eigenvalue \( w[i] \) belongs to.

**NOTE**
In the (theoretically impossible) event that bisection does not converge for some or all eigenvalues, \( info \) is set to 1 and the ones for which it did not are identified by a negative block number.

\( isplit \) (global)

Array of size \( n \).

Contains the splitting points, at which \( T \) breaks up into submatrices. The first submatrix consists of rows/columns 1 to \( isplit[0] \), the second of rows/columns \( isplit[0]+1 \) through \( isplit[1] \), and so on, and the \( nsplit \)-th submatrix consists of rows/columns \( isplit[nsplit-2]+1 \) through \( isplit[nsplit-1]=n \). (Only the first \( nsplit \) elements are used, but since the \( nsplit \) values are not known, \( n \) words must be reserved for \( isplit \).)

\( info \) (global)

If \( info = 0 \), the execution is successful.

If \( info < 0 \), if \( info = -i \), the \( i \)-th argument has an illegal value.

If \( info > 0 \), some or all of the eigenvalues fail to converge or are not computed.

If \( info = 1 \), bisection fails to converge for some eigenvalues; these eigenvalues are flagged by a negative block number. The effect is that the eigenvalues may not be as accurate as the absolute and relative tolerances.

If \( info = 2 \), mismatch between the number of eigenvalues output and the number desired.

If \( info = 3 \): range='I', and the Gershgorin interval initially used is incorrect. No eigenvalues are computed. Probable cause: the machine has a sloppy floating-point arithmetic. Increase the \( fudge \) parameter, recompile, and try again.

**See Also**
Overview for details of ScaLAPACK array descriptor structures and related notations.

p?stedc
Computes all eigenvalues and eigenvectors of a symmetric tridiagonal matrix in parallel.
Syntax

void psstedc (const char* compz, const MKL_INT n, float* d, float* e, float* q, const MKL_INT* iq, const MKL_INT* jq, const MKL_INT* descq, float* work, MKL_INT* lwork, MKL_INT* iwork, const MKL_INT* liwork, MKL_INT* info);

void pdstedc (const char* compz, const MKL_INT n, double* d, double* e, double* q, const MKL_INT* iq, const MKL_INT* jq, const MKL_INT* descq, double* work, MKL_INT* lwork, MKL_INT* iwork, const MKL_INT* liwork, MKL_INT* info);

Include Files

• mkl_scalapack.h

Description

p?stedc computes all eigenvalues and eigenvectors of a symmetric tridiagonal matrix in parallel, using the divide and conquer algorithm.

Input Parameters

compz

= 'N': Compute eigenvalues only. (NOT IMPLEMENTED YET)
= 'I': Compute eigenvectors of tridiagonal matrix also.
= 'V': Compute eigenvectors of original dense symmetric matrix also. On entry, Z contains the orthogonal matrix used to reduce the original matrix to tridiagonal form. (NOT IMPLEMENTED YET)

n

(global)
The order of the tridiagonal matrix \( T \). \( n \geq 0 \).

d

(global)
Array, size \((n)\)
On entry, the diagonal elements of the tridiagonal matrix.

e

(global)
Array, size \((n-1)\).
On entry, the subdiagonal elements of the tridiagonal matrix.

iq

(global)
Q's global row index, which points to the beginning of the submatrix which is to be operated on.

jq

(global)
Q's global column index, which points to the beginning of the submatrix which is to be operated on.

descq

(global and local)
Array of size \( dlen_\).
The array descriptor for the distributed matrix \( Q \).

work

(local)
Array, size \((lwork)\)
**lwork**

(llocal)

The size of the array \( \text{work} \).

\[ lwork = 6*n + 2*NP*NQ \]

\[ NP = \text{numroc}( n, NB, MYROW, \text{DESCQ}( \text{rsrc}_\text{r}), \text{NPROW} ) \]

\[ NQ = \text{numroc}( n, NB, MYCOL, \text{DESCQ}( \text{csrc}_\text{c}), \text{NPCOL} ) \]

\text{numroc} \text{ is a ScaLAPACK tool function.}

If \( lwork = -1 \), the \( lwork \) is global input and a workspace query is assumed; the routine only calculates the minimum size for the \( \text{work} \) array. The required workspace is returned as the first element of \( \text{work} \) and no error message is issued by \text{p}\text{xerbla}.

**iwork**

(llocal)

Array, size (\( liwork \))

**liwork**

The size of the array \( \text{iwork} \).

\[ liwork = 2 + 7*n + 8*\text{NPCOL} \]

**Output Parameters**

\( d \)  

On exit, if \( info = 0 \), the eigenvalues in descending order.

\( q \)  

(llocal)

Array, local size (\( lld_q \), \text{LOCc}(jq+n-1))

\( q \) contains the orthonormal eigenvectors of the symmetric tridiagonal matrix.

On output, \( q \) is distributed across the P processes in block cyclic format.

\( \text{work} \)  

On output, \( \text{work}[0] \) returns the workspace needed.

\( iwork \)  

On exit, if \( liwork > 0 \), \( iwork[0] \) returns the optimal \( liwork \).

\( info \)  

(global)

\( = 0 \): successful exit.

\( < 0 \): If the \( i \)-th argument is an array and the \( j \)-th entry had an illegal value, then \( info = -(i*100+j) \), if the \( i \)-th argument is a scalar and had an illegal value, then \( info = -i \).

\( > 0 \): The algorithm failed to compute the \( info/(n+1) \)-th eigenvalue while working on the submatrix lying in global rows and columns \( \text{mod}(info,n+1) \).

**p?stein**

Computes the eigenvectors of a tridiagonal matrix using inverse iteration.
Syntax

```c
void psstein (MKL_INT *n, float *d, float *e, MKL_INT *m, float *w, MKL_INT *iblock,
              MKL_INT *isplit, float *orfac, float *z, MKL_INT *iz, MKL_INT *jz,
              MKL_INT *descz, float *work, MKL_INT *lwork, MKL_INT *iwork,
              MKL_INT *ifail, MKL_INT *iclustr, float *gap, MKL_INT *info);
void pdstein (MKL_INT *n, double *d, double *e, MKL_INT *m, double *w, MKL_INT *iblock,
              MKL_INT *isplit, double *orfac, double *z, MKL_INT *iz, MKL_INT *jz,
              MKL_INT *descz, double *work, MKL_INT *lwork, MKL_INT *iwork,
              MKL_INT *ifail, MKL_INT *iclustr, double *gap, MKL_INT *info);
void pcstein (MKL_INT *n, float *d, float *e, MKL_INT *m, float *w, MKL_INT *iblock,
              MKL_INT *isplit, float *orfac, MKL_Complex8 *z, MKL_INT *iz, MKL_INT *jz,
              MKL_INT *descz, float *work, MKL_INT *lwork, MKL_INT *iwork,
              MKL_INT *ifail, MKL_INT *iclustr, float *gap, MKL_INT *info);

Description

The `p?stein` function computes the eigenvectors of a symmetric tridiagonal matrix \( T \) corresponding to specified eigenvalues, by inverse iteration. `p?stein` does not orthogonalize vectors that are on different processes. The extent of orthogonalization is controlled by the input parameter `lwork`. Eigenvectors that are to be orthogonalized are computed by the same process. `p?stein` decides on the allocation of work among the processes and then calls `?stein2` (modified LAPACK function) on each individual process. If insufficient workspace is allocated, the expected orthogonalization may not be done.

**NOTE**

If the eigenvectors obtained are not orthogonal, increase `lwork` and run the code again.

\( p = \text{NPROW} \times \text{NPCOL} \) is the total number of processes.

**Input Parameters**

- \( n \) (global) The order of the matrix \( T(n \geq 0) \).
- \( m \) (global) The number of eigenvectors to be returned.
- \( d, e, w \) (global) Arrays:
  - \( d \) of size \( n \) contains the diagonal elements of \( T \).
  - \( e \) of size \( n-1 \) contains the off-diagonal elements of \( T \).
  - \( w \) of size \( m \) contains all the eigenvalues grouped by split-off block. The eigenvalues are supplied from smallest to largest within the block. (Here the output array \( w \) from `p?stebz` with order = 'B' is expected. The array should be replicated in all processes.)
iblock

(global)
Array of size n. The submatrix indices associated with the corresponding
eigenvalues in w: 1 for eigenvalues belonging to the first submatrix from
the top, 2 for those belonging to the second submatrix, etc. (The output
array iblock from p?stebz is expected here).

isplit

(global)
Array of size n. The splitting points at which T breaks up into submatrices.
The first submatrix consists of rows/columns 1 to isplit[0], the second of
rows/columns isplit[0]+1 through isplit[1], and so on, and the
nsplit-th submatrix consists of rows/columns isplit[nsplit-2]+1
through isplit[nsplit-1]=n. (The output array isplit from p?stebz is
expected here.)

orfac

(global)
orfac specifies which eigenvectors should be orthogonalized. Eigenvectors
that correspond to eigenvalues within orfac*||T|| of each other are to be
orthogonalized. However, if the workspace is insufficient (see lwork), this
tolerance may be decreased until all eigenvectors can be stored in one
process. No orthogonalization is done if orfac is equal to zero. A default
value of 1000 is used if orfac is negative. orfac should be identical on all
processes

iz, jz

(global) The row and column indices in the global matrix Z indicating the
first row and the first column of the submatrix Z, respectively.

descz

(global and local) array of size dlen_. The array descriptor for the
distributed matrix Z.

work

(local).
Workspace array of size lwork.

lwork

(local)
lwork controls the extent of orthogonalization which can be done. The
number of eigenvectors for which storage is allocated on each process is
nvec = floor((lwork-max(5*n,np00*mq00))/n). Eigenvectors
corresponding to eigenvalue clusters of size (nvec - ceil(m/p) + 1) are
guaranteed to be orthogonal (the orthogonality is similar to that obtained
from ?stein2).

NOTE

lwork must be no smaller than max(5*n,np00*mq00) +
ceil(m/p)*n and should have the same input value on all
processes.

It is the minimum value of lwork input on different processes that is
significant.
If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

**iwork**

(local)
Workspace array of size $3n+p+1$.

**liwork**

(local) The size of the array `iwork`. It must be greater than $3n+p+1$.
If $liwork = -1$, then `liwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

**Output Parameters**

**z**

(local)
Array of size `descz[dlen_-1], n/NPCOL + NB`). `z` contains the computed eigenvectors associated with the specified eigenvalues. Any vector which fails to converge is set to its current iterate after MAXIT iterations (See `?stein2`). On output, `z` is distributed across the $p$ processes in block cyclic format.

**work**

On exit, `work[0]` gives a lower bound on the workspace (`lwork`) that guarantees the user desired orthogonalization (see `orfac`). Note that this may overestimate the minimum workspace needed.

**iwork**

On exit, `iwork[0]` contains the amount of integer workspace required.

On exit, the `iwork[1]` through `iwork[p+1]` indicate the eigenvectors computed by each process. Process $i$ computes eigenvectors indexed `iwork[i+1]+1` through `iwork[i+2]`.

**ifail**

(global) Array of size $m$. On normal exit, all elements of `ifail` are zero. If one or more eigenvectors fail to converge after MAXIT iterations (as in `?stein`), then `info > 0` is returned. If $\mod(info, m+1)>0$, then for $i=1$ to $\mod(info, m+1)$, the eigenvector corresponding to the eigenvalue $w[ifail[i-1]-1]$ failed to converge ($w$ refers to the array of eigenvalues on output).

**NOTE**

\( \mod(x, y) \) is the integer remainder of \(x/y\).

**iclustr**

(global) Array of size $2*p$.

This output array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be orthogonalized due to insufficient workspace (see `lwork`, `orfac` and `info`). Eigenvectors corresponding to clusters of eigenvalues indexed `iclustr(2*I-1)` to `iclustr(2*I)`, $i = 1$ to $\mod(info, m+1)$, could not be orthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal. `iclustr` is a zero terminated array; `iclustr[2*k-1] ≠ 0` and `iclustr[2*k] = 0` if and only if $k$ is the number of clusters.
This output array contains the gap between eigenvalues whose eigenvectors could not be orthogonalized. The $\text{info}/m$ output values in this array correspond to the $\text{info}/(m+1)$ clusters indicated by the array $\text{iclustr}$. As a result, the dot product between eigenvectors corresponding to the $i$-th cluster may be as high as $(O(n)*\text{macheps})/\text{gap}[i-1]$.

If $\text{info} = 0$, the execution is successful.

If $\text{info} < 0$: If the $i$-th argument is an array and the $j$-th entry, indexed $j-1$, had an illegal value, then $\text{info} = -(i*100+j)$.

If the $i$-th argument is a scalar and had an illegal value, then $\text{info} = -i$.

If $\text{info} < 0$: if $\text{info} = -i$, the $i$-th argument had an illegal value.

If $\text{info} > 0$: if $\text{mod}(\text{info}, m+1) = i$, then $i$ eigenvectors failed to converge in MAXIT iterations. Their indices are stored in the array $\text{ifail}$. If $\text{info}/(m+1) = i$, then eigenvectors corresponding to $i$ clusters of eigenvalues could not be orthogonalized due to insufficient workspace. The indices of the clusters are stored in the array $\text{iclustr}$.

Nonsymmetric Eigenvalue Problems: ScaLAPACK Computational Routines
This section describes ScaLAPACK routines for solving nonsymmetric eigenvalue problems, computing the Schur factorization of general matrices, as well as performing a number of related computational tasks.

To solve a nonsymmetric eigenvalue problem with ScaLAPACK, you usually need to reduce the matrix to the upper Hessenberg form and then solve the eigenvalue problem with the Hessenberg matrix obtained.

Table "Computational Routines for Solving Nonsymmetric Eigenproblems" lists ScaLAPACK routines for reducing the matrix to the upper Hessenberg form by an orthogonal (or unitary) similarity transformation $A=QHQ^H$, as well as routines for solving eigenproblems with Hessenberg matrices, and multiplying the matrix after reduction.

$p?gehrd$

Reduces a general matrix to upper Hessenberg form.

Syntax

```c
void psgehrd (MKL_INT *n, MKL_INT *ilo, MKL_INT *ihi, float *a, MKL_INT *ia,
MKL_INT *ja, MKL_INT *desca, float *tau, float *work, MKL_INT *lwork, MKL_INT
*info );
```
void pdgehrd (MKL_INT *n, MKL_INT *ilo, MKL_INT *ihi, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *tau, double *work, MKL_INT *lwork, MKL_INT *info);

void pcgehrd (MKL_INT *n, MKL_INT *ilo, MKL_INT *ihi, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_Complex8 *tau, MKL_Complex8 *work, MKL_INT *lwork, MKL_INT *info);

void pzgehrd (MKL_INT *n, MKL_INT *ilo, MKL_INT *ihi, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_Complex16 *tau, MKL_Complex16 *work, MKL_INT *lwork, MKL_INT *info);

Include Files

- mkl_scalapack.h

Description

The p?gehrd function reduces a real/complex general distributed matrix sub(A) to upper Hessenberg form $H$ by an orthogonal or unitary similarity transformation $Q^*\text{sub}(A)Q = H$, where sub(A) = $A(ia:ia+n-1, ja:ja+n-1)$.

Input Parameters

- **n** (global). The order of the distributed matrix sub(A) ($n \geq 0$).
- **ilo, ihi** (global). It is assumed that sub(A) is already upper triangular in rows $ia:ia+ilo-2$ and $ia+ihi:ia+n-1$ and columns $ja:ja+ilo-2$ and $ja+ihi:ja+n-1$. (See Application Notes below).
- **a** (local) Pointer into the local memory to an array of size $ldd_a*\text{LOCc}(ja+n-1)$. On entry, this array contains the local pieces of the $n$-by-$n$ general distributed matrix sub(A) to be reduced.
- **ia, ja** (global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix $A$.
- **desca** (global and local) array of size $dlen_$. The array descriptor for the distributed matrix $A$.
- **work** (local) Workspace array of size $lwork$.
- **lwork** (local or global) size of the array $\text{work}$. $lwork$ is local input and must be at least

\[ lwork \geq \text{NB} \times \text{NB} + \text{NB} \times \max(ihip+1, ihlp+inlq) \]

where $\text{NB} = mb_a = nb_a$, $iroff_a = \text{mod}(ia-1, \text{NB})$, $icoff_a = \text{mod}(ja-1, \text{NB})$,
ioff = mod(ia+ilo-2, NB), iarow = indxg2p(ia, NB, MYROW, rsra, NPRW), ihip = numroc(ihi+iroff, NB, MYROW, iarow, NPRW),
ilrow = indxg2p(ia+ilo-1, NB, MYROW, rsra, NPRW),
ihlp = numroc(ihi-ilo+ioff+1, NB, MYROW, ilrow, NPRW),
ilcol = indxg2p(ja+ilo-1, NB, MYCOL, csrca, NPCOL),
inlq = numroc(n-ilo+ioff+1, NB, MYCOL, ilcol, NPCOL),

**NOTE**
mod(x, y) is the integer remainder of x/y.

indxg2p and numroc are ScaLAPACK tool functions; MYROW, MYCOL, NPRW and NPCOL can be determined by calling the function blacs_gridinfo.

If lwork = -1, then lwork is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

## Output Parameters

**a**

On exit, the upper triangle and the first subdiagonal of sub(A) are overwritten with the upper Hessenberg matrix $H$, and the elements below the first subdiagonal, with the array $tau$, represent the orthogonal/unitary matrix $Q$ as a product of elementary reflectors (see Application Notes below).

**tau**

(local).

Array of size at least max(ja+n-2).

The scalar factors of the elementary reflectors (see Application Notes below). Elements ja:ja+ilo-2 and ja+ihi:ja+n-2 of the global vector $tau$ are set to zero. $tau$ is tied to the distributed matrix $A$.

**work[0]**

On exit work[0] contains the minimum value of lwork required for optimum performance.

**info**

(global)

= 0: the execution is successful.

< 0: if the i-th argument is an array and the j-th entry, indexed j - 1, had an illegal value, then info = -(i*100+j); if the i-th argument is a scalar and had an illegal value, then info = -i.

## Application Notes

The matrix $Q$ is represented as a product of (ihi-ilo) elementary reflectors

$Q = H(ilo)*H(ilo+1)*...*H(ihi-1)$.

Each $H(i)$ has the form

$H(i) = i - tau*v*v'$
where \( \tau \) is a real/complex scalar, and \( \nu \) is a real/complex vector with \( \nu(1:) = 0, \nu(i+1) = 1 \) and \( \nu(ihi +1:n) = 0 \); \( \nu(i+2:ihi) \) is stored on exit in \( A(ia+ilo+1:ia+ihi-1, ja+ilo+i-2) \), and \( \tau \) in \( \tau[ja+ilo+i-3] \). The contents of \( A(ia:ia+n-1, ja:ja+n-1) \) are illustrated by the following example, with \( n = 7, ilo = 2 \) and \( ihi = 6 \):

on entry

\[
\begin{bmatrix}
a & a & a & a & a & a & a \\
ad & a & a & a & a & a \\
ad & d & a & a & a & a \\
d & d & d & a & a & a \\
a & a & a & a & a & a \\
a & d & a & a & a & a \\
a & d & d & d & d & a \\
\end{bmatrix}
\]

on exit

\[
\begin{bmatrix}
a & a & a & h & h & h & a \\
ad & h & h & h & h & h & a \\
h & h & h & h & h & h \\
v2 & h & h & h & h \\
v2 & v3 & h & h & h \\
v2 & v3 & v4 & h & h \\
\end{bmatrix}
\]

where \( a \) denotes an element of the original matrix \( \text{sub}(A) \), \( H \) denotes a modified element of the upper Hessenberg matrix \( H \), and \( vi \) denotes an element of the vector defining \( H(ja+ilo+i-2) \).

**See Also**

See Overview for details of ScaLAPACK array descriptor structures and related notations.

**p?ormhr**

Multiplies a general matrix by the orthogonal transformation matrix from a reduction to Hessenberg form determined by \( p?gehrd \).

**Syntax**

```c
void psormhr (char *side, char *trans, MKL_INT *m, MKL_INT *n, MKL_INT *ilo, MKL_INT *ihi, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *tau, float *c, MKL_INT *ic, MKL_INT *jc, MKL_INT *descc, float *work, MKL_INT *lwork, MKL_INT *info );
```
void pdormhr (char *side, char *trans, MKL_INT *m, MKL_INT *n, MKL_INT *ilo, MKL_INT *ihi, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *tau, double *c, MKL_INT *ic, MKL_INT *jc, MKL_INT *descc, double *work, MKL_INT *lwork, MKL_INT *info);

Include Files
- mkl_scalapack.h

Description
The pormhr function overwrites the general real distributed m-by-n matrix sub(C) = C(ic:ic+m-1,ja:ja+n-1) with

\[
\begin{align*}
\text{side} = 'L' & \quad \text{side} = 'R' \\
\text{trans} = 'N' & \quad Q \cdot \text{sub}(C) & \quad \text{sub}(C) \cdot Q \\
\text{trans} = 'T' & \quad Q^T \cdot \text{sub}(C) & \quad \text{sub}(C) \cdot Q^T
\end{align*}
\]

where Q is a real orthogonal distributed matrix of order \(n_q\), with \(n_q = m\) if \(\text{side} = 'L'\) and \(n_q = n\) if \(\text{side} = 'R'\).

Q is defined as the product of \(ihi-ilo\) elementary reflectors, as returned by pgehrd.

\[Q = H(ilo) H(ilo+1) \ldots H(ihi-1)\]

Input Parameters

\textit{side} (global)
- '=L': Q or \(Q^T\) is applied from the left.
- '=R': Q or \(Q^T\) is applied from the right.

\textit{trans} (global)
- '=N', no transpose, Q is applied.
- '=T', transpose, \(Q^T\) is applied.

\textit{m} (global) The number of rows in the distributed matrix sub(C) (\(m \geq 0\)).

\textit{n} (global) The number of columns in the distributed matrix sub(C) (\(n \geq 0\)).

\textit{ilo, ihi} (global)
\- \textit{ilo} and \textit{ihi} must have the same values as in the previous call of pgehrd.
\- Q is equal to the unit matrix except for the distributed submatrix \(Q(ia+ilo:ihi-1,ja+ilo:ja+ihi-1)\).
\- If \textit{side} = 'L', \(1 \leq ilo \leq ihi \leq \max(1,m)\);
\- If \textit{side} = 'R', \(1 \leq ilo \leq ihi \leq \max(1,n)\);
\- \textit{ilo} and \textit{ihi} are relative indexes.

\textit{a} (local)
\- Pointer into the local memory to an array of size \(lld_a*\text{LOC}c(ja+m-1)\) if \textit{side} = 'L', and \(lld_a*\text{LOC}c(ja+n-1)\) if \textit{side} = 'R'.
\- Contains the vectors which define the elementary reflectors, as returned by pgehrd.
\(ia, ja\) (global) The row and column indices in the global matrix \(A\) indicating the first row and the first column of the submatrix \(A\), respectively.

\(desca\) (global and local) array of size \(dlen_.\) The array descriptor for the distributed matrix \(A\).

\(tau\) (local)

Array of size \(\text{LOC}(ja+m-2)\) if \(side = 'L'\), and \(\text{LOC}(ja+n-2)\) if \(side = 'R'\).

\(\tau[j]\) contains the scalar factor of the elementary reflector \(H(j+1)\) as returned by \(p?gehrd\) \((0 \leq j < \text{size}(\tau))\). \(\tau\) is tied to the distributed matrix \(A\).

\(c\) (local)

Pointer into the local memory to an array of size \(\text{lld}_c^{*}\text{LOC}(jc+n-1)\).

Contains the local pieces of the distributed matrix \(\text{sub}(C)\).

\(ic, jc\) (global) The row and column indices in the global matrix \(C\) indicating the first row and the first column of the submatrix \(C\), respectively.

\(desccc\) (global and local) array of size \(dlen_.\) The array descriptor for the distributed matrix \(C\).

\(work\) (local)

Workspace array with size \(lwork\).

\(lwork\) (local or global)

The size of the array \(work\).

\(lwork\) must be at least \(iaa = ia + ilo; jaa = ja+ilo-1;\)

If \(side = 'L'\),

\(mi = ihi-ilo; ni = n; icc = ic + ilo; jcc = jc; lwork \geq \max((\text{nb}_a*(\text{nb}_a-1))/2, (\text{nqc}_0+\text{mpc}_0)*\text{nb}_a) + \text{nb}_a*\text{nb}_a\)

else if \(side = 'R'\),

\(mi = m; ni = ihi-ilo; icc = ic; jcc = jc + ilo; lwork \geq \max((\text{nb}_a*(\text{nb}_a-1))/2, (\text{nqc}_0+\max(\text{npa}_0+\text{numroc}(\text{numroc}(ni + \text{icoff}_c, \text{nb}_a, 0, 0, \text{NPCOL}), \text{nb}_a, 0, 0, \text{lcm}_q), \text{mpc}_0))*\text{nb}_a) + \text{nb}_a*\text{nb}_a\)

end if

where \(\text{lcm}_q = \text{lcm}/\text{NPCOL}\) with \(\text{lcm} = \text{ilcm}(\text{NPROW}, \text{NFCOL})\),

\(\text{irowf} = \text{mod}(iaa-1, \text{mb}_a),\)

\(\text{icoff}_a = \text{mod}(jaa-1, \text{nb}_a),\)

\(\text{iarow} = \text{indxg2p}(iaa, \text{mb}_a, \text{MYROW}, \text{rsr}_c, \text{NPROW}),\)

\(\text{npa}_0 = \text{numroc}(ni + \text{icoff}_a, \text{mb}_a, \text{MYROW}, \text{iarow}, \text{NPROW}),\)

\(\text{icoff}_c = \text{mod}(icc-1, \text{mb}_c), \text{icoff}_c = \text{mod}(jcc-1, \text{nb}_c),\)

\(\text{icrow} = \text{indxg2p}(icc, \text{mb}_c, \text{MYROW}, \text{rsr}_c, \text{NPROW}),\)

\(\text{icol} = \text{indxg2p}(jcc, \text{nb}_c, \text{MYCOL}, \text{csr}_c, \text{NPCOL}),\)
mpc0 = numroc(mi+iroffc, mb_c, MYROW, icrow, NPROW),

nqc0 = numroc(ni+icoffc, nb_c, MYCOL, iccol, NPCOL),

NOTE

mod(x,y) is the integer remainder of x/y.

ilcm, indxg2p and numroc are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function blacs_gridinfo.

If lwork = -1, then lwork is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

Sub(C) is overwritten by Q*sub(C), or Q'*sub(C), or sub(C)*Q', or sub(C)*Q.

work[0] On exit work[0] contains the minimum value of lwork required for optimum performance.

info (global) = 0: the execution is successful.
< 0: if the i-th argument is an array and the j-th entry, indexed j - 1, had an illegal value, then info = -(i*100+j); if the i-th argument is a scalar and had an illegal value, then info = -i.

Description

This function overwrites the general complex distributed $m$-by-$n$ matrix $\text{sub}(C) = C(i_c:i_c+m-1,j_c:j_c+n-1)$ with

$$\begin{align*}
\text{side} &= 'L' \\
\text{trans} &= 'N': Q \cdot \text{sub}(C) \\
&= 'H': Q^H \cdot \text{sub}(C)
\end{align*}$$

where $Q$ is a complex unitary distributed matrix of order $n_q$, with $n_q = m$ if $\text{side} = 'L'$ and $n_q = n$ if $\text{side} = 'R'$.

$Q$ is defined as the product of $ihi$-$ilo$ elementary reflectors, as returned by $\text{p?gehrd}$.

$Q = H(ilo) H(ilo+1) \ldots H(ihi-1)$.

Input Parameters

- **side** (global)
  - '='L': $Q$ or $Q^H$ is applied from the left.
  - '='R': $Q$ or $Q^H$ is applied from the right.

- **trans** (global)
  - '='N', no transpose, $Q$ is applied.
  - '='C', conjugate transpose, $Q^H$ is applied.

- **m** (global) The number of rows in the distributed matrix $\text{sub}(C)$ ($m \geq 0$).

- **n** (global) The number of columns in the distributed matrix $\text{sub}(C)$ ($n \geq 0$).

- **ilo, ihi** (global)
  - These must be the same parameters $ilo$ and $ihi$, respectively, as supplied to $\text{p?gehrd}$. $Q$ is equal to the unit matrix except in the distributed submatrix $Q(ia+ilo:ia+ihi-1,ja+ilo:ja+ihi-1)$.
  - If $\text{side} = 'L'$, then $1 \leq ilo \leq ihi \leq \text{max}(1,m)$.
  - If $\text{side} = 'R'$, then $1 \leq ilo \leq ihi \leq \text{max}(1,n)$

  $ilo$ and $ihi$ are relative indexes.

- **a** (local)
  - Pointer into the local memory to an array of size $lld_a*\text{LOCc}(ja+m-1)$ if $\text{side} = 'L'$, and $lld_a*\text{LOCc}(ja+n-1)$ if $\text{side} = 'R'$.
  - Contains the vectors which define the elementary reflectors, as returned by $\text{p?gehrd}$.

- **ia, ja** (global)
  - The row and column indices in the global matrix $A$ indicating the first row and the first column of the submatrix $A$, respectively.

- **desca** (global and local) array of size $\text{dlen}_\text{a}$. The array descriptor for the distributed matrix $A$.

- **tau** (local)
Array of size $\text{LOC}(ja+m-2)$, if $\text{side} = 'L'$, and $\text{LOC}(ja+n-2)$ if $\text{side} = 'R'$.

$\tau[j]$ contains the scalar factor of the elementary reflector $H(j+1)$ as returned by $\text{p?gehrd}$ ($0 \leq j < \text{size}(\tau)$). $\tau$ is tied to the distributed matrix $A$.

c
Pointer into the local memory to an array of size $\text{lld}_c \times \text{LOC}(jc+n-1)$.

Contains the local pieces of the distributed matrix $\text{sub}(C)$.

$\text{ic, jc}$

(global) The row and column indices in the global matrix $C$ indicating the first row and the first column of the submatrix $C$, respectively.

$\text{descC}$

(global and local) array of size $\text{dlen}_c$. The array descriptor for the distributed matrix $C$.

$\text{work}$

(local)

Workspace array with size $lwork$.

$lwork$

(local or global)

The size of the array $\text{work}$.

$lwork$ must be at least $iaa = ia + ilo; jaa = ja + ilo - 1$;

If $\text{side} = 'L'$, $mi = ihi - ilo; ni = n; icc = ic + ilo; jcc = jc$;

$lwork \geq \max((\text{nb}_a*(\text{nb}_a-1))/2, (\text{numroc}(\text{numroc}(ni + icoffc, \text{nb}_a, 0, 0, \text{NPCOL}), \text{nb}_a, 0, 0, \text{lcmq})), \text{mpc0}) \times \text{nb}_a) + \text{nb}_a \times \text{nb}_a$

else if $\text{side} = 'R'$,

$mi = m; ni = ihi - ilo; icc = ic; jcc = jc + ilo; lwork \geq \max((\text{nb}_a*(\text{nb}_a-1))/2, (\text{numroc}(\text{numroc}(ni + icoffc, \text{nb}_a, 0, 0, \text{NPCOL}), \text{nb}_a, 0, 0, \text{lcmq})), \text{mpc0}) \times \text{nb}_a) + \text{nb}_a \times \text{nb}_a$

end if

where $\text{lcmq} = \text{lcm}/\text{NPCOL}$ with $\text{lcm} = \text{lcm}(\text{NPROW}, \text{NPCOL})$,

$\text{iroffa} = \text{mod}(iaa-1, \text{mb}_a),$

$\text{icoffa} = \text{mod}(jaa-1, \text{nb}_a),$

$\text{iarow} = \text{indxg2p}(iaa, \text{mb}_a, \text{MYROW}, \text{rsrca}, \text{NPROW}),$

$\text{npa0} = \text{numroc}(\text{numroc}(\text{numroc}(ni + icoffa, \text{mb}_a, \text{MYROW}, \text{iarow}, \text{NPROW}), \text{nb}_a, 0, 0, \text{lcmq})), \text{mpc0}) \times \text{nb}_a) + \text{nb}_a \times \text{nb}_a$

$\text{icrow} = \text{indxg2p}(icc, \text{mb}_c, \text{MYROW}, \text{rsrcc}, \text{NPROW}),$

$\text{iccol} = \text{indxg2p}(jcc, \text{nb}_c, \text{MYCOL}, \text{csrc_c}, \text{NPCOL}),$

$\text{mpc0} = \text{numroc}(\text{numroc}(\text{numroc}(mi + iroffc, \text{mb}_c, \text{MYROW}, \text{icrow}, \text{NPROW}), \text{nb}_a, 0, 0, \text{lcmq})), \text{mpc0}) \times \text{nb}_a) + \text{nb}_a \times \text{nb}_a$

$\text{mpc0} = \text{numroc}(\text{numroc}(\text{numroc}(mi + iroffc, \text{mb}_c, \text{MYROW}, \text{icrow}, \text{NPROW}), \text{nb}_a, 0, 0, \text{lcmq})), \text{mpc0}) \times \text{nb}_a) + \text{nb}_a \times \text{nb}_a$
NOTE
mod(x, y) is the integer remainder of x/y.

ilcm, indxg2p and numroc are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function blacs_gridinfo.

If lwork = -1, then lwork is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

c
C is overwritten by Q* sub(C) or Q'*sub(C) or sub(C)*Q' or sub(C)*Q.

work[0])
On exit work[0] contains the minimum value of lwork required for optimum performance.

info (global)
= 0: the execution is successful.
< 0: if the i-th argument is an array and the j-th entry, indexed j - 1, had an illegal value, then info = -((i*100+j)); if the i-th argument is a scalar and had an illegal value, then info = -i.

Include Files

• mkl_scalapack.h

Description

This is an auxiliary function used to find the Schur decomposition and/or eigenvalues of a matrix already in Hessenberg form from columns ilo and ihi.

NOTE

These restrictions apply to the use of p?lahqr:

• The code requires the distributed block size to be square and at least 6.
• The code requires A and Z to be distributed identically and have identical contexts.
• The matrix A must be in upper Hessenberg form. If elements below the subdiagonal are non-zero, the resulting transformations can be nonsimilar.
• All eigenvalues are distributed to all the nodes.

Input Parameters

wantt (global)
If wantt≠ 0, the full Schur form T is required;
If wantt = 0, only eigenvalues are required.

wantz (global)
If wantz≠ 0, the matrix of Schur vectors Z is required;
If wantz = 0, Schur vectors are not required.

n (global) The order of the Hessenberg matrix A (and z if wantz is non-zero). n≥0.

ило, ihi (global)
It is assumed that A is already upper quasi-triangular in rows and columns ihi+1:n, and that A(ilo, ilo-1) = 0 (unless ilo = 1). p?lahqr works primarily with the Hessenberg submatrix in rows and columns ilo to ihi, but applies transformations to all of H if wantt is non-zero. 1≤ilo≤max(1,ihi); ihi ≤ n.

a (global)
Array, of size lld_a * LOCc(n). On entry, the upper Hessenberg matrix A.

desca (global and local) array of size dlen_. The array descriptor for the distributed matrix A.

iloz, ihiz (global) Specify the rows of the matrix Z to which transformations must be applied if wantz is non-zero. 1≤iloz≤ilo; ihi≤ihiz≤n.
Array. If wantz is non-zero, on entry z must contain the current matrix Z of transformations accumulated by pdhseqr. If wantz is zero, z is not referenced.

descz
(global and local) array of size dlen_. The array descriptor for the distributed matrix Z.

work
(local)
Workspace array with size lwork.

lwork
(local) The size of work. lwork is assumed big enough so that lwork≥3*n + max(2*max(lld_z, lld_a) + 2*LOCq(n), 7*ceil(n/hbl)/lcm(NPROW, NPCOL))).

If lwork = -1, then work[0] gets set to the above number and the code returns immediately.

iwork
(global and local) array of size ilwork. Not referenced and can be NULL pointer.

ilwork
(local) This holds some of the iblk integer arrays. Not referenced and can be NULL pointer.

Output Parameters

a
On exit, if wantt is non-zero, A is upper quasi-triangular in rows and columns ilo:ihi, with any 2-by-2 or larger diagonal blocks not yet in standard form. If wantt is zero, the contents of A are unspecified on exit.

work[0]
On exit work[0] contains the minimum value of lwork required for optimum performance.

wr, wi
(global replicated output)
Arrays of size n each. The real and imaginary parts, respectively, of the computed eigenvalues ilo to ihi are stored in the corresponding elements of wr and wi. If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of wr and wi, say the i-th and (i+1)-th, with wi[i-1]> 0 and wi[i] < 0. If wantt is zero, the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in A. A may be returned with larger diagonal blocks until the next release.

w
(global replicated output)
Array of size n. The computed eigenvalues ilo to ihi are stored in the corresponding elements of w. If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of w, say the i-th and (i+1)-th, with w[i-1]> 0 and w[i] < 0. If wantt is zero, the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in A. A may be returned with larger diagonal blocks until the next release.

z
On exit z has been updated; transformations are applied only to the submatrix Z(ilo:ihi, ilo:ihi).

info
(global)
= 0: the execution is successful.
< 0: the parameter number - info is incorrect or inconsistent
> 0: p?lahqr failed to compute all the eigenvalues ilo to ihi in a total of
30*(ihi-ilo+1) iterations; if info = i, elements i+1 to ihi of wr and wi
contain the eigenvalues that have been successfully computed.

const MKL_INT* descvr, const MKL_INT* mm, MKL_INT* m, float* work, MKL_INT* info);

Include Files
• mkl_scalapack.h

Description
p?trevc computes some or all of the right and/or left eigenvectors of a complex upper triangular matrix T in
parallel.

The right eigenvector x and the left eigenvector y of T corresponding to an eigenvalue w are defined by:
T*x = w*x,
y'*T = w*y'
where y' denotes the conjugate transpose of the vector y.
If all eigenvectors are requested, the routine may either return the matrices X and/or Y of right or left
eigenvectors of T, or the products Q*X and/or Q*Y, where Q is an input unitary matrix. If T was obtained
from the Schur factorization of an original matrix A = Q*T*Q', then Q*X and Q*Y are the matrices of right or
left eigenvectors of A.

Input Parameters

side (global)
howmny
(global)
= 'A': compute all right and/or left eigenvectors;
= 'B': compute all right and/or left eigenvectors, and backtransform them
using the input matrices supplied in vr and/or vl;
= 'S': compute selected right and/or left eigenvectors, specified by the
logical array select.

select
(global)
Array, size (n)
If howmny = 'S', select specifies the eigenvectors to be computed.
If howmny = 'A' or 'B', select is not referenced. To select the eigenvector
 corresponding to the j-th eigenvalue, select[j - 1] must be set to non-zero.

n
(global)
The order of the matrix T. n >= 0.

t
(local)
Array, size lld_t*LOCc(n).
The upper triangular matrix T. T is modified, but restored on exit.

desct
(global and local)
Array of size dlen_.
The array descriptor for the distributed matrix T.

vl
(local)
Array, size (descvl(lld_), mm)
On entry, if side = 'L' or 'B' and howmny = 'B', vl must contain an n-by-n
matrix Q (usually the unitary matrix Q of Schur vectors returned
by ?hseqr).

descvl
(global and local)
Array of size dlen_.
The array descriptor for the distributed matrix VL.

vr
(local)
Array, size descvr(lld_)*mm.
On entry, if side = 'R' or 'B' and howmny = 'B', vr must contain an n-by-n
matrix Q (usually the unitary matrix Q of Schur vectors returned
by ?hseqr).

descvr
(global and local)
Array of size dlen_.

= 'R': compute right eigenvectors only;
= 'L': compute left eigenvectors only;
= 'B': compute both right and left eigenvectors.
The array descriptor for the distributed matrix \( VR \).

\( mm \) (global)

The number of columns in the arrays \( vl \) and/or \( vr \). \( mm \geq m \).

\( work \) (local)

Array, size \( \left( 2 \times \text{desct}(lld_\_\_ ) \right) \)

Additional workspace may be required if \( p\text{lattrs} \) is updated to use \( work \).

\( rwork \) (local)

Array, size \( \left( \text{desct}(lld_\_\_ ) \right) \)

**Output Parameters**

\( t \)

The upper triangular matrix \( T \). \( T \) is modified, but restored on exit.

\( vl \)

On exit, if \( side = 'L' \) or \( 'B' \), \( vl \) contains:

- If \( howmny = 'A' \), the matrix \( Y \) of left eigenvectors of \( T \);
- If \( howmny = 'B' \), the matrix \( Q^*Y \);
- If \( howmny = 'S' \), the left eigenvectors of \( T \) specified by \( select \), stored consecutively in the columns of \( vl \), in the same order as their eigenvalues. If \( side = 'R' \), \( vl \) is not referenced.

\( vr \)

On exit, if \( side = 'R' \) or \( 'B' \), \( vr \) contains:

- If \( howmny = 'A' \), the matrix \( X \) of right eigenvectors of \( T \);
- If \( howmny = 'B' \), the matrix \( Q^*X \);
- If \( howmny = 'S' \), the right eigenvectors of \( T \) specified by \( select \), stored consecutively in the columns of \( vr \), in the same order as their eigenvalues. If \( side = 'L' \), \( vr \) is not referenced.

\( m \) (global)

The number of columns in the arrays \( vl \) and/or \( vr \) actually used to store the eigenvectors. If \( howmny = 'A' \) or \( 'B' \), \( m \) is set to \( n \). Each selected eigenvector occupies one column.

\( info \) (global)

- \( = 0 \): successful exit
- \( < 0 \): if \( info = -i \), the i-th argument had an illegal value

**Application Notes**

The algorithm used in this program is basically backward (forward) substitution. Scaling should be used to make the code robust against possible overflow. But scaling has not yet been implemented in \( p\text{lattrs} \) which is called by this routine to solve the triangular systems. \( p\text{lattrs} \) just calls \( p\text{trsv} \).

Each eigenvector is normalized so that the element of largest magnitude has magnitude 1; here the magnitude of a complex number \((x,y)\) is taken to be \( |x| + |y| \).

**Singular Value Decomposition: ScaLAPACK Driver Routines**

This section describes ScaLAPACK routines for computing the singular value decomposition (SVD) of a general \( m \)-by-\( n \) matrix \( A \) (see "Singular Value Decomposition" in LAPACK chapter).
To find the SVD of a general matrix $A$, this matrix is first reduced to a bidiagonal matrix $B$ by a unitary (orthogonal) transformation, and then SVD of the bidiagonal matrix is computed. Note that the SVD of $B$ is computed using the LAPACK routine `?bdsqr`.

Table "Computational Routines for Singular Value Decomposition (SVD)" lists ScaLAPACK computational routines for performing this decomposition.

### Computational Routines for Singular Value Decomposition (SVD)

#### p?gebrd

*Reduces a general matrix to bidiagonal form.*

**Syntax**

```c
void psgebrd (MKL_INT *m, MKL_INT *n, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *d, float *e, float *tauq, float *taup, float *work, MKL_INT *lwork, MKL_INT *info);
void pdgebrd (MKL_INT *m, MKL_INT *n, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *d, double *e, double *tauq, double *taup, double *work, MKL_INT *lwork, MKL_INT *info);
void pcgebrd (MKL_INT *m, MKL_INT *n, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *d, float *e, MKL_Complex8 *tauq, MKL_Complex8 *taup, MKL_Complex8 *work, MKL_INT *lwork, MKL_INT *info);
void pzgebrd (MKL_INT *m, MKL_INT *n, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *d, double *e, MKL_Complex16 *tauq, MKL_Complex16 *taup, MKL_Complex16 *work, MKL_INT *lwork, MKL_INT *info);
```

**Include Files**

- mkl_scalapack.h

**Description**

The p?gebrd function reduces a real/complex general $m$-by-$n$ distributed matrix $\text{sub}(A) = A(\text{i}a:\text{i}a+m-1, j\text{a}:j\text{a}+n-1)$ to upper or lower bidiagonal form $B$ by an orthogonal/unitary transformation:

$$Q^*\text{sub}(A)*P = B.$$ 

If $m \geq n$, $B$ is upper bidiagonal; if $m < n$, $B$ is lower bidiagonal.

**Input Parameters**

- $m$ (global) The number of rows in the distributed matrix $\text{sub}(A)$ ($m \geq 0$).
- $n$ (global) The number of columns in the distributed matrix $\text{sub}(A)$ ($n \geq 0$).
- $a$ (local)
  
  Real pointer into the local memory to an array of size $\text{lld}_a*\text{LOCc}(j\text{a}+n-1)$.

  On entry, this array contains the distributed matrix sub $(A)$.
- $\text{i}a, j\text{a}$ (global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the submatrix $A$, respectively.
desca (global and local) array of size dlen_. The array descriptor for the distributed matrix A.

work (local) Workspace array of size lwork.

lwork (local or global) size of work, must be at least:
\[ \text{lwork} \geq \text{nb} \times (\text{mpa} + \text{nqa} + 1) + \text{nqa} \]
where \( \text{nb} = \text{mb}_a = \text{nb}_a \),
\[ \text{iroffa} = \text{mod}(\text{ia}-1, \text{nb}), \]
\[ \text{icoffa} = \text{mod}(\text{ja}-1, \text{nb}), \]
\[ \text{iarow} = \text{indxg2p}(\text{ia}, \text{nb}, \text{MYROW}, \text{rsrc}_a, \text{NPROW}), \]
\[ \text{iacol} = \text{indxg2p}(\text{ja}, \text{nb}, \text{MYCOL}, \text{csrc}_a, \text{NPCOL}), \]
\[ \text{mpa} = \text{numroc}(\text{m} + \text{iroffa}, \text{nb}, \text{MYROW}, \text{iarow}, \text{NPROW}), \]
\[ \text{nqa} = \text{numroc}(\text{n} + \text{icoffa}, \text{nb}, \text{MYCOL}, \text{iacol}, \text{NPCOL}), \]

**NOTE**
\( \text{mod}(x, y) \) is the integer remainder of \( x/y \).

indxg2p and numroc are ScALAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function blacs_gridinfo.

If \( \text{lwork} = -1 \), then \( \text{lwork} \) is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

**Output Parameters**

\( a \)
On exit, if \( m \geq n \), the diagonal and the first superdiagonal of sub(\( A \)) are overwritten with the upper bidiagonal matrix \( B \); the elements below the diagonal, with the array taug, represent the orthogonal/unitary matrix \( Q \) as a product of elementary reflectors, and the elements above the first superdiagonal, with the array taup, represent the orthogonal matrix \( P \) as a product of elementary reflectors. If \( m < n \), the diagonal and the first subdiagonal are overwritten with the lower bidiagonal matrix \( B \); the elements below the first subdiagonal, with the array taug, represent the orthogonal/unitary matrix \( Q \) as a product of elementary reflectors, and the elements above the diagonal, with the array taup, represent the orthogonal matrix \( P \) as a product of elementary reflectors. See Application Notes below.

\( d \)
Array of size \( \text{LOCc}(ja+\min(m,n)-1) \) if \( m \geq n \) and \( \text{LOCr}(ia+\min(m,n)-1) \) otherwise. The distributed diagonal elements of the bidiagonal matrix \( B \):
\[ d[i] = A(i+1,i+1), \quad 0 \leq i < \text{size}(d). \]
\( d \) is tied to the distributed matrix \( A \).

\( e \)
(local)
Array of size $\text{LOCr}(i_a+\min(m,n)-1)$ if $m \geq n$; $\text{LOCc}(j_a+\min(m,n)-2)$ otherwise. The distributed off-diagonal elements of the bidiagonal distributed matrix $B$:

If $m \geq n$, $e[i] = A(i+1,i+2)$ for $i = 0,1,\ldots, n-2$; if $m < n$, $e[i] = A(i+2,i+1)$ for $i = 0,1,\ldots, m-2$. $e$ is tied to the distributed matrix $A$.

$\tau_q, \tau_p$

(local)

Arrays of size $\text{LOCc}(j_a+\min(m,n)-1)$ for $\tau_q$ and $\text{LOCr}(i_a+\min(m,n)-1)$ for $\tau_p$. Contain the scalar factors of the elementary reflectors that represent the orthogonal/unitary matrices $Q$ and $P$, respectively. $\tau_q$ and $\tau_p$ are tied to the distributed matrix $A$. See Application Notes below.

work[0]

On exit work[0] contains the minimum value of lwork required for optimum performance.

info

(global)

$= 0$: the execution is successful.

$< 0$: if the $i$-th argument is an array and the $j$-th entry, indexed $j-1$, had an illegal value, then $\text{info} = -(\text{INFO}+j)$; if the $i$-th argument is a scalar and had an illegal value, then $\text{info} = -i$.

Application Notes

The matrices $Q$ and $P$ are represented as products of elementary reflectors:

If $m \geq n$,

$Q = H(1)*H(2)*\ldots*H(n)$, and $P = G(1)*G(2)*\ldots*G(n-1)$.

Each $H(i)$ and $G(i)$ has the form:

$H(i) = i - \tau_q * v * v'$ and $G(i) = i - \tau_p * u * u'$

where $\tau_q$ and $\tau_p$ are real/complex scalars, and $v$ and $u$ are real/complex vectors;

$v(1:i-1) = 0$, $v(i) = 1$, and $v(i+1:m)$ is stored on exit in $A(i_a+i:i_a+m-1,j_a+i-1)$;

$u(1:i) = 0$, $u(i+1) = 1$, and $u(i+2:n)$ is stored on exit in $A(i_a+i-1,j_a+i+1:j_a+n-1)$;

$\tau_q$ is stored in $\tau_q[a+i-2]$ and $\tau_p$ in $\tau_p[a+i-2]$.

If $m < n$,

$Q = H(1)*H(2)*\ldots*H(m-1)$, and $P = G(1)*G(2)*\ldots*G(m)$

Each $H(i)$ and $G(i)$ has the form:

$H(i) = i - \tau_q * v * v'$ and $G(i) = i - \tau_p * u * u'$

here $\tau_q$ and $\tau_p$ are real/complex scalars, and $v$ and $u$ are real/complex vectors;

$v(1:i) = 0$, $v(i+1) = 1$, and $v(i+2:m)$ is stored on exit in $A(i_a+i:i_a+m-1,j_a+i-1)$;

$u(1:i-1) = 0$, $u(i) = 1$, and $u(i+1:n)$ is stored on exit in $A(i_a+i-1,j_a+i+1:j_a+n-1)$;

$\tau_q$ is stored in $\tau_q[a+i-2]$ and $\tau_p$ in $\tau_p[a+i-2]$.

The contents of sub($A$) on exit are illustrated by the following examples:

$m = 6$ and $n = 5 (m > n)$:
where $d$ and $e$ denote diagonal and off-diagonal elements of $B$, $v_i$ denotes an element of the vector defining $H(i)$, and $u_i$ an element of the vector defining $G(i)$.

Overview for details of ScaLAPACK array descriptor structures and related notations.

**p?ormbr**

Multiplies a general matrix by one of the orthogonal matrices from a reduction to bidiagonal form determined by p?gebrd.

**Syntax**

```c
void psormbr (char *vect, char *side, char *trans, MKL_INT *m, MKL_INT *n, MKL_INT *k, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *tau, float *c, MKL_INT *ic, MKL_INT *jc, MKL_INT *descb, float *work, MKL_INT *lwork, MKL_INT *info);
void pdormbr (char *vect, char *side, char *trans, MKL_INT *m, MKL_INT *n, MKL_INT *k, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *tau, double *c, MKL_INT *ic, MKL_INT *jc, MKL_INT *descb, double *work, MKL_INT *lwork, MKL_INT *info);
```

**Include Files**

- mkl_scalapack.h

**Description**

If vect = 'Q', the p?ormbr function overwrites the general real distributed $m$-by-$n$ matrix sub($C$) = $C(\text{ic}:	ext{ic} + m-1, \text{jc}:	ext{jc} + n-1)$ with

$$side = 'L' \quad \quad side = 'R'$$
### Input Parameters

**vect** (global)
- If `vect = 'Q'`, then $Q$ or $Q^T$ is applied.
- If `vect = 'P'`, then $P$ or $P^T$ is applied.

**side** (global)
- If `side = 'L'`, then $Q$ or $Q^T$, $P$ or $P^T$ is applied from the left.
- If `side = 'R'`, then $Q$ or $Q^T$, $P$ or $P^T$ is applied from the right.

**trans** (global)
- If `trans = 'N'`, no transpose, $Q$ or $P$ is applied.
- If `trans = 'T'`, then $Q^T$ or $P^T$ is applied.

**m** (global) The number of rows in the distributed matrix sub(C).

**n** (global) The number of columns in the distributed matrix sub(C).

**k** (global)
- If `vect = 'Q'`, the number of columns in the original distributed matrix reduced by `pgebrd`.
- If `vect = 'P'`, the number of rows in the original distributed matrix reduced by `pgebrd`.

**Constraints:** $k \geq 0$. 

**a** (local)
Pointer into the local memory to an array of size lld_a * LOCC(ja + min(nq,k)-1) if vect='Q', and lld_a * LOCC(ja+nq-1) if vect = 'P'.

nq = m if side = 'L', and nq = n otherwise.

The vectors that define the elementary reflectors H(i) and G(i), whose products determine the matrices Q and P, as returned by p?gebrd.

If vect = 'Q', lld_a≥max(1, LOCr(ia+nq-1));
If vect = 'P', lld_a≥max(1, LOCr(ia+min(nq, k)-1)).

ia, ja (global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A, respectively.

desca (global and local) array of size dlen_. The array descriptor for the distributed matrix A.

tau (local)
Array of size LOCC(ja+min(nq, k)-1), if vect = 'Q', and LOCr(ia +min(nq, k)-1), if vect = 'P'.

tau[i] must contain the scalar factor of the elementary reflector H(i+1) or G(i+1)
which determines Q or P, as returned by pdgebrd in its array argument tauq or taup. tau is tied to the distributed matrix A.

c (local)
Pointer into the local memory to an array of size lld_c*LOCC(jc+n-1).
Contains the local pieces of the distributed matrix sub (C).

ic, jc (global) The row and column indices in the global matrix C indicating the first row and the first column of the submatrix C, respectively.

desc c (global and local) array of size dlen_. The array descriptor for the distributed matrix C.

work (local)
Workspace array of size lwork.

lwork (local or global) size of work, must be at least:

If side = 'L'
  nq = m;
  if ((vect = 'Q' and nq≥k) or (vect is not equal to 'Q' and nq>k)),
  iaa=ia; jaa=ja; mi=m; ni=n; icc=ic; jcc=jc;
else
  iaa= ia+1; jaa=ja; mi=m-1; ni=n; icc=ic+1; jcc= jc;
end if
else
If side = 'R', nq = n;
if((vect = 'Q' and nq≥k) or (vect is not equal to 'Q' and nq>k)),

\( i_{aa} = i_a; \ j_{aa} = j_a; \ m_i = m; \ n_i = n; \ i_{cc} = i_c; \ j_{cc} = j_c; \)

else

\( i_{aa} = i_a; \ j_{aa} = j_a + 1; \ m_i = m; \ n_i = n - 1; \ i_{cc} = i_c; \ j_{cc} = j_c + 1; \)

end if

end if

If \( \text{vect} = 'Q' \),

If \( \text{side} = 'L' \), \( l_{work} \geq \max((n_b_a \times (n_b_a - 1))/2, (n_q_c_0 + m_p_c_0) \times n_b_a) + n_b_a \times n_b_a \)

else if \( \text{side} = 'R' \),

\( l_{work} \geq \max((n_b_a \times (n_b_a - 1))/2, (n_q_c_0 + n_p_a_0) + \text{numroc}(\text{numroc}(n_i + i_{coff_a}, n_b_a, 0, 0, \text{NPCOL}), n_b_a, 0, 0, l_{cm}, m_p_c_0) \times n_b_a) + n_b_a \times n_b_a \)

end if

else if \( \text{vect} \) is not equal to \( 'Q' \), if \( \text{side} = 'L' \),

\( l_{work} \geq \max((m_b_a \times (m_b_a - 1))/2, (m_p_c_0 + \max(m_q_a_0 + \text{numroc}(\text{numroc}(m_i + i_{roff_c}, m_b_a, 0, 0, \text{NPROW}), m_b_a, 0, 0, l_{cmp}), n_q_c_0) \times m_b_a) + m_b_a \times m_b_a \)

else if \( \text{side} = 'R' \),

\( l_{work} \geq \max((m_b_a \times (m_b_a - 1))/2, (m_p_c_0 + n_q_c_0) \times m_b_a) + m_b_a \times m_b_a \)

end if

end if

where \( l_{cmp} = l_{cm}/\text{NPROW}, \ l_{cmq} = l_{cm}/\text{NPCOL} \), with \( l_{cm} = \text{lcm}(\text{NPROW}, \ \text{NPCOL}) \),

\( i_{roff_a} = \text{mod}(i_{aa}-1, m_b_a) \),

\( i_{coff_a} = \text{mod}(j_{aa}-1, n_b_a) \),

\( i_{arow} = \text{indxg2p}(i_{aa}, m_b_a, \ \text{MYROW}, \ rsrc_a, \ \text{NPROW}) \),

\( i_{icol} = \text{indxg2p}(j_{aa}, n_b_a, \ \text{MYCOL}, \ csrc_a, \ \text{NPCOL}) \),

\( m_q_a_0 = \text{numroc}(n_i + i_{coff_a}, n_b_a, \ \text{MYCOL}, \ i_{arow}, \ \text{NPROW}) \),

\( n_p_a_0 = \text{numroc}(n_i + i_{roff_a}, m_b_a, \ \text{MYROW}, \ i_{arlo}, \ \text{NPROW}) \),

\( i_{roff_c} = \text{mod}(i_{cc}-1, m_b_c) \),

\( i_{coff_c} = \text{mod}(j_{cc}-1, n_b_c) \),

\( i_{icrow} = \text{indxg2p}(i_{cc}, m_b_c, \ \text{MYROW}, \ rsrc_c, \ \text{NPROW}) \),

\( i_{icol} = \text{indxg2p}(j_{cc}, n_b_c, \ \text{MYCOL}, \ csrc_c, \ \text{NPCOL}) \),

\( m_p_c_0 = \text{numroc}(m_i + i_{roff_c}, m_b_c, \ \text{MYROW}, \ i_{icrow}, \ \text{NPROW}) \),

\( n_q_c_0 = \text{numroc}(n_i + i_{coff_c}, n_b_c, \ \text{MYCOL}, \ i_{icol}, \ \text{NPCOL}) \),

**NOTE**

\( \text{mod}(x, y) \) is the integer remainder of \( x/y \).
indxg2p and numroc are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function blacs_gridinfo.

If lwork = -1, then lwork is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

\text{c}

On exit, if vect='Q', sub(C) is overwritten by Q*sub(C), or Q'*sub(C), or sub(C)*Q', or sub(C)*Q; if vect='P', sub(C) is overwritten by P*sub(C), or P'*sub(C), or sub(C)*P, or sub(C)*P'.

work[0]

On exit work[0] contains the minimum value of lwork required for optimum performance.

\text{info}

(global)

\text{info} = 0: the execution is successful.

\text{info} < 0: if the \text{i}-th argument is an array and the \text{j}-th entry, indexed \text{j} - 1, had an illegal value, then \text{info} = -(\text{i}*100+\text{j}); if the \text{i}-th argument is a scalar and had an illegal value, then \text{info} = -\text{i}.

See Also

\text{p?unmbr}

Multiplies a general matrix by one of the unitary transformation matrices from a reduction to bidiagonal form determined by \text{p?gebrd}.

Syntax

\begin{verbatim}
void pcunmbr (char *vect, char *side, char *trans, MKL_INT *m, MKL_INT *n, MKL_INT *k, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_Complex8 *tau, MKL_Complex8 *c, MKL_INT *ic, MKL_INT *jc, MKL_INT *descc, MKL_Complex8 *work, MKL_INT *lwork, MKL_INT *info);
void pzunmbr (char *vect, char *side, char *trans, MKL_INT *m, MKL_INT *n, MKL_INT *k, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_Complex16 *tau, MKL_Complex16 *c, MKL_INT *ic, MKL_INT *jc, MKL_INT *descc, MKL_Complex16 *work, MKL_INT *lwork, MKL_INT *info);
\end{verbatim}

Include Files

- mkl_scalapack.h

Description

If vect = 'Q', the \text{p?unmbr} function overwrites the general complex distributed \text{m}-by-\text{n} matrix sub(C) = C(\text{ic}:\text{ic}+\text{m}-1,\text{jc}:\text{jc}+\text{n}-1) with

\begin{align*}
\text{trans} = 'N': & \quad \text{Q*sub(C)} & \quad \text{trans} = 'C': & \quad \text{Q}^\dagger*\text{sub(C)} \\
\text{trans} = 'L': & \quad \text{Q} & \quad \text{trans} = 'R': & \quad \text{Q}^\dagger
\end{align*}
If vect = 'P', the function overwrites sub(C) with

\[ \begin{align*}
\text{side} &= \text{'L'} & \text{side} &= \text{'R'} \\
\text{trans} &= \text{'N'}: & P^{*}\text{sub}(C) & & \text{sub}(C)^{*}P \\
\text{trans} &= \text{'C'}: & P^{H}\text{sub}(C) & & \text{sub}(C)^{*}P^{H}
\end{align*} \]

Here Q and PH are the unitary distributed matrices determined by p?gebrd when reducing a complex distributed matrix \( A(ia:* , ja:* ) \) to bidiagonal form: \( A(ia:* , ja:* ) = Q^{*}B^{*}P^{H} \).

Q and PH are defined as products of elementary reflectors \( H(i) \) and \( G(i) \) respectively.

Let \( nq = m \) if side = 'L' and \( nq = n \) if side = 'R'. Therefore \( nq \) is the order of the unitary matrix \( Q \) or \( P^{H} \) that is applied.

If vect = 'Q', \( A(ia:* , ja:* ) \) is assumed to have been an \( nq \)-by-\( k \) matrix:

1. If \( nq \geq k \), \( Q = H(1)H(2)\ldots H(k) \);
2. If \( nq < k \), \( Q = H(1)H(2)\ldots H(nq-1) \).

If vect = 'P', \( A(ia:* , ja:* ) \) is assumed to have been a \( k \)-by-\( nq \) matrix:

1. If \( k < nq \), \( P = G(1)G(2)\ldots G(k) \);
2. If \( k \geq nq \), \( P = G(1)G(2)\ldots G(nq-1) \).

**Input Parameters**

**vect**

(global)

- If vect = 'Q', then Q or \( Q^{H} \) is applied.
- If vect = 'P', then P or \( P^{H} \) is applied.

**side**

(global)

- If side = 'L', then Q or \( Q^{H} \), P or \( P^{H} \) is applied from the left.
- If side = 'R', then Q or \( Q^{H} \), P or \( P^{H} \) is applied from the right.

**trans**

(global)

- If trans = 'N', no transpose, Q or P is applied.
- If trans = 'C', conjugate transpose, \( Q^{H} \) or \( P^{H} \) is applied.

**m**

(global) The number of rows in the distributed matrix sub (C) \( m \geq 0 \).

**n**

(global) The number of columns in the distributed matrix sub (C) \( n \geq 0 \).

**k**

(global)

- If vect = 'Q', the number of columns in the original distributed matrix reduced by p?gebrd;
- If vect = 'P', the number of rows in the original distributed matrix reduced by p?gebrd.

Constraints: \( k \geq 0 \).

**a**

(local)

Pointer into the local memory to an array of size \( lld_{a} \times \text{LOCc}(ja + \min(nq,k)-1) \) if vect = 'Q', and \( lld_{a} \times \text{LOCc}(ja+nq-1) \) if vect = 'P'.

- \( nq = m \) if side = 'L', and \( nq = n \) otherwise.
The vectors that define the elementary reflectors \( H(i) \) and \( G(i) \), whose products determine the matrices \( Q \) and \( P \), as returned by \texttt{pgebrd}.

If \( \text{vect} = 'Q' \), \( \text{lld}_a \geq \max(1, \text{LOCr}(i\text{a} + nq - 1)) \);
If \( \text{vect} = 'P' \), \( \text{lld}_a \geq \max(1, \text{LOCr}(i\text{a} + \min(nq, k) - 1)) \).

\( ia, ja \) (global) The row and column indices in the global matrix \( A \) indicating the first row and the first column of the submatrix \( A \), respectively.

\( \text{desca} \) (global and local) array of size \( dlen_\). The array descriptor for the distributed matrix \( A \).

\( \text{tau} \) (local)
Array of size \( \text{LOCc}(ja + \min(nq, k) - 1) \), if \( \text{vect} = 'Q' \), and \( \text{LOCr}(ia + \min(nq, k) - 1) \), if \( \text{vect} = 'P' \).
\( \text{tau}[i] \) must contain the scalar factor of the elementary reflector \( H(i+1) \) or \( G(i+1) \), which determines \( Q \) or \( P \), as returned by \texttt{pgebrd} in its array argument \text{taqu} or \text{taup}. \( \text{tau} \) is tied to the distributed matrix \( A \).

\( c \) (local)
Pointer into the local memory to an array of size \( lld_c*\text{LOCc}(jc+n-1) \).
Contains the local pieces of the distributed matrix sub \( (C) \).

\( ic, jc \) (global) The row and column indices in the global matrix \( C \) indicating the first row and the first column of the submatrix \( C \), respectively.

\( \text{descC} \) (global and local) array of size \( dlen_\). The array descriptor for the distributed matrix \( C \).

\( \text{work} \) (local)
Workspace array of size \( lwork \).

\( lwork \) (local or global) size of \( \text{work} \), must be at least:
If \( \text{side} = 'L' \)
\( nq = m; \)
if \( ((\text{vect} = 'Q' \text{ and } nq \geq k) \text{ or (vect is not equal to 'Q' and } nq>k)) \),
\( iaa = ia; jaa = ja; mi = m; ni = n; icc = ic; jcc = jc; \)
else
\( iaa = ia+1; jaa = ja; mi = m-1; ni = n; icc = ic+1; jcc = jc; \)
end if
else
If \( \text{side} = 'R', nq = n; \)
if \( ((\text{vect} = 'Q' \text{ and } nq \geq k) \text{ or (vect is not equal to 'Q' and } nq>k)) \),
\( iaa = ia; jaa = ja; mi = m; ni = n; icc = ic; jcc = jc; \)
else
\( iaa = ia; jaa = ja+1; mi = m; ni = n-1; icc = ic; jcc = jc+1; \)
end if
end if

Generalized Symmetric-Definite Eigenvalue Problems: ScALAPACK Computational Routines

This section describes ScALAPACK routines that allow you to reduce the generalized symmetric-definite eigenvalue problems (see Generalized Symmetric-Definite Eigenvalue Problems in LAPACK chapters) to standard symmetric eigenvalue problem $Cy = \lambda y$, which you can solve by calling ScALAPACK routines described earlier in this chapter (see Symmetric Eigenproblems).

Table "Computational Routines for Reducing Generalized Eigenproblems to Standard Problems" lists these routines.

$p?sygst$

Reduces a real symmetric-definite generalized eigenvalue problem to the standard form.

Syntax

void pssygst (MKL_INT *ibtype , char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb , float *scale , MKL_INT *info );

void pdsygst (MKL_INT *ibtype , char *uplo , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb , double *scale , MKL_INT *info );
Include Files

- mkl_scalapack.h

Description

The `p?sygst` function reduces real symmetric-definite generalized eigenproblems to the standard form.

In the following sub\((A)\) denotes \(A(ia:ia+n-1, ja:ja+n-1)\) and sub\((B)\) denotes \(B(ib:ib+n-1, jb:jb+n-1)\).

If \(ibtype = 1\), the problem is

\[ sub(A)^*x = \lambda*sub(B)^*x, \]

and \(sub(A)\) is overwritten by \(\text{inv}(U^T)*sub(A)^*\text{inv}(U)\), or \(\text{inv}(L)*sub(A)^*\text{inv}(L^T)\).

If \(ibtype = 2\) or \(3\), the problem is

\[ sub(A)^*sub(B)^*x = \lambda*x, \]
\[ \text{or} \quad sub(B)^*sub(A)^*x = \lambda*x, \]

and \(sub(A)\) is overwritten by \(U*sub(A)^*U^T\), or \(L^T*sub(A)^*L\).

\(sub(B)\) must have been previously factorized as \(U^T*U\) or \(L*L^T\) by \(p?potrf\).

Input Parameters

\(ibtype\)  
(global) Must be 1 or 2 or 3.
- If \(itype = 1\), compute \(\text{inv}(U^T)*sub(A)^*\text{inv}(U)\), or \(\text{inv}(L)*sub(A)^*\text{inv}(L^T)\);
- If \(itype = 2\) or \(3\), compute \(U*sub(A)^*U^T\), or \(L^T*sub(A)^*L\).

\(uplo\)  
(global) Must be '\(U'\) or '\(L'\).
- If \(uplo = 'U'\), the upper triangle of \(sub(A)\) is stored and \(sub(B)\) is factored as \(U^T*U\).
- If \(uplo = 'L'\), the lower triangle of \(sub(A)\) is stored and \(sub(B)\) is factored as \(L*L^T\).

\(n\)  
(global) The order of the matrices \(sub(A)\) and \(sub(B)\) \((n \geq 0)\).

\(a\)  
(local)
Pointer into the local memory to an array of size \(lld_a*LOCc(ja+n-1)\). On entry, the array contains the local pieces of the \(n\)-by-\(n\) symmetric distributed matrix \(sub(A)\).
- If \(uplo = 'U'\), the leading \(n\)-by-\(n\) upper triangular part of \(sub(A)\) contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced.
- If \(uplo = 'L'\), the leading \(n\)-by-\(n\) lower triangular part of \(sub(A)\) contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced.

\(ia, ja\)  
(global) The row and column indices in the global matrix \(A\) indicating the first row and the first column of the submatrix \(A\), respectively.

\(desca\)  
(global and local) array of size \(dlen_\). The array descriptor for the distributed matrix \(A\).

\(b\)  
(local)
Pointer into the local memory to an array of size $ld_b*LOCc(jb+n-1)$. On entry, the array contains the local pieces of the triangular factor from the Cholesky factorization of sub $(B)$ as returned by `p?potrf`.

$ib, jb$  
(global) The row and column indices in the global matrix $B$ indicating the first row and the first column of the submatrix $B$, respectively.

descb  
(global and local) array of size $dlen_\_$. The array descriptor for the distributed matrix $B$.

**Output Parameters**

$a$  
On exit, if $info = 0$, the transformed matrix, stored in the same format as sub$(A)$.

$scale$  
(global)  
Amount by which the eigenvalues should be scaled to compensate for the scaling performed in this function. At present, $scale$ is always returned as $1.0$, it is returned here to allow for future enhancement.

$info$  
(global)  
If $info = 0$, the execution is successful. If $info < 0$, if the $i$-th argument is an array and the $j$-th entry, indexed $j - 1$, had an illegal value, then $info = -(i*100+j)$; if the $i$-th argument is a scalar and had an illegal value, then $info = -i$.

**p?hegst**

Reduces a Hermitian positive-definite generalized eigenvalue problem to the standard form.

**Syntax**

```c
void pchegst (MKL_INT *ibtype , char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *descb , MKL_Complex8 *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *desca , float *scale , MKL_INT *info );
void pzhegst (MKL_INT *ibtype , char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *descb , MKL_Complex16 *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *desca , double *scale , MKL_INT *info );
```

**Include Files**

- `mkl_scalapack.h`

**Description**

The `p?hegst` function reduces complex Hermitian positive-definite generalized eigenproblems to the standard form.

In the following sub$(A)$ denotes $A(ia:ia+n-1, ja:ja+n-1)$ and sub$(B)$ denotes $B(ib:ib+n-1, jb:jb+n-1)$. If $ibtype = 1$, the problem is

$\text{sub}(A)\text{x} = \lambda \text{sub}(B)\text{x},$

and sub$(A)$ is overwritten by $\text{inv}(U^H)\text{sub}(A)\text{inv}(U)$, or $\text{inv}(L)\text{sub}(A)\text{inv}(L^H)$. 

4 Intel® Math Kernel Library Developer Reference

1426
If \( ibtype = 2 \) or \( 3 \), the problem is

\[
\text{sub}(A)\cdot\text{sub}(B)\cdot x = \lambda x, \quad \text{or} \quad \text{sub}(B)\cdot\text{sub}(A)\cdot x = \lambda x,
\]
and \( \text{sub}(A) \) is overwritten by \( U^*\text{sub}(A)U^H \), or \( L^H*\text{sub}(A)*L \).

\( \text{sub}(B) \) must have been previously factorized as \( U^H*U \) or \( L*L^H \) by \text{p?potrf}.

**Input Parameters**

- \( ibtype \) (global) Must be 1 or 2 or 3.
  - If \( itype = 1 \), compute \( \text{inv}(U^H)\cdot\text{sub}(A)\cdot\text{inv}(U) \), or \( \text{inv}(L)\cdot\text{sub}(A)\cdot\text{inv}(L^H) \);
  - If \( itype = 2 \) or \( 3 \), compute \( U\cdot\text{sub}(A)\cdot U^H \), or \( L^H*\text{sub}(A)*L \).

- \( uplo \) (global) Must be 'U' or 'L'.
  - If \( uplo = 'U' \), the upper triangle of \( \text{sub}(A) \) is stored and \( \text{sub}(B) \) is factored as \( U^H*U \).
  - If \( uplo = 'L' \), the lower triangle of \( \text{sub}(A) \) is stored and \( \text{sub}(B) \) is factored as \( L*L^H \).

- \( n \) (global) The order of the matrices \( \text{sub}(A) \) and \( \text{sub}(B) \) (\( n \geq 0 \)).

- \( a \) (local)

  Pointer into the local memory to an array of size \( lld_a*\text{LOCc}(ja+n-1) \). On entry, the array contains the local pieces of the \( n \)-by-\( n \) Hermitian distributed matrix \( \text{sub}(A) \). If \( uplo = 'U' \), the leading \( n \)-by-\( n \) upper triangular part of \( \text{sub}(A) \) contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If \( uplo = 'L' \), the leading \( n \)-by-\( n \) lower triangular part of \( \text{sub}(A) \) contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced.

- \( ia, ja \) (global) The row and column indices in the global matrix \( A \) indicating the first row and the first column of the submatrix \( A \), respectively.

- \( desca \) (global and local) array of size \( dlen_\) . The array descriptor for the distributed matrix \( A \).

- \( b \) (local)

  Pointer into the local memory to an array of size \( lld_b*\text{LOCc}(jb+n-1) \). On entry, the array contains the local pieces of the triangular factor from the Cholesky factorization of \( \text{sub}(B) \) as returned by \text{p?potrf}.

- \( ib, jb \) (global) The row and column indices in the global matrix \( B \) indicating the first row and the first column of the submatrix \( B \), respectively.

- \( descb \) (global and local) array of size \( dlen_\) . The array descriptor for the distributed matrix \( B \).

**Output Parameters**

- \( a \)
  - On exit, if \( info = 0 \), the transformed matrix, stored in the same format as \( \text{sub}(A) \).

- \( scale \) (global)
Amount by which the eigenvalues should be scaled to compensate for the scaling performed in this function. At present, `scale` is always returned as 1.0, it is returned here to allow for future enhancement.

`info` (global)
If `info = 0`, the execution is successful. If `info < 0`, if the i-th argument is an array and the j-th entry, indexed `j - 1`, had an illegal value, then `info = -(i*100+j)`; if the i-th argument is a scalar and had an illegal value, then `info = -i`.

`p?gesv`

Computes the solution to the system of linear equations with a square distributed matrix and multiple right-hand sides.

Syntax

```c
void psgesv (MKL_INT *n , MKL_INT *nrhs , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desc , MKL_INT *ipiv , float *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb , MKL_INT *info );
```
void pdgesv (MKL_INT *n, MKL_INT *nrhs, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_INT *ipiv, double *b, MKL_INT *ib, MKL_INT *jb, MKL_INT *descb, MKL_INT *info);

void pcgesv (MKL_INT *n, MKL_INT *nrhs, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_INT *ipiv, MKL_Complex8 *b, MKL_INT *ib, MKL_INT *jb, MKL_INT *descb, MKL_INT *info);

void pzgesv (MKL_INT *n, MKL_INT *nrhs, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_INT *ipiv, MKL_Complex16 *b, MKL_INT *ib, MKL_INT *jb, MKL_INT *descb, MKL_INT *info);

**Include Files**

- mkl_scalapack.h

**Description**

The `p?gesv` function computes the solution to a real or complex system of linear equations \( \text{sub}(A) \cdot X = \text{sub}(B) \), where \( \text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1) \) is an \( n \)-by-\( n \) distributed matrix and \( X \) and \( \text{sub}(B) = B(ib:ib+n-1, jb:jb+nrhs-1) \) are \( n \)-by-\( nrhs \) distributed matrices.

The LU decomposition with partial pivoting and row interchanges is used to factor \( \text{sub}(A) \) as \( \text{sub}(A) = P \cdot L \cdot U \), where \( P \) is a permutation matrix, \( L \) is unit lower triangular, and \( U \) is upper triangular. \( L \) and \( U \) are stored in \( \text{sub}(A) \). The factored form of \( \text{sub}(A) \) is then used to solve the system of equations \( \text{sub}(A) \cdot X = \text{sub}(B) \).

**Input Parameters**

- \( n \) (global) The number of rows and columns to be operated on, that is, the order of the distributed submatrix \( \text{sub}(A) \) \( (n \geq 0) \).
- \( nrhs \) (global) The number of right hand sides, that is, the number of columns of the distributed submatrices \( B \) and \( X \) \( (nrhs \geq 0) \).
- \( a, b \) (local) Pointers into the local memory to arrays of local size \( a: lld_a \cdot \text{LOCc}(ja+n-1) \) and \( b: lld_b \cdot \text{LOCc}(jb+nrhs-1) \), respectively.
- \( ia, ja \) (global) The row and column indices in the global matrix \( A \) indicating the first row and the first column of \( \text{sub}(A) \), respectively.
- \( desca \) (global and local) array of size \( dlen_\). The array descriptor for the distributed matrix \( A \).
- \( ib, jb \) (global) The row and column indices in the global matrix \( B \) indicating the first row and the first column of \( \text{sub}(B) \), respectively.
- \( descb \) (global and local) array of size \( dlen_\). The array descriptor for the distributed matrix \( B \).
Output Parameters

- $a$ Overwritten by the factors $L$ and $U$ from the factorization $\text{sub}(A) = P^T L U$; the unit diagonal elements of $L$ are not stored.
- $b$ Overwritten by the solution distributed matrix $X$.
- $\text{ipiv}$ (local) Array of size $\text{LOCr}(m_a)+mb_a$. This array contains the pivoting information. The (local) row $i$ of the matrix was interchanged with the (global) row $\text{ipiv}[i-1]$.
- $\text{info}$ (global) If $\text{info}=0$, the execution is successful.
  - $\text{info} < 0$: If the $i$-th argument is an array and the $j$-th entry had an illegal value, then $\text{info} = -(i*100+j)$; if the $i$-th argument is a scalar and had an illegal value, then $\text{info} = -i$.
  - $\text{info} > 0$: If $\text{info} = k$, $U(ia+k-1,ja+k-1)$ is exactly zero. The factorization has been completed, but the factor $U$ is exactly singular, so the solution could not be computed.

See Also
Overview for details of ScaLAPACK array descriptor structures and related notations.

**p?gesvx**

Uses the LU factorization to compute the solution to the system of linear equations with a square matrix $A$ and multiple right-hand sides, and provides error bounds on the solution.

**Syntax**

```c
void pgesvx (char *fact, char *trans, MKL_INT *n, MKL_INT *nrhs, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *af, MKL_INT *iaf, MKL_INT *jaf, MKL_INT *descf, MKL_INT *ipiv, char *equed, float *r, float *c, float *b, MKL_INT *ib, MKL_INT *jb, MKL_INT *descb, float *x, MKL_INT *ix, MKL_INT *jx, MKL_INT *descx, float *rcond, float *ferr, float *berr, float *work, MKL_INT *lwork, MKL_INT *iwork, MKL_INT *liwork, MKL_INT *info);
void pdgesvx (char *fact, char *trans, MKL_INT *n, MKL_INT *nrhs, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *af, MKL_INT *iaf, MKL_INT *jaf, MKL_INT *descf, MKL_INT *ipiv, char *equed, double *r, double *c, double *b, MKL_INT *ib, MKL_INT *jb, MKL_INT *descb, double *x, MKL_INT *ix, MKL_INT *jx, MKL_INT *descx, double *rcond, double *ferr, double *berr, double *work, MKL_INT *lwork, MKL_INT *iwork, MKL_INT *liwork, MKL_INT *info);
void pcgesvx (char *fact, char *trans, MKL_INT *n, MKL_INT *nrhs, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_Complex8 *af, MKL_INT *iaf, MKL_INT *jaf, MKL_INT *descf, MKL_INT *ipiv, char *equed, float *r, float *c, MKL_Complex8 *b, MKL_INT *ib, MKL_INT *jb, MKL_INT *descb, MKL_Complex8 *x, MKL_INT *ix, MKL_INT *jx, MKL_INT *descx, float *rcond, float *ferr, float *berr, MKL_Complex8 *work, MKL_INT *lwork, float *rwork, MKL_INT *lrwork, MKL_INT *info);
```
void pzgesvx (char *fact, char *trans, MKL_INT *n, MKL_INT *nrhs, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_Complex16 *af, MKL_INT *iaf, MKL_INT *jaf, MKL_INT *descaf, MKL_INT *ipiv, char *equed, double *r, double *c, MKL_Complex16 *b, MKL_INT *ib, MKL_INT *jb, MKL_INT *descb, MKL_Complex16 *x, MKL_INT *ix, MKL_INT *jx, MKL_INT *descx, double *rcond, double *ferr, double *berr, MKL_Complex16 *work, MKL_INT *lwork, double *rwork, MKL_INT *lrwork, MKL_INT *info);

Include Files

- mkl_scalapack.h

Description

The pzgesvx function uses the LU factorization to compute the solution to a real or complex system of linear equations $AX = B$, where $A$ denotes the $n$-by-$n$ submatrix $A(ia:ia+n-1, ja:ja+n-1)$, $B$ denotes the $n$-by-$nrhs$ submatrix $B(ib:ib+n-1, jb:jb+nrhs-1)$ and $X$ denotes the $n$-by-$nrhs$ submatrix $X(ix:ix+n-1, jx:jx+nrhs-1)$.

Error bounds on the solution and a condition estimate are also provided.

In the following description, $af$ stands for the subarray of $af$ from row $iaf$ and column $jaf$ to row $iaf+n-1$ and column $jaf+n-1$.

The function pzgesvx performs the following steps:

1. If fact = 'E', real scaling factors $R$ and $C$ are computed to equilibrate the system:
   
   - $trans = 'N'$: $\text{diag}(R) * A * \text{diag}(C) * (\text{diag}(C))^{-1} * X = \text{diag}(R) * B$
   - $trans = 'T'$: $(\text{diag}(R) * A * \text{diag}(C))^{T} * (\text{diag}(R))^{-1} * X = \text{diag}(C) * B$
   - $trans = 'C'$: $(\text{diag}(R) * A * \text{diag}(C))^{H} * (\text{diag}(R))^{-1} * X = \text{diag}(C) * B$

   Whether or not the system will be equilibrated depends on the scaling of the matrix $A$, but if equilibration is used, $A$ is overwritten by $\text{diag}(R) * A * \text{diag}(C)$ and $B$ by $\text{diag}(R) * B$ (if $trans = 'N'$) or $\text{diag}(C) * B$ (if $trans = 'T'$ or 'C').

2. If fact = 'N' or 'E', the LU decomposition is used to factor the matrix $A$ (after equilibration if fact = 'E') as $A = PLU$, where $P$ is a permutation matrix, $L$ is a unit lower triangular matrix, and $U$ is upper triangular.

3. The factored form of $A$ is used to estimate the condition number of the matrix $A$. If the reciprocal of the condition number is less than relative machine precision, steps 4 - 6 are skipped.

4. The system of equations is solved for $X$ using the factored form of $A$.

5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

6. If equilibration was used, the matrix $X$ is premultiplied by $\text{diag}(C)$ (if $trans = 'N'$) or $\text{diag}(R)$ (if $trans = 'T'$ or 'C') so that it solves the original system before equilibration.

Input Parameters

- $fact$ (global) Must be 'F', 'N', or 'E'.

   Specifies whether or not the factored form of the matrix $A$ is supplied on entry, and if not, whether the matrix $A$ should be equilibrated before it is factored.

   - If $fact = 'F'$ then, on entry, $af$ and $ipiv$ contain the factored form of $A$. If equed is not 'N', the matrix $A$ has been equilibrated with scaling factors given by $r$ and $c$. Arrays $a$, $af$, and $ipiv$ are not modified.
   - If $fact = 'N'$, the matrix $A$ is copied to $af$ and factored.
If $\text{fact} = \text{'E'}$, the matrix $A$ is equilibrated if necessary, then copied to $af$ and factored.

**trans**

(global) Must be 'N', 'T', or 'C'.

Specifies the form of the system of equations:

If trans = 'N', the system has the form $A\times X = B$ (No transpose);

If trans = 'T', the system has the form $A^T\times X = B$ (Transpose);

If trans = 'C', the system has the form $A^H\times X = B$ (Conjugate transpose);

**n**

(global) The number of linear equations; the order of the submatrix $A$ ($n \geq 0$).

**nrhs**

(global) The number of right hand sides; the number of columns of the distributed submatrices $B$ and $X$ ($nrhs \geq 0$).

**a, af, b, work**

(local)

Pointers into the local memory to arrays of local size $a$: $\text{ld}_a \times \text{LOCc}(ja + n - 1)$, $af$: $\text{ld}_af \times \text{LOCc}(ja + n - 1)$, $b$: $\text{ld}_b \times \text{LOCc}(jb + nrhs - 1)$, work: $lwork$.

The array $a$ contains the matrix $A$. If $\text{fact} = \text{'F'}$ and $\text{equed}$ is not 'N', then $A$ must have been equilibrated by the scaling factors in $r$ and/or $c$.

The array $af$ is an input argument if $\text{fact} = \text{'F'}$. In this case it contains on entry the factored form of the matrix $A$, that is, the factors $L$ and $U$ from the factorization $A = P \times L \times U$ as computed by $\text{p?getrf}$. If $\text{equed}$ is not 'N', then $af$ is the factored form of the equilibrated matrix $A$.

The array $b$ contains on entry the matrix $B$ whose columns are the right-hand sides for the systems of equations.

$work$ is a workspace array. The size of $work$ is ($lwork$).

**ia, ja**

(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the submatrix $A(ia:ia+n-1, ja:ja+n-1)$, respectively.

**desca**

(global and local) array of size $\text{dlen}_a$. The array descriptor for the distributed matrix $A$.

**iaf, jaf**

(global) The row and column indices in the global matrix $AF$ indicating the first row and the first column of the subarray $af$, respectively.

**descaf**

(global and local) array of size $\text{dlen}_a$. The array descriptor for the distributed matrix $AF$.

**ib, jb**

(global) The row and column indices in the global matrix $B$ indicating the first row and the first column of the submatrix $B(ib:ib+n-1, jb:jb+nrhs-1)$, respectively.

**descb**

(global and local) array of size $\text{dlen}_b$. The array descriptor for the distributed matrix $B$.

**ipiv**

(local) Array of size $\text{LOCr}(m_a) + mb_a$.

The array $ipiv$ is an input argument if $\text{fact} = \text{'F'}$.
On entry, it contains the pivot indices from the factorization $A = P^*L^*U$ as computed by `p?getrf`; (local) row $i$ of the matrix was interchanged with the (global) row $ipiv[i - 1]$.

This array must be aligned with $A(is:is+n-1, \ast)$.

**equed**

(global) Must be 'N', 'R', 'C', or 'B'. `equed` is an input argument if `fact` = 'F'. It specifies the form of equilibration that was done:

If `equed` = 'N', no equilibration was done (always true if `fact` = 'N');

If `equed` = 'R', row equilibration was done, that is, $A$ has been premultiplied by $\text{diag}(r)$;

If `equed` = 'C', column equilibration was done, that is, $A$ has been postmultiplied by $\text{diag}(c)$;

If `equed` = 'B', both row and column equilibration was done; $A$ has been replaced by $\text{diag}(r) * A * \text{diag}(c)$.

**r, c**

Arrays of size $\text{LOCr}(n_a)$ and $\text{LOCc}(n_a)$, respectively.

The array $r$ contains the row scale factors for $A$, and the array $c$ contains the column scale factors for $A$. These arrays are input arguments if `fact` = 'F' only; otherwise they are output arguments. If `equed` = 'R' or 'B', $A$ is multiplied on the left by $\text{diag}(r)$; if `equed` = 'N' or 'C', $r$ is not accessed.

If `fact` = 'F' and `equed` = 'R' or 'B', each element of $r$ must be positive.

If `equed` = 'C' or 'B', $A$ is multiplied on the right by $\text{diag}(c)$; if `equed` = 'N' or 'R', $c$ is not accessed.

If `fact` = 'F' and `equed` = 'C' or 'B', each element of $c$ must be positive. Array $r$ is replicated in every process column, and is aligned with the distributed matrix $A$. Array $c$ is replicated in every process row, and is aligned with the distributed matrix $A$.

**ix, jx**

(global) The row and column indices in the global matrix $X$ indicating the first row and the first column of the submatrix $X(ix:ix+n-1, jx:jx+nrhs-1)$, respectively.

**descx**

(global and local) array of size $\text{dlen}_x$. The array descriptor for the distributed matrix $X$.

**lwork**

(local or global) The size of the array `work`; must be at least $\max(p?gecon(lwork), p?gerfs(lwork)) + \text{LOCr}(n_a)$.

**iwork**

(local, pgesvx/pdgesvx only). Workspace array. The size of `iwork` is $(liwork)$.

**liwork**

(local, pgesvx/pdgesvx only). The size of the array `iwork`, must be at least $\text{LOCr}(n_a)$.

**rwork**

(local) Workspace array, used in complex flavors only.
The size of rwork is (lrwork).

\( lrwork \) (local or global, pcgesvx/pzgesvx only). The size of the array rwork; must be at least \( 2 \times \text{LOCc}(n_a) \).

**Output Parameters**

\( x \) (local)

Pointer into the local memory to an array of local size \( \text{lld}_x \times \text{LOCc}(jx +nrhs-1) \).

If info = 0, the array x contains the solution matrix \( X \) to the original system of equations. Note that \( A \) and \( B \) are modified on exit if \( \text{equed} \neq 'N' \), and the solution to the equilibrated system is:

\[
\begin{align*}
\text{diag}(C)-1 & \times X, \text{ if } \text{trans} = 'N' \text{ and } \text{equed} = 'C' \text{ or } 'B'; \text{ and} \\
\text{diag}(R)-1 & \times X, \text{ if } \text{trans} = 'T' \text{ or } 'C' \text{ and } \text{equed} = 'R' \text{ or } 'B'. \\
\end{align*}
\]

Array \( a \) is not modified on exit if \( \text{fact} = 'F' \) or 'N', or if \( \text{fact} = 'E' \) and \( \text{equed} = 'N' \).

If \( \text{equed} \neq 'N' \), \( A \) is scaled on exit as follows:

- \( \text{equed} = 'R': A = \text{diag}(R) \times A \)
- \( \text{equed} = 'C': A = A \times \text{diag}(c) \)
- \( \text{equed} = 'B': A = \text{diag}(R) \times A \times \text{diag}(c) \)

\( af \)

If \( \text{fact} = 'N' \) or 'E', then \( af \) is an output argument and on exit returns the factors \( L \) and \( U \) from the factorization \( A = P \times L \times U \) of the original matrix \( A \) (if \( \text{fact} = 'N' \)) or of the equilibrated matrix \( A \) (if \( \text{fact} = 'E' \)). See the description of \( a \) for the form of the equilibrated matrix.

\( b \)

Overwritten by \( \text{diag}(R) \times B \) if \( \text{trans} = 'N' \) and \( \text{equed} = 'R' \) or 'B'; overwritten by \( \text{diag}(c) \times B \) if \( \text{trans} = 'T' \) and \( \text{equed} = 'C' \) or 'B'; not changed if \( \text{equed} = 'N' \).

\( r, c \)

These arrays are output arguments if \( \text{fact} \neq 'F' \).

See the description of \( r, c \) in Input Arguments section.

\( rcond \)

(global).

An estimate of the reciprocal condition number of the matrix \( A \) after equilibration (if done). The function sets \( rcond = 0 \) if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime \( rcond \) is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.

\( ferr, berr \)

(local)

Arrays of size \( \text{LOCc}(n_b) \) each. Contain the component-wise forward and relative backward errors, respectively, for each solution vector.

Arrays \( ferr \) and \( berr \) are both replicated in every process row, and are aligned with the matrices \( B \) and \( X \).
If fact = 'N' or 'E', then ipiv is an output argument and on exit contains the pivot indices from the factorization \( A = P*L*U \) of the original matrix \( A \) (if fact = 'N') or of the equilibrated matrix \( A \) (if fact = 'E').

If fact\#'E', then equed is an output argument. It specifies the form of equilibration that was done (see the description of equed in Input Arguments section).

If info=0, on exit work[0] returns the minimum value of lwork required for optimum performance.

If info=0, on exit iwork[0] returns the minimum value of liwork required for optimum performance.

If info=0, on exit rwork[0] returns the minimum value of lrwork required for optimum performance.

If info=0, the execution is successful.

See Also Overview for details of ScaLAPACK array descriptor structures and related notations.

\textbf{p?gbsv}

\textit{Computes the solution to the system of linear equations with a general banded distributed matrix and multiple right-hand sides.}

\textbf{Syntax}

```c
void psgbsv (MKL_INT *n, MKL_INT *bwl, MKL_INT *bwu, MKL_INT *nrhs, float *a, MKL_INT *ja, MKL_INT *desca, MKL_INT *ipiv, float *b, MKL_INT *ib, MKL_INT *descb, float *work, MKL_INT *lwork, MKL_INT *info);
void pdgbsv (MKL_INT *n, MKL_INT *bwl, MKL_INT *bwu, MKL_INT *nrhs, double *a, MKL_INT *ja, MKL_INT *desca, MKL_INT *ipiv, double *b, MKL_INT *ib, MKL_INT *descb, double *work, MKL_INT *lwork, MKL_INT *info);
void pcgbsv (MKL_INT *n, MKL_INT *bwl, MKL_INT *bwu, MKL_INT *nrhs, MKL_Complex8 *a, MKL_INT *ja, MKL_INT *desca, MKL_INT *ipiv, MKL_Complex8 *b, MKL_INT *ib, MKL_INT *descb, MKL_Complex8 *work, MKL_INT *lwork, MKL_INT *info);

```
Include Files
• mkl_scalapack.h

Description
The `p?gbsv` function computes the solution to a real or complex system of linear equations

\[ \text{sub}(A) \times X = \text{sub}(B), \]

where \( \text{sub}(A) = A(1:n, ja:ja+n-1) \) is an \( n \)-by-\( n \) real/complex general banded distributed matrix with \( \text{bwl} \) subdiagonals and \( \text{bwu} \) superdiagonals, and \( X \) and \( \text{sub}(B) = B(ib:ib+n-1, 1:nrhs) \) are \( n \)-by-\( nrhs \) distributed matrices.

The LU decomposition with partial pivoting and row interchanges is used to factor \( \text{sub}(A) \) as \( \text{sub}(A) = P \times L \times U \times Q \), where \( P \) and \( Q \) are permutation matrices, and \( L \) and \( U \) are banded lower and upper triangular matrices, respectively. The matrix \( Q \) represents reordering of columns for the sake of parallelism, while \( P \) represents reordering of rows for numerical stability using classic partial pivoting.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

\( n \)  
(global) The number of rows and columns to be operated on, that is, the order of the distributed matrix \( \text{sub}(A) \) (\( n \geq 0 \)).

\( \text{bwl} \)  
(global) The number of subdiagonals within the band of \( A \) (\( 0 \leq \text{bwl} \leq n-1 \)).

\( \text{bwu} \)  
(global) The number of superdiagonals within the band of \( A \) (\( 0 \leq \text{bwu} \leq n-1 \)).

\( nrhs \)  
(global) The number of right hand sides; the number of columns of the distributed matrix \( \text{sub}(B) \) (\( nrhs \geq 0 \)).

\( a, b \)  
(local) Pointers into the local memory to arrays of local size \( a: lld_a*\text{LOCc}(ja+n-1) \) and \( b: lld_b*\text{LOCc}(nrhs) \).

On entry, the array \( a \) contains the local pieces of the global array \( A \).

On entry, the array \( b \) contains the right hand side distributed matrix \( \text{sub}(B) \).

\( ja \)  
(global) The index in the global matrix \( A \) indicating the start of the matrix to be operated on (which may be either all of \( A \) or a submatrix of \( A \)).

\( \text{desca} \)  
(global and local) array of size \( dlen_\). The array descriptor for the distributed matrix \( A \).

If \( \text{desca}[\text{dtype}_-1] = 501 \), then \( dlen \geq 7 \);
else if \( \text{desca}[\text{dtype} - 1] = 1 \), then \( dlen \geq 9 \).

\( \text{ib} \)

(global) The row index in the global matrix \( B \) indicating the first row of the matrix to be operated on (which may be either all of \( B \) or a submatrix of \( B \)).

\( \text{descb} \)

(global and local) array of size \( dlen \). The array descriptor for the distributed matrix \( B \).

If \( \text{descb}[\text{dtype} - 1] = 502 \), then \( dlen \geq 7 \);

else if \( \text{descb}[\text{dtype} - 1] = 1 \), then \( dlen \geq 9 \).

\( \text{work} \)

(local)

Workspace array of size \( lwork \).

\( lwork \)

(local or global) The size of the array \( \text{work} \), must be at least \( lwork \geq (NB + bwu) \times (bwl + bwu) + 6 \times (bwl + bwu) \times (bwl + 2 \times bwu) + \max(nrhs \times (NB + 2 \times bwl + 4 \times bwu), 1) \).

Output Parameters

\( a \)

On exit, contains details of the factorization. Note that the resulting factorization is not the same factorization as returned from LAPACK. Additional permutations are performed on the matrix for the sake of parallelism.

\( b \)

On exit, this array contains the local pieces of the solution distributed matrix \( X \).

\( \text{ipiv} \)

(local) array.

The size of \( \text{ipiv} \) must be at least \( \text{desca}[\text{NB} - 1] \). This array contains pivot indices for local factorizations. You should not alter the contents between factorization and solve.

\( \text{work[0]} \)

On exit, \( \text{work}[0] \) contains the minimum value of \( lwork \) required for optimum performance.

\( \text{info} \)

If \( \text{info}=0 \), the execution is successful. \( \text{info} < 0 \):

If the \( i \)-th argument is an array and the \( j \)-th entry had an illegal value, then \( \text{info} = -(i \times 100 + j) \); if the \( i \)-th argument is a scalar and had an illegal value, then \( \text{info} = -i \).

\( \text{info} > 0 \):

If \( \text{info} = k \leq \text{NPROCS} \), the submatrix stored on processor \( \text{info} \) and factored locally was not nonsingular, and the factorization was not completed. If \( \text{info} = k > \text{NPROCS} \), the submatrix stored on processor \( \text{info} - \text{NPROCS} \) representing interactions with other processors was not nonsingular, and the factorization was not completed.

Include Files

• mkl_scalapack.h

Description

The p?dbsv function solves the following system of linear equations:

\[ A(1:n, ja:ja+n-1) \times X = B(ib:ib+n-1, 1:nrhs), \]

where \( A(1:n, ja:ja+n-1) \) is an \( n \)-by-\( n \) real/complex banded diagonally dominant-like distributed matrix with bandwidth \( bwl, bwu \).

Gaussian elimination without pivoting is used to factor a reordering of the matrix into \( LU \).

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

\( n \) (global) The order of the distributed submatrix \( A \), \( n \geq 0 \).

\( bwl \) (global) Number of subdiagonals. \( 0 \leq bwl \leq n-1 \).

\( bwu \) (global) Number of subdiagonals. \( 0 \leq bwu \leq n-1 \).

\( nrhs \) (global) The number of right-hand sides; the number of columns of the distributed submatrix \( B \), \( nrhs \geq 0 \).

\( a \) (local).
Pointer into the local memory to an array with leading size \( lld\_a \geq (bwl + bwu+1) \) (stored in \( desca \)). On entry, this array contains the local pieces of the distributed matrix.

\( ja \)

(global) The index in the global matrix \( A \) indicating the start of the matrix to be operated on (which may be either all of \( A \) or a submatrix of \( A \)).

\( desca \)

(global and local) array of size \( dlen \).
If 1d type (\( dtype\_a = 501 \) or 502), \( dlen \geq 7 \);
If 2d type (\( dtype\_a = 1 \)), \( dlen \geq 9 \).
The array descriptor for the distributed matrix \( A \).
Contains information of mapping of \( A \) to memory.

\( b \)

(local)
Pointer into the local memory to an array of local lead size \( lld\_b \geq nb \). On entry, this array contains the local pieces of the right hand sides \( B(ib:ib + n-1, 1:nrhs) \).

\( ib \)

(global) The row index in the global matrix \( B \) indicating the first row of the matrix to be operated on (which may be either all of \( b \) or a submatrix of \( B \)).

\( descb \)

(global and local) array of size \( dlen \).
If 1d type (\( dtype\_b = 502 \)), \( dlen \geq 7 \);
If 2d type (\( dtype\_b = 1 \)), \( dlen \geq 9 \).
The array descriptor for the distributed matrix \( B \).
Contains information of mapping of \( B \) to memory.

\( work \)

(local).
Temporary workspace. This space may be overwritten in between calls to functions. \( work \) must be the size given in \( lwork \).

\( lwork \)

(local or global) Size of user-input workspace \( work \). If \( lwork \) is too small, the minimal acceptable size will be returned in \( work[0] \) and an error code is returned.

\[ lwork \geq nb(bwi+bwu)+6\max(bwl,bwu)\max(bwl,bwu)+\max((\max(bwl,bwu)\max\( bwl,bwu)), \max(bwl,bwu)\max(bwl,bwu)) \]

**Output Parameters**

\( a \)

On exit, this array contains information containing details of the factorization.
Note that permutations are performed on the matrix, so that the factors returned are different from those returned by LAPACK.

\( b \)

On exit, this contains the local piece of the solutions distributed matrix \( X \).

\( work \)

On exit, \( work[0] \) contains the minimal \( lwork \).

\( info \)

(local) If \( info=0 \), the execution is successful.
If the \(i\)-th argument is an array and the \(j\)-entry had an illegal value, then \(info = -(i*100+j)\), if the \(i\)-th argument is a scalar and had an illegal value, then \(info = -i\).

> 0: If \(info = k < \text{NPROCS}\), the submatrix stored on processor \(info\) and factored locally was not positive definite, and the factorization was not completed.

If \(info = k > \text{NPROCS}\), the submatrix stored on processor \(info - \text{NPROCS}\) representing interactions with other processors was not positive definite, and the factorization was not completed.

\end{verbatim}

\textbf{Include Files}

- mkl_scalapack.h

\textbf{Description}

The function solves a system of linear equations

\[ A(1:n, ja:ja+n-1) * X = B(ib:ib+n-1, 1:nrhs), \]

where \(A(1:n, ja:ja+n-1)\) is an \(n\)-by-\(n\) complex tridiagonal diagonally dominant-like distributed matrix. Gaussian elimination without pivoting is used to factor a reordering of the matrix into \(L U\).
Optimization Notice

Optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

\( n \) (global) The order of the distributed submatrix \( A(n \geq 0) \).

\( nrhs \)

The number of right hand sides; the number of columns of the distributed matrix \( B(nrhs \geq 0) \).

\( dl \) (local).

Pointer to local part of global vector storing the lower diagonal of the matrix. Globally, \( dl[0] \) is not referenced, and \( dl \) must be aligned with \( d \).

Must be of size \( > desca[\text{nb}_- - 1] \).

\( d \) (local).

Pointer to local part of global vector storing the main diagonal of the matrix.

\( du \) (local).

Pointer to local part of global vector storing the upper diagonal of the matrix. Globally, \( du[n - 1] \) is not referenced, and \( du \) must be aligned with \( d \).

\( ja \) (global) The index in the global matrix \( A \) indicating the start of the matrix to be operated on (which may be either all of \( A \) or a submatrix of \( A \)).

\( desca \) (global and local) array of size \( dlen \).

If 1d type (\( \text{dtype}_a=501 \) or 502), \( dlen \geq 7 \);  
If 2d type (\( \text{dtype}_a=1 \)), \( dlen \geq 9 \).

The array descriptor for the distributed matrix \( A \).

Contains information of mapping of \( A \) to memory.

\( b \) (local)

Pointer into the local memory to an array of local lead size \( lld_b > \text{nb} \). On entry, this array contains the local pieces of the right hand sides \( B(\text{ib}:\text{ib} + n-1, 1:nh\text{rhs}) \).

\( ib \) (global) The row index in the global matrix \( B \) indicating the first row of the matrix to be operated on (which may be either all of \( B \) or a submatrix of \( B \)).

\( descb \) (global and local) array of size \( dlen \).

If 1d type (\( \text{dtype}_b =502 \)), \( dlen \geq 7 \);  
If 2d type (\( \text{dtype}_b =1 \)), \( dlen \geq 9 \).

The array descriptor for the distributed matrix \( B \).

Contains information of mapping of \( B \) to memory.

\( work \) (local).
lwork

(local or global) Size of user-input workspace work. If lwork is too small, the minimal acceptable size will be returned in work[0] and an error code is returned. lwork > (12*NPCOL+3*nb)+max((10+2*min(100, nrhs))*NP COL+4*nrhs, 8*NP COL)

Output Parameters

dl

On exit, this array contains information containing the * factors of the matrix.

d

On exit, this array contains information containing the * factors of the matrix. Must be of size > desca[nb_ - 1].

du

On exit, this array contains information containing the * factors of the matrix. Must be of size > desca[nb_ - 1].

b

On exit, this contains the local piece of the solutions distributed matrix X.

work

On exit, work[0] contains the minimal lwork.

info

(output) If info=0, the execution is successful.

< 0: If the i-th argument is an array and the j-entry had an illegal value, then info = -(i*100+j), if the j-th argument is a scalar and had an illegal value, then info = -i.

> 0: If info = k<NPROCS, the submatrix stored on processor info and factored locally was not positive definite, and the factorization was not completed.

If info = k > NPROCS, the submatrix stored on processor info-NPROCS representing interactions with other processors was not positive definite, and the factorization was not completed.

Include Files
• mkl_scalapack.h

Description
The p?posv function computes the solution to a real/complex system of linear equations
sub(A) * X = sub(B),
where sub(A) denotes \( A(ia:ia+n-1, ja:ja+n-1) \) and is an \( n \)-by-\( n \) symmetric/Hermitian distributed positive definite matrix and \( X \) and sub(\( B \)) denoting \( B(ib:ib+n-1, jb:jb+nrhs-1) \) are \( n \)-by-\( nrhs \) distributed matrices. The Cholesky decomposition is used to factor sub(A) as
\[
\begin{align*}
\text{sub}(A) &= U^T \ast U, & \text{if } \text{uplo} = 'U' , \\
\text{sub}(A) &= L \ast L^T, & \text{if } \text{uplo} = 'L',
\end{align*}
\]
where \( U \) is an upper triangular matrix and \( L \) is a lower triangular matrix. The factored form of sub(A) is then used to solve the system of equations.

Input Parameters

uplo (global) Must be 'U' or 'L'.
Indicates whether the upper or lower triangular part of sub(A) is stored.

n (global) The order of the distributed matrix sub(A) \( (n \geq 0) \).

nrhs
The number of right-hand sides; the number of columns of the distributed matrix sub(\( B \)) \( (nrhs \geq 0) \).

a (local)
Pointer into the local memory to an array of size \( lld_a^* \text{LOCc}(ja+n-1) \). On entry, this array contains the local pieces of the \( n \)-by-\( n \) symmetric distributed matrix sub(A) to be factored.

If \( \text{uplo} = 'U' \), the leading \( n \)-by-\( n \) upper triangular part of sub(A) contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced.

If \( \text{uplo} = 'L' \), the leading \( n \)-by-\( n \) lower triangular part of sub(A) contains the lower triangular part of the distributed matrix, and its strictly upper triangular part is not referenced.

ia, ja (global) The row and column indices in the global matrix \( A \) indicating the first row and the first column of the submatrix \( A \), respectively.

desca (global and local) array of size \( dlen_ \). The array descriptor for the distributed matrix \( A \).

b (local)
Pointer into the local memory to an array of size \( lld_b^* \text{LOCc}(jb+nrhs-1) \). On entry, the local pieces of the right hand sides distributed matrix sub(\( B \)).

ib, jb (global) The row and column indices in the global matrix \( B \) indicating the first row and the first column of the submatrix \( B \), respectively.

descb (global and local) array of size \( dlen_ \). The array descriptor for the distributed matrix \( B \).
**Output Parameters**

- **a**
  
  On exit, if \( \text{info} = 0 \), this array contains the local pieces of the factor \( U \) or \( L \) from the Cholesky factorization \( \text{sub}(A) = U^T U \) or \( L^H L \).

- **b**
  
  On exit, if \( \text{info} = 0 \), \( \text{sub}(B) \) is overwritten by the solution distributed matrix \( X \).

- **info**

  (global)

  If \( \text{info} = 0 \), the execution is successful.

  If \( \text{info} < 0 \): If the \( i \)-th argument is an array and the \( j \)-th entry, indexed \( j-1 \), had an illegal value, then \( \text{info} = -(i*100+j) \), if the \( i \)-th argument is a scalar and had an illegal value, then \( \text{info} = -i \).

  If \( \text{info} > 0 \): If \( \text{info} = k \), the leading minor of order \( k \), \( A(ia:ia+k-1, ja:ja+k-1) \) is not positive definite, and the factorization could not be completed, and the solution has not been computed.

Description
The p?posvx function uses the Cholesky factorization \( A = U^T U \) or \( A = L L^T \) to compute the solution to a real or complex system of linear equations

\[
A(ia:ia+n-1, ja:ja+n-1)X = B(ib:ib+n-1, jb:jb+nrhs-1),
\]

where \( A(ia:ia+n-1, ja:ja+n-1) \) is a \( n \times n \) matrix and \( X \) and \( B(ib:ib+n-1, jb:jb+nrhs-1) \) are \( n \times nrhs \) matrices.

Error bounds on the solution and a condition estimate are also provided.

In the following comments \( y \) denotes \( Y(iy:iy+m-1, jy:jy+k-1) \), an \( m \times k \) matrix where \( y \) can be \( a, af, b \) and \( x \).

The function p?posvx performs the following steps:

1. If \( \text{fact} = 'E' \), real scaling factors \( s \) are computed to equilibrate the system:

\[
\text{diag}(sr) * A * \text{diag}(sc) * \text{inv(diag(sc)}) * X = \text{diag}(sr) * B
\]

Whether or not the system will be equilibrated depends on the scaling of the matrix \( A \), but if equilibration is used, \( A \) is overwritten by \( \text{diag}(sr) * A * \text{diag}(sc) \) and \( B \) by \( \text{diag}(sr) * B \).

2. If \( \text{fact} = 'N' \) or \( 'E' \), the Cholesky decomposition is used to factor the matrix \( A \) (after equilibration if \( \text{fact} = 'E' \)) as

\[
A = U^T U, \text{ if } \text{uplo} = 'U', \text{ or } A = L L^T, \text{ if } \text{uplo} = 'L',
\]

where \( U \) is an upper triangular matrix and \( L \) is a lower triangular matrix.

3. The factored form of \( A \) is used to estimate the condition number of the matrix \( A \). If the reciprocal of the condition number is less than machine precision, steps 4-6 are skipped.

4. The system of equations is solved for \( X \) using the factored form of \( A \).

5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

6. If equilibration was used, the matrix \( X \) is premultiplied by \( \text{diag}(sr) \) so that it solves the original system before equilibration.

Input Parameters

\( \text{fact} \) (global) Must be \( 'F', 'N', \) or \( 'E' \).

Specifies whether or not the factored form of the matrix \( A \) is supplied on entry, and if not, whether the matrix \( A \) should be equilibrated before it is factored.

If \( \text{fact} = 'F' \): on entry, \( af \) contains the factored form of \( A \). If \( \text{equed} = 'Y' \), the matrix \( A \) has been equilibrated with scaling factors given by \( s. a \) and \( af \) will not be modified.

If \( \text{fact} = 'N' \), the matrix \( A \) will be copied to \( af \) and factored.

If \( \text{fact} = 'E' \), the matrix \( A \) will be equilibrated if necessary, then copied to \( af \) and factored.

\( \text{uplo} \) (global) Must be \( 'U' \) or \( 'L' \).

Indicates whether the upper or lower triangular part of \( A \) is stored.
(global) The order of the distributed matrix sub(A) \( (n \geq 0) \).

\( nrhs \) (global) The number of right-hand sides; the number of columns of the distributed submatrices \( B \) and \( X \). \( (nrhs \geq 0) \).

\( a \) (local) Pointer into the local memory to an array of local size \( lld_a \cdot \text{LOCc}(ja + n - 1) \). On entry, the symmetric/Hermitian matrix \( A \), except if \( \text{fact} = 'F' \) and \( \text{equed} = 'Y' \), then \( A \) must contain the equilibrated matrix \( \text{diag}(sr) \cdot A \cdot \text{diag}(sc) \).

If \( \text{uplo} = 'U' \), the leading \( n \)-by-\( n \) upper triangular part of \( A \) contains the upper triangular part of the matrix \( A \), and the strictly lower triangular part of \( A \) is not referenced.

If \( \text{uplo} = 'L' \), the leading \( n \)-by-\( n \) lower triangular part of \( A \) contains the lower triangular part of the matrix \( A \), and the strictly upper triangular part of \( A \) is not referenced. \( A \) is not modified if \( \text{fact} = 'F' \) or \( 'N' \), or if \( \text{fact} = 'E' \) and \( \text{equed} = 'N' \) on exit.

\( ia, ja \) (global) The row and column indices in the global matrix \( A \) indicating the first row and the first column of the submatrix \( A \), respectively.

\( desca \) (global and local) array of size \( dlen_\). The array descriptor for the distributed matrix \( A \).

\( af \) (local) Pointer into the local memory to an array of local size \( lld_{af} \cdot \text{LOCc}(ja + n - 1) \).

If \( \text{fact} = 'F' \), then \( af \) is an input argument and on entry contains the triangular factor \( U \) or \( L \) from the Cholesky factorization \( A = U^T \cdot U \) or \( A = L \cdot L^T \), in the same storage format as \( A \). If \( \text{equed} \neq 'N' \), then \( af \) is the factored form of the equilibrated matrix \( \text{diag}(sr) \cdot A \cdot \text{diag}(sc) \).

\( iaf, jaf \) (global) The row and column indices in the global matrix \( AF \) indicating the first row and the first column of the submatrix \( AF \), respectively.

\( descaf \) (global and local) array of size \( dlen_\). The array descriptor for the distributed matrix \( AF \).

\( equed \) (global) Must be \( 'N' \) or \( 'Y' \).

\( equed \) is an input argument if \( \text{fact} = 'F' \). It specifies the form of equilibration that was done:

- If \( \text{equed} = 'N' \), no equilibration was done (always true if \( \text{fact} = 'N' \));
- If \( \text{equed} = 'Y' \), equilibration was done and \( A \) has been replaced by \( \text{diag}(sr) \cdot A \cdot \text{diag}(sc) \).

\( sr \) (local) Array of size \( lld_a \).

The array \( s \) contains the scale factors for \( A \). This array is an input argument if \( \text{fact} = 'F' \) only; otherwise it is an output argument.

If \( \text{equed} = 'N' \), \( s \) is not accessed.
If \( \text{fact} = 'F' \) and \( \text{equed} = 'Y' \), each element of \( s \) must be positive.

\( b \)  
(local)  
Pointer into the local memory to an array of local size \( lld_b \* \text{LOCc}(jb +nrhs-1) \). On entry, the \( n \)-by-\( nrhs \) right-hand side matrix \( B \).

\( ib, jb \)  
(global) The row and column indices in the global matrix \( B \) indicating the first row and the first column of the submatrix \( B \), respectively.

\( descb \)  
(global and local) Array of size \( dlen_ \). The array descriptor for the distributed matrix \( B \).

\( x \)  
(local)  
Pointer into the local memory to an array of local size \( lld_x \* \text{LOCc}(jx +nrhs-1) \).

\( ix, jx \)  
(global) The row and column indices in the global matrix \( X \) indicating the first row and the first column of the submatrix \( X \), respectively.

\( descx \)  
(global and local) Array of size \( dlen_ \). The array descriptor for the distributed matrix \( X \).

\( work \)  
(local)  
Workspace array of size \( lwork \).

\( lwork \)  
(local or global)  
The size of the array \( work \). \( lwork \) is local input and must be at least \( lwork = \max(p \text{-pocon}(lwork), p \text{-porfs}(lwork)) + \text{LOCr}(n_a) \).

\( lwork = 3 \* \text{desca}[lld - 1] \).

If \( lwork = -1 \), then \( lwork \) is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by \text{pxerbla}.

\( iwork \)  
(local)  
Workspace array of size \( liwork \).

\( liwork \)  
(local or global)  
The size of the array \( iwork \). \( liwork \) is local input and must be at least \( liwork = \text{desca}[lld - 1] \* \text{liwork} = \text{LOCr}(n_a) \).

If \( liwork = -1 \), then \( liwork \) is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by \text{pxerbla}.

Output Parameters

\( a \)  
On exit, if \( \text{fact} = 'E' \) and \( \text{equed} = 'Y' \), \( a \) is overwritten by \( \text{diag}(sr) \* a \* \text{diag}(sc) \).

\( af \)  
If \( \text{fact} = 'N' \), then \( af \) is an output argument and on exit returns the triangular factor \( U \) or \( L \) from the Cholesky factorization \( A = U^T \* U \) or \( A = L \* L^T \) of the original matrix \( A \).
If \( \text{fact} = 'E' \), then \( af \) is an output argument and on exit returns the triangular factor \( U \) or \( L \) from the Cholesky factorization \( A = U^T U \) or \( A = L^T L \) of the equilibrated matrix \( A \) (see the description of \( A \) for the form of the equilibrated matrix).

**equed**

If \( \text{fact} \neq 'F' \), then \( \text{equed} \) is an output argument. It specifies the form of equilibration that was done (see the description of \( \text{equed} \) in Input Arguments section).

**sr**

This array is an output argument if \( \text{fact} \neq 'F' \).

See the description of \( sr \) in Input Arguments section.

**sc**

This array is an output argument if \( \text{fact} \neq 'F' \).

See the description of \( sc \) in Input Arguments section.

**b**

On exit, if \( \text{equed} = 'N' \), \( b \) is not modified; if \( \text{trans} = 'N' \) and \( \text{equed} = 'R' \) or \( 'B' \), \( b \) is overwritten by \( \text{diag}(r) \cdot b \); if \( \text{trans} = 'T' \) or \( 'C' \) and \( \text{equed} = 'C' \) or \( 'B' \), \( b \) is overwritten by \( \text{diag}(c) \cdot b \).

**x**

If \( \text{info} = 0 \) the \( n \)-by-\( nrhs \) solution matrix \( X \) to the original system of equations.

Note that \( A \) and \( B \) are modified on exit if \( \text{equed} \neq 'N' \), and the solution to the equilibrated system is

\[
\text{inv(diag(sc))} \cdot X \quad \text{if trans} = 'N' \quad \text{and} \quad \text{equed} = 'C' \quad \text{or} \quad 'B',
\]

or

\[
\text{inv(diag(sr))} \cdot X \quad \text{if trans} = 'T' \quad \text{or} \quad 'C' \quad \text{and} \quad \text{equed} = 'R' \quad \text{or} \quad 'B'.
\]

**rcond**

An estimate of the reciprocal condition number of the matrix \( A \) after equilibration (if done). If \( rcond \) is less than the machine precision (in particular, if \( rcond=0 \)), the matrix is singular to working precision. This condition is indicated by a return code of \( \text{info} > 0 \).

**ferr**

Arrays of size at least \( \max(LOC,n_b) \). The estimated forward error bounds for each solution vector \( X(j) \) (the \( j \)-th column of the solution matrix \( X \)). If \( xtrue \) is the true solution, \( ferr[j - 1] \) bounds the magnitude of the largest entry in \( (X(j) - xtrue) \) divided by the magnitude of the largest entry in \( X(j) \). The quality of the error bound depends on the quality of the estimate of \( \text{norm(inv}(A)) \) computed in the code; if the estimate of \( \text{norm(inv}(A)) \) is accurate, the error bound is guaranteed.

**berr**

Arrays of size at least \( \max(LOC,n_b) \). The componentwise relative backward error of each solution vector \( X(j) \) (the smallest relative change in any entry of \( A \) or \( B \) that makes \( X(j) \) an exact solution).

**work[0]**

(\( local \)) On exit, \( \text{work}[0] \) returns the minimal and optimal \( liwork \).

**info**

(\( global \))

If \( \text{info}=0 \), the execution is successful.

\(< 0 \): if \( \text{info} = -i \), the \( i \)-th argument had an illegal value.
> 0: if info = i, and i is ≤ n: if info = i, the leading minor of order i of a is not positive definite, so the factorization could not be completed, and the solution and error bounds could not be computed.

= n+1: rcond is less than machine precision. The factorization has been completed, but the matrix is singular to working precision, and the solution and error bounds have not been computed.

Description
The p?pbsv function solves a system of linear equations
\[ A(1:n, ja:ja+n-1)*X = B(ib:ib+n-1, 1:nrhs), \]
where \( A(1:n, ja:ja+n-1) \) is an \( n \)-by-\( n \) real/complex banded symmetric positive definite distributed matrix with bandwidth \( bw \).

Cholesky factorization is used to factor a reordering of the matrix into \( L*L' \).

Optimization Notice
Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.
Input Parameters

**uplo**

(global) Must be 'U' or 'L'.

Indicates whether the upper or lower triangular of \(A\) is stored.

If \(uplo = 'U'\), the upper triangular \(A\) is stored

If \(uplo = 'L'\), the lower triangular of \(A\) is stored.

**n**

(global) The order of the distributed matrix \(A\) (\(n \geq 0\)).

**bw**

(global) The number of subdiagonals in \(L\) or \(U\). \(0 \leq bw \leq n-1\).

**nrhs**

(global) The number of right-hand sides; the number of columns in \(B\) (\(nrhs \geq 0\)).

**a**

(local).

Pointer into the local memory to an array with leading size \(lld_a \geq (bw +1)\) (stored in \(desca\)). On entry, this array contains the local pieces of the distributed matrix \(\text{sub}(A)\) to be factored.

**ja**

(global) The index in the global matrix \(A\) indicating the start of the matrix to be operated on (which may be either all of \(A\) or a submatrix of \(A\)).

**desca**

(global and local) array of size \(dlen\). The array descriptor for the distributed matrix \(A\).

**b**

(local)

Pointer into the local memory to an array of local lead size \(lld_b \geq nb\). On entry, this array contains the local pieces of the right hand sides \(B(ib:ib+n-1, 1:nrhs)\).

**ib**

(global) The row index in the global matrix \(B\) indicating the first row of the matrix to be operated on (which may be either all of \(b\) or a submatrix of \(B\)).

**descb**

(global and local) array of size \(dlen\).

If 1D type \((dtype_b = 502)\), \(dlen \geq 7\);

If 2D type \((dtype_b = 1)\), \(dlen \geq 9\).

The array descriptor for the distributed matrix \(B\).

Contains information of mapping of \(B\) to memory.

**work**

(local).

Temporary workspace. This space may be overwritten in between calls to functions. \(work\) must be the size given in \(lwork\).

**lwork**

(local or global) Size of user-input workspace \(work\). If \(lwork\) is too small, the minimal acceptable size will be returned in \(work[0]\) and an error code is returned. \(lwork \geq (nb+2*bw)*bw + \max((bw*nrhs), bw*bw)\)
Output Parameters

- **a**: On exit, this array contains information containing details of the factorization. Note that permutations are performed on the matrix, so that the factors returned are different from those returned by LAPACK.

- **b**: On exit, contains the local piece of the solutions distributed matrix $X$.

- **work**: On exit, `work[0]` contains the minimal `lwork`.

- **info**: (global) If `info`=0, the execution is successful.
  - If the $i$-th argument is an array and the $j$-entry had an illegal value, then `info = -(i*100+j)`, if the $i$-th argument is a scalar and had an illegal value, then `info = -i`.
  - If `info = k ≤ NPROCS`, the submatrix stored on processor `info` and factored locally was not positive definite, and the factorization was not completed.
  - If `info = k > NPROCS`, the submatrix stored on processor `info-NPROCS` representing interactions with other processors was not positive definite, and the factorization was not completed.

Overview for details of ScaLAPACK array descriptor structures and related notations.

**p?ptsv**

**Syntax**

Solves a symmetric or Hermitian positive definite tridiagonal system of linear equations.

```c
void psptsv (MKL_INT *n, MKL_INT *nrhs, float *d, float *e, MKL_INT *ja, MKL_INT *desca, float *b, MKL_INT *ib, MKL_INT *descb, float *work, MKL_INT *lwork, MKL_INT *info);
void pdptsv (MKL_INT *n, MKL_INT *nrhs, double *d, double *e, MKL_INT *ja, MKL_INT *desca, double *b, MKL_INT *ib, MKL_INT *descb, double *work, MKL_INT *lwork, MKL_INT *info);
void pcptsv (char *uplo, MKL_INT *n, MKL_INT *nrhs, float *d, MKL_Complex8 *e, MKL_INT *ja, MKL_INT *desca, MKL_Complex8 *b, MKL_INT *ib, MKL_INT *descb, MKL_Complex8 *work, MKL_INT *lwork, MKL_INT *info);
void pzptsv (char *uplo, MKL_INT *n, MKL_INT *nrhs, double *d, MKL_Complex16 *e, MKL_INT *ja, MKL_INT *desca, MKL_Complex16 *b, MKL_INT *ib, MKL_INT *descb, MKL_Complex16 *work, MKL_INT *lwork, MKL_INT *info);
```

**Include Files**

- `mkl_scalapack.h`

**Description**

The `p?ptsv` function solves a system of linear equations

$$A(1:n, ja:ja+n-1)X = B(ib:ib+n-1, 1:nrhs),$$

where $A(1:n, ja:ja+n-1)$ is an $n$-by-$n$ real tridiagonal symmetric positive definite distributed matrix.
Cholesky factorization is used to factor a reordering of the matrix into $L^*L'$.

</tr>
</tbody>
</table>
Temporary workspace. This space may be overwritten in between calls to functions. work must be the size given in lwork.

(llocal or global) Size of user-input workspace work. If lwork is too small, the minimal acceptable size will be returned in work[0] and an error code is returned. \( lwork > (12*NPCOL+3*nb)+\max((10+2*\min(100, nrhs))*NPCOL+4*nrhs, 8*NPCOL) \).

Output Parameters

d

On exit, this array contains information containing the factors of the matrix. Must be of size greater than or equal to desca[\(nb\) - 1].

e

On exit, this array contains information containing the factors of the matrix. Must be of size greater than or equal to desca[\(nb\) - 1].

b

On exit, this contains the local piece of the solutions distributed matrix \(X\).

work

On exit, work[0] contains the minimal lwork.

info

(local) If info=0, the execution is successful.

< 0: If the \(i\)-th argument is an array and the \(j\)-entry had an illegal value, then info = -(\(i*100+j\)), if the \(i\)-th argument is a scalar and had an illegal value, then info = -\(i\).

> 0: If info = \(k\) \(\leq\) NPROCS, the submatrix stored on processor info and factored locally was not positive definite, and the factorization was not completed.

If info = \(k\) > NPROCS, the submatrix stored on processor info-NPROCS representing interactions with other processors was not positive definite, and the factorization was not completed.

void p cgels (char *trans, MKL_INT *m, MKL_INT *n, MKL_INT *nrhs, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_Complex8 *b, MKL_INT *ib, MKL_INT *jb, MKL_INT *descb, MKL_Complex8 *work, MKL_INT *lwork, MKL_INT *info);
void pzgels ( char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *nrhs , MKL_Complex16 *a ,
MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb , MKL_Complex16 *work , MKL_INT *lwork , MKL_INT *info );

Include Files
- mkl_scalapack.h

Description
The pzgels function solves overdetermined or underdetermined real/complex linear systems involving an 
m-by-n matrix sub(A) = A(ia:ia+m-1,ja:ja+n-1), or its transpose/conjugate-transpose, using a QTQ or 
LQ factorization of sub(A). It is assumed that sub(A) has full rank.

The following options are provided:
1. If trans = 'N' and m≥n: find the least squares solution of an overdetermined system, that is, solve
   the least squares problem
   
   minimize ||sub(B) - sub(A)*X||

2. If trans = 'N' and m < n: find the minimum norm solution of an underdetermined system sub(A)*X = sub(B).

3. If trans = 'T' and m≥n: find the minimum norm solution of an underdetermined system sub(A)^T*X = sub(B).

4. If trans = 'T' and m < n: find the least squares solution of an overdetermined system, that is, solve
   the least squares problem
   
   minimize ||sub(B) - sub(A)^T*X||,

   where sub(B) denotes B(ib:ib+m-1, jb:jb+nrhs-1) when trans = 'N' and B(ib:ib+n-1, 
   jb:jb+nrhs-1) otherwise. Several right hand side vectors b and solution vectors x can be handled in a 
single call; when trans = 'N', the solution vectors are stored as the columns of the n-by-nrhs right 
hand side matrix sub(B) and the m-by-nrhs right hand side matrix sub(B) otherwise.

Input Parameters

trans
   (global) Must be 'N', or 'T'.
   If trans = 'N', the linear system involves matrix sub(A);
   If trans = 'T', the linear system involves the transposed matrix A^T (for 
   real flavors only).

m
   (global) The number of rows in the distributed matrix sub(A) (m≥0).

n
   (global) The number of columns in the distributed matrix sub(A) (n≥0).

nrhs
   (global) The number of right-hand sides; the number of columns in the 
distributed submatrices sub(B) and X. (nrhs≥0).

a
   (local)
   Pointer into the local memory to an array of size lld_a*LOCc(ja+n-1). On 
   entry, contains the m-by-n matrix A.

ia, ja
   (global) The row and column indices in the global matrix A indicating the 
   first row and the first column of the submatrix A, respectively.

desca
   (global and local) array of size dlen_. The array descriptor for the 
distributed matrix A.
b

(Pointer into the local memory to an array of local size lld_b*LOCc(jb +nrhs-1). On entry, this array contains the local pieces of the distributed matrix B of right-hand side vectors, stored columnwise; sub(B) is m-by-nrhs if trans='N', and n-by-nrhs otherwise.

ib, jb

 The row and column indices in the global matrix B indicating the first row and the first column of the submatrix B, respectively.

descb

 (global and local) array of size dlen_. The array descriptor for the distributed matrix B.

work

 (local)

 Workspace array with size lwork.

lwork

 (local or global).

 The size of the array work/lwork is local input and must be at least lwork \geq ltau + \max(lwf, lws), where if m > n, then

 ltau = numroc(ja+min(m,n)-1, nb_a, MYCOL, csra_a, NPCOL),
lwf = nb_a*(mpa0 + nqa0 + nb_a)
lws = \max((nb_a*(nb_a-1))/2, (nrhsqb0 + mpb0)*nb_a) + nb_a*nb_a
else
 ltau = numroc(ia+min(m,n)-1, mb_a, MYROW, rsca_a, NPROW),
lwf = mb_a * (mpa0 + nqa0 + mb_a)
lws = \max((mb_a*(mb_a-1))/2, (npb0 + \max(nqa0 + numroc(numroc(n+iroffb, mb_a, 0, 0, NPROW), mb_a, 0, 0, lcm), nrhsqb0))*mb_a) + mb_a*mb_a
end if,

 where lcm = lcm/NPROW with lcm = ilcm(NPROW, NPCOL),
iroff = mod(ia-1, mb_a),
icoff = mod(ja-1, nb_a),
iarow = indxg2p(ia, mb_a, MYROW, rsca_a, NPROW),
iacol= indxg2p(ja, nb_a, MYROW, rsca_a, NPROW)
mpa0 = numroc(m+iroff, mb_a, MYROW, iarow, NPROW),
nqa0 = numroc(n+icoff, nb_a, MYCOL, iacol, NPCOL),
iroff = mod(ib-1, mb_b),
icoff = mod(jb-1, nb_b),
ibrow = indxg2p(ib, mb_b, MYROW, rsrb_b, NPROW),
ibcol = indxg2p(jb, nb_b, MYCOL, srcsb_b, NPCOL),
mpb0 = numroc(m+iroff, mb_b, MYROW, icrow, NPROW),
nqb0 = numroc(n+icoff, nb_b, MYCOL, ibcol, NPCOL),
NOTE
mod(x, y) is the integer remainder of \( x/y \).

ilcm, indx2p and numroc are ScaLAPACK tool functions; MYROW, MYCOL, NPROW, and NPCOL can be determined by calling the function blacs_gridinfo.

If \( lwork = -1 \), then \( lwork \) is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

\( a \)
On exit, If \( m \geq n \), sub(\( A \)) is overwritten by the details of its QR factorization as returned by \( p?geqrf \); if \( m < n \), sub(\( A \)) is overwritten by details of its LQ factorization as returned by \( p?gelqf \).

\( b \)
On exit, sub(\( B \)) is overwritten by the solution vectors, stored columnwise: if \( trans = 'N' \) and \( m \geq n \), rows 1 to \( n \) of sub(\( B \)) contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of elements \( n+1 \) to \( m \) in that column;
If \( trans = 'N' \) and \( m < n \), rows 1 to \( n \) of sub(\( B \)) contain the minimum norm solution vectors;
If \( trans = 'T' \) and \( m \geq n \), rows 1 to \( m \) of sub(\( B \)) contain the minimum norm solution vectors; if \( trans = 'T' \) and \( m < n \), rows 1 to \( m \) of sub(\( B \)) contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of elements \( m+1 \) to \( n \) in that column.

\( work[0] \)
On exit, \( work[0] \) contains the minimum value of \( lwork \) required for optimum performance.

\( info \)
(global)
\( = 0 \): the execution is successful.
\( < 0 \): if the \( i \)-th argument is an array and the \( j \)-entry had an illegal value, then \( info = -(i*100+j) \); if the \( i \)-th argument is a scalar and had an illegal value, then \( info = -i \).

\( p?syev \)
Computes selected eigenvalues and eigenvectors of a symmetric matrix.
Syntax
void pssyev (char *jobz, char *uplo, MKL_INT *n, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *w, float *z, MKL_INT *iz, MKL_INT *jz, MKL_INT *descz, float *work, MKL_INT *lwork, MKL_INT *info);
void pdsyev (char *jobz, char *uplo, MKL_INT *n, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *w, double *z, MKL_INT *iz, MKL_INT *jz, MKL_INT *descz, double *work, MKL_INT *lwork, MKL_INT *info);

Include Files
• mkl_scalapack.h

Description
The `p?syev` function computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix $A$ by calling the recommended sequence of ScaLAPACK functions.

In its present form, the function assumes a homogeneous system and makes no checks for consistency of the eigenvalues or eigenvectors across the different processes. Because of this, it is possible that a heterogeneous system may return incorrect results without any error messages.

Input Parameters
$n_p$ = the number of rows local to a given process.
$n_q$ = the number of columns local to a given process.

`jobz` (global) Must be 'N' or 'V'. Specifies if it is necessary to compute the eigenvectors:
If `jobz` = 'N', then only eigenvalues are computed.
If `jobz` = 'V', then eigenvalues and eigenvectors are computed.

`uplo` (global) Must be 'U' or 'L'. Specifies whether the upper or lower triangular part of the symmetric matrix $A$ is stored:
If `uplo` = 'U', $a$ stores the upper triangular part of $A$.
If `uplo` = 'L', $a$ stores the lower triangular part of $A$.

$n$ (global) The number of rows and columns of the matrix $A (n \geq 0)$.

$a$ (local)
Block cyclic array of global size $n \times n$ and local size $lld_a \times \text{LOCc}(ja+n-1)$. On entry, the symmetric matrix $A$.
If `uplo` = 'U', only the upper triangular part of $A$ is used to define the elements of the symmetric matrix.
If `uplo` = 'L', only the lower triangular part of $A$ is used to define the elements of the symmetric matrix.

`ia`, `ja` (global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the submatrix $A$, respectively.

desca (global and local) array of size $dlen_$. The array descriptor for the distributed matrix $A$. 
(global) The row and column indices in the global matrix $Z$ indicating the first row and the first column of the submatrix $Z$, respectively.

(global and local) array of size $dlen_$. The array descriptor for the distributed matrix $Z$.

(local) Array of size $lwork$.

(local) See below for definitions of variables used to define $lwork$.

If no eigenvectors are requested ($jobz = 'N'$), then $lwork \geq 5*n + $ sizesytrd + 1, where sizesytrd is the workspace for $p?sytrd$ and is $\max(NB*(np +1)$, $3*NB$).

If eigenvectors are requested ($jobz = 'V'$) then the amount of workspace required to guarantee that all eigenvectors are computed is:

$$qrmem = 2*n-2$$

$$lwmin = 5*n + n*ldc + \max(sizemqrleft, qrmem) + 1$$

Variable definitions:

$$nn = \max(n, nb, 2);$$

$$np = \text{numroc}(nn, nb, 0, 0, NPROW)$$

$$nq = \text{numroc}(\max(n, nb, 2), nb, 0, 0, NPCOL)$$

$$nrc = \text{numroc}(n, nb, myprowc, 0, NPROCS)$$

$$ldc = \max(1, nrc)$$

$sizemqrleft$ is the workspace for $p?ormtr$ when its side argument is 'L'.

$myprowc$ is defined when a new context is created as follows:

```
call blacs_get(desca[ctxt - 1], 0, contextc)
call blacs_gridinit(contextc, 'R', NPROCS, 1)
call blacs_gridinfo(contextc, nprowc, npcolc, myprowc, mypcolc)
```

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by $pxerbla$.

### Output Parameters

$a$

On exit, the lower triangle (if $uplo='L'$) or the upper triangle (if $uplo='U'$) of $A$, including the diagonal, is destroyed.

$w$

(global).
Array of size $n$.
On normal exit, the first $m$ entries contain the selected eigenvalues in ascending order.

$z$
Array, global size $n \times n$, local size $lld_z \times LOCc(jz+n-1)$. If $jobz = 'V$', then on normal exit the first $m$ columns of $z$ contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues.
If $jobz = 'N'$, then $z$ is not referenced.

work[0]
On output, $work[0]$ returns the workspace needed to guarantee completion. If the input parameters are incorrect, $work[0]$ may also be incorrect.
If $jobz = 'N'$, $work[0] = \text{minimal (optimal) amount of workspace}$
If $jobz = 'V'$, $work[0] = \text{minimal workspace required to generate all the eigenvectors}$

info (global)
If $info = 0$, the execution is successful.
If $info < 0$: If the $i$-th argument is an array and the $j$-entry had an illegal value, then $info = -(i \times 100 + j)$, if the $i$-th argument is a scalar and had an illegal value, then $info = -i$.
If $info > 0$:
If $info = 1$ through $n$, the $i$-th eigenvalue did not converge in steqr2 after a total of $30n$ iterations.
If $info = n+1$, then p?syev has detected heterogeneity by finding that eigenvalues were not identical across the process grid. In this case, the accuracy of the results from p?syev cannot be guaranteed.

See Also
Overview for details of ScaLAPACK array descriptor structures and related notations.

p?syevd
Computes all eigenvalues and eigenvectors of a real symmetric matrix by using a divide and conquer algorithm.

Syntax
void pssyevd (char *jobz , char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *w , float *z , MKL_INT *iz , MKL_INT *jz , MKL_INT *descz , float *work , MKL_INT *lwork , MKL_INT *iwork , MKL_INT *liwork , MKL_INT *info );
void pdsyevd (char *jobz , char *uplo , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *w , double *z , MKL_INT *iz , MKL_INT *jz , MKL_INT *descz , double *work , MKL_INT *lwork , MKL_INT *iwork , MKL_INT *liwork , MKL_INT *info );
Include Files

- mkl_scalapack.h

Description

The `p?syevd` function computes all eigenvalues and eigenvectors of a real symmetric matrix `A` by using a divide and conquer algorithm.

Input Parameters

`np` = the number of rows local to a given process.

`nq` = the number of columns local to a given process.

`jobz` (global) Must be 'N' or 'V'.

Specifies if it is necessary to compute the eigenvectors:

If `jobz` = 'N', then only eigenvalues are computed.

If `jobz` = 'V', then eigenvalues and eigenvectors are computed.

`uplo` (global) Must be 'U' or 'L'.

Specifies whether the upper or lower triangular part of the Hermitian matrix `A` is stored:

If `uplo` = 'U', `a` stores the upper triangular part of `A`.

If `uplo` = 'L', `a` stores the lower triangular part of `A`.

`n` (global) The number of rows and columns of the matrix `A` (`n ≥ 0`).

`a` (local).

Block cyclic array of global size `n*n` and local size `lld_a*LOCc(ja+n-1)`. On entry, the symmetric matrix `A`.

If `uplo` = 'U', only the upper triangular part of `A` is used to define the elements of the symmetric matrix.

If `uplo` = 'L', only the lower triangular part of `A` is used to define the elements of the symmetric matrix.

`ia`, `ja` (global) The row and column indices in the global matrix `A` indicating the first row and the first column of the submatrix `A`, respectively.

`desca` (global and local) array of size `dlenn_.` The array descriptor for the distributed matrix `A`. If `desca[ctxt_ - 1]` is incorrect, `p?syevd` cannot guarantee correct error reporting.

`iz`, `jz` (global) The row and column indices in the global matrix `Z` indicating the first row and the first column of the submatrix `Z`, respectively.

`descz` (global and local) array of size `dlenn_.` The array descriptor for the distributed matrix `Z`. `descz[ctxt_ - 1]` must equal `desca[ctxt_ - 1]`.

`work` (local).

Array of size `lwork`.

`lwork` (local) The size of the array `work`.

If eigenvalues are requested:
lwork ≥ \( \max(1 + 6n + 2npnq, \text{trilwmin}) + 2n \)
with \( \text{trilwmin} = 3n + \max(nb(n + 1), 3nb) \)

\( np = \text{numroc}(n, nb, \text{myrow}, \text{iarow}, \text{NPROW}) \)
\( nq = \text{numroc}(n, nb, \text{mycol}, \text{iacol}, \text{NPCOL}) \)

If \( lwork = -1 \), then \( lwork \) is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. The required workspace is returned as the first element of the corresponding work arrays, and no error message is issued by pxerbla.

\( iwork \)
(local) Workspace array of size \( liwork \).
\( liwork \)
(local), size of \( iwork \).
\( liwork = 7n + 8nq + 2 \).

Output Parameters

\( a \)
On exit, the lower triangle (if \( \text{uplo} = 'L' \)) or the upper triangle (if \( \text{uplo} = 'U' \)) of \( A \), including the diagonal, is overwritten.

\( w \)
Array of size \( n \). If \( info = 0 \), \( w \) contains the eigenvalues in the ascending order.

\( z \)
(local).
Array, global size \((n, n)\), local size \( lld_z*\text{LOCc}(jz+n-1) \).
The \( z \) parameter contains the orthonormal eigenvectors of the matrix \( A \).

\( \text{work}[0] \)
On exit, returns adequate workspace to allow optimal performance.

\( \text{iwork}[0] \)
On exit, if \( liwork > 0 \), \( \text{iwork}[0] \) returns the optimal \( liwork \).

\( info \)
(global)
If \( info = 0 \), the execution is successful.
If \( info < 0 \):
If the \( i \)-th argument is an array and the \( j \)-entry had an illegal value, then \( info = -(i*100+j) \). If the \( i \)-th argument is a scalar and had an illegal value, then \( info = -i \).
If \( info > 0 \):
The algorithm failed to compute the \( info/(n+1) \)-th eigenvalue while working on the submatrix lying in global rows and columns \( \text{mod}(info, n + 1) \).

**NOTE**
\( \text{mod}(x, y) \) is the integer remainder of \( x/y \).
See Also
Overview for details of ScaLAPACK array descriptor structures and related notations.

p?syevr
Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix using Relatively Robust Representation.

Syntax
void pssyevr(char* jobz, char* range, char* uplo, MKL_INT* n, float* a, MKL_INT* ia, MKL_INT* ja, MKL_INT* desca, float* vl, float* vu, MKL_INT* il, MKL_INT* iu, MKL_INT* m, MKL_INT* nz, float* w, float* z, MKL_INT* iz, MKL_INT* jz, MKL_INT* descz, float* work, MKL_INT* lwork, MKL_INT* iwork, MKL_INT* liwork, MKL_INT* info);

void pdsyevr(char* jobz, char* range, char* uplo, MKL_INT* n, double* a, MKL_INT* ia, MKL_INT* ja, MKL_INT* desca, double* vl, double* vu, MKL_INT* il, MKL_INT* iu, MKL_INT* m, MKL_INT* nz, double* w, double* z, MKL_INT* iz, MKL_INT* jz, MKL_INT* descz, double* work, MKL_INT* lwork, MKL_INT* iwork, MKL_INT* liwork, MKL_INT* info);

Include Files
- mkl_scalapack.h

Description
p?syevr computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A distributed in 2D blockcyclic format by calling the recommended sequence of ScaLAPACK functions.

First, the matrix A is reduced to real symmetric tridiagonal form. Then, the eigenproblem is solved using the parallel MRRR algorithm. Last, if eigenvectors have been computed, a backtransformation is done.

Upon successful completion, each processor stores a copy of all computed eigenvalues in w. The eigenvector matrix z is stored in 2D block-cyclic format distributed over all processors.

Note that subsets of eigenvalues/vectors can be selected by specifying a range of values or a range of indices for the desired eigenvalues.

Optimization Notice
Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.
Notice revision #20110804

Input Parameters

jobz (global)
Specifies whether or not to compute the eigenvectors:
= 'N': Compute eigenvalues only.
= 'V': Compute eigenvalues and eigenvectors.
**range** (global)

- 'A': all eigenvalues will be found.
- 'V': all eigenvalues in the interval \([vl, vu]\) will be found.
- 'I': the \(i_l\)-th through \(i_u\)-th eigenvalues will be found.

**uplo** (global)

Specifies whether the upper or lower triangular part of the symmetric matrix \(A\) is stored:
- 'U': Upper triangular
- 'L': Lower triangular

**n** (global)

The number of rows and columns of the matrix \(A\). \(n \geq 0\)

**a**

Block cyclic array of global size \(n \times n\), local size \(lld_a \times LOC_c(ja+n-1)\).

This array contains the local pieces of the symmetric distributed matrix \(A\). If \(uplo = 'U'\), only the upper triangular part of \(a\) is used to define the elements of the symmetric matrix. If \(uplo = 'L'\), only the lower triangular part of \(a\) is used to define the elements of the symmetric matrix.

On exit, the lower triangle (if \(uplo='L'\)) or the upper triangle (if \(uplo='U'\)) of \(a\), including the diagonal, is destroyed.

**ia** (global)

Global row index in the global matrix \(A\) that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.

**ja** (global)

Global column index in the global matrix \(A\) that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.

**desca** (global and local) array of size \(dlen_\_=9\).

The array descriptor for the distributed matrix \(a\).

**vl** (global)

If \(range='V'\), the lower bound of the interval to be searched for eigenvalues. Not referenced if \(range = 'A'\) or 'I'.

**vu** (global)

If \(range='V'\), the upper bound of the interval to be searched for eigenvalues. Not referenced if \(range = 'A'\) or 'I'.

**il** (global)

If \(range='I'\), the index (from smallest to largest) of the smallest eigenvalue to be returned. \(il \geq 1\).

Not referenced if \(range = 'A'\).

**iu** (global)
If range='I', the index (from smallest to largest) of the largest eigenvalue to be returned. min(il,n) ≤ iu ≤ n.

Not referenced if range = 'A'.

iz

(global )

Global row index in the global matrix Z that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.

jz

(global )

Global column index in the global matrix Z that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.

descz

array of size dlen_.

The array descriptor for the distributed matrix z.

The context descz[ctxt_ - 1] must equal desca[ctxt_ - 1]. Also note the array alignment requirements specified below.

work

(local workspace) array of size lwork

lwork

(local )

Size of work, must be at least 3.

See below for definitions of variables used to define lwork.

If no eigenvectors are requested (jobz = 'N') then

lwork≥ 2 + 5*n + max( 12 * nn, neig * ( np0 + 1 ) )

If eigenvectors are requested (jobz = 'V' ) then the amount of workspace required is:

lwork≥ 2 + 5*n + max( 18*nn, np0 * mq0 + 2 * neig * neig ) + (2 + iceil( neig, nprow*ncol))*nn

Variable definitions:

neig = number of eigenvectors requested

nb = desca[ mb_ - 1] = desca( nb_ ) = descz[ mb_ - 1] = descz( nb_ )

nn = max( n, neig, 2 )

np0 = numroc( nn, neig, 0, 0, nprow )

mq0 = numroc( max( neig, neig, 2 ), neig, 0, 0, npcol )

iceil( x, y ) is a ScALAPACK function returning ceiling(x/y), and nprow and npcol can be determined by calling the function blacs_gridinfo.

If lwork = -1, then lwork is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by pxerbla.
liwork

(size of iwork)

Let \( nnp = \max(n, nprow \times npcol + 1, 4) \). Then:

\[
liwork \geq 12 \times nnp + 2 \times n \quad \text{when the eigenvectors are desired}
\]

\[
liwork \geq 10 \times nnp + 2 \times n \quad \text{when only the eigenvalues have to be computed}
\]

If \( liwork = -1 \), then \( liwork \) is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by \texttt{pxerbla}.

**OUTPUT Parameters**

\( m \) (global )

Total number of eigenvalues found. 0 \( \leq m \leq n \).

\( nz \) (global )

Total number of eigenvectors computed. 0 \( \leq nz \leq m \).

The number of columns of \( z \) that are filled.

If \( jobz \neq 'V' \), \( nz \) is not referenced.

If \( jobz = 'V' \), \( nz = m \)

\( w \) (global ) array of size \( n \)

Upon successful exit, the first \( m \) entries contain the selected eigenvalues in ascending order.

\( z \)

Block-cyclic array, global size \( n \times n \), local size \( lld_z \times LOC_C(jz+n-1) \).

On exit, contains local pieces of distributed matrix \( Z \).

\( work \)

On return, \( work[0] \) contains the optimal amount of workspace required for efficient execution. If \( jobz = 'N' \), \( work[0] \) = optimal amount of workspace required to compute the eigenvalues. If \( jobz = 'V' \), \( work[0] \) = optimal amount of workspace required to compute eigenvalues and eigenvectors.

\( iwork \) (local workspace) array

On return, \( iwork[0] \) contains the amount of integer workspace required.

\( info \) (global )

= 0: successful exit

< 0: If the \( i \)-th argument is an array and the \( j \)-th entry had an illegal value, then \( info = -(i \times 100+j) \), if the \( i \)-th argument is a scalar and had an illegal value, then \( info = -i \).

**Application Notes**

The distributed submatrices \( a(ia:*, ja:* \) and \( z(iz:iz+m-1, jz:jz+n-1) \) must satisfy the following alignment properties:

1. Identical (quadratic) dimension: \( desca[m - 1] = descz[m - 1] = desca[n - 1] = descz[n - 1] \)
2. Quadratic conformal blocking: \( \text{desca}[mb - 1] = \text{desca}[nb - 1] = \text{descz}[mb - 1] = \text{descz}[nb - 1] \),
\( \text{desca}[src - 1] = \text{descz}[src - 1] \)

3. \( \text{mod}( ia - 1, mb_a ) = \text{mod}( iz - 1, mb_z ) = 0 \)

**NOTE**
\( \text{mod}(x, y) \) is the integer remainder of \( x/y \).

**p?syevx**
Computes selected eigenvalues and, optionally, eigenvectors of a symmetric matrix.

**Syntax**
```c
void pssyevx (char *jobz, char *range, char *uplo, MKL_INT *n, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *vl, float *vu, MKL_INT *il, MKL_INT *iu, float *abstol, MKL_INT *m, MKL_INT *nz, float *w, float *orfac, float *z, MKL_INT *iz, MKL_INT *jz, MKL_INT *descz, float *work, MKL_INT *lwork, MKL_INT *iwork, MKL_INT *iifail, MKL_INT *iclustr, float *gap, MKL_INT *info );
void pdsyevx (char *jobz, char *range, char *uplo, MKL_INT *n, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *vl, double *vu, MKL_INT *il, MKL_INT *iu, double *abstol, MKL_INT *m, MKL_INT *nz, double *w, double *orfac, double *z, MKL_INT *iz, MKL_INT *jz, MKL_INT *descz, double *work, MKL_INT *lwork, MKL_INT *iwork, MKL_INT *iifail, MKL_INT *iclustr, double *gap, MKL_INT *info );
```

**Include Files**
- mkl_scalapack.h

**Description**
The p?syevx function computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix \( A \) by calling the recommended sequence of ScalAPACK functions. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

**Optimization Notice**
Intel’s compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

**Input Parameters**
\( np \) = the number of rows local to a given process.
$nq$ = the number of columns local to a given process.

$\text{jobz}$ (global) Must be 'N' or 'V'. Specifies if it is necessary to compute the eigenvectors:

- If $\text{jobz} =$'N', then only eigenvalues are computed.
- If $\text{jobz} =$'V', then eigenvalues and eigenvectors are computed.

$\text{range}$ (global) Must be 'A', 'V', or 'I'.

- If $\text{range} =$ 'A', all eigenvalues will be found.
- If $\text{range} =$ 'V', all eigenvalues in the half-open interval $[vl, vu]$ will be found.
- If $\text{range} =$ 'I', the eigenvalues with indices $il$ through $iu$ will be found.

$\text{uplo}$ (global) Must be 'U' or 'L'.

Specifies whether the upper or lower triangular part of the symmetric matrix $A$ is stored:

- If $\text{uplo} =$ 'U', $a$ stores the upper triangular part of $A$.
- If $\text{uplo} =$ 'L', $a$ stores the lower triangular part of $A$.

$n$ (global) The number of rows and columns of the matrix $A$ ($n \geq 0$).

$a$ (local).

Block cyclic array of global size $n \times n$ and local size $lld_a \times \text{LOCc}(ja+n-1)$.

On entry, the symmetric matrix $A$.

- If $\text{uplo} =$ 'U', only the upper triangular part of $A$ is used to define the elements of the symmetric matrix.
- If $\text{uplo} =$ 'L', only the lower triangular part of $A$ is used to define the elements of the symmetric matrix.

$\text{ia, ja}$ (global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the submatrix $A$, respectively.

$\text{desca}$ (global and local) array of size $dlen_\_$. The array descriptor for the distributed matrix $A$.

$vl, vu$ (global)

- If $\text{range} =$ 'V', the lower and upper bounds of the interval to be searched for eigenvalues; $vl \leq vu$. Not referenced if $\text{range} =$ 'A' or 'I'.

$il, iu$ (global)

- If $\text{range} =$'I', the indices of the smallest and largest eigenvalues to be returned.

Constraints: $il \geq 1$

$\min(il, n) \leq iu \leq n$

Not referenced if $\text{range} =$ 'A' or 'V'.

$\text{abstol}$ (global).

- If $\text{jobz} =$'V', setting $\text{abstol}$ to $\text{p?lamch(context, 'U')}$ yields the most orthogonal eigenvectors.
The absolute error tolerance for the eigenvalues. An approximate
eigenvalue is accepted as converged when it is determined to lie in an
interval \([a, b]\) of width less than or equal to

\[abstol + eps \times \max(|a|, |b|),\]

where \(eps\) is the machine precision. If \(abstol\) is less than or equal to zero,
then \(eps\times\text{norm}(T)\) will be used in its place, where \(\text{norm}(T)\) is the 1-norm of
the tridiagonal matrix obtained by reducing \(A\) to tridiagonal form.

Eigenvalues will be computed most accurately when \(abstol\) is set to twice
the underflow threshold \(2\times\text{lamch}'S'\) not zero. If this function returns
with \((\text{mod(info,2)} \neq 0)\) or \((\text{mod(info/8,2)} \neq 0)\), indicating that some
eigenvalues or eigenvectors did not converge, try setting \(abstol\) to
\(2\times\text{lamch}'S'\).

\(orfac\)

(global).

Specifies which eigenvectors should be reorthogonalized. Eigenvectors that
correspond to eigenvalues which are within \(tol=orfac\times\text{norm}(A)\) of each
other are to be reorthogonalized. However, if the workspace is insufficient
(see \(lwork\)), \(tol\) may be decreased until all eigenvectors to be
reorthogonalized can be stored in one process. No reorthogonalization will
be done if \(orfac\) equals zero. A default value of 1.0e-3 is used if \(orfac\) is
negative. \(orfac\) should be identical on all processes.

\(iz, jz\)

(global) The row and column indices in the global matrix \(Z\) indicating the
first row and the first column of the submatrix \(Z\), respectively.

\(descz\)

(global and local) array of size \(dlen_\).
The array descriptor for the
distributed matrix \(Z\). \(descz[ctxt_ - 1]\) must equal \(desca[ctxt_ - 1]\).

\(work\)

(local)

Array of size \(lwork\).

\(lwork\)

(local) The size of the array \(work\).

See below for definitions of variables used to define \(lwork\).

If no eigenvectors are requested \((jobz = 'N')\), then
\(lwork \geq 5\times n + \max(5\times n, \text{NB} \times (np0 + 1))\).

If eigenvectors are requested \((jobz = 'V')\), then the amount of workspace
required to guarantee that all eigenvectors are computed is:

\(lwork \geq 5\times n + \max(5\times n, np0 \times mq0 + 2 \times \text{NB} \times \text{NB}) + \text{iceil}(\text{neig}, \text{NPROW} \times \text{NPCOL}) \times n\)

The computed eigenvectors may not be orthogonal if the minimal
workspace is supplied and \(orfac\) is too small. If you want to guarantee
orthogonality (at the cost of potentially poor performance) you should add
the following to \(lwork\):

\((\text{clustersize}-1) \times n,\)

where \(\text{clustersize}\) is the number of eigenvalues in the largest cluster, where
a cluster is defined as a set of close eigenvalues:

\([w[k - 1], ..., w[k+\text{clustersize}-2]|w[j] \leq w[j-1]) + orfac \times 2 \times \text{norm}(A),\)
where

\( \text{neig} = \text{number of eigenvectors requested} \)
\( \text{nb} = \text{desca}[\text{mb} - 1] = \text{desca}[\text{nb} - 1] = \text{descz}[\text{mb} - 1] = \text{descz}[\text{nb} - 1]; \)
\( \text{nn} = \max(n, \text{nb}, 2); \)
\( \text{desca}[\text{rsr}_c - 1] = \text{desca}[\text{nb} - 1] = \text{descz}[\text{rsr}_c - 1] = \text{descz}[\text{csr}_c - 1] = 0; \)
\( np0 = \text{numroc}(n, \text{nb}, 0, 0, \text{NPROW}); \)
\( mq0 = \text{numroc}(\max(\text{neig}, \text{nb}, 2), \text{nb}, 0, 0, \text{NPCOL}); \)
\( \text{iceil}(x, y) \text{ is a ScaLAPACK function returning ceiling}(x/y) \)

If \( lwork \) is too small to guarantee orthogonality, \( \text{p?syevx} \) attempts to maintain orthogonality in the clusters with the smallest spacing between the eigenvalues.

If \( lwork \) is too small to compute all the eigenvectors requested, no computation is performed and \( \text{info} = -23 \) is returned.

Note that when \( \text{range} = 'V' \), number of requested eigenvectors are not known until the eigenvalues are computed. In this case and if \( lwork \) is large enough to compute the eigenvalues, \( \text{p?sygvx} \) computes the eigenvalues and as many eigenvectors as possible.

\textbf{Relationship between workspace, orthogonality & performance:}

Greater performance can be achieved if adequate workspace is provided. In some situations, performance can decrease as the provided workspace increases above the workspace amount shown below:

\[ lwork \geq \max(lwork, 5*n + n\text{symrd}_{lwopt}) \]

where \( lwork \), as defined previously, depends upon the number of eigenvectors requested, and

\[ n\text{sytrd}_{lwopt} = n + 2*(anb+1)*(4*nps+2) + (nps + 3)*nps; \]
\[ anb = \text{pjlaenv}(\text{desca}[\text{ctxt} - 1], 3, 'p\text{?sytrd}', 'L', 0, 0, 0, 0); \]
\[ \text{sqnpc} = \text{int}(\text{sqrt}(\text{dble}(\text{NPROW} * \text{NPCOL}))); \]
\[ nps = \max(\text{numroc}(n, 1, 0, 0, \text{sqnpc}), 2*anb); \]
\[ \text{numroc} \text{ is a ScaLAPACK tool functions;} \]
\[ \text{pjlaenv} \text{ is a ScaLAPACK environmental inquiry function} \]

\( \text{MYROW, MYCOL, NPROW and NPCOL} \) can be determined by calling the function \( \text{blacs_gridinfo} \).

For large \( n \), no extra workspace is needed, however the biggest boost in performance comes for small \( n \), so it is wise to provide the extra workspace (typically less than a megabyte per process).

If \( \text{clustersize} > n/\text{sqrt}(\text{NPROW}\times\text{NPCOL}) \), then providing enough space to compute all the eigenvectors orthogonally will cause serious degradation in performance. At the limit (that is, \( \text{clustersize} = n-1 \) \( \text{p?stein} \) will perform no better than \( ?\text{stein} \) on single processor.)
For \( \text{clustersize} = n / \sqrt{NPROW \times NPCOL} \) reorthogonalizing all eigenvectors will increase the total execution time by a factor of 2 or more.

For \( \text{clustersize} > n / \sqrt{NPROW \times NPCOL} \) execution time will grow as the square of the cluster size, all other factors remaining equal and assuming enough workspace. Less workspace means less reorthogonalization but faster execution.

If \( lwork = -1 \), then \( lwork \) is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by \text{pxerbla}.

\text{iwork} \\
(\text{local}) \text{ Workspace array.}

\text{liwork} \\
(\text{local}), \text{ size of iwork}. \text{liwork} \geq 6 \times \text{nnp}

Where: \( \text{nnp} = \max(n, NPROW \times NPCOL + 1, 4) \)

If \( liwork = -1 \), then \( liwork \) is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by \text{pxerbla}.

Output Parameters

\text{a} \\
On exit, the lower triangle (if uplo = 'L') or the upper triangle (if uplo = 'U') of \( A \), including the diagonal, is overwritten.

\text{m} \\
(globally) The total number of eigenvalues found; \( 0 \leq m \leq n \).

\text{nz} \\
(globally) The total number of eigenvectors computed. \( 0 \leq nz \leq m \).

The number of columns of \( z \) that are filled.

If \( \text{jobz} \neq 'V' \), \( nz \) is not referenced.

If \( \text{jobz} = 'V' \), \( nz = m \) unless the user supplies insufficient space and \text{p?syevx} is not able to detect this before beginning computation. To get all the eigenvectors requested, the user must supply both sufficient space to hold the eigenvectors in \( z \) \((m \leq \text{descz}[n-1])\) and sufficient workspace to compute them. (See \text{lwork}). \text{p?syevx} is always able to detect insufficient space without computation unless \text{range} = 'V'.

\text{w} \\
(\text{global}).

Array of size \( n \). The first \( m \) elements contain the selected eigenvalues in ascending order.

\text{z} \\
(\text{local}).

Array, global size \( n \times n \), local size \( lld_z \times \text{LOCc}(jz+n-1) \).

If \( \text{jobz} = 'V' \), then on normal exit the first \( m \) columns of \( z \) contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of \( z \) contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in \text{ifail}. 

1470
If \( \text{jobz} = 'N' \), then \( z \) is not referenced.

\text{work}[0]

On exit, returns workspace adequate workspace to allow optimal performance.

\text{iwork}[0]

On return, \( \text{iwork}[0] \) contains the amount of integer workspace required.

\text{ifail}

Array of size \( n \).

If \( \text{jobz} = 'V' \), then on normal exit, the first \( m \) elements of \( \text{ifail} \) are zero. If \( \mod(\text{info},2) \neq 0 \) on exit, then \( \text{ifail} \) contains the indices of the eigenvectors that failed to converge.

If \( \text{jobz} = 'N' \), then \( \text{ifail} \) is not referenced.

\text{iclustr}

(global) Array of size \((2*\text{NPROW}*\text{NPCOL})\)

This array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be reorthogonalized due to insufficient workspace (see \text{iwork}, \text{orfac} and \text{info}). Eigenvectors corresponding to clusters of eigenvalues indexed \( \text{iclustr}(2*i-1) \) to \( \text{iclustr}(2*i) \), could not be reorthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal. \text{iclustr} is a zero terminated array, \text{iclustr}[2*k - 1] \neq 0 \text{ and } \text{iclustr}[2*k] = 0 \text{ if and only if } k \text{ is the number of clusters.}

\text{iclustr} \text{ is not referenced if } \text{jobz} = 'N'.

\text{gap}

(global)

Array of size \( \text{NPROW}*\text{NPCOL} \)

This array contains the gap between eigenvalues whose eigenvectors could not be reorthogonalized. The output values in this array correspond to the clusters indicated by the array \text{iclustr}. As a result, the dot product between eigenvectors corresponding to the \( i \)th cluster may be as high as \( (C*n)/\text{gap}[i - 1] \) where \( C \) is a small constant.

\text{info}

(global)

If \( \text{info} = 0 \), the execution is successful.

If \( \text{info} < 0 \):

If the \( i \)-th argument is an array and the \( j \)-entry had an illegal value, then \( \text{info} = -(i*100+j) \), if the \( i \)-th argument is a scalar and had an illegal value, then \( \text{info} = -i \).

If \( \text{info} > 0 \):

if \( \mod(\text{info},2)\neq0 \), then one or more eigenvectors failed to converge. Their indices are stored in \text{ifail}. Ensure \( \text{abstol}=2.0*\text{p?lamch('U')} \).

If \( \mod(\text{info}/2,2)\neq0 \), then eigenvectors corresponding to one or more clusters of eigenvalues could not be reorthogonalized because of insufficient workspace. The indices of the clusters are stored in the array \text{iclustr}.

If \( \mod(\text{info}/4,2)\neq0 \), then space limit prevented \( \text{p?syevxf} \) computing all of the eigenvectors between \( vl \) and \( vu \). The number of eigenvectors computed is returned in \( nz \).
If \( \text{mod}(\text{info}/8,2)\neq 0 \), then \( \text{p?stebz} \) failed to compute eigenvalues. Ensure \( \text{abstol}=2.0*\text{p?lamch('U')} \).

NOTE
\[ \text{mod}(x,y) \] is the integer remainder of \( x/y \).

**p?heev**
Computes all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix.

**Syntax**

```c
void pcheev (char *jobz , char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *w , MKL_Complex8 *z , MKL_INT *iz , MKL_INT *jz , MKL_INT *descz , MKL_Complex8 *work , MKL_INT *lwork , float *rwork , MKL_INT *lrwork , MKL_INT *info);
void pzheev (char *jobz , char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *w , MKL_Complex16 *z , MKL_INT *iz , MKL_INT *jz , MKL_INT *descz , MKL_Complex16 *work , MKL_INT *lwork , double *rwork , MKL_INT *lrwork , MKL_INT *info);
```

**Include Files**
* mkl_scalapack.h

**Description**
The p?heev function computes all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix \( A \) by calling the recommended sequence of ScaLAPACK functions. The function assumes a homogeneous system and makes spot checks of the consistency of the eigenvalues across the different processes. A heterogeneous system may return incorrect results without any error messages.

**Input Parameters**

\( np \) = the number of rows local to a given process.

\( nq \) = the number of columns local to a given process.

\( \text{jobz} \)
(global) Must be 'N' or 'V'.

Specifies if it is necessary to compute the eigenvectors:

If \( \text{jobz} = 'N' \), then only eigenvalues are computed.

If \( \text{jobz} = 'V' \), then eigenvalues and eigenvectors are computed.

\( \text{uplo} \)
(global) Must be 'U' or 'L'.

Specifies whether the upper or lower triangular part of the Hermitian matrix \( A \) is stored:

If \( \text{uplo} = 'U' \), \( a \) stores the upper triangular part of \( A \).

If \( \text{uplo} = 'L' \), \( a \) stores the lower triangular part of \( A \).
The number of rows and columns of the matrix $A$ ($n \geq 0$).

Block cyclic array of global size $n \times n$ and local size $lld_a \times \text{LOC}(ja+n-1)$. On entry, the Hermitian matrix $A$.

If $\text{uplo} = 'U'$, only the upper triangular part of $A$ is used to define the elements of the Hermitian matrix.

If $\text{uplo} = 'L'$, only the lower triangular part of $A$ is used to define the elements of the Hermitian matrix.

The row and column indices in the global matrix $A$ indicating the first row and the first column of the submatrix $A$, respectively.

(global and local) array of size $\text{dlen}_\text{a}$. The array descriptor for the distributed matrix $A$. If $\text{desca}[\text{ctxt} - 1]$ is incorrect, $p\text{?heev}$ cannot guarantee correct error reporting.

The row and column indices in the global matrix $Z$ indicating the first row and the first column of the submatrix $Z$, respectively.

(global and local) array of size $\text{dlen}_\text{z}$. The array descriptor for the distributed matrix $Z$. $\text{descz}[\text{ctxt} - 1]$ must equal $\text{desca}[\text{ctxt} - 1]$.

Array of size $lwork$.

The size of the array $\text{work}$.

If only eigenvalues are requested ($\text{jobz} = 'N'$):

$lwork \geq \max(nb \times np0 + 1, 3) + 3 \times n$

If eigenvectors are requested ($\text{jobz} = 'V'$), then the amount of workspace required:

$lwork \geq (np0 + nq0 + nb) \times nb + 3 \times n + n^2$

with $nb = \text{desca}[mb - 1] = \text{desca}[nb - 1] = nb = \text{descz}[mb - 1] = \text{descz}[nb - 1]$

$np0 = \text{numroc}(nn, nb, 0, 0, \text{NPROW})$.

$nq0 = \text{numroc}(\max(n, nb, 2), nb, 0, 0, \text{NPCOL})$.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. The required workspace is returned as the first element of the corresponding work arrays, and no error message is issued by $\text{pxerbla}$.

Workspace array of size $lrwork$.

The size of the array $\text{rwork}$.

See below for definitions of variables used to define $lrwork$.

If no eigenvectors are requested ($\text{jobz} = 'N'$), then $lrwork \geq 2 \times n$.

If eigenvectors are requested ($\text{jobz} = 'V'$), then $lrwork \geq 2 \times n + 2 \times n - 2$. 

1473
If \( lrwork = -1 \), then \( lrwork \) is global input and a workspace query is assumed; the function only calculates the minimum size required for the \( rwork \) array. The required workspace is returned as the first element of \( rwork \), and no error message is issued by \texttt{pxerbla}.

**Output Parameters**

\textbf{a}

On exit, the lower triangle (if \( uplo = 'L' \)), or the upper triangle (if \( uplo = 'U' \)) of \( A \), including the diagonal, is overwritten. (global).

\textbf{w}

Array of size \( n \). The first \( m \) elements contain the selected eigenvalues in ascending order. (local).

\textbf{z}

Array, global size \( n \times n \), local size \( lld_z \times \text{LOCc}(jz+n-1) \).

If \( jobz = 'V' \), then on normal exit the first \( m \) columns of \( z \) contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of \( z \) contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in \( ifail \).

If \( jobz = 'N' \), then \( z \) is not referenced.

\textbf{work[0]}

On exit, returns adequate workspace to allow optimal performance. If \( jobz = 'N' \), then \( \text{work[0]} = \) minimal workspace only for eigenvalues. If \( jobz = 'V' \), then \( \text{work[0]} = \) minimal workspace required to generate all the eigenvectors. (local)

\textbf{rwork[0]}

On output, \( rwork[0] \) returns workspace required to guarantee completion. (local)

\textbf{info}

(global)

If \( info = 0 \), the execution is successful.

If \( info < 0 \):

If the \( i \)-th argument is an array and the \( j \)-entry had an illegal value, then \( info = -(i*100+j) \). If the \( i \)-th argument is a scalar and had an illegal value, then \( info = -i \).

If \( info > 0 \):

If \( info = 1 \) through \( n \), the \( i \)-th eigenvalue did not converge in \?steqr2 after a total of \( 30 \times n \) iterations.

If \( info = n+1 \), then \texttt{p?heev} detected heterogeneity, and the accuracy of the results cannot be guaranteed.

**See Also**

- mkl_scalapack.h

Description

The `p?heevd` function computes all eigenvalues and eigenvectors of a complex Hermitian matrix \( A \) by using a divide and conquer algorithm.

Input Parameters

- \( np \) = the number of rows local to a given process.
- \( nq \) = the number of columns local to a given process.

\( \text{jobz} \) (global) Must be 'N' or 'V'.

- Specifies if it is necessary to compute the eigenvectors:
  - If \( \text{jobz} = 'N' \), then only eigenvalues are computed.
  - If \( \text{jobz} = 'V' \), then eigenvalues and eigenvectors are computed.

\( \text{uplo} \) (global) Must be 'U' or 'L'.

- Specifies whether the upper or lower triangular part of the Hermitian matrix \( A \) is stored:
  - If \( \text{uplo} = 'U' \), \( a \) stores the upper triangular part of \( A \).
  - If \( \text{uplo} = 'L' \), \( a \) stores the lower triangular part of \( A \).

\( n \) (global) The number of rows and columns of the matrix \( A (n \geq 0) \).

\( a \) (local).

- Block cyclic array of global size \( n \times n \) and local size \( lld_a * \text{LOCc}(ja+n-1) \).
- On entry, the Hermitian matrix \( A \).
- If \( \text{uplo} = 'U' \), only the upper triangular part of \( A \) is used to define the elements of the Hermitian matrix.
- If \( \text{uplo} = 'L' \), only the lower triangular part of \( A \) is used to define the elements of the Hermitian matrix.
ia, ja  
(global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A, respectively.

desca  
(global and local) array of size dlen_. The array descriptor for the distributed matrix A. If desca[ctxt_ - 1] is incorrect, p?heevd cannot guarantee correct error reporting.

iz, jz  
(global) The row and column indices in the global matrix Z indicating the first row and the first column of the submatrix Z, respectively.

descz  
(global and local) array of size dlen_. The array descriptor for the distributed matrix Z. descz[ctxt_ - 1] must equal desca[ctxt_ - 1].

work  
(local).
Array of size lwork.
lwork  
(local) The size of the array work.
If eigenvalues are requested:
lwork = n + (nb0 + mq0 + nb)*nb
with np0 = numroc( max( n, nb, 2 ), nb, 0, 0, NPROW)
mq0 = numroc( max( n, nb, 2 ), nb, 0, 0, NPCOL)
If lwork = -1, then lwork is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. The required workspace is returned as the first element of the corresponding work arrays, and no error message is issued by pxerbla.

rwork  
(local).
Workspace array of size lrwork.
lrwork  
(local) The size of the array rwork.
lrwork ≥ 1 + 9*n + 3*np*nq,
with np = numroc( n, nb, myrow, iarow, NPROW)
nq = numroc( n, nb, mycol, iacol, NPCOL)
iwork  
(local) Workspace array of size liwork.
liwork  
(local), size of iwork.
liwork = 7*n + 8*npcol + 2.

Output Parameters

a  
On exit, the lower triangle (if uplo = 'L'), or the upper triangle (if uplo = 'U') of A, including the diagonal, is overwritten.

w  
(global).
Array of size n. If info = 0, w contains the eigenvalues in the ascending order.

z  
(local).
Array, global size n*n, local size lld_z*LOCc(jz+n-1).
The \( z \) parameter contains the orthonormal eigenvectors of the matrix \( A \).

\textbf{work[0]}  
On exit, returns adequate workspace to allow optimal performance.

\textbf{rwork[0]}  
(local)  
On output, \textit{rwork[0]} returns workspace required to guarantee completion.

\textbf{iwork[0]}  
(local)  
On return, \textit{iwork[0]} contains the amount of integer workspace required.

\textbf{info}  
(global)  
If \( \text{info} = 0 \), the execution is successful.

If \( \text{info} < 0 \):
If the \( i \)-th argument is an array and the \( j \)-entry had an illegal value, then \( \text{info} = -(i*100+j) \). If the \( i \)-th argument is a scalar and had an illegal value, then \( \text{info} = -i \).

If \( \text{info} > 0 \):
If \( \text{info} = 1 \) through \( n \), the \( i \)-th eigenvalue did not converge.

\textbf{p?heevr}

\textit{Computes selected eigenvalues and, optionally, eigenvectors of a Hermitian matrix using Relatively Robust Representation.}

\textbf{Syntax}

\begin{verbatim}
void pcheevr(char* jobz, char* range, char* uplo, MKL_INT* n, MKL_Complex8* a, MKL_INT* ia, MKL_INT* ja, MKL_INT* desca, float* vl, float* vu, MKL_INT* il, MKL_INT* iu, MKL_INT* m, MKL_INT* nz, float* w, MKL_Complex8* z, MKL_INT* iz, MKL_INT* jz, MKL_INT* descz, MKL_Complex8* work, MKL_INT* lwork, float* rwork, MKL_INT* lrwork, MKL_INT* iwork, MKL_INT* liwork, MKL_INT* info);
void pzheevr(char* jobz, char* range, char* uplo, MKL_INT* n, MKL_Complex16* a, MKL_INT* ia, MKL_INT* ja, MKL_INT* desca, double* vl, double* vu, MKL_INT* il, MKL_INT* iu, MKL_INT* m, MKL_INT* nz, double* w, MKL_Complex16* z, MKL_INT* iz, MKL_INT* jz, MKL_INT* descz, MKL_Complex16* work, MKL_INT* lwork, double* rwork, MKL_INT* lrwork, MKL_INT* iwork, MKL_INT* liwork, MKL_INT* info);
\end{verbatim}

\textbf{Include Files}

- mkl_scalapack.h

\textbf{Description}

\textit{p?heevr} computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix \( A \) distributed in 2D blockcyclic format by calling the recommended sequence of ScaLAPACK functions.

First, the matrix \( A \) is reduced to complex Hermitian tridiagonal form. Then, the eigenproblem is solved using the parallel MRRR algorithm. Last, if eigenvectors have been computed, a backtransformation is done.

Upon successful completion, each processor stores a copy of all computed eigenvalues in \( w \). The eigenvector matrix \( Z \) is stored in 2D block-cyclic format distributed over all processors.
Input Parameters

**jobz**

Specifies whether or not to compute the eigenvectors:

- 'N': Compute eigenvalues only.
- 'V': Compute eigenvalues and eigenvectors.

**range**

Specifies whether the upper or lower triangular part of the Hermitian matrix \( A \) is stored:

- 'U': Upper triangular
- 'L': Lower triangular

**n**

The number of rows and columns of the matrix \( A \). \( n \geq 0 \)

**a**

Block-cyclic array, global size \( n * n \), local size \( lld_a * LOC_c(ja+n-1) \)

Contains the local pieces of the Hermitian distributed matrix \( A \). If \( uplo = 'U' \), only the upper triangular part of \( a \) is used to define the elements of the Hermitian matrix. If \( uplo = 'L' \), only the lower triangular part of \( a \) is used to define the elements of the Hermitian matrix.

**ia**

Global row index in the global matrix \( A \) that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.

**ja**

Global column index in the global matrix \( A \) that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.
desca  (global and local) array of size dlen_. (The ScaLAPACK descriptor length is 
dlen_ = 9.)

The array descriptor for the distributed matrix a. The descriptor stores 
details about the 2D block-cyclic storage, see the notes below. If desca is 
incorrect, p?heevr cannot work correctly.

Also note the array alignment requirements specified below

vl  (global)

If range='V', the lower bound of the interval to be searched for 
eigenvalues. Not referenced if range = 'A' or 'I'.

vu  (global)

If range='V', the upper bound of the interval to be searched for 
eigenvalues. Not referenced if range = 'A' or 'I'.

il  (global )

If range='I', the index (from smallest to largest) of the smallest eigenvalue 
to be returned. il≥ 1.

Not referenced if range = 'A'.

iu  (global )

If range='I', the index (from smallest to largest) of the largest eigenvalue 
to be returned. min(il,n)≤iu≤n.

Not referenced if range = 'A'.

iz  (global )

Global row index in the global matrix Z that points to the beginning of the 
submatrix which is to be operated on. It should be set to 1 when operating 
on a full matrix.

jz  (global )

Global column index in the global matrix Z that points to the beginning of the 
submatrix which is to be operated on. It should be set to 1 when 
operating on a full matrix.

descz  (global and local) array of size dlen_.

The array descriptor for the distributed matrix z. descz[ctxt_ - 1] must 
equal desca[ctxt_ - 1]

work  (local workspace) array of size lwork

lwork  (local )

Size of work array, must be at least 3.
If only eigenvalues are requested:

lwork≥n + max( nb * ( np00 + 1 ), nb * 3 )

If eigenvectors are requested:

lwork≥n + ( np00 + mq00 + nb ) * nb

For definitions of np00 and mq00, see lrwork.
For optimal performance, greater workspace is needed, i.e.
\[ lwork \geq \max( lwork, nhetrd_lwork ) \]
Where \( lwork \) is as defined above, and
\[ nhetrd_lwork = n + 2*( anb+1 )* ( 4*nps+2 ) + ( nps + 1 ) * nps \]
\( ictx = desca[ctxt - 1] \)
\( anb = pjlaenv( ictx, 3, 'PCHETRD', 'L', 0, 0, 0, 0 ) \)
\( sqnpc = \sqrt{ \text{real}( nprow * npcol ) } \)
\( nps = \max( \text{numroc}( n, 1, 0, 0, sqnpc ), 2*anb ) \)
If \( lwork = -1 \), then \( lwork \) is global input and a workspace query is assumed; the function only calculates the optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by \textit{pxerbla}.

\( rwork \)
(local workspace) array of size \( lrwork \)

\( lrwork \)
(local )
Size of \( rwork \), must be at least 3.
See below for definitions of variables used to define \( lrwork \).
If no eigenvectors are requested (\( jobz = 'N' \)) then
\[ lrwork \geq 2 + 5 \ast n + \max( 12 \ast n, nb \ast ( np00 + 1 ) ) \]
If eigenvectors are requested (\( jobz = 'V' \)) then the amount of workspace required is:
\[ lrwork \geq 2 + 5 \ast n + \max( 18 \ast n, np00 \ast mq00 + 2 \ast nb \ast nb ) + (2 + \text{iceil}( neig, nprow*ncol))*n \]

\textbf{NOTE}
\( \text{iceil}(x,y) \) is the ceiling of \( x/y \).

Variable definitions:
\( neig = \) number of eigenvectors requested
\( nb = \) desca[\( mb_ - 1\)] = desca[\( nb_ - 1\)] = descz[\( mb_ - 1\)] = descz[\( nb_ - 1\)]
\( nn = \max( n, nb, 2 ) \)
\( desca[\( rsrc_ - 1\)] = desca[\( csr_ - 1\)] = descz[\( rsrc_ - 1\)] = descz[\( csr_ - 1\)] = 0 \)
\( np00 = \text{numroc}( nn, nb, 0, 0, nprow ) \)
\( mq00 = \text{numroc}( \max( neig, nb, 2 ), nb, 0, 0, npcol ) \)
\( \text{iceil}(x, y) \) is a \textit{ScaLAPACK} function returning \( \text{ceiling}(x/y) \), and \( nprow \) and \( npcol \) can be determined by calling the function \textit{blacs_gridinfo}. 
If \( \text{lrwork} = -1 \), then \( \text{lrwork} \) is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by \( \text{pxerbla} \)

\text{liwork} \\
(\text{local workspace}) \text{array of size liwork} \\
\text{liwork} \\
(\text{local}) \quad \text{size of iwork}

Let \( nnp = \max(n, nprow*ncol + 1, 4) \). Then:

\[
\text{liwork} \geq 12 \times nnp + 2 \times n \quad \text{when the eigenvectors are desired}
\]

\[
\text{liwork} \geq 10 \times nnp + 2 \times n \quad \text{when only the eigenvalues have to be computed}
\]

If \( \text{liwork} = -1 \), then \( \text{liwork} \) is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by \( \text{pxerbla} \)

**OUTPUT Parameters**

\( a \)  
The lower triangle (if \( \text{uplo} = 'L' \)) or the upper triangle (if \( \text{uplo} = 'U' \)) of \( a \), including the diagonal, is destroyed.

\( m \)  
(global) 
Total number of eigenvalues found. \( 0 \leq m \leq n \).

\( nz \)  
(global) 
Total number of eigenvectors computed. \( 0 \leq nz \leq m \).
The number of columns of \( z \) that are filled.
If \( \text{jobz} \neq 'V' \), \( nz \) is not referenced.
If \( \text{jobz} = 'V' \), \( nz = m \)

\( w \)  
(global) \text{array of size } n 
On normal exit, the first \( m \) entries contain the selected eigenvalues in ascending order.

\( z \)  
(\text{local}) \text{array, global size } n \times n \), local size \( \text{lid_z*LOC_c(jz+n-1)} \)
If \( \text{jobz} = 'V' \), then on normal exit the first \( m \) columns of \( z \) contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues.
If \( \text{jobz} = 'N' \), then \( z \) is not referenced.

\( \text{work} \)  
\( \text{work[0]} \) \text{returns workspace adequate workspace to allow optimal performance.}
On return, \( rwork[0] \) contains the optimal amount of workspace required for efficient execution. If \( jobz='N' \) \( rwork[0] \) = optimal amount of workspace required to compute the eigenvalues. If \( jobz='V' \) \( rwork[0] \) = optimal amount of workspace required to compute eigenvalues and eigenvectors.

On return, \( iwork[0] \) contains the amount of integer workspace required.

\( info \) (global )

\( = 0: \) successful exit

\( < 0: \) If the \( i \)-th argument is an array and the \( j \)-th entry had an illegal value, then \( info = -(i*100+j) \), if the \( i \)-th argument is a scalar and had an illegal value, then \( info = -i \).

### Application Notes

The distributed submatrices \( a(ia:*, ja:*) \) and \( z(iz:iz+m-1, jz:jz+n-1) \) must satisfy the following alignment properties:

1. Identical (quadratic) dimension: \( desca[m_-1] = descz[m_-1] = desca[n_-1] = descz[n_-1] \)
3. \( \text{mod}(ia-1, mb_a) = \text{mod}(iz-1, mb_z) = 0 \)

**NOTE**

\( \text{mod}(x,y) \) is the integer remainder of \( x/y \).

```

#### Include Files

- `mkl_scalapack.h`
Description
The p?heevx function computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix \( A \) by calling the recommended sequence of ScaLAPACK functions. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Optimization Notice
Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.
Notice revision #20110804

Input Parameters
\( np \) = the number of rows local to a given process.
\( nq \) = the number of columns local to a given process.

\( jobz \) (global) Must be 'N' or 'V'.
Specifies if it is necessary to compute the eigenvectors:
If \( jobz = 'N' \), then only eigenvalues are computed.
If \( jobz = 'V' \), then eigenvalues and eigenvectors are computed.

\( range \) (global) Must be 'A', 'V', or 'I'.
If \( range = 'A' \), all eigenvalues will be found.
If \( range = 'V' \), all eigenvalues in the half-open interval \([vl, vu]\) will be found.
If \( range = 'I' \), the eigenvalues with indices \( il \) through \( iu \) will be found.

\( uplo \) (global) Must be 'U' or 'L'.
Specifies whether the upper or lower triangular part of the Hermitian matrix \( A \) is stored:
If \( uplo = 'U' \), \( a \) stores the upper triangular part of \( A \).
If \( uplo = 'L' \), \( a \) stores the lower triangular part of \( A \).

\( n \) (global) The number of rows and columns of the matrix \( A \) (\( n \geq 0 \)).

\( a \) (local).
Block cyclic array of global size \( n^*n \) and local size \( lld_arcc(ja+n-1) \).
On entry, the Hermitian matrix \( A \).
If \( uplo = 'U' \), only the upper triangular part of \( A \) is used to define the elements of the Hermitian matrix.
If \( uplo = 'L' \), only the lower triangular part of \( A \) is used to define the elements of the Hermitian matrix.
\(ia, ja\) (global) The row and column indices in the global matrix \(A\) indicating the first row and the first column of the submatrix \(A\), respectively.

\(desca\) (global and local) array of size \(dlen_\). The array descriptor for the distributed matrix \(A\). If \(desca[\text{ctxt}_-1]\) is incorrect, \(p?\text{heevx}\) cannot guarantee correct error reporting.

\(vl, vu\) (global) If \(\text{range} = 'V'\), the lower and upper bounds of the interval to be searched for eigenvalues; not referenced if \(\text{range} = 'A'\) or 'I'.

\(il, iu\) (global) If \(\text{range} = 'I'\), the indices of the smallest and largest eigenvalues to be returned.

Constraints:
\[il \geq 1; \min(il, n) \leq iu \leq n.\]

Not referenced if \(\text{range} = 'A'\) or 'V'.

\(abstol\) (global).

If \(\text{jobz}= 'V'\), setting \(abstol\) to \(p?\text{lamch}(context, 'U')\) yields the most orthogonal eigenvectors.

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval \([a, b]\) of width less than or equal to \(\text{abstol} + \text{eps} \cdot \max(|a|, |b|)\), where \(\text{eps}\) is the machine precision. If \(\text{abstol}\) is less than or equal to zero, then \(\text{eps} \cdot \text{norm}(T)\) will be used in its place, where \(\text{norm}(T)\) is the 1-norm of the tridiagonal matrix obtained by reducing \(A\) to tridiagonal form.

Eigenvalues are computed most accurately when \(\text{abstol}\) is set to twice the underflow threshold \(2 \cdot p?\text{lamch('S')}\), not zero. If this function returns with \(((\text{mod}(\text{info}, 2) \neq 0)\) or \((\text{mod}(\text{info}/8, 2) \neq 0))\), indicating that some eigenvalues or eigenvectors did not converge, try setting \(abstol\) to \(2 \cdot p?\text{lamch('S')}\).

\textbf{NOTE}
\[\text{mod}(x, y)\] is the integer remainder of \(x/y\).

\(orfac\) (global).

Specifies which eigenvectors should be reorthogonalized. Eigenvectors that correspond to eigenvalues which are within \(tol = orfac \cdot \text{norm}(A)\) of each other are to be reorthogonalized. However, if the workspace is insufficient (see \(lwork\)), \(tol\) may be decreased until all eigenvectors to be reorthogonalized can be stored in one process. No reorthogonalization will be done if \(orfac\) equals zero. A default value of 1.0e-3 is used if \(orfac\) is negative.

\(orfac\) should be identical on all processes.

\(iz, jz\) (global) The row and column indices in the global matrix \(Z\) indicating the first row and the first column of the submatrix \(Z\), respectively.
(global and local) array of size \textit{dlen\_}. The array descriptor for the
distributed matrix \textit{Z}. \textit{descz}[^{\text{ctxt\_ - 1}}] must equal \textit{desca}[^{\text{ctxt\_ - 1}}].

\textit{work}

Array of size \textit{lwork}.

\textit{lwork}

\textit{work} (local). The size of the array \textit{work}.

If only eigenvalues are requested:
\[ lwork \geq n + \max(nb^* (np0 + 1), 3) \]

If eigenvectors are requested:
\[ lwork \geq n + (np0 + mq0 + nb)^* nb \]

with \[ nq0 = \text{numroc}(nn, nb, 0, 0, NPCOL). \]
\[ lwork \geq 5*n + \max(5*nn, np0*mq0 + 2*nb*nb) + \text{ceil}(neig, NPROW*NPCOL)^* nn \]

For optimal performance, greater workspace is needed, that is
\[ lwork \geq \max(lwork, \text{nhetrd\_lwork}) \]

where \textit{lwork} is as defined above, and \textit{nhetrd\_lwork} = \[ n + 2* (\text{anb} +1)^* (4* \text{nps} + 2) + \text{nps} \]

\textit{ictxt} = \text{desca}[^{\text{ctxt\_ - 1}}]

\[ \text{anb} = \text{pjlaenv}(\text{ictxt}, 3, 'pchettrd', 'L', 0, 0, 0, 0) \]

\[ \text{sqnpc} = \sqrt{\text{dble}(\text{NPROW * NPCOL})} \]

\[ \text{nps} = \max(\text{numroc}(n, 1, 0, 0, \text{sqnpc}), 2*\text{anb}) \]

If \textit{lwork} = -1, then \textit{lwork} is global input and a workspace query is
assumed; the function only calculates the size required for optimal
performance for all work arrays. Each of these values is returned in the first
entry of the corresponding work arrays, and no error message is issued by
\text{pxerbla}.

\textit{rwork}

Workspace array of size \textit{lrwork}.

\textit{lrwork}

The size of the array \textit{work}.

See below for definitions of variables used to define \textit{lwork}.

If no eigenvectors are requested (\textit{jobz} = 'N'), then \textit{lrwork} \[ \geq 5*nn + 4*n \.

If eigenvectors are requested (\textit{jobz} = 'V'), then the amount of workspace
required to guarantee that all eigenvectors are computed is:
\[ lrwork \geq 4*n + \max(5*nn, np0*mq0 + 2*nb*nb) + \text{ceil}(neig, NPROW*NPCOL)^* \text{nn} \]

The computed eigenvectors may not be orthogonal if the minimal
workspace is supplied and \textit{orfac} is too small. If you want to guarantee
orthogonality (at the cost of potentially poor performance) you should add
the following values to \textit{lrwork}:
\[ (\text{clustersize}-1)^*n, \]
where \textit{clustersize} is the number of eigenvalues in the largest cluster, where a cluster is defined as a set of close eigenvalues:

\[ |w[k-1],\ldots, w[k+\text{clustersize}-2]| w[j] \leq w[j-1] + \text{orfac} \times 2 \times \text{norm}(A). \]

Variable definitions:

\[ \text{neig} = \text{number of eigenvectors requested}; \]

\[ \text{nb} = \text{desca}[^{mb_1} - 1] = \text{desca}[^{nb_1} - 1] = \text{descz}[^{mb_1} - 1]; \]

\[ \text{nn} = \max(n, \text{NB}, 2); \]

\[ \text{desca}[rsrc_1 - 1] = \text{desca}[nb_1 - 1] = \text{descz}[rsrc_1 - 1] = \]

\[ \text{descz}[csrc_1 - 1] = 0; \]

\[ \text{np} = \text{numroc}(\text{nn}, \text{nb}, 0, 0, \text{NPROW}); \]

\[ \text{mq} = \text{numroc}(\max(\text{neig}, \text{nb}, 2), \text{nb}, 0, 0, \text{NPCOL}); \]

\[ \text{iceil}(x, y) \] is a ScaLAPACK function returning \( \text{ceiling}(x/y) \)

When \textit{lwork} is too small:

If \textit{lwork} is too small to guarantee orthogonality, \texttt{p?heevx} attempts to maintain orthogonality in the clusters with the smallest spacing between the eigenvalues. If \textit{lwork} is too small to compute all the eigenvectors requested, no computation is performed and \textit{info} = -23 is returned. Note that when \textit{range} = 'V', \texttt{p?heevx} does not know how many eigenvectors are requested until the eigenvalues are computed. Therefore, when \textit{range} = 'V' and as long as \textit{lwork} is large enough to allow \texttt{p?heevx} to compute the eigenvalues, \texttt{p?heevx} will compute the eigenvalues and as many eigenvectors as it can.

Relationship between workspace, orthogonality and performance:

If \textit{clustersize} \geq \frac{n}{\sqrt{\text{NPROW} \times \text{NPCOL}}}, then providing enough space to compute all the eigenvectors orthogonally will cause serious degradation in performance. In the limit (that is, \textit{clustersize} = \( n-1 \)) \texttt{p?stein} will perform no better than \texttt{?stein} on 1 processor.

For \textit{clustersize} = \frac{n}{\sqrt{\text{NPROW} \times \text{NPCOL}}} reorthogonalizing all eigenvectors will increase the total execution time by a factor of 2 or more.

For \textit{clustersize} > \frac{n}{\sqrt{\text{NPROW} \times \text{NPCOL}}} execution time will grow as the square of the cluster size, all other factors remaining equal and assuming enough workspace. Less workspace means less reorthogonalization but faster execution.

If \textit{lwork} = -1, then \textit{lwork} is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by \texttt{pxerbla}.

\texttt{iwork} \hspace{1cm} (local) Workspace array.

\texttt{liwork} \hspace{1cm} (local), size of \texttt{iwork}.

\[ \text{liwork} \geq 6 \times \text{nnp} \]

Where: \text{nnp} = \max(n, \text{NPROW} \times \text{NPCOL}+1, 4)
If `liwork = -1`, then `liwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

**Output Parameters**

- **a**
  On exit, the lower triangle (if `uplo = 'L'`), or the upper triangle (if `uplo = 'U'`) of `A`, including the diagonal, is overwritten.

- **m**
  (global) The total number of eigenvalues found; `0 ≤ m ≤ n`.

- **nz**
  (global) Total number of eigenvectors computed. `0 ≤ nz ≤ m`.

  The number of columns of `z` that are filled.

  If `jobz ≠ 'V'`, `nz` is not referenced.

  If `jobz = 'V'`, `nz = m` unless the user supplies insufficient space and `p?heevx` is not able to detect this before beginning computation. To get all the eigenvectors requested, the user must supply both sufficient space to hold the eigenvectors in `z` (`m×descz[n - 1]`) and sufficient workspace to compute them. (See `lwork`). `p?heevx` is always able to detect insufficient space without computation unless `range = 'V'`.

- **w**
  (global).
  Array of size `n`. The first `m` elements contain the selected eigenvalues in ascending order.

- **z**
  (local).
  Array, global size `n×n`, local size `lld_z×LOCc(jz+n-1)`.

  If `jobz = 'V'`, then on normal exit the first `m` columns of `z` contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of `z` contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in `ifail`.

  If `jobz = 'N'`, then `z` is not referenced.

- **work[0]**
  On exit, returns adequate workspace to allow optimal performance.

- **rwork**
  (local).
  Array of size `lrwork`. On return, `rwork[0]` contains the optimal amount of workspace required for efficient execution.

  If `jobz = 'N'` `rwork[0]` = optimal amount of workspace required to compute eigenvalues efficiently.

  If `jobz = 'V'` `rwork[0]` = optimal amount of workspace required to compute eigenvalues and eigenvectors efficiently with no guarantee on orthogonality.

  If `range = 'V'`, it is assumed that all eigenvectors may be required.

- **iwork[0]**
  (local)
  On return, `iwork[0]` contains the amount of integer workspace required.

- **ifail**
  (global)
Array of size $n$.

If $jobz = 'V'$, then on normal exit, the first $m$ elements of $ifail$ are zero. If $(\text{mod}(\text{info},2)\neq 0)$ on exit, then $ifail$ contains the indices of the eigenvectors that failed to converge.

If $jobz = 'N'$, then $ifail$ is not referenced.

**iclustr**

Array of size $2*NPROW*NPCOL$.

This array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be reorthogonalized due to insufficient workspace (see $lwork$, $orfac$ and $info$). Eigenvectors corresponding to clusters of eigenvalues indexed $iclustr[2*i - 2]$ to $iclustr[2*i - 1]$, could not be reorthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal.

$iclustr$ is a zero terminated array. $(iclustr[2*k - 1] \neq 0$ and $iclustr[2*k] = 0)$ if and only if $k$ is the number of clusters. $iclustr$ is not referenced if $jobz = 'N'$.

**gap**

Array of size $(NPROW*NPCOL)$

This array contains the gap between eigenvalues whose eigenvectors could not be reorthogonalized. The output values in this array correspond to the clusters indicated by the array $iclustr$. As a result, the dot product between eigenvectors corresponding to the $i$-th cluster may be as high as $(C*n)/\text{gap}(i)$ where $C$ is a small constant.

**info**

If $info = 0$, the execution is successful.

If $info < 0$:

If the $i$-th argument is an array and the $j$-entry had an illegal value, then $info = -(i*100+j)$. If the $i$-th argument is a scalar and had an illegal value, then $info = -i$.

If $info > 0$:

If $(\text{mod}(\text{info},2)\neq 0)$, then one or more eigenvectors failed to converge. Their indices are stored in $ifail$. Ensure $abstol=2.0*p?lamch('U')$

If $(\text{mod}(\text{info}/2,2)\neq 0)$, then eigenvectors corresponding to one or more clusters of eigenvalues could not be reorthogonalized because of insufficient workspace. The indices of the clusters are stored in the array $iclustr$.

If $(\text{mod}(\text{info}/4,2)\neq 0)$, then space limit prevented $p?syevx$ from computing all of the eigenvectors between $vl$ and $vu$. The number of eigenvectors computed is returned in $nz$.

If $(\text{mod}(\text{info}/8,2)\neq 0)$, then $p?stebz$ failed to compute eigenvalues. Ensure $abstol=2.0*p?lamch('U')$.

**Description**

The p?gesvd function computes the singular value decomposition (SVD) of an $m$-by-$n$ matrix $A$, optionally computing the left and/or right singular vectors. The SVD is written

$$A = U \Sigma V^T,$$

where $\Sigma$ is an $m$-by-$n$ matrix that is zero except for its $\min(m, n)$ diagonal elements, $U$ is an $m$-by-$m$ orthogonal matrix, and $V$ is an $n$-by-$n$ orthogonal matrix. The diagonal elements of $\Sigma$ are the singular values of $A$ and the columns of $U$ and $V$ are the corresponding right and left singular vectors, respectively. The singular values are returned in array $s$ in decreasing order and only the first $\min(m,n)$ columns of $U$ and rows of $vt = V^T$ are computed.

**Optimization Notice**

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804
NOTE
The distributed submatrix sub(A) must verify certain alignment properties. These expressions must be true:

- \( mb_a = nb_a = nb \)
- \( iroffa = icoffa \)

where:

- \( iroffa = \text{mod}(ia-1, nb) \)
- \( icoffa = \text{mod}(ja-1, nb) \)

Input Parameters

- \( mp = \) number of local rows in \( A \) and \( U \)
- \( nq = \) number of local columns in \( A \) and \( VT \)
- \( size = \) \( \min(m, n) \)
- \( sizeq = \) number of local columns in \( U \)
- \( sizep = \) number of local rows in \( VT \)

- \( jobu \) (global) Specifies options for computing all or part of the matrix \( U \).
  - If \( jobu = 'V' \), the first \( size \) columns of \( U \) (the left singular vectors) are returned in the array \( u \);
  - If \( jobu = 'N' \), no columns of \( U \) (no left singular vectors) are computed.

- \( jobvt \) (global)
  - Specifies options for computing all or part of the matrix \( V^T \).
  - If \( jobvt = 'V' \), the first \( size \) rows of \( V^T \) (the right singular vectors) are returned in the array \( vt \);
  - If \( jobvt = 'N' \), no rows of \( V^T \) (no right singular vectors) are computed.

- \( m \) (global) The number of rows of the matrix \( A \) (\( m \geq 0 \)).
- \( n \) (global) The number of columns in \( A \) (\( n \geq 0 \)).
- \( a \) (local).
  - Block cyclic array, global size \((m, n)\), local size \((mp, nq)\).

- \( ia, ja \) (global) The row and column indices in the global matrix \( A \) indicating the first row and the first column of the submatrix \( A \), respectively.

- \( desca \) (global and local) array of size \( dlen_\). The array descriptor for the distributed matrix \( A \).

- \( iu, ju \) (global) The row and column indices in the global matrix \( U \) indicating the first row and the first column of the submatrix \( U \), respectively.

- \( descu \) (global and local) array of size \( dlen_\). The array descriptor for the distributed matrix \( U \).

- \( ivt, jvt \) (global) The row and column indices in the global matrix \( VT \) indicating the first row and the first column of the submatrix \( VT \), respectively.
(global and local) array of size $dlen_\ast$. The array descriptor for the distributed matrix $VT$.

(work) Workspace array of size $lwork$

(lwork) The size of the array $work$;

\[ lwork > 2 + 6\times sizeb + \max(watobd, wbdtosvd), \]

where $sizeb = \max(m, n)$, and $watobd$ and $wbdtosvd$ refer, respectively, to the workspace required to bidiagonalize the matrix $A$ and to go from the bidiagonal matrix to the singular value decomposition $USVT$.

For $watobd$, the following holds:

\[ watobd = \max(\max(wp?lange, wp?gebrd), \max(wp\!\!lared2d, wp\!\!lared1d)), \]

\[ mp = \text{numroc}(m, mb, MYROW, desca[\ast - 1], NPROW), \]
\[ nq = \text{numroc}(n, nb, MYCOL, desca[lld\!\! - 1], NPCOL), \]

the workspaces required for the above subprograms are

\[ wp?lange = mp, \]
\[ wp?lared1d = nq0, \]
\[ wp?lared2d = mp0, \]
\[ wp?gebrd = nb\times(mp + nq + 1) + nq, \]

where $nq0$ and $mp0$ refer, respectively, to the values obtained at $MYCOL = 0$ and $MYROW = 0$. In general, the upper limit for the workspace is given by a workspace required on processor $(0,0)$:

\[ watobd \leq nb\times(mp0 + nq0 + 1) + nq0. \]

In case of a homogeneous process grid this upper limit can be used as an estimate of the minimum workspace for every processor.

For $wbdtosvd$, the following holds:

\[ wbdtosvd = size\times(wantu\times nru + wantvt\times ncvt) + \max(w?bdsqr, \max(wantu\times wp?ormbrqql, wantvt\times wp?ormbrprt)), \]

where

\[ wantu(wantt) = 1, \text{ if left/right singular vectors are wanted, and } \]
\[ wantu(wantt) = 0, \text{ otherwise. } w?bdsqr, wp?ormbrqql, \text{ and } wp?ormbrprt \]
\[ \text{refer respectively to the workspace required for the subprograms } ?bdsqr, \]
\[ p?ormbr(qln), \text{ and } p?ormbr(prt), \text{ where } qln \text{ and } prt \text{ are the values of the } \]
\[ \text{arguments } vect, \text{ side, and } trans \text{ in the call to } p?ormbr. nru \text{ is equal to the } \]
\[ \text{local number of rows of the matrix } U \text{ when distributed 1-dimensional } \]
\[ \text{"column" of processes. Analogously, } ncvt \text{ is equal to the local number of } \]
\[ \text{columns of the matrix } VT \text{ when distributed across 1-dimensional "row" of } \]
\[ \text{processes. Calling the LAPACK procedure } ?bdsqr \text{ requires } \]
\[ w?bdsqr = \max(1, 2\times size + (2\times size - 4)\times \max(wantu, wantvt)) \]
on every processor. Finally,

\[
\begin{align*}
wp\text{ormbrqin} &= \max((nb*(nb-1))/2, (sizeq*mp)*nb)+nb*nb, \\
wp\text{ormbrprt} &= \max((mb*(mb-1))/2, (sizep+nq)*mb)+mb*mb,
\end{align*}
\]

If \text{lwork} = -1, then \text{lwork} is global input and a workspace query is assumed; the function only calculates the minimum size for the work array. The required workspace is returned as the first element of \text{work} and no error message is issued by \text{pxerbla}.

\textit{rwork}

Workspace array of size \(1 + 4*\text{sizeb}\). Not used for \text{p}gesvd and \text{pdgesvd}.

\textbf{Output Parameters}

\textit{a}

On exit, the contents of \textit{a} are destroyed.

\textit{s}

(gridal).

Array of size \textit{size}.

Contains the singular values of \(A\) sorted so that \(s(i) \geq s(i+1)\).

\textit{u}

(local).

local size \(mp*\text{sizeq}\), global size \(m*\text{size}\)

If \textit{jobu} = 'V', \textit{u} contains the first \(\min(m, n)\) columns of \(U\).

If \textit{jobu} = 'N' or 'O', \textit{u} is not referenced.

\textit{vt}

(local).

local size \((\text{sizep, nq})\), global size \((\text{size, n})\)

If \textit{jobvt} = 'V', \textit{vt} contains the first \textit{size} rows of \(V^T\) if \textit{jobu} = 'N', \textit{vt} is not referenced.

\textit{work}

On exit, if \textit{info} = 0, then \textit{work}[0] returns the required minimal size of \textit{lwork}.

\textit{rwork}

On exit, if \textit{info} = 0, then \textit{rwork}[0] returns the required size of \textit{rwork}.

\textit{info}

(global)

If \textit{info} = 0, the execution is successful.

If \textit{info} < 0, if \textit{info} = -i, the \textit{i}th parameter had an illegal value.

If \textit{info} > 0 \(i\), then if \textit{?bdsqr} did not converge,

If \textit{info} = \(\min(m,n) + 1\), then \textit{p}gesvd has detected heterogeneity by finding that eigenvalues were not identical across the process grid. In this case, the accuracy of the results from \textit{p}gesvd cannot be guaranteed.

\textbf{See Also}

\textbf{Overview} for details of ScaLAPACK array descriptor structures and related notations.

\textit{p}\textit{sygvx}

Computes selected eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem.
Syntax

Description

The `pssygvx` function computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form

\[
\text{sub}(A)x = \lambda\text{sub}(B)x , \quad \text{sub}(A)\text{sub}(B)x = \lambda x , \quad \text{or} \quad \text{sub}(B)\text{sub}(A)x = \lambda x .
\]

Here \(x\) denotes eigen vectors, \(\lambda\) (\(\text{lambda}\)) denotes eigenvalues, \(\text{sub}(A)\) denoting \(A(ia:ia+n-1, ja:ja+n-1)\) is assumed to symmetric, and \(\text{sub}(B)\) denoting \(B(ib:ib+n-1, jb:jb+n-1)\) is also positive definite.

Input Parameters

- **ibtype**
  (global) Must be 1 or 2 or 3.
  Specifies the problem type to be solved:
  - If \(ibtype = 1\), the problem type is \(\text{sub}(A)x = \lambda\text{sub}(B)x\);
  - If \(ibtype = 2\), the problem type is \(\text{sub}(A)\text{sub}(B)x = \lambda x\);
  - If \(ibtype = 3\), the problem type is \(\text{sub}(B)\text{sub}(A)x = \lambda x\).

- **jobz**
  (global) Must be 'N' or 'V'.
  - If \(jobz = 'N'\), then compute eigenvalues only.
  - If \(jobz = 'V'\), then compute eigenvalues and eigenvectors.
range
(global) Must be 'A' or 'V' or 'I'.
If range = 'A', the function computes all eigenvalues.
If range = 'V', the function computes eigenvalues in the interval: [vl, vu]
If range = 'I', the function computes eigenvalues with indices il through iu.

uplo
(global) Must be 'U' or 'L'.
If uplo = 'U', arrays a and b store the upper triangles of sub(A) and sub (B);
If uplo = 'L', arrays a and b store the lower triangles of sub(A) and sub (B).

n
(global) The order of the matrices sub(A) and sub (B), n ≥ 0.

a
(local)
Pointer into the local memory to an array of size lld_a*LOCc(ja+n-1). On
entry, this array contains the local pieces of the n-by-n symmetric
distributed matrix sub(A).
If uplo = 'U', the leading n-by-n upper triangular part of sub(A) contains
the upper triangular part of the matrix.
If uplo = 'L', the leading n-by-n lower triangular part of sub(A) contains
the lower triangular part of the matrix.

ia, ja
(global) The row and column indices in the global matrix A indicating the
first row and the first column of the submatrix A, respectively.

desca
(global and local) array of size dlen_. The array descriptor for the
distributed matrix A. If desca[ctxt_ - 1] is incorrect, p?sygvx cannot
guarantee correct error reporting.

b
(local).
Pointer into the local memory to an array of size lld_b*LOCc(jb+n-1). On
entry, this array contains the local pieces of the n-by-n symmetric
distributed matrix sub(B).
If uplo = 'U', the leading n-by-n upper triangular part of sub(B) contains
the upper triangular part of the matrix.
If uplo = 'L', the leading n-by-n lower triangular part of sub(A) contains
the lower triangular part of the matrix.

ib, jb
(global) The row and column indices in the global matrix B indicating the
first row and the first column of the submatrix B, respectively.

descb
(global and local) array of size dlen_. The array descriptor for the
distributed matrix B. descb[ctxt_ - 1] must be equal to desca[ctxt_ - 1].

vl, vu
(global)
If range = 'V', the lower and upper bounds of the interval to be searched
for eigenvalues.
If range = 'A' or 'I', vl and vu are not referenced.

\( il, iu \)  
(global)

If range = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint: \( il \geq 1, \min(il, n) \leq iu \leq n \)

If range = 'A' or 'V', il and iu are not referenced.

\( abstol \)  
(global)

If jobz='V', setting \( abstol \) to \( p\text{?lamch('S')} \) yields the most orthogonal eigenvectors.

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval \([a, b]\) of width less than or equal to

\[
abstol + \text{eps}\cdot\max(|a|,|b|),
\]

where \( \text{eps} \) is the machine precision. If \( abstol \) is less than or equal to zero, then \( \text{eps}\cdot\text{norm}(T) \) will be used in its place, where \( \text{norm}(T) \) is the 1-norm of the tridiagonal matrix obtained by reducing \( A \) to tridiagonal form.

Eigenvalues will be computed most accurately when \( abstol \) is set to twice the underflow threshold \( 2\cdot p\text{?lamch('S')} \) not zero. If this function returns with ((mod(info,2)\neq0) or (mod(info/8,2)\neq0)), indicating that some eigenvalues or eigenvectors did not converge, try setting \( abstol \) to \( 2\cdot p\text{?lamch('S')} \).

**NOTE**

\( \text{mod}(x,y) \) is the integer remainder of \( x/y \).

\( orfac \)  
(global).

Specifies which eigenvectors should be reorthogonalized. Eigenvectors that correspond to eigenvalues which are within \( \text{tol}=\text{orfac}\cdot\text{norm}(A) \) of each other are to be reorthogonalized. However, if the workspace is insufficient (see \( lwork \)), \( \text{tol} \) may be decreased until all eigenvectors to be reorthogonalized can be stored in one process. No reorthogonalization will be done if \( orfac \) equals zero. A default value of 1.0e-3 is used if \( orfac \) is negative. \( orfac \) should be identical on all processes.

\( iz, jz \)  
(global) The row and column indices in the global matrix \( Z \) indicating the first row and the first column of the submatrix \( Z \), respectively.

\( descz \)  
(global and local) array of size \( dlen_\). The array descriptor for the distributed matrix \( Z_\text{descz}[\text{ctxt}_-1] \) must equal \( \text{desca}[\text{ctxt}_-1] \).

\( work \)  
(local)

Workspace array of size \( lwork \)

\( lwork \)  
(local)

Size of the array \( work \). See below for definitions of variables used to define \( lwork \).

If no eigenvectors are requested (jobz = 'N'), then \( lwork \geq 5*n + \max(5*nn, NB*(np0 + 1)) \).
If eigenvectors are requested (jobz = 'V'), then the amount of workspace required to guarantee that all eigenvectors are computed is:

\[ lwork \geq 5*n + \max(5*nn, np0*mq0 + 2*nbp) + \text{ceil}(neig, NPROW*NPCOL)*nn. \]

The computed eigenvectors may not be orthogonal if the minimal workspace is supplied and orfac is too small. If you want to guarantee orthogonality at the cost of potentially poor performance you should add the following to lwork:

\[(\text{clustersize}-1)*n,\]

where clustersize is the number of eigenvalues in the largest cluster, where a cluster is defined as a set of close eigenvalues:

\[\{w[k-1], ..., w[k+\text{clustersize}-2]|w[j] \leq w[j-1] + \text{orfac}*2*\text{norm}(A)\}\]

Variable definitions:

\[ neig = \text{number of eigenvectors requested}, \]
\[ nb = \text{desca}[mb - 1] = \text{desca}[nb - 1] = \text{descz}[mb - 1] = \text{descz}[nb - 1], \]
\[ nn = \max(n, nb, 2), \]
\[ \text{desca}[rsrca - 1] = \text{desca}[nb - 1] = \text{descz}[rsrca - 1] = \text{descz}[csrca - 1] = 0, \]
\[ np0 = \text{numroc}(nn, nb, 0, 0, NPROW), \]
\[ mq0 = \text{numroc}(\max(neig, nb, 2), nb, 0, 0, NPCOL) \]

iceil(x, y) is a ScaLAPACK function returning ceiling(x/y)

If lwork is too small to guarantee orthogonality, p?syevx attempts to maintain orthogonality in the clusters with the smallest spacing between the eigenvalues.

If lwork is too small to compute all the eigenvectors requested, no computation is performed and info = -23 is returned.

Note that when range='V', number of requested eigenvectors are not known until the eigenvalues are computed. In this case and if lwork is large enough to compute the eigenvalues, p?sygvx computes the eigenvalues and as many eigenvectors as possible.

Greater performance can be achieved if adequate workspace is provided. In some situations, performance can decrease as the provided workspace increases above the workspace amount shown below:

\[ lwork \geq \max(lwork, 5*n + \text{nSYTRD_LWOPT}, \text{nSYGST_LWOPT}), \]

where lwork, as defined previously, depends upon the number of eigenvectors requested, and

\[ \text{nSYTRD_LWOPT} = n + 2*(anb+1)*(4*nps+2) + (nps+3)*nps \]
\[ \text{nSYGST_LWOPT} = 2*np0*nb + ng0*nb + nb*nb \]
\[ anb = \text{pJLAEVN}(\text{desca}[ctxt - 1], 3, \text{pSYTTRD}', 'L', 0, 0, 0, 0) \]
\[ sqnpc = \text{int}(\sqrt{\text{dble}(NPROW \times NPCOL)}) \]
\[ nps = \max(\text{numroc}(n, 1, 0, 0, sqnpc), 2 \times anb) \]
\[ NB = \text{desca}[mb_- - 1] \]
\[ np0 = \text{numroc}(n, nb, 0, 0, NPROW) \]
\[ nq0 = \text{numroc}(n, nb, 0, 0, NPCOL) \]

\text{numroc} is a ScaLAPACK tool functions;
\text{pjlaenv} is a ScaLAPACK environmental inquiry function

MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function \text{blacs_gridinfo}.

For large \( n \), no extra workspace is needed, however the biggest boost in performance comes for small \( n \), so it is wise to provide the extra workspace (typically less than a Megabyte per process).

If \text{clustersize} \geq n/\sqrt{\text{NPROW} \times \text{NPCOL}} \), then providing enough space to compute all the eigenvectors orthogonally will cause serious degradation in performance. At the limit (that is, \text{clustersize} = n-1) \text{p?stein} will perform no better than \text{?stein} on a single processor.

For \text{clustersize} = n/\sqrt{\text{NPROW} \times \text{NPCOL}} \) reorthogonalizing all eigenvectors will increase the total execution time by a factor of 2 or more.

For \text{clustersize} > n/\sqrt{\text{NPROW} \times \text{NPCOL}} \) execution time will grow as the square of the cluster size, all other factors remaining equal and assuming enough workspace. Less workspace means less reorthogonalization but faster execution.

If \text{iwork} = -1, then \text{iwork} is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by \text{pxerbla}.

\[ \text{iwork} \] (local) Workspace array.

\[ \text{liwork} \] (local), size of \text{iwork}.
\[ \text{liwork} \geq 6 \times nnp \]

Where:
\[ nnp = \max(n, \text{NPROW} \times \text{NPCOL} + 1, 4) \]

If \text{liwork} = -1, then \text{liwork} is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by \text{pxerbla}.

Output Parameters

\[ a \]

On exit, 
If \text{jobz} = 'V', and if \text{info} = 0, \text{sub}(A) contains the distributed matrix \( Z \) of eigenvectors. The eigenvectors are normalized as follows:
for \text{ibtype} = 1 or 2, \( Z^T \times \text{sub}(B) \times Z = \text{I} \);
for ibtype = 3, \( Z^T \text{inv}(\text{sub}(B)) Z = i. \)

If jobz = 'N', then on exit the upper triangle (if uplo='U') or the lower triangle (if uplo='L') of sub(A), including the diagonal, is destroyed.

On exit, if info \( \leq n \), the part of sub(B) containing the matrix is overwritten by the triangular factor \( U \) or \( L \) from the Cholesky factorization \( \text{sub}(B) = U^T U \) or \( \text{sub}(B) = L^T L \).

\( b \)

(global) The total number of eigenvalues found, \( 0 \leq m \leq n \).

\( m \)

Total number of eigenvectors computed. \( 0 \leq nz \leq m \). The number of columns of \( z \) that are filled.

If jobz \( \neq 'V' \), nz is not referenced.

If jobz = 'V', nz = m unless the user supplies insufficient space and p?sygvx is not able to detect this before beginning computation. To get all the eigenvectors requested, the user must supply both sufficient space to hold the eigenvectors in \( z \) (\( m \leq \text{descz}(n) \)) and sufficient workspace to compute them. (See lwork below.) p?sygvx is always able to detect insufficient space without computation unless range='V'.

\( w \)

(global)

Array of size \( n \). On normal exit, the first \( m \) entries contain the selected eigenvalues in ascending order.

\( z \)

(local).

global size \( n * n \), local size \( \text{lld}\_z * \text{LOCc}(jz+n-1) \).

If jobz = 'V', then on normal exit the first \( m \) columns of \( z \) contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of \( z \) contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in ifail.

If jobz = 'N', then \( z \) is not referenced.

\( \text{work} \)

If jobz='N', work[0] = optimal amount of workspace required to compute eigenvalues efficiently

If jobz = 'V', work[0] = optimal amount of workspace required to compute eigenvalues and eigenvectors efficiently with no guarantee on orthogonality.

If range='V', it is assumed that all eigenvectors may be required.

\( \text{ifail} \)

(global)

Array of size \( n \).

\( \text{ifail} \) provides additional information when info\#0

If \( \text{mod}(\text{info}\_16,2) \neq 0 \) then ifail[0] indicates the order of the smallest minor which is not positive definite. If \( \text{mod}(\text{info},2) \neq 0 \) on exit, then ifail contains the indices of the eigenvectors that failed to converge.
If neither of the above error conditions hold and \( \text{jobz} = 'V' \), then the first \( m \) elements of \( \text{ifail} \) are set to zero.

\( \text{iclustr} \) (global)

Array of size \((2*NPROW*NPCOL)\). This array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be reorthogonalized due to insufficient workspace (see \( \text{lwork}, \text{orfac} \) and \( \text{info} \)). Eigenvectors corresponding to clusters of eigenvalues indexed \( \text{iclustr}[2*i - 2] \) to \( \text{iclustr}[2*i - 1] \), could not be reorthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal. \( \text{iclustr} \) is a zero terminated array.

\((\text{iclustr}[2*k - 1]\neq 0. \text{and. iclustr}[2*k]=0) \) if and only if \( k \) is the number of clusters \( \text{iclustr} \) is not referenced if \( \text{jobz} = 'N' \).

\( \text{gap} \) (global)

Array of size \( NPROW*NPCOL \). This array contains the gap between eigenvalues whose eigenvectors could not be reorthogonalized. The output values in this array correspond to the clusters indicated by the array \( \text{iclustr} \). As a result, the dot product between eigenvectors corresponding to the \( i \)-th cluster may be as high as \( (C*n)/\text{gap}[i - 1] \), where \( C \) is a small constant.

\( \text{info} \) (global)

If \( \text{info} = 0 \), the execution is successful.

If \( \text{info} < 0 \): the \( i \)-th argument is an array and the \( j \)-entry had an illegal value, then \( \text{info} = -(i*100+j) \), if the \( i \)-th argument is a scalar and had an illegal value, then \( \text{info} = -i \).

If \( \text{info} > 0 \):

If \( (\text{mod(}\text{info},2)\neq 0) \), then one or more eigenvectors failed to converge. Their indices are stored in \( \text{ifail} \).

If \( (\text{mod(}\text{info},2,2)\neq 0) \), then eigenvectors corresponding to one or more clusters of eigenvalues could not be reorthogonalized because of insufficient workspace. The indices of the clusters are stored in the array \( \text{iclustr} \).

If \( (\text{mod(}\text{info},4,2)\neq 0) \), then space limit prevented \( \text{p?sygvx} \) from computing all of the eigenvectors between \( \text{vl} \) and \( \text{vu} \). The number of eigenvectors computed is returned in \( \text{nz} \).

If \( (\text{mod(}\text{info},8,2)\neq 0) \), then \( \text{p?stebz} \) failed to compute eigenvalues.

If \( (\text{mod(}\text{info},16,2)\neq 0) \), then \( B \) was not positive definite. \( \text{ifail}(1) \) indicates the order of the smallest minor which is not positive definite.

Description

The p?hegvx function computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian positive-definite eigenproblem, of the form

\[ \text{sub}(A) \ast x = \lambda \ast \text{sub}(B) \ast x, \text{ or } \text{sub}(B) \ast \text{sub}(A) \ast x = \lambda \ast x. \]

Here \( \text{sub}(A) \) denoting \( A(ia:ia+n-1, ja:ja+n-1) \) and \( \text{sub}(B) \) are assumed to be Hermitian and \( \text{sub}(B) \) denoting \( B(ib:ib+n-1, jb:jb+n-1) \) is also positive definite.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

ibtype

(global) Must be 1 or 2 or 3.

Specifies the problem type to be solved:
If \( ibtype = 1 \), the problem type is
\[ \text{sub}(A) \ast x = \lambda \ast \text{sub}(B) \ast x; \]
If \( ibtype = 2 \), the problem type is
\[ \text{sub}(B) \ast \text{sub}(A) \ast x = \lambda \ast x; \]
If \( ibtype = 3 \), the problem type is
sub(B)*sub(A)*x = lambda*x.

jobz (global) Must be 'N' or 'V'.
If jobz = 'N', then compute eigenvalues only.
If jobz = 'V', then compute eigenvalues and eigenvectors.

range (global) Must be 'A' or 'V' or 'I'.
If range = 'A', the function computes all eigenvalues.
If range = 'V', the function computes eigenvalues in the interval: [vl, vu]
If range = 'I', the function computes eigenvalues with indices il through iu.

uplo (global) Must be 'U' or 'L'.
If uplo = 'U', arrays a and b store the upper triangles of sub(A) and sub(B);
If uplo = 'L', arrays a and b store the lower triangles of sub(A) and sub(B).

n (global)
The order of the matrices sub(A) and sub(B) (n ≥ 0).

a (local)
Pointer into the local memory to an array of size lld_a*LOCc(ja+n-1). On entry, this array contains the local pieces of the n-by-n Hermitian distributed matrix sub(A). If uplo = 'U', the leading n-by-n upper triangular part of sub(A) contains the upper triangular part of the matrix. If uplo = 'L', the leading n-by-n lower triangular part of sub(A) contains the lower triangular part of the matrix.

ia, ja (global)
The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A, respectively.

desca (global and local) array of size dlen_.
The array descriptor for the distributed matrix A. If desca[ctxt_ - 1] is incorrect, p?hegvx cannot guarantee correct error reporting.

b (local).
Pointer into the local memory to an array of size lld_b*LOCc(jb+n-1). On entry, this array contains the local pieces of the n-by-n Hermitian distributed matrix sub(B).
If uplo = 'U', the leading n-by-n upper triangular part of sub(B) contains the upper triangular part of the matrix.
If uplo = 'L', the leading n-by-n lower triangular part of sub(B) contains the lower triangular part of the matrix.

ib, jb (global)
The row and column indices in the global matrix $B$ indicating the first row and the first column of the submatrix $B$, respectively.

descb

(global and local) array of size $dlen_\cdot$

The array descriptor for the distributed matrix $B$. $descb[ctxt_\cdot - 1]$ must be equal to $desca[ctxt_\cdot - 1]$.

$v\ell, vu$

(global)

If $range = 'V'$, the lower and upper bounds of the interval to be searched for eigenvalues.

If $range = 'A'$ or $'I'$, $v\ell$ and $vu$ are not referenced.

$il, iu$

(global)

If $range = 'I'$, the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint: $il \geq 1$, $\min(il, n) \leq iu \leq n$

If $range = 'A'$ or $'V'$, $il$ and $iu$ are not referenced.

$abstol$

(global)

If $jobz='V'$, setting $abstol$ to $\max\{2*p?lamch('S')\}$ yields the most orthogonal eigenvectors.

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a, b]$ of width less than or equal to

$$abstol + eps*\max(|a|,|b|),$$

where $eps$ is the machine precision. If $abstol$ is less than or equal to zero, then $eps*\max(T)$ will be used in its place, where $\max(T)$ is the 1-norm of the tridiagonal matrix obtained by reducing $A$ to tridiagonal form.

Eigenvalues will be computed most accurately when $abstol$ is set to twice the underflow threshold $2*p?lamch('S')$ not zero. If this function returns with $(\mod(info,2)\neq0)$.or. $(\mod(info,8,2)\neq0))$, indicating that some eigenvalues or eigenvectors did not converge, try setting $abstol$ to $2*p?lamch('S')$.

**NOTE**

$\mod(x,y)$ is the integer remainder of $x/y$.

$orfac$

(global).

Specifies which eigenvectors should be reorthogonalized. Eigenvectors that correspond to eigenvalues which are within $tol=orfac*\max(A)$ of each other are to be reorthogonalized. However, if the workspace is insufficient (see $lwork$), $tol$ may be decreased until all eigenvectors to be reorthogonalized can be stored in one process. No reorthogonalization will be done if $orfac$ equals zero. A default value of 1.0E-3 is used if $orfac$ is negative. $orfac$ should be identical on all processes.

$iz, jz$

(global) The row and column indices in the global matrix $Z$ indicating the first row and the first column of the submatrix $Z$, respectively.
(global and local) array of size \( dlen_\). The array descriptor for the distributed matrix \( Z \). The array descriptor for the distributed matrix \( Z \) must equal \( desca[ctxt_-1] \).

\textbf{work}

(local)

Workspace array of size \( lwork \)

\textbf{lwork}

(local).

The size of the array \( work \).

If only eigenvalues are requested:

\[ lwork \geq n \times \max(NB \times (np0 + 1), 3) \]

If eigenvectors are requested:

\[ lwork \geq n + (np0 + mq0 + NB) \times NB \]

with \( np0 = \text{numroc}(nn, NB, 0, 0, NPCOL) \).

For optimal performance, greater workspace is needed, that is

\[ lwork \geq \max(lwork, n, \text{nhetrd_lwopt}, \text{nhegst_lwopt}) \]

where \( lwork \) is as defined above, and

\[ \text{nhetrd_lwopt} = 2 \times (\text{anb} + 1) \times (4 \times \text{nps} + 2) \times (\text{nps} + 1) \times \text{nps}; \]

\[ \text{nhegst_lwopt} = 2 \times \text{np0} \times \text{nb} + \text{np0} \times \text{nb} + \text{nb} \times \text{nb} \]

\[ \text{nb} = \text{desca}[mb_-1] \]

\[ np0 = \text{numroc}(n, nb, 0, 0, NPROW) \]

\[ npq0 = \text{numroc}(n, nb, 0, 0, NPCOL) \]

\[ \text{ictxt} = \text{desca}[ctxt_-1] \]

\[ \text{anb} = \text{pjlaenv}(\text{ictxt}, 3, 'p?hettrd', 'L', 0, 0, 0, 0) \]

\[ \text{sqnpc} = \sqrt{\text{dble}(NPROW \times NPCOL)} \]

\[ \text{nps} = \max(\text{numroc}(n, 1, 0, 0, \text{sqnpc}), 2 \times \text{anb}) \]

\textbf{numroc} is a ScaLAPACK tool functions;

\textbf{pjlaenv} is a ScaLAPACK environmental inquiry function \textbf{MYROW}, \textbf{MYCOL}, \textbf{NPROW} and \textbf{NPCOL} can be determined by calling the function \textbf{blacs_gridinfo}.

If \( lwork = -1 \), then \( lwork \) is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by \textbf{pxerbla}.

\textbf{rwork}

(local)

Workspace array of size \( lrwork \).

\textbf{lrwork}

(local) The size of the array \( rwork \).

See below for definitions of variables used to define \( lrwork \).

If no eigenvectors are requested (\( jobz = 'N' \)), then \( lrwork \geq 5 \times nn + 4 \times n \)
If eigenvectors are requested (\texttt{jobz = 'V'}), then the amount of workspace required to guarantee that all eigenvectors are computed is:

\[ lrwork \geq 4n + \max(5nn, np0*mq0) + \text{iceil}(\text{neig}, \text{NPROW}*\text{NPCOL})*nn \]

The computed eigenvectors may not be orthogonal if the minimal workspace is supplied and \texttt{orfac} is too small. If you want to guarantee orthogonality (at the cost of potentially poor performance) you should add the following value to \texttt{lrwork}:

\[ (\text{clustersize}-1)*n, \]

where \texttt{clustersize} is the number of eigenvalues in the largest cluster, where a cluster is defined as a set of close eigenvalues:

\[ \{w[k - 1], ..., w[k+\text{clustersize} - 2]|w[j] \leq w[j-1]+\text{orfac}*2*\text{norm}(A)\} \]

Variable definitions:

\texttt{neig} = number of eigenvectors requested;

\texttt{nb} = \texttt{desca}[mb - 1] = \texttt{desca}[nb - 1] = \texttt{descz}[mb - 1] = \texttt{descz}[nb - 1];

\texttt{nn} = \max(n, nb, 2);

\texttt{np0 = numroc(nn, nb, 0, 0, NPROW)};

\texttt{mq0 = numroc(max(neig, nb, 2), nb, 0, 0, NPCOL)};

\texttt{iceil(x, y)} is a ScaLAPACK function returning ceiling(x/y).

When \texttt{lrwork} is too small:

If \texttt{lwork} is too small to guarantee orthogonality, \texttt{p?hegvx} attempts to maintain orthogonality in the clusters with the smallest spacing between the eigenvalues.

If \texttt{lwork} is too small to compute all the eigenvectors requested, no computation is performed and \texttt{info} = -25 is returned. Note that when \texttt{range='V'}, \texttt{p?hegvx} does not know how many eigenvectors are requested until the eigenvalues are computed. Therefore, when \texttt{range='V'} and as long as \texttt{lwork} is large enough to allow \texttt{p?hegvx} to compute the eigenvalues, \texttt{p?hegvx} will compute the eigenvalues and as many eigenvectors as it can.

Relationship between workspace, orthogonality & performance:

If \texttt{clustersize} > \(n/\sqrt{\text{NPROW}*\text{NPCOL}}\), then providing enough space to compute all the eigenvectors orthogonally will cause serious degradation in performance. In the limit (that is, \texttt{clustersize} = \(n-1\)) \texttt{p?stein} will perform no better than \texttt{?stein} on 1 processor.

For \texttt{clustersize} = \(n/\sqrt{\text{NPROW}*\text{NPCOL}}\) reorthogonalizing all eigenvectors will increase the total execution time by a factor of 2 or more.

For \texttt{clustersize}>\(n/\sqrt{\text{NPROW}*\text{NPCOL}}\) execution time will grow as the square of the cluster size, all other factors remaining equal and assuming enough workspace. Less workspace means less reorthogonalization but faster execution.
If \( lwork = -1 \), then \( lwork \) is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by \( \text{p} \text{xerbla} \).

\( iwork \) (local) Workspace array.

\( liwork \), size of \( iwork \).

\( liwork \geq 6 \times nnp \)

Where: \( nnp = \max(n, \text{NPROW} \times \text{NPCOL} + 1, 4) \)

If \( liwork = -1 \), then \( liwork \) is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by \( \text{p} \text{xerbla} \).

Output Parameters

\( a \) On exit, if \( \text{jobz} = \text{'}V\text{'} \), then if \( \text{info} = 0 \), sub(\( A \)) contains the distributed matrix \( Z \) of eigenvectors.

The eigenvectors are normalized as follows:

If \( ibtype = 1 \) or 2, then \( Z^* \text{sub}(B) Z = I \);

If \( ibtype = 3 \), then \( Z^* \text{inv(sub}(B)) Z = I \).

If \( \text{jobz} = \text{'}N\text{'} \), then on exit the upper triangle (if \( \text{uplo} = \text{'}U\text{'}) or the lower triangle (if \( \text{uplo} = \text{'}L\text{'}) of sub(\( A \)), including the diagonal, is destroyed.

\( b \) On exit, if \( \text{info} \leq n \), the part of sub(\( B \)) containing the matrix is overwritten by the triangular factor \( U \) or \( L \) from the Cholesky factorization sub(\( B \)) = \( U^* U \), or sub(\( B \)) = \( L L^* \).

\( m \) (global) The total number of eigenvalues found, \( 0 \leq m \leq n \).

\( nz \) (global) Total number of eigenvectors computed. \( 0 < nz < m \). The number of columns of \( z \) that are filled.

If \( \text{jobz} \neq \text{'}V\text{'} \), \( nz \) is not referenced.

If \( \text{jobz} = \text{'}V\text{'} \), \( nz = m \) unless the user supplies insufficient space and \( \text{p} \text{hegvx} \) is not able to detect this before beginning computation. To get all the eigenvectors requested, the user must supply both sufficient space to hold the eigenvectors in \( z \) (\( m \leq \text{descz}[n_--1] \)) and sufficient workspace to compute them. (See \( lwork \) below.) The function \( \text{p} \text{hegvx} \) is always able to detect insufficient space without computation unless \( \text{range} = \text{'}V\text{'} \).

\( w \) (global)

Array of size \( n \). On normal exit, the first \( m \) entries contain the selected eigenvalues in ascending order.

\( z \) (local).

Global size \( n \times n \), local size \( \text{ld}_z \times \text{LOCc}(jz+n-1) \).
If `jobz = 'V'`, then on normal exit the first `m` columns of `z` contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of `z` contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in `ifail`.

If `jobz = 'N'`, then `z` is not referenced.

**work**
On exit, `work[0]` returns the optimal amount of workspace.

**rwork**
On exit, `rwork[0]` contains the amount of workspace required for optimal efficiency

- If `jobz='N' rwork[0] = optimal amount of workspace required to compute eigenvalues efficiently
- If `jobz='V' rwork[0] = optimal amount of workspace required to compute eigenvalues and eigenvectors efficiently with no guarantee on orthogonality.

If `range='V'`, it is assumed that all eigenvectors may be required when computing optimal workspace.

**ifail**
Array of size `n`.

- `ifail` provides additional information when `info≠0`
- If `(mod(info,16,2)≠0), then ifail[0] indicates the order of the smallest minor which is not positive definite.
- If `(mod(info,2)≠0) on exit, then ifail[0] contains the indices of the eigenvectors that failed to converge.
- If neither of the above error conditions are held, and `jobz = 'V'`, then the first `m` elements of `ifail` are set to zero.

**iclustr**
Array of size `(2*NPROW*NPCOL)`. This array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be reorthogonalized due to insufficient workspace (see `lwork`, `orfac` and `info`). Eigenvectors corresponding to clusters of eigenvalues indexed `iclustr(2*i-1)` to `iclustr(2*i)`, could not be reorthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal.

- `iclustr()` is a zero terminated array. `(iclustr(2*k) ≠0 and clustr(2*k+1)=0) if and only if `k` is the number of clusters.
- `iclustr` is not referenced if `jobz = 'N'`.

**gap**
Array of size `NPROW*NPCOL`.

This array contains the gap between eigenvalues whose eigenvectors could not be reorthogonalized. The output values in this array correspond to the clusters indicated by the array `iclustr`. As a result, the dot product between eigenvectors corresponding to the `i`-th cluster may be as high as \((C*n)/gap(i)\), where `C` is a small constant.
If $info = 0$, the execution is successful.

If $info < 0$: the $i$-th argument is an array and the $j$-entry had an illegal value, then $info = -(i*100+j)$, if the $i$-th argument is a scalar and had an illegal value, then $info = -i$.

If $info > 0$:

If $(\text{mod}(info, 2) \neq 0)$, then one or more eigenvectors failed to converge. Their indices are stored in $ifail$.

If $(\text{mod}(info, 2, 2) \neq 0)$, then eigenvectors corresponding to one or more clusters of eigenvalues could not be reorthogonalized because of insufficient workspace. The indices of the clusters are stored in the array $iclustr$.

If $(\text{mod}(info/4, 2) \neq 0)$, then space limit prevented $p$sygvx from computing all of the eigenvectors between $vl$ and $vu$. The number of eigenvectors computed is returned in $nz$.

If $(\text{mod}(info/8, 2) \neq 0)$, then $p$stebz failed to compute eigenvalues.

If $(\text{mod}(info/16, 2) \neq 0)$, then $B$ was not positive definite. $ifail(1)$ indicates the order of the smallest minor which is not positive definite.

**Optimization Notice**

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804
**p?lacgv**

*Conjugates a complex vector.*

**Syntax**

```c
void pclacgv (MKL_INT *n, MKL_Complex8 *x, MKL_INT *ix, MKL_INT *jx, MKL_INT *descx, MKL_INT *incx);
void pzlacgv (MKL_INT *n, MKL_Complex16 *x, MKL_INT *ix, MKL_INT *jx, MKL_INT *descx, MKL_INT *incx);
```

**Include Files**

- mkl_scalapack.h

**Description**

The `p?lacgv` function conjugates a complex vector `sub(X)` of length `n`, where `sub(X)` denotes `X(ix, jx:jx+n-1)` if `incx = m_x`, and `X(ix:ix+n-1, jx)` if `incx = 1`.

**Input Parameters**

- `n` (global) The length of the distributed vector `sub(X)`.
- `x` (local). Pointer into the local memory to an array of size `lld_x * LOCc(n_x)`. On entry the vector to be conjugated `x[i] = X(ix+(jx-1)*m_x+i*incx)` if `incx = m_x`, and `x[i] = x[ix+jx+(i-1)*incx]` if `incx = 1`.
- `ix` (global) The row index in the global matrix `X` indicating the first row of `sub(X)`.
- `jx` (global) The column index in the global matrix `X` indicating the first column of `sub(X)`.
- `descx` (global and local) Array of size `dlen_ = 9`. The array descriptor for the distributed matrix `X`.
- `incx` (global) The global increment for the elements of `X`. Only two values of `incx` are supported in this version, namely 1 and `m_x`. `incx` must not be zero.

**Output Parameters**

- `x` (local).
  On exit, the local pieces of conjugated distributed vector `sub(X)`.

**See Also**

**p?max1**

*Finds the index of the element whose real part has maximum absolute value (similar to the Level 1 PBLAS `p?amax`, but using the absolute value to the real part).*
Syntax

void pcmax1 (MKL_INT *n, MKL_Complex8 *amax, MKL_INT *indx, MKL_Complex8 *x,
MKL_INT *ix, MKL_INT *jx, MKL_INT *descx, MKL_INT *incx);

void pzmax1 (MKL_INT *n, MKL_Complex16 *amax, MKL_INT *indx, MKL_Complex16 *x,
MKL_INT *ix, MKL_INT *jx, MKL_INT *descx, MKL_INT *incx);

Include Files
• mkl_scalapack.h

Description
The \texttt{p?max1} function computes the global index of the maximum element in absolute value of a distributed vector \texttt{sub(X)}. The global index is returned in \texttt{indx} and the value is returned in \texttt{amax}, where \texttt{sub(X)} denotes \texttt{X(ix:ix}+\texttt{n-1,jx:} if \texttt{incx = 1}, \texttt{X(ix,jx:jx}+\texttt{n-1)} if \texttt{incx = m_x}.

Input Parameters

\begin{itemize}
\item \texttt{n} (global). The number of components of the distributed vector \texttt{sub(X)}. \texttt{n} \geq 0.
\item \texttt{x} (local) Pointer into the local memory to an array of size \texttt{lld_x} \times \texttt{LOCc} \texttt{(jx}+\texttt{n-1). On entry this array contains the local pieces of the distributed vector \texttt{sub(X)}.
\item \texttt{ix} (global) The row index in the global matrix \texttt{X} indicating the first row of \texttt{sub(X)}.
\item \texttt{jx} (global) The column index in the global matrix \texttt{X} indicating the first column of \texttt{sub(X)}.
\item \texttt{descx} (global and local) Array of size \texttt{dlen__. The array descriptor for the distributed matrix \texttt{X}.
\item \texttt{incx} (global). The global increment for the elements of \texttt{X}. Only two values of \texttt{incx} are supported in this version, namely \texttt{1} and \texttt{m_x}. \texttt{incx} must not be zero.
\end{itemize}

Output Parameters

\begin{itemize}
\item \texttt{amax} (global output). The absolute value of the largest entry of the distributed vector \texttt{sub(X)} only in the scope of \texttt{sub(X)}.
\item \texttt{indx} (global output). The global index of the element of the distributed vector \texttt{sub(X)} whose real part has maximum absolute value.
\end{itemize}

See Also

\texttt{Overview} for details of ScaLAPACK array descriptor structures and related notations.

\texttt{pilaver}

Returns the ScaLAPACK version.

Syntax

void pilaver (MKL_INT* vers_major, MKL_INT* vers_minor, MKL_INT* vers_patch);
Include Files

- mkl_scalapack.h

Description

This function returns the ScaLAPACK version.

Output Parameters

- vers_major
  Return the ScaLAPACK major version.
- vers_minor
  Return the ScaLAPACK minor version from the major version.
- vers_patch
  Return the ScaLAPACK patch version from the minor version.

pmpcol

Finds the collaborators of a process.

Syntax

```c
void pmpcol(MKL_INT* myproc, MKL_INT* nprocs, MKL_INT* iill, MKL_INT* needil, MKL_INT* neediu, MKL_INT* pmyils, MKL_INT* pmyius, MKL_INT* colbrt, MKL_INT* frstcl, MKL_INT* lastcl);
```

Include Files

- mkl_scalapack.h

Description

Using the output from pmpim2 and given the information on eigenvalue clusters, pmpcol finds the collaborators of myproc.

Optimization Notice

Intel’s compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

- myproc
  The processor number, 0 ≤ myproc < nprocs.
- nprocs
  The total number of processors available.
- iill
  The index of the leftmost eigenvalue in the eigenvalue cluster.
- needil
  The leftmost position in the eigenvalue cluster needed by myproc.
- neediu
  The rightmost position in the eigenvalue cluster needed by myproc.
For each processor $p$, $0 < p \leq \text{nprocs}$, $p\text{myils}[p-1]$ is the index of the first eigenvalue in the eigenvalue cluster to be computed. $p\text{myils}[p-1]$ equals zero if $p$ stays idle.

$p\text{myius}$ array

For each processor $p$, $p\text{myius}[p-1]$ is the index of the last eigenvalue in the eigenvalue cluster to be computed. $p\text{myius}[p-1]$ equals zero if $p$ stays idle.

**OUTPUT Parameters**

$\text{colbrt}$

Non-zero if $\text{myproc}$ collaborates.

$\text{frstcl, lastcl}$

First and last collaborator of $\text{myproc}$.

$\text{myproc}$ collaborates with:

$\text{frstcl}, ..., \text{myproc}-1, \text{myproc}+1, ..., \text{lastcl}$

If $\text{myproc} = \text{frstcl}$, there are no collaborators on the left. If $\text{myproc} = \text{lastcl}$, there are no collaborators on the right.

If $\text{frstcl} = 0$ and $\text{lastcl} = \text{nprocs}-1$, then $\text{myproc}$ collaborates with everybody

**See Also**

**pmpim2**

*Computes the eigenpair range assignments for all processes.*

**Syntax**

```c
void pmpim2(MKL_INT* il, MKL_INT* iu, MKL_INT* nprocs, MKL_INT* pmyils, MKL_INT* pmyius);
```

**Include Files**

- mkl_scalapack.h

**Description**

$pmpim2$ is the scheduling function. It computes for all processors the eigenpair range assignments.

**Optimization Notice**

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain
Input Parameters

*il, iu*
The range of eigenpairs to be computed.

*nprocs*
The total number of processors available.

Output Parameters

*pmyils*
array
For each processor *p*, *pmyils*[p-1] is the index of the first eigenvalue in a cluster to be computed.
*pmyils*[p-1] equals zero if *p* stays idle.

*pmyius*
array
For each processor *p*, *pmyius*[p-1] is the index of the last eigenvalue in a cluster to be computed.
*pmyius*[p-1] equals zero if *p* stays idle.

**?combamax1**

*Finds the element with maximum real part absolute value and its corresponding global index.*

**Syntax**

```c
void ccombamax1 (MKL_Complex8 *v1 , MKL_Complex8 *v2 );
void zcombamax1 (MKL_Complex16 *v1 , MKL_Complex16 *v2 );
```

**Include Files**

- `mkl_scalapack.h`

**Description**

The `?combamax1` function finds the element having maximum real part absolute value as well as its corresponding global index.

**Input Parameters**

`v1` (local)

`v2` (local)

**Output Parameters**

v1  (local).

The first maximum absolute value element and its global index.

**See Also**

Overview for details of ScaLAPACK array descriptor structures and related notations.

**p?sum1**

Forms the 1-norm of a complex vector similar to Level 1 PBLAS p?asum, but using the true absolute value.

**Syntax**

void pscsum1 (MKL_INT *n, float *asum, MKL_Complex8 *x, MKL_INT *ix, MKL_INT *jx, MKL_INT *descx, MKL_INT *incx);

void pdzsum1 (MKL_INT *n, double *asum, MKL_Complex16 *x, MKL_INT *ix, MKL_INT *jx, MKL_INT *descx, MKL_INT *incx);

**Include Files**

- mkl_scalapack.h

**Description**

The p?sum1 function returns the sum of absolute values of a complex distributed vector sub(x) in asum, where sub(x) denotes X(ix:ix+n-1, jx:jx), if incx = 1, X(ix:ix, jx:jx+n-1), if incx = m_x.

Based on p?asum from the Level 1 PBLAS. The change is to use the 'genuine' absolute value.

**Input Parameters**

n  (global). The number of components of the distributed vector sub(x). n ≥ 0.

x  (local )

Pointer into the local memory to an array of size lld_x * LOCc(jx+n-1). This array contains the local pieces of the distributed vector sub(X).

ix  (global) The row index in the global matrix X indicating the first row of sub(X).

jx  (global) The column index in the global matrix X indicating the first column of sub(X)

descx  (local) Array of size dien_ =9. The array descriptor for the distributed matrix X.

incx  (global) The global increment for the elements of X. Only two values of incx are supported in this version, namely 1 and m_x.
Output Parameters

\texttt{asum} \quad (\text{(local)})

The sum of absolute values of the distributed vector sub\((X)\) only in its scope.

\texttt{p\texttt{d}dbtrsv}

Computes an LU factorization of a general triangular matrix with no pivoting. The function is called by \texttt{p\texttt{d}dbtrs}.

Syntax

\begin{verbatim}
void psdbtrsv (char *uplo, char *trans, MKL_INT *n, MKL_INT *bwl, MKL_INT *bwu, MKL_INT *nrhs, float *a, MKL_INT *ja, MKL_INT *desca, float *b, MKL_INT *ib, MKL_INT *descb, float *af, MKL_INT *laf, float *work, MKL_INT *lwork, MKL_INT *info);
void pddbtrsv (char *uplo, char *trans, MKL_INT *n, MKL_INT *bwl, MKL_INT *bwu, MKL_INT *nrhs, double *a, MKL_INT *ja, MKL_INT *desca, double *b, MKL_INT *ib, MKL_INT *descb, double *af, MKL_INT *laf, double *work, MKL_INT *lwork, MKL_INT *info);
void pcdbtrsv (char *uplo, char *trans, MKL_INT *n, MKL_INT *bwl, MKL_INT *bwu, MKL_INT *nrhs, MKL_Complex8 *a, MKL_INT *ja, MKL_INT *desca, MKL_Complex8 *b, MKL_INT *ib, MKL_INT *descb, MKL_Complex8 *af, MKL_INT *laf, MKL_Complex8 *work, MKL_INT *lwork, MKL_INT *info);
void pzdbtrsv (char *uplo, char *trans, MKL_INT *n, MKL_INT *bwl, MKL_INT *bwu, MKL_INT *nrhs, MKL_Complex16 *a, MKL_INT *ja, MKL_INT *desca, MKL_Complex16 *b, MKL_INT *ib, MKL_INT *descb, MKL_Complex16 *af, MKL_INT *laf, MKL_Complex16 *work, MKL_INT *lwork, MKL_INT *info);
\end{verbatim}

Include Files

- mkl_scalapack.h

Description

The \texttt{p\texttt{d}dbtrsv} function solves a banded triangular system of linear equations
\begin{align*}
A(1:n, ja:ja+n-1) \times X &= B(ib:ib+n-1, 1:nrhs) \quad \text{(for real flavors)}; \\
A(1:n, ja:ja+n-1)^T \times X &= B(ib:ib+n-1, 1:nrhs) \quad \text{(for complex flavors)},
\end{align*}
where \(A(1:n, ja:ja+n-1)\) is a banded triangular matrix factor produced by the Gaussian elimination code of \texttt{p\texttt{d}dbtrf} and is stored in \(A(1:n, ja:ja+n-1)\) and \(af\). The matrix stored in \(A(1:n, ja:ja+n-1)\) is either upper or lower triangular according to \texttt{uplo}, and the choice of solving \(A(1:n, ja:ja+n-1)\) or \((A(1:n, ja:ja+n-1))^T\) is dictated by the user by the parameter \texttt{trans}.

The function \texttt{p\texttt{d}dbtrf} must be called first.
Input Parameters

**uplo**

If `uplo='U'`, the upper triangle of \( A(1:n, ja:ja+n-1) \) is stored, if `uplo = 'L'`, the lower triangle of \( A(1:n, ja:ja+n-1) \) is stored.

**trans**

If `trans = 'N'`, solve with \( A(1:n, ja:ja+n-1) \), if `trans = 'C'`, solve with conjugate transpose \( A(1:n, ja:ja+n-1) \).

**n**

The order of the distributed submatrix \( A; (n \geq 0) \).

**bwl**

Number of subdiagonals. \( 0 \leq bwl \leq n-1 \).

**bwu**

Number of subdiagonals. \( 0 \leq bwu \leq n-1 \).

**nrhs**

The number of right-hand sides; the number of columns of the distributed submatrix \( B \) \( (nrhs \geq 0) \).

**a**

Pointer into the local memory to an array of size \( lld_a * LOCc(ja+n-1) \), where \( lld_a \geq (bwl+bwu+1) \). On entry, this array contains the local pieces of the \( n \)-by-\( n \) unsymmetric banded distributed Cholesky factor \( L \) or \( L^T \), represented in global \( A \) as \( A(1:n, ja:ja+n-1) \). This local portion is stored in the packed banded format used in LAPACK. See the Application Notes below and the ScaLAPACK manual for more detail on the format of distributed matrices.

**ja**

The index in the global matrix \( A \) that points to the start of the matrix to be operated on (which may be either all of \( A \) or a submatrix of \( A \)).

**desca**

Array of size \( dlen_ \).

If 1d type \( (dtype_a = 501 \text{ or } 502) \), \( dlen \geq 7 \);

If 2d type \( (dtype_a = 1) \), \( dlen \geq 9 \). The array descriptor for the distributed matrix \( A \). Contains information of mapping of \( A \) to memory.

**b**

Pointer into the local memory to an array of local lead dimension \( lld_b \geq nb \). On entry, this array contains the local pieces of the right-hand sides \( B(ib:ib+n-1, 1:nrhs) \).

**ib**

The row index in the global matrix \( B \) that points to the first row of the matrix to be operated on (which may be either all of \( B \) or a submatrix of \( B \)).

**descb**

Array of size \( dlen_ \).

If 1d type \( (dtype_b = 502) \), \( dlen \geq 7 \);

If 2d type \( (dtype_b = 1) \), \( dlen \geq 9 \). The array descriptor for the distributed matrix \( B \). Contains information of mapping \( B \) to memory.

**laf**

Size of user-input auxiliary fill-in space \( af \).
If $\text{laf}$ is not large enough, an error code is returned and the minimum acceptable size will be returned in $\text{af}[0]$.

**work**

(local).

Temporary workspace. This space may be overwritten in between function calls.

*work* must be the size given in *lwork*.

**lwork**

(local or global)

Size of user-input workspace *work*. If *lwork* is too small, the minimal acceptable size will be returned in *work[0]* and an error code is returned.

$lwork \geq \max(bwl, bwu) \times \text{nrhs}$.

### Output Parameters

**$a$**

(local).

This local portion is stored in the packed banded format used in LAPACK. Please see the ScaLAPACK manual for more detail on the format of distributed matrices.

**$b$**

On exit, this contains the local piece of the solutions distributed matrix $X$.

**$af$**

(auxiliary fill-in space. The fill-in space is created in a call to the factorization function $p\text{?dbtrf}$ and is stored in $af$. If a linear system is to be solved using $p\text{?dbtrf}$ after the factorization function, $af$ must not be altered after the factorization.)

On exit, *work[0]* contains the minimal *lwork*.

**info**

(local).

If *info* = 0, the execution is successful.

$< 0$: If the $i$-th argument is an array and the $j$-th entry, indexed $j-1$, had an illegal value, then $\text{info} = -(i \times 100 + j)$, if the $i$-th argument is a scalar and had an illegal value, then $\text{info} = -i$.

### See Also

**Overview** for details of ScaLAPACK array descriptor structures and related notations.

**p?dttrs**

Computes an LU factorization of a general band matrix, using partial pivoting with row interchanges. The function is called by $p\text{?dttrs}$.

**Syntax**

```c
void psdttrsv (char *uplo, char *trans, MKL_INT *n, MKL_INT *nrhs, float *dl, float *d, float *du, MKL_INT *ja, MKL_INT *desca, float *b, MKL_INT *ib, MKL_INT *descb, float *af, MKL_INT *iaf, float *work, MKL_INT *iwork, MKL_INT *info);
```
void pddttrsv(char *uplo, char *trans, MKL_INT *n, MKL_INT *nrhs, double *dl, double *d, double *du, MKL_INT *ja, MKL_INT *descb, double *b, MKL_INT *ib, MKL_INT *descb, double *af, MKL_INT *laf, double *work, MKL_INT *lwork, MKL_INT *info);

void pcdttrsv(char *uplo, char *trans, MKL_INT *n, MKL_INT *nrhs, MKL_Complex8 *dl, MKL_Complex8 *d, MKL_Complex8 *du, MKL_INT *ja, MKL_INT *desca, MKL_Complex8 *b, MKL_INT *ib, MKL_INT *descb, MKL_Complex8 *af, MKL_INT *laf, MKL_Complex8 *work, MKL_INT *lwork, MKL_INT *info);

void pzdtttrs (char *uplo, char *trans, MKL_INT *n, MKL_INT *nrhs, MKL_Complex16 *dl, MKL_Complex16 *d, MKL_Complex16 *du, MKL_INT *ja, MKL_INT *desca, MKL_Complex16 *b, MKL_INT *ib, MKL_INT *descb, MKL_Complex16 *af, MKL_INT *laf, MKL_Complex16 *work, MKL_INT *lwork, MKL_INT *info);

Include Files

- mkl_scalapack.h

Description

The p?dttrsv function solves a tridiagonal triangular system of linear equations

\[ A(1:n, ja:ja+n-1)X = B(ib:ib+n-1, 1:nrhs) \]

\[ A(1:n, ja:ja+n-1)^T X = B(ib:ib+n-1, 1:nrhs) \] for real flavors; \( A(1:n, ja:ja+n-1)^H X = B(ib:ib+n-1, 1:nrhs) \) for complex flavors,

where \( A(1:n, ja:ja+n-1) \) is a tridiagonal matrix factor produced by the Gaussian elimination code of p?dttrf and is stored in \( A(1:n, ja:ja+n-1) \) and \( af \). The matrix stored in \( A(1:n, ja:ja+n-1) \) is either upper or lower triangular according to \( uplo \), and the choice of solving \( A(1:n, ja:ja+n-1) \) or \( A(1:n, ja:ja+n-1)^T \) is dictated by the user by the parameter \( trans \).

The function p?dttrf must be called first.

Input Parameters

uplo

(global)

If \( uplo = 'U' \), the upper triangle of \( A(1:n, ja:ja+n-1) \) is stored,

if \( uplo = 'L' \), the lower triangle of \( A(1:n, ja:ja+n-1) \) is stored.

trans

(global)

If \( trans = 'N' \), solve with \( A(1:n, ja:ja+n-1) \),

if \( trans = 'C' \), solve with conjugate transpose \( A(1:n, ja:ja+n-1) \).

n

(global) The order of the distributed submatrix \( A; (n \geq 0) \).

nrhs

(global) The number of right-hand sides; the number of columns of the distributed submatrix \( B(ib:ib+n-1, 1:nrhs) \). \( (nrhs \geq 0) \).

dl

(local).

Pointer to local part of global vector storing the lower diagonal of the matrix.

Globally, \( dl[0] \) is not referenced, and \( dl \) must be aligned with \( d \).
Must be of size \( \geq nb_a \).

\( d \)

(local).

Pointer to local part of global vector storing the main diagonal of the matrix.

\( du \)

(local).

Pointer to local part of global vector storing the upper diagonal of the matrix.

Globally, \( du[n-1] \) is not referenced, and \( du \) must be aligned with \( d \).

\( ja \)

(global) The index in the global matrix \( A \) that points to the start of the matrix to be operated on (which may be either all of \( A \) or a submatrix of \( A \)).

\( desca \)

(global and local) array of size \( dlen_\).

if 1d type (\( dtype_a = 501 \) or 502), \( dlen \geq 7 \);

if 2d type (\( dtype_a = 1 \)), \( dlen \geq 9 \).

The array descriptor for the distributed matrix \( A \). Contains information of mapping of \( A \) to memory.

\( b \)

(local)

Pointer into the local memory to an array of local lead dimension \( lld_b : \geq nb \). On entry, this array contains the local pieces of the right-hand sides \( B(ib : ib+n-1, 1 : nrhs) \).

\( ib \)

(global) The row index in the global matrix \( B \) that points to the first row of the matrix to be operated on (which may be either all of \( B \) or a submatrix of \( B \)).

\( descb \)

(global and local) array of size \( dlen_\).

if 1d type (\( dtype_b = 502 \)), \( dlen \geq 7 \);

if 2d type (\( dtype_b = 1 \)), \( dlen \geq 9 \).

The array descriptor for the distributed matrix \( B \). Contains information of mapping \( B \) to memory.

\( laf \)

(local).

Size of user-input auxiliary fill-in space \( af \).

\( laf \geq 2*(nb+2) \). If \( laf \) is not large enough, an error code is returned and the minimum acceptable size will be returned in \( af[0] \).

\( work \)

(local).

Temporary workspace. This space may be overwritten in between function calls.

\( work \) must be the size given in \( lwork \).

\( lwork \)

(local or global)

Size of user-input workspace \( work \). If \( lwork \) is too small, the minimal acceptable size will be returned in \( work[0] \) and an error code is returned.

\( lwork \geq 10*ncol+4*nrhs \).
Output Parameters

\(dl\)

On exit, this array contains information containing the factors of the matrix.

\(d\)

On exit, this array contains information containing the factors of the matrix.

Must be of size \(\geq nb_a\).

\(b\)

On exit, this contains the local piece of the solutions distributed matrix X.

\(af\)

Auxiliary fill-in space. The fill-in space is created in a call to the factorization function \(p?dttrf\) and is stored in \(af\). If a linear system is to be solved using \(p?dttrs\) after the factorization function, \(af\) must not be altered after the factorization.

\(work\)

On exit, \(work[0]\) contains the minimal \(lwork\).

\(info\)

If \(info=0\), the execution is successful.

if \(info<0\): If the \(i\)-th argument is an array and the \(j\)-th entry, indexed \(j-1\), had an illegal value, then \(info = -(i*100+j)\), if the \(i\)-th argument is a scalar and had an illegal value, then \(info = -i\).

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

\(p?gebal\)

Balances a general real/complex matrix.

Syntax

```
void psgebal(char* job, MKL_INT* n, float* a, MKL_INT* desca, MKL_INT* ilo, MKL_INT* ihi, float* scale, MKL_INT* info);
void pdgebal(char* job, MKL_INT* n, double* a, MKL_INT* desca, MKL_INT* ilo, MKL_INT* ihi, double* scale, MKL_INT* info);
void pcgebal(char* job, MKL_INT* n, complex float* a, MKL_INT* desca, MKL_INT* ilo, MKL_INT* ihi, float* scale, MKL_INT* info);
void pzgebal(char* job, MKL_INT* n, complex double* a, MKL_INT* desca, MKL_INT* ilo, MKL_INT* ihi, double* scale, MKL_INT* info);
```

Include Files

- mkl_scalapack.h

Description

\(p?gebal\) balances a general real/complex matrix \(A\). This involves, first, permuting \(A\) by a similarity transformation to isolate eigenvalues in the first \(ilo\)-1 and last \(ihi+1\) to \(n\) elements on the diagonal; and second, applying a diagonal similarity transformation to rows and columns \(ilo\) to \(ihi\) to make the rows and columns as close in norm as possible. Both steps are optional.

Balancing may reduce the 1-norm of the matrix, and improve the accuracy of the computed eigenvalues and/or eigenvectors.
**Input Parameters**

\textit{job}  
(global )  
Specifies the operations to be performed on \( a \):
- = 'N': none: simply set \( ilo = 1, ihi = n, \text{scale}[i] = 1.0 \) for \( i = 0,\ldots,n-1 \);
- = 'P': permute only;
- = 'S': scale only;
- = 'B': both permute and scale.

\textit{n}  
(global )  
The order of the matrix \( A \) \((n \geq 0)\).

\textit{a}  
(local )  
Pointer into the local memory to an array of size \( \text{lld}_a \times \text{LOC}_{c(n)} \)  
This array contains the local pieces of global input matrix \( A \).

\textit{desca}  
(global and local) array of size \( \text{dlen}_c \)  
The array descriptor for the distributed matrix \( A \).

**OUTPUT Parameters**

\textit{a}  
On exit, \( a \) is overwritten by the balanced matrix \( A \).
If \( \text{job} = 'N' \), \( a \) is not referenced.
See Notes for further details.

\textit{ilo, ihi}  
(global )  
\( ilo \) and \( ihi \) are set to integers such that on exit matrix elements \( A(i,j) \) are zero if \( i > j \) and \( j = 1,\ldots,ilo-1 \) or \( i = ihi+1,\ldots,n \).
If \( \text{job} = 'N' \) or 'S', \( ilo = 1 \) and \( ihi = n \).

\textit{scale}  
(global )  
array of size \( n \).
Details of the permutations and scaling factors applied to \( a \). If \( pj \) is the index of the row and column interchanged with row and column \( j \) and \( dj \) is the scaling factor applied to row and column \( j \), then
\[
\text{scale}[j-1] = pj \quad \text{for } j = 1,\ldots,ilo-1, \ ihi+1,\ldots, n \]
\[
\text{scale}[j-1] = dj \quad \text{for } j = ilo,\ldots,ihi
\]
The order in which the interchanges are made is \( n \) to \( ihi+1 \), then \( 1 \) to \( ilo-1 \).

\textit{info}  
(global )  
= 0: successful exit.
< 0: if \( \text{info} = -i \), the \( i \)-th argument had an illegal value.

**Application Notes**
The permutations consist of row and column interchanges which put the matrix in the form
where $T_1$ and $T_2$ are upper triangular matrices whose eigenvalues lie along the diagonal. The column indices $ilo$ and $ihi$ mark the starting and ending columns of the submatrix $B$. Balancing consists of applying a diagonal similarity transformation $D^{-1}BD$ to make the 1-norms of each row of $B$ and its corresponding column nearly equal. The output matrix is

$$
\begin{pmatrix}
T_1 & XD & Y \\
0 & D^{-1}BD & D^{-1}Z \\
0 & 0 & T_2
\end{pmatrix}
$$

Information about the permutations $P$ and the diagonal matrix $D$ is returned in the vector $scale$.

See Also
Overview for details of ScalAPACK array descriptor structures and related notations.

**p?gebd2**

*Reduces a general rectangular matrix to real bidiagonal form by an orthogonal/unitary transformation (unblocked algorithm).*

**Syntax**

```c
void psgebd2 (MKL_INT *m, MKL_INT *n, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *d, float *e, float *taup, float *work, MKL_INT *iwork, MKL_INT *info);
void pdgebd2 (MKL_INT *m, MKL_INT *n, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *d, double *e, double *taup, double *work, MKL_INT *iwork, MKL_INT *info);
void pcgebd2 (MKL_INT *m, MKL_INT *n, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *d, float *e, MKL_Complex8 *taup, MKL_Complex8 *work, MKL_INT *iwork, MKL_INT *info);
void pzgebd2 (MKL_INT *m, MKL_INT *n, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *d, double *e, MKL_Complex16 *taup, MKL_Complex16 *work, MKL_INT *iwork, MKL_INT *info);
```

**Include Files**
- mkl_scalapack.h

**Description**

The `p?gebd2` function reduces a real/complex general $m$-by-$n$ distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ to upper or lower bidiagonal form $B$ by an orthogonal/unitary transformation:

$$Q^*\text{sub}(A)*P = B.$$ 

If $m \geq n$, $B$ is the upper bidiagonal; if $m < n$, $B$ is the lower bidiagonal.
Input Parameters

\(m\)  
(global)  
The number of rows of the distributed matrix \(\text{sub}(A)\). \((m \geq 0)\).

\(n\)  
(global)  
The number of columns in the distributed matrix \(\text{sub}(A)\). \((n \geq 0)\).

\(a\)  
(local).  
Pointer into the local memory to an array of size \(\text{lld}_a \times \text{LOC}(ja+n-1)\).  
On entry, this array contains the local pieces of the general distributed matrix \(\text{sub}(A)\).

\(ia, ja\)  
(global)  
The row and column indices in the global matrix \(A\) indicating the first row and the first column of the matrix \(\text{sub}(A)\), respectively.

\(\text{desca}\)  
(global and local) array of size \(\text{dlen}_\text{a}\). The array descriptor for the distributed matrix \(A\).

\(\text{work}\)  
(local).  
This is a workspace array of size \(lwork\).

\(lwork\)  
(local or global)  
The size of the array \(\text{work}\).  
\(\text{lwork}\) is local input and must be at least \(lwork \geq \max(\text{mpa}0, \text{nqa}0)\),  
where \(nb = \text{mb}_a = \text{nb}_a\), \(\text{ioffa} = \text{mod}(\text{ia}-1, \text{nb})\),  
\(\text{irow} = \text{indxg2p}(\text{ia}, \text{nb}, \text{myrow}, \text{rsrc}_a, \text{nprow})\),  
\(\text{icol} = \text{indxg2p}(\text{ja}, \text{nb}, \text{mycol}, \text{csrc}_a, \text{npcol})\),  
\(\text{mpa}0 = \text{numroc}(m+\text{ioffa}, \text{nb}, \text{myrow}, \text{iarow}, \text{nprow})\),  
\(\text{nqa}0 = \text{numroc}(n+i\text{coff}a, \text{nb}, \text{mycol}, \text{iacol}, \text{ncol})\).  
\text{indxg2p} and \text{numroc} are ScaLAPACK tool functions; \text{myrow}, \text{mycol}, \text{nprow}, and \text{npcol} can be determined by calling the function \text{blacs_gridinfo}.

If \(lwork = -1\), then \(\text{lwork}\) is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by \text{pxerbla}.

Output Parameters

\(a\)  
(local).  
On exit, if \(m \geq n\), the diagonal and the first superdiagonal of \(\text{sub}(A)\) are overwritten with the upper bidiagonal matrix \(B\); the elements below the diagonal, with the array \(\text{tauq}\), represent the orthogonal/unitary matrix \(Q\) as a product of elementary reflectors, and the elements above the first superdiagonal, with the array \(\text{taup}\), represent the orthogonal matrix \(P\) as a product of elementary reflectors. If \(m < n\), the diagonal and the first subdiagonal are overwritten with the lower bidiagonal matrix \(B\); the elements below the first subdiagonal, with the array \(\text{tauq}\), represent the
orthogonal/unitary matrix Q as a product of elementary reflectors, and the
elements above the diagonal, with the array $\text{taup}$, represent the orthogonal
matrix $P$ as a product of elementary reflectors. See Applications Notes
below.

$d$

(local)

Array of size $\text{LOCc}(ja+\min(m,n)-1)$ if $m \geq n$; $\text{LOCr}(ia+\min(m,n)-1)$
otherwise. The distributed diagonal elements of the bidiagonal matrix $B$:

$d[i] = A(i+1,i+1)$, $i=0, 1, ..., \text{size}(d) - 1$.

$d$ is tied to the distributed matrix $A$.

e

(local)

Array of size $\text{LOCc}(ja+\min(m,n)-1)$ if $m \geq n$; $\text{LOCr}(ia+\min(m,n)-2)$
otherwise. The distributed diagonal elements of the bidiagonal matrix $B$:

if $m \geq n$, $e[i] = A(i+2,i+1)$ for $i = 0, 1, ..., m-2$.

$e$ is tied to the distributed matrix $A$.

tauq

(local).

Array of size $\text{LOCc}(ja+\min(m,n)-1)$. The scalar factors of the elementary
reflectors which represent the orthogonal/unitary matrix $Q$. $\text{tauq}$ is tied to
the distributed matrix $A$.

taup

(local).

Array of size $\text{LOCr}(ia+\min(m,n)-1)$. The scalar factors of the elementary
reflectors which represent the orthogonal/unitary matrix $P$. $\text{taup}$ is tied to
the distributed matrix $A$.

work

On exit, $\text{work}[0]$ returns the minimal and optimal $lwork$. 

info

(local)

If $\text{info} = 0$, the execution is successful.

if $\text{info} < 0$: If the $i$-th argument is an array and the $j$-th entry, indexed

$j-1$, had an illegal value, then $\text{info} = -(i*100+j)$, if the $i$-th argument is a

scalar and had an illegal value, then $\text{info} = -i$.

Application Notes

The matrices $Q$ and $P$ are represented as products of elementary reflectors:

If $m \geq n$,

$Q = H(1)H(2)\ldots H(n)$, and $P = G(1)G(2)\ldots G(n-1)$

Each $H(i)$ and $G(i)$ has the form:

$H(i) = I - \text{tauq}v^*v'$, and $G(i) = I - \text{taup}u^*u'$,

where $\text{tauq}$ and $\text{taup}$ are real/complex scalars, and $v$ and $u$ are real/complex vectors. $v(1:i-1) = 0$, $v(i) = 1$, and $v(i+i:m)$ is stored on exit in

$A(ia+i-ia+m-1, ja+i-1)$;

$u(1:i) = 0$, $u(i+1) = 1$, and $u(i+2:n)$ is stored on exit in $A(ia+i-1, ja+i+1:ja+n-1)$;
tauq is stored in \( \text{tauq}[ja+i-2] \) and \( \text{taup} \) in \( \text{taup}[ia+i-2] \).

If \( m < n \),

\[
\begin{align*}
v(1: i) &= 0, \quad v(i+1) = 1, \quad \text{and} \quad v(i+2:m) \text{ is stored on exit in } A(ia+i+1: ia+m-1, ja+i-1); \\
u(1: i-1) &= 0, \quad u(i) = 1, \quad \text{and} \quad u(i+1:n) \text{ is stored on exit in } A(ia+i-1, ja+i: ja+n-1);
\end{align*}
\]

\( \tau \) is stored in \( \text{tauq}[ja+i-2] \) and \( \text{taup} \) in \( \text{taup}[ia+i-2] \).

The contents of sub(A) on exit are illustrated by the following examples:

\[
\begin{array}{c}
m = 6 \text{ and } n = 5 (m > n): \\
\begin{bmatrix}
v1 & v2 & v3 & v4 & v5 \\
v1 & v2 & v3 & v4 & d \\
v1 & v2 & v3 & e & d \\
v1 & d & e & u3 & u2 \\
v & d & e & u2 & u1 \\
v & d & u1 & u1 & u1
\end{bmatrix}
\end{array}
\]

where \( d \) and \( e \) denote diagonal and off-diagonal elements of \( B \), \( vi \) denotes an element of the vector defining \( H(i) \), and \( ui \) an element of the vector defining \( G(i) \).

p?gehd2

Reduces a general matrix to upper Hessenberg form by an orthogonal/unitary similarity transformation (unblocked algorithm).

Syntax

void psgehd2 (MKL_INT *n, MKL_INT *ilo, MKL_INT *ihi, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *tau, float *work, MKL_INT *iwork, MKL_INT *info);

void pdgehd2 (MKL_INT *n, MKL_INT *ilo, MKL_INT *ihi, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *tau, double *work, MKL_INT *iwork, MKL_INT *info);

void pcgehd2 (MKL_INT *n, MKL_INT *ilo, MKL_INT *ihi, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_Complex8 *tau, MKL_Complex8 *work, MKL_INT *iwork, MKL_INT *info);

void pzgehd2 (MKL_INT *n, MKL_INT *ilo, MKL_INT *ihi, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_Complex16 *tau, MKL_Complex16 *work, MKL_INT *iwork, MKL_INT *info);

Include Files

- mkl_scalapack.h

Description

The p?gehd2 function reduces a real/complex general distributed matrix sub(A) to upper Hessenberg form \( H \) by an orthogonal/unitary similarity transformation: \( Q' \)*sub(A)*Q = H, where sub(A) = A(ia+n-1 : ia +n-1, ja+n-1 : ja+n-1).
Input Parameters

\( n \) (global) The order of the distributed submatrix \( A \). \((n \geq 0)\).  

\( ilo, \text{ ihi} \) (global) It is assumed that the matrix \( \text{sub}(A) \) is already upper triangular in rows \( ia:ia+ilo-2 \) and \( ia+ihi:ia+n-1 \) and columns \( ja:ja+jlo-2 \) and \( ja+jhi:ja+n-1 \). See Application Notes for further information.  

If \( n \geq 0, 1 \leq ilo \leq ihi \leq n \); otherwise set \( ilo = 1, ihi = n \).

\( a \) (local).  

Pointer into the local memory to an array of size \( lld_a * \text{LOC}(ja+n-1) \).  

On entry, this array contains the local pieces of the \( n \)-by-\( n \) general distributed matrix \( \text{sub}(A) \) to be reduced.

\( ia, ja \) (global) The row and column indices in the global matrix \( A \) indicating the first row and the first column of \( \text{sub}(A) \), respectively.

\( \text{desca} \) (global and local) array of size \( dlen\_ \). The array descriptor for the distributed matrix \( A \).

\( \text{work} \) (local).  

This is a workspace array of size \( lwork \).

\( lwork \) (local or global)  

The size of the array \( \text{work} \).  

\( lwork \) is local input and must be at least \( lwork \geq nb + \max( npa0, nb ) \), where \( nb = mb_a = nb_a, iroff_a = \text{mod}( ia-1, nb ), iarow = \text{indxg2p}( ia, nb, myrow, rsrq_a, nprow ), npa0 = \text{numroc}(ihi +iroff_a, nb, myrow, iarow, nprow ) \).  

\text{indxg2p} and \text{numroc} are ScALAPACK tool functions; \text{myrow, mycol, nprow, and npcol} can be determined by calling the function \text{blacs_gridinfo}.  

If \( lwork = -1 \), then \( lwork \) is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by \text{pxerbla}.

Output Parameters

\( a \) (local).  

On exit, the upper triangle and the first subdiagonal of sub\( (A) \) are overwritten with the upper Hessenberg matrix \( H \), and the elements below the first subdiagonal, with the array \( \text{tau} \), represent the orthogonal/unitary matrix \( Q \) as a product of elementary reflectors. (see Application Notes below).

\( \text{tau} \) (local).  

Array of size \( \text{LOCc}(ja+n-2) \) The scalar factors of the elementary reflectors (see Application Notes below). Elements \( ja:ja+ilo-2 \) and \( ja+ihi:ja+n-2 \) of the global vector \( \text{tau} \) are set to zero. \( \text{tau} \) is tied to the distributed matrix \( A \).  

\( \text{work} \)  

On exit, \( \text{work}[0] \) returns the minimal and optimal \( lwork \).
If $info = 0$, the execution is successful.

if $info < 0$: If the $i$-th argument is an array and the $j$-th entry, indexed $j-1$, had an illegal value, then $info = -(i*100+j)$, if the $i$-th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

The matrix $Q$ is represented as a product of $(ihi-ilo)$ elementary reflectors

$$ Q = H(ilo)*H(ilo+1)*...*H(ihi-1). $$

Each $H(i)$ has the form

$$ H(i) = I - \tau a^T v^T, $$

where $\tau$ is a real/complex scalar, and $v$ is a real/complex vector with $v(1:i)=0, v(i+1)=1$ and $v(i+1:n)=0; v(i+2:ihi)$ is stored on exit in $A(ia+ilo+ia+ihi-1, ia+ilo+i-2)$, and $\tau$ in $\tau[ja+ilo+i-3]$.

The contents of $A(ia:ia+n-1, ja:ja+n-1)$ are illustrated by the following example, with $n = 7, ilo = 2$ and $ihi = 6$:

<table>
<thead>
<tr>
<th>on entry</th>
<th>on exit</th>
</tr>
</thead>
<tbody>
<tr>
<td>a a a a a a a</td>
<td>a a h h h h a</td>
</tr>
<tr>
<td>a a a a a a a</td>
<td>a h h h h h</td>
</tr>
<tr>
<td>a a a a a a a</td>
<td>a v2 h h h h</td>
</tr>
<tr>
<td>a a a a a a a</td>
<td>v2 v3 h h h h</td>
</tr>
<tr>
<td>a a a a a a a</td>
<td>a v2 v3 v4 h h h</td>
</tr>
</tbody>
</table>

where $a$ denotes an element of the original matrix sub($A$), $h$ denotes a modified element of the upper Hessenberg matrix $H$, and $vi$ denotes an element of the vector defining $H(ja+ilo+i-2)$.

p?gelq2

Computes an LQ factorization of a general rectangular matrix (unblocked algorithm).

Syntax

```c
void psgelq2 (MKL_INT *m, MKL_INT *n, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *tau, float *work, MKL_INT *lwork, MKL_INT *info);
void pdgelq2 (MKL_INT *m, MKL_INT *n, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *tau, double *work, MKL_INT *lwork, MKL_INT *info);
void pcgelq2 (MKL_INT *m, MKL_INT *n, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_Complex8 *tau, MKL_Complex8 *work, MKL_INT *lwork, MKL_INT *info);
void pzgelq2 (MKL_INT *m, MKL_INT *n, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_Complex16 *tau, MKL_Complex16 *work, MKL_INT *lwork, MKL_INT *info);
```
Include Files

- mkl_scalapack.h

Description

The \texttt{p?gelq2} function computes an LQ factorization of a real/complex distributed \( m \)-by-\( n \) matrix \( \text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1) = L*Q \).

Input Parameters

\( m \)

(global)

The number of rows of the distributed matrix \( \text{sub}(A) \). \( (m \geq 0) \).

\( n \)

(global)

The number of columns of the distributed matrix \( \text{sub}(A) \). \( (n \geq 0) \).

\( a \)

(local).

Pointer into the local memory to an array of size \( lld_a * \text{LOC}(ja+n-1) \).

On entry, this array contains the local pieces of the \( m \)-by-\( n \) distributed matrix \( \text{sub}(A) \) which is to be factored.

\( ia, ja \)

(global) The row and column indices in the global matrix \( A \) indicating the first row and the first column of \( \text{sub}(A) \), respectively.

\( \text{desca} \)

(global and local) array of size \( dlen_\). The array descriptor for the distributed matrix \( A \).

\( \text{work} \)

(local).

This is a workspace array of size \( lwork \).

\( lwork \)

(local or global)

The size of the array \( \text{work} \).

\( lwork \) is local input and must be at least \( lwork \geq nq0 + \max(1, mp0) \), where

\[
\text{iroff} = \text{mod}(ia-1, mb_a), \quad \text{icoff} = \text{mod}(ja-1, nb_a),
\]

\[
\text{iarow} = \text{indxg2p}(ia, mb_a, myrow, rsrc_a, nprow),
\]

\[
\text{iacol} = \text{indxg2p}(ja, nb_a, mycol, csrc_a, npcol),
\]

\[
mp0 = \text{numroc}(m+\text{iroff}, mb_a, myrow, iarow, nprow),
\]

\[
nq0 = \text{numroc}(n+\text{icoff}, nb_a, mycol, iacol, npcol),
\]

\( \text{indxg2p} \) and \( \text{numroc} \) are ScaLAPACK tool functions; \( \text{myrow, mycol, nprow, and npcol} \) can be determined by calling the function \text{blacs_gridinfo}.

If \( lwork = -1 \), then \( lwork \) is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by \text{pxerbla}.

Output Parameters

\( a \)

(local).
On exit, the elements on and below the diagonal of \( \text{sub}(A) \) contain the \( m \) by \( \min(m,n) \) lower trapezoidal matrix \( L \) (\( L \) is lower triangular if \( m \leq n \)); the elements above the diagonal, with the array \( \text{tau} \), represent the orthogonal/unitary matrix \( Q \) as a product of elementary reflectors (see Application Notes below).

\[\text{tau}\] (local).

Array of size \( \text{LOCr}(\text{ia}+\min(m,n)-1) \). This array contains the scalar factors of the elementary reflectors. \( \text{tau} \) is tied to the distributed matrix \( A \).

\[\text{work}\] On exit, \( \text{work}[0] \) returns the minimal and optimal \( lwork \).

\[\text{info}\] (local) If \( \text{info} = 0 \), the execution is successful. If \( \text{info} < 0 \): If the \( i \)-th argument is an array and the \( j \)-th entry, indexed \( j-1 \), had an illegal value, then \( \text{info} = - (i*100+j) \), if the \( i \)-th argument is a scalar and had an illegal value, then \( \text{info} = -i \).

Application Notes

The matrix \( Q \) is represented as a product of elementary reflectors

\[ Q = H(ia+k-1)*H(ia+k-2)*..*H(ia) \text{ for real flavors, } Q = (H(ia+k-1))^H*(H(ia+k-2))^H...*(H(ia))^H \text{ for complex flavors, } \]

where \( k = \min(m,n) \).

Each \( H(i) \) has the form

\[ H(i) = I - \tau_i v_i v_i^T \]

where \( \tau_i \) is a real/complex scalar, and \( v_i \) is a real/complex vector with \( v(1:i-1) = 0 \) and \( v(i) = 1; v(i+1:n) \) (for real flavors) or \( \text{conjg}(v(i+1:n)) \) (for complex flavors) is stored on exit in \( A(ia+i-1,ja+i:ja+n-1) \), and \( \tau_i \) in \( \text{tau}[ia+i-2] \).

See Also

Include Files
• mkl_scalapack.h

Description
The pageql2 function computes a QL factorization of a real/complex distributed \( m \)-by-\( n \) matrix \( \text{sub}(A) = A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+n-1) = Q^*L \).

Input Parameters
\( m \) (global)
The number of rows in the distributed matrix \( \text{sub}(A) \). \( (m \geq 0) \).
\( n \) (global)
The number of columns in the distributed matrix \( \text{sub}(A) \). \( (n \geq 0) \).
a (local).
Pointer into the local memory to an array of size \( lld_a \times \text{LOC}_c(\text{ja}+n-1) \).
On entry, this array contains the local pieces of the \( m \)-by-\( n \) distributed matrix \( \text{sub}(A) \) which is to be factored.
\( \text{ia}, \text{ja} \) (global) The row and column indices in the global matrix \( A \) indicating the first row and the first column of \( \text{sub}(A) \), respectively.
desca (global and local) array of size \( dlen_ \). The array descriptor for the distributed matrix \( A \).
work (local).
This is a workspace array of size \( lwork \).
lwork (local or global)
The size of the array \( \text{work} \).
lwork is local input and must be at least \( lwork \geq mp0 + \max(1, nq0) \), where \( iroff = \text{mod}(\text{ia}-1, \text{mb}_a), \text{icoff} = \text{mod}(\text{ja}-1, \text{nb}_a) \), \( \text{irow} = \text{indxg2p}(\text{ia}, \text{mb}_a, \text{myrow}, \text{rsrc}_a, \text{nprow}) \), \( \text{icol} = \text{indxg2p}(\text{ja}, \text{nb}_a, \text{mycol}, \text{csrc}_a, \text{npcol}) \), \( mp0 = \text{numroc}(m+iroff, \text{mb}_a, \text{myrow}, \text{irow}, \text{nprow}) \), \( nq0 = \text{numroc}(n+icoff, \text{nb}_a, \text{mycol}, \text{icol}, \text{npcol}) \), \( \text{indxg2p} \) and \( \text{numroc} \) are ScALAPACK tool functions; \( \text{myrow}, \text{mycol}, \text{nprow}, \) and \( \text{npcol} \) can be determined by calling the function \text{blacs_gridinfo}.
If \( lwork = -1 \), then \( lwork \) is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by \text{pxerbla}.

Output Parameters
a (local).
On exit,
if \( m \geq n \), the lower triangle of the distributed submatrix \( A((ia+m-n),ia+m-1,ja:ja+n-1) \) contains the \( n \)-by-\( n \) lower triangular matrix \( L \);  
if \( m \leq n \), the elements on and below the \((n-m)\)-th superdiagonal contain the \( m \)-by-\( n \) lower trapezoidal matrix \( L \); the remaining elements, with the array \( tau \), represent the orthogonal/unitary matrix \( Q \) as a product of elementary reflectors (see Application Notes below).

\[
\text{tau} (\text{local}).
\]

Array of size \( \text{LOCc}(ja+n-1) \). This array contains the scalar factors of the elementary reflectors. \( \text{tau} \) is tied to the distributed matrix \( A \).

\[
\text{work} (\text{local}).
\]

On exit, \( \text{work}[0] \) returns the minimal and optimal \( \text{lwork} \).

\[

\]
Include Files
- mkl_scalapack.h

Description
The `pgeqr2` function computes a QR factorization of a real/complex distributed \( m \)-by-\( n \) matrix
\[
\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1) = Q^*R.
\]

Input Parameters

- \( m \) (global)
The number of rows in the distributed matrix \( \text{sub}(A) \). \((m \geq 0)\).

- \( n \) (global)
The number of columns in the distributed matrix \( \text{sub}(A) \). \((n \geq 0)\).

- \( a \) (local)
Pointer into the local memory to an array of size \( \text{lid}_a \ast \text{LOC}(ja+n-1) \).
On entry, this array contains the local pieces of the \( m \)-by-\( n \) distributed matrix \( \text{sub}(A) \) which is to be factored.

- \( ia, ja \) (global)
The row and column indices in the global matrix \( A \) indicating the first row and the first column of \( \text{sub}(A) \), respectively.

- \( \text{desca} \) (global and local) array of size \( \text{dlen}_- \). The array descriptor for the distributed matrix \( A \).

- \( \text{work} \) (local)
This is a workspace array of size \( \text{lwork} \).

- \( \text{lwork} \) (local or global)
The size of the array \( \text{work} \).
\( \text{lwork} \) is local input and must be at least \( \text{lwork} \geq mp_0 + \max(1, nq_0) \), where \( \text{iroff} = \text{mod}(ia-1, \text{mb}_a) \), \( \text{icoff} = \text{mod}(ja-1, \text{nb}_a) \),
\( \text{iarow} = \text{indxg2p}(ia, \text{mb}_a, \text{myrow}, \text{rsrc}_a, \text{nprow}) \),
\( \text{iacol} = \text{indxg2p}(ja, \text{nb}_a, \text{mycol}, \text{csrc}_a, \text{npcol}) \),
\( mp_0 = \text{numroc}(m+\text{iroff}, \text{mb}_a, \text{myrow}, \text{iarow}, \text{nprow}) \),
\( nq_0 = \text{numroc}(n+\text{icoff}, \text{nb}_a, \text{mycol}, \text{iacol}, \text{npcol}) \).
\( \text{indxg2p} \) and \( \text{numroc} \) are ScaLAPACK tool functions; \( \text{myrow}, \text{mycol}, \text{nprow} \), and \( \text{npcol} \) can be determined by calling the function \( \text{blacs_gridinfo} \).
If \( \text{lwork} = -1 \), then \( \text{lwork} \) is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by \( \text{pxerbla} \).

Output Parameters

- \( a \) (local).

On exit, the elements on and above the diagonal of sub$(A)$ contain the \(\min(m,n)\) by \(n\) upper trapezoidal matrix \(R\) (\(R\) is upper triangular if \(m\geq n\)); the elements below the diagonal, with the array \(\tau\), represent the orthogonal/unitary matrix \(Q\) as a product of elementary reflectors (see Application Notes below).

\textbf{tau} (local).

Array of size \(\text{LOCc}(ja+\min(m,n)-1)\). This array contains the scalar factors of the elementary reflectors. \(\tau\) is tied to the distributed matrix \(A\).

\textbf{work} (local)

On exit, \(\text{work}[0]\) returns the minimal and optimal \(lwork\).

\textbf{info} (local)

If \(\text{info} = 0\), the execution is successful. If \(\text{info} < 0\):

If the \(i\)-th argument is an array and the \(j\)-th entry, indexed \(j-1\), had an illegal value, then \(\text{info} = -(i*100+j)\),

if the \(i\)-th argument is a scalar and had an illegal value, then \(\text{info} = -i\).

\textbf{Application Notes}

The matrix \(Q\) is represented as a product of elementary reflectors

\[Q = H(ja)*H(ja+1)*\ldots*H(ja+k-1), \text{ where } k = \min(m,n).\]

Each \(H(i)\) has the form

\[H(j) = I - \tau v^*v',\]

where \(\tau\) is a real/complex scalar, and \(v\) is a real/complex vector with \(v(1:i-1) = 0\) and \(v(i) = 1\); \(v(i+1:m)\) is stored on exit in \(A(ia+i:ia+m-1, ja+i-1)\), and \(\tau\) in \(\tau[a+j-2]\).

\textbf{See Also}

\textbf{p?gerq2}

\textit{Computes an RQ factorization of a general rectangular matrix (unblocked algorithm).}

\textbf{Syntax}

\begin{verbatim}
void psgerq2 (MKL_INT *m, MKL_INT *n, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *tau, float *work, MKL_INT *lwork, MKL_INT *info);
void pdgerq2 (MKL_INT *m, MKL_INT *n, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *tau, double *work, MKL_INT *lwork, MKL_INT *info);
void pcgerq2 (MKL_INT *m, MKL_INT *n, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_Complex8 *tau, MKL_Complex8 *work, MKL_INT *lwork, MKL_INT *info);
void pzgerq2 (MKL_INT *m, MKL_INT *n, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_Complex16 *tau, MKL_Complex16 *work, MKL_INT *lwork, MKL_INT *info);
\end{verbatim}

\textbf{Include Files}

- mkl_scalapack.h
The *pgerq2* function computes an $RQ$ factorization of a real/complex distributed $m$-by-$n$ matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1) = R*Q$.

**Input Parameters**

$m$ (global) The number of rows in the distributed matrix $\text{sub}(A)$. ($m \geq 0$).

$n$ (global) The number of columns in the distributed matrix $\text{sub}(A)$. ($n \geq 0$).

$a$ (local). Pointer into the local memory to an array of size $\text{lld}_a * \text{LOC}(ja+n-1)$.

On entry, this array contains the local pieces of the $m$-by-$n$ distributed matrix $\text{sub}(A)$ which is to be factored.

$ia, ja$ (global) The row and column indices in the global matrix $A$ indicating the first row and the first column of $\text{sub}(A)$, respectively.

$\text{desca}$ (global and local) array of size $\text{dlen}_a$. The array descriptor for the distributed matrix $A$.

$\text{work}$ (local). This is a workspace array of size $\text{lwork}$.

$lwork$ (local or global) The size of the array $\text{work}$.

$lwork$ is local input and must be at least $lwork_0 = \text{nq} + \max(1, mp_0)$, where

\begin{align*}
\text{iroff} & = \text{mod}(ia-1, \text{mb}_a), \\
\text{icoff} & = \text{mod}(ja-1, \text{nb}_a), \\
\text{iarow} & = \text{indxg2p}(ia, \text{mb}_a, \text{myrow}, \text{rsrc}_a, \text{nprow}), \\
\text{iacol} & = \text{indxg2p}(ja, \text{nb}_a, \text{mycol}, \text{csrc}_a, \text{npcol}), \\
\text{mp} & = \text{numroc}(m+\text{iroff}, \text{mb}_a, \text{myrow}, \text{iarow}, \text{nprow}), \\
\text{nq} & = \text{numroc}(n+\text{icoff}, \text{nb}_a, \text{mycol}, \text{iacol}, \text{npcol}), \\
\text{indxg2p} \text{ and } \text{numroc} \text{ are ScALAPACK tool functions; } \text{myrow, mycol, nprow,} \\
\text{and } \text{npcol} \text{ can be determined by calling the function } \text{blacs_gridinfo}. \\
\end{align*}

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pxerbla*.

**Output Parameters**

$a$ (local).

On exit,

if $m \leq n$, the upper triangle of $A(ia+m-n:ia+m-1, ja:ja+n-1)$ contains the $m$-by-$m$ upper triangular matrix $R$;
if \( m \geq n \), the elements on and above the \((m-n)\)-th subdiagonal contain the \( m \)-by-\( n \) upper trapezoidal matrix \( R \); the remaining elements, with the array \( \tau \), represent the orthogonal/ unitary matrix \( Q \) as a product of elementary reflectors (see Application Notes below).

\( \tau \) (local).

Array of size \( \text{LOCr}(ia+m-1) \). This array contains the scalar factors of the elementary reflectors. \( \tau \) is tied to the distributed matrix \( A \).

\( \text{work} \) (local).

On exit, \( \text{work}[0] \) returns the minimal and optimal \( lwork \).

\( \text{info} \) (local)

If \( \text{info} = 0 \), the execution is successful.

If \( \text{info} < 0 \): If the \( i \)-th argument is an array and the \( j \)-th entry, indexed \( j-1 \), had an illegal value, then \( \text{info} = -(i*100+j) \), if the \( i \)-th argument is a scalar and had an illegal value, then \( \text{info} = -i \).

**Application Notes**

The matrix \( Q \) is represented as a product of elementary reflectors

\[
Q = H(ia)*H(ia+1)*...*H(ia+k-1) \quad \text{for real flavors},
\]

\[
Q = (H(ia))^H*(H(ia+1))^H*...*(H(ia+k-1))^H \quad \text{for complex flavors},
\]

where \( k = \min(m, n) \).

Each \( H(i) \) has the form

\[
H(i) = I - \tau_v v^v',
\]

where \( \tau \) is a real/complex scalar, and \( v \) is a real/complex vector with \( v(n-k+i+1:n) = 0 \) and \( v(n-k+i) = 1; v(1:n-k+i-1) \) for real flavors or \( \text{conjg}(v(1:n-k+i-1)) \) for complex flavors is stored on exit in \( A(ia+m-k+i-1, ja:ja+n-k+i-2) \), and \( \tau \) in \( \text{tau}[ia+m-k+i-2] \).

**See Also**

**p?getf2**

Computes an LU factorization of a general matrix, using partial pivoting with row interchanges (local blocked algorithm).

**Syntax**

```c
void psgetf2 (MKL_INT *m, MKL_INT *n, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_INT *ipiv, MKL_INT *info);
void pdgetf2 (MKL_INT *m, MKL_INT *n, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_INT *ipiv, MKL_INT *info);
void pcgetf2 (MKL_INT *m, MKL_INT *n, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_INT *ipiv, MKL_INT *info);
void pzgetf2 (MKL_INT *m, MKL_INT *n, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_INT *ipiv, MKL_INT *info);
```
Include Files

- mkl_scalapack.h

Description

The \( p\text{-}getf2 \) function computes an LU factorization of a general \( m \)-by-\( n \) distributed matrix \( \text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1) \) using partial pivoting with row interchanges.

The factorization has the form \( \text{sub}(A) = P \times L \times U \), where \( P \) is a permutation matrix, \( L \) is lower triangular with unit diagonal elements (lower trapezoidal if \( m > n \)), and \( U \) is upper triangular (upper trapezoidal if \( m < n \)). This is the right-looking Parallel Level 2 BLAS version of the algorithm.

Optimization Notice

Intel’s compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Notice revision #20110804

Input Parameters

\( m \) (global)
The number of rows in the distributed matrix \( \text{sub}(A) \). \( (m \geq 0) \).

\( n \) (global) The number of columns in the distributed matrix \( \text{sub}(A) \). \( (nb_a - \text{mod}(ja-1, nb_a) \geq n \geq 0) \).

\( a \) (local).

Pointer into the local memory to an array of size \( lld_a \times \text{LOC}(ja+n-1) \).

On entry, this array contains the local pieces of the \( m \)-by-\( n \) distributed matrix \( \text{sub}(A) \).

\( ia, ja \) (global) The row and column indices in the global matrix \( A \) indicating the first row and the first column of the matrix \( \text{sub}(A) \), respectively.

\( desca \) (global and local) array of size \( dlen_ \). The array descriptor for the distributed matrix \( A \).

Output Parameters

\( ipiv \) (local)

Array of size \( \text{LOC}(m_a) + mb_a \). This array contains the pivoting information. \( ipiv[i] \rightarrow \) The global row that local row \((i + 1)\) was swapped with, \( i = 0, 1, \ldots, \text{LOC}(m_a) + mb_a - 1 \). This array is tied to the distributed matrix \( A \).

\( info \) (local).

If \( info = 0 \): successful exit.
If \( \text{info} < 0 \):

- if the \( i \)-th argument is an array and the \( j \)-th entry, indexed \( j-1 \), had an illegal value, then \( \text{info} = -(i*100+j) \),
- if the \( i \)-th argument is a scalar and had an illegal value, then \( \text{info} = -i \).

If \( \text{info} > 0 \): If \( \text{info} = k \), the matrix element \( U(ia+k-1, ja+k-1) \) is exactly zero. The factorization has been completed, but the factor \( U \) is exactly singular, and division by zero will occur if it is used to solve a system of equations.

**See Also**

**p?labrd**

Reduces the first \( nb \) rows and columns of a general rectangular matrix \( A \) to real bidiagonal form by an orthogonal/unitary transformation, and returns auxiliary matrices that are needed to apply the transformation to the unreduced part of \( A \).

**Syntax**

```c
void pslabrd (MKL_INT *m, MKL_INT *n, MKL_INT *nb, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *d, float *e, float *tauq, float *taup, float *x, MKL_INT *ix, MKL_INT *jx, MKL_INT *descx, float *y, MKL_INT *iy, MKL_INT *jy, MKL_INT *descy, float *work);
void pdlabrd (MKL_INT *m, MKL_INT *n, MKL_INT *nb, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *d, double *e, double *tauq, double *taup, double *x, MKL_INT *ix, MKL_INT *jx, MKL_INT *descx, double *y, MKL_INT *iy, MKL_INT *jy, MKL_INT *descy, double *work);
void pclabrd (MKL_INT *m, MKL_INT *n, MKL_INT *nb, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *d, float *e, MKL_Complex8 *tauq, MKL_Complex8 *x, MKL_INT *ix, MKL_INT *jx, MKL_INT *descx, MKL_Complex8 *y, MKL_INT *iy, MKL_INT *jy, MKL_INT *descy, MKL_Complex8 *work);
void pzlabrd (MKL_INT *m, MKL_INT *n, MKL_INT *nb, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *d, double *e, MKL_Complex16 *tauq, MKL_Complex16 *x, MKL_INT *ix, MKL_INT *jx, MKL_INT *descx, MKL_Complex16 *y, MKL_INT *iy, MKL_INT *jy, MKL_INT *descy, MKL_Complex16 *work);
```

**Include Files**

- mkl_scalapack.h

**Description**

The p?labrd function reduces the first \( nb \) rows and columns of a real/complex general \( m \)-by-\( n \) distributed matrix \( \text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1) \) to upper or lower bidiagonal form by an orthogonal/unitary transformation \( Q^* A * P \), and returns the matrices \( X \) and \( Y \) necessary to apply the transformation to the unreduced part of \( \text{sub}(A) \).

If \( m \geq n \), \( \text{sub}(A) \) is reduced to upper bidiagonal form; if \( m < n \), \( \text{sub}(A) \) is reduced to lower bidiagonal form.

This is an auxiliary function called by p?gebrd.
Input Parameters

\( m \)  
(global) The number of rows in the distributed matrix \( \text{sub}(A) \). \((m \geq 0)\).

\( n \)  
(global) The number of columns in the distributed matrix \( \text{sub}(A) \). \((n \geq 0)\).

\( nb \)  
(global)  
The number of leading rows and columns of \( \text{sub}(A) \) to be reduced.

\( a \)  
(local).  
Pointer into the local memory to an array of size \( lld_a \times \text{LOC}(ja+n-1) \).  
On entry, this array contains the local pieces of the general distributed matrix \( \text{sub}(A) \).

\( ia, ja \)  
(global) The row and column indices in the global matrix \( A \) indicating the first row and the first column of the matrix \( \text{sub}(A) \), respectively.

\( desca \)  
(global and local) array of size \( dlen_\) . The array descriptor for the distributed matrix \( A \).

\( ix, jx \)  
(global) The row and column indices in the global matrix \( X \) indicating the first row and the first column of the matrix \( \text{sub}(X) \), respectively.

\( descx \)  
(global and local) array of size \( dlen_\) . The array descriptor for the distributed matrix \( X \).

\( iy, jy \)  
(global) The row and column indices in the global matrix \( Y \) indicating the first row and the first column of the matrix \( \text{sub}(Y) \), respectively.

\( descy \)  
(global and local) array of size \( dlen_\) . The array descriptor for the distributed matrix \( Y \).

\( work \)  
(local).  
Workspace array of size \( lwork \).  
\( lwork \geq nb_a + nq \),  
with \( nq = \text{numroc}(n+\text{mod}(ia-1, nb_y), nb_y, mycol, iacol, npcol) \)  
\( iacol = \text{indxg2p} (ja, nb_a, mycol, csrc_a, npcol) \)  
\( \text{indxg2p} \) and \( \text{numroc} \) are \text{ScALAPACK} tool functions; \( myrow, mycol, nprow, \) and \( npcol \) can be determined by calling the function \text{blacs_gridinfo}.

Output Parameters

\( a \)  
(local)  
On exit, the first \( nb \) rows and columns of the matrix are overwritten; the rest of the distributed matrix \( \text{sub}(A) \) is unchanged.

If \( m \geq n \), elements on and below the diagonal in the first \( nb \) columns, with the array \( \text{tauq} \), represent the orthogonal/unitary matrix \( Q \) as a product of elementary reflectors; and elements above the diagonal in the first \( nb \) rows, with the array \( \text{taup} \), represent the orthogonal/unitary matrix \( P \) as a product of elementary reflectors.
If \( m < n \), elements below the diagonal in the first \( nb \) columns, with the array \( \text{tauq} \), represent the orthogonal/unitary matrix \( Q \) as a product of elementary reflectors, and elements on and above the diagonal in the first \( nb \) rows, with the array \( \text{taup} \), represent the orthogonal/unitary matrix \( P \) as a product of elementary reflectors. See Application Notes below.

\( d \) (local).

Array of size \( \text{LOCr}(ia+\min(m,n)-1) \) if \( m \geq n \); \( \text{LOCc}(ja+\min(m,n)-1) \) otherwise. The distributed diagonal elements of the bidiagonal distributed matrix \( B \):

\[ d[i] = A(ia+i, ja+i), \quad i = 0, 1, \ldots, \text{size}(d)-1 \]

\( d \) is tied to the distributed matrix \( A \).

\( e \) (local).

Array of size \( \text{LOCr}(ia+\min(m,n)-1) \) if \( m \geq n \); \( \text{LOCc}(ja+\min(m,n)-2) \) otherwise. The distributed off-diagonal elements of the bidiagonal distributed matrix \( B \):

if \( m \geq n \), \( e[i] = A(ia+i, ja+i+1) \) for \( i = 0, 1, \ldots, n-2 \); 
if \( m < n \), \( e[i] = A(ia+i+1, ja+i) \) for \( i = 0, 1, \ldots, m-2 \).

\( e \) is tied to the distributed matrix \( A \).

\( \text{tauq}, \text{taup} \) (local).

Array size \( \text{LOCc}(ja+\min(m,n)-1) \) for \( \text{tauq} \), size \( \text{LOCr}(ia+\min(m,n)-1) \) for \( \text{taup} \). The scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix \( Q \) for \( \text{tauq} \), \( P \) for \( \text{taup} \). \( \text{tauq} \) and \( \text{taup} \) are tied to the distributed matrix \( A \). See Application Notes below.

\( x \) (local)

Pointer into the local memory to an array of size \( lld_x \times nb \). On exit, the local pieces of the distributed \( m \)-by-\( nb \) matrix \( X(ix:ix+m-1, jx:jx+nb-1) \) required to update the unreduced part of \( \text{sub}(A) \).

\( y \) (local)

Pointer into the local memory to an array of size \( lld_y \times nb \). On exit, the local pieces of the distributed \( n \)-by-\( nb \) matrix \( Y(iy:iy+n-1, jy:jy+nb-1) \) required to update the unreduced part of \( \text{sub}(A) \).

Application Notes

The matrices \( Q \) and \( P \) are represented as products of elementary reflectors:

\[
Q = H(1)*H(2)*\ldots*H(nb), \quad \text{and} \quad P = G(1)*G(2)*\ldots*G(nb)
\]

Each \( H(i) \) and \( G(i) \) has the form:

\[
H(i) = I - \text{tauq}^*v*v', \quad \text{and} \quad G(i) = I - \text{taup}^*u*u',
\]

where \( \text{tauq} \) and \( \text{taup} \) are real/complex scalars, and \( v \) and \( u \) are real/complex vectors.

If \( m \geq n \), \( v(1: i-1) = 0 \), \( v(i) = 1 \), and \( v(i:m) \) is stored on exit in
\[
A(ia+i-1:ia+m-1, ja+i-1); \quad u(1:i) = 0, \quad u(i+1) = 1, \quad \text{and} \quad u(i+1:n) \text{ is stored on exit in } A(ia+i-1, ja+i:ja+n-1); \quad \text{tauq is stored in } \text{tauq}[ja+i-2] \quad \text{and} \quad \text{taup in } \text{taup}[ia+i-2].
\]
If $m < n$, $v(1:i) = 0, v(i+1) = 1$, and $v(i+1:m)$ is stored on exit in $A(ia+i:ia+m-1, ja+i-1); u(1:i-1) = 0, u(i) = 1$, and $u(i:n)$ is stored on exit in $A(ia+i-1, ja+i:j+a+n-1); taq$ is stored in $taq(ia+i-2)$ and $taup$ in $taup(ia+i-2)$. The elements of the vectors $v$ and $u$ together form the $m$-by-$nb$ matrix $V$ and the $nb$-by-$n$ matrix $U'$ which are necessary, with $X$ and $Y$, to apply the transformation to the unreduced part of the matrix, using a block update of the form: $sub(A) := sub(A) - V*Y' - X*U'$. The contents of $sub(A)$ on exit are illustrated by the following examples with $nb = 2$:

$$
\begin{matrix}
m = 6 \mod n = 6 \geq nb & m = 5 \mod n = 5 \geq nb \\
1 & 1 & 1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 & 1 & 1 \\
v1 & 1 & 2 & 1 & 2 & 1 \\
v1 & 2 & 1 & 2 & 1 & 2 \\
v1 & 2 & 1 & 2 & 1 & 2 \\
v1 & 2 & 1 & 2 & 1 & 2 \\
\end{matrix}
$$

where $a$ denotes an element of the original matrix which is unchanged, $vi$ denotes an element of the vector defining $H(i)$, and $ui$ an element of the vector defining $G(i)$.

p?lacon
Estimates the 1-norm of a square matrix, using the reverse communication for evaluating matrix-vector products.

Syntax

void pslacon (MKL_INT *n, float *v, MKL_INT *iv, MKL_INT *jv, MKL_INT *descv, float *x, MKL_INT *ix, MKL_INT *jx, MKL_INT *descx, MKL_INT *isgn, float *est, MKL_INT *kase);

void pdlacon (MKL_INT *n, double *v, MKL_INT *iv, MKL_INT *jv, MKL_INT *descv, double *x, MKL_INT *ix, MKL_INT *jx, MKL_INT *descx, MKL_INT *isgn, double *est, MKL_INT *kase);

void pclacon (MKL_INT *n, MKL_Complex8 *v, MKL_INT *iv, MKL_INT *jv, MKL_INT *descv, MKL_Complex8 *x, MKL_INT *ix, MKL_INT *jx, MKL_INT *descx, float *est, MKL_INT *kase);

void pzlacon (MKL_INT *n, MKL_Complex16 *v, MKL_INT *iv, MKL_INT *jv, MKL_INT *descv, MKL_Complex16 *x, MKL_INT *ix, MKL_INT *jx, MKL_INT *descx, double *est, MKL_INT *kase);

Include Files
• mkl_scalapack.h

Description
The p?lacon function estimates the 1-norm of a square, real/unitary distributed matrix A. Reverse communication is used for evaluating matrix-vector products. $x$ and $v$ are aligned with the distributed matrix $A$, this information is implicitly contained within $iv, ix, descv$, and $descx$.

Input Parameters

$n$

(global) The length of the distributed vectors $v$ and $x. n \geq 0.$
v (local).
Pointer into the local memory to an array of size $\text{LOCr}(n + \text{mod}(iv-1, \text{mb}_v))$.
On the final return, $v = a^*w$, where $est = \text{norm}(v)/\text{norm}(w)$ ($w$ is not returned).

$iv, jv$ (global) The row and column indices in the global matrix $V$ indicating the first row and the first column of the submatrix $V$, respectively.

descv (global and local) array of size $dlen_\_$. The array descriptor for the distributed matrix $V$.

$x$ (local).
Pointer into the local memory to an array of size $\text{LOCr}(n + \text{mod}(ix-1, \text{mb}_x))$.

$ix, jx$ (global) The row and column indices in the global matrix $X$ indicating the first row and the first column of the submatrix $X$, respectively.

descx (global and local) array of size $dlen_\_$. The array descriptor for the distributed matrix $X$.

$\text{isgn}$ (local).
Array of size $\text{LOCr}(n + \text{mod}(ix-1, \text{mb}_x))$. $\text{isgn}$ is aligned with $x$ and $v$.

$kase$ (local).
On the initial call to $\text{p?lacon}$, $kase$ should be 0.

**Output Parameters**

$x$ (local).
On an intermediate return, $X$ should be overwritten by $A^*X$, if $kase=1$, $A^T*X$, if $kase=2$,
$p?\text{lacon}$ must be re-called with all the other parameters unchanged.

$est$ (global).

$kase$ (local)
On an intermediate return, $kase$ is 1 or 2, indicating whether $X$ should be overwritten by $A^*X$, or $A^{\prime}\_\_\_\_\_\_X$. On the final return from $p?\text{lacon}$, $kase$ is again 0.

**See Also**

Overview for details of ScaLAPACK array descriptor structures and related notations.

**p?laconsb**

*Looks for two consecutive small subdiagonal elements.*

**Syntax**

```c
void pslaconsb (const float *a, const MKL_INT *desca, const MKL_INT *i, const MKL_INT *l,
                const float *m, const float *h44, const float *h33, const float *h43h34, float *buf,
                const MKL_INT *lwork );
```
void pdlaconsb (const double *a, const MKL_INT *desca, const MKL_INT *i, const MKL_INT *l, MKL_INT *m, const double *h44, const double *h33, const double *h43h34, double *buf, const MKL_INT *lwork);

void pclaconsb (const MKL_Complex8 *a, const MKL_INT *desca, const MKL_INT *i, const MKL_INT *l, MKL_INT *m, const MKL_Complex8 *h44, const MKL_Complex8 *h33, const MKL_Complex8 *h43h34, MKL_Complex8 *buf, const MKL_INT *lwork);

void pzlaconsb (const MKL_Complex16 *a, const MKL_INT *desca, const MKL_INT *i, const MKL_INT *l, MKL_INT *m, const MKL_Complex16 *h44, const MKL_Complex16 *h33, const MKL_Complex16 *h43h34, MKL_Complex16 *buf, const MKL_INT *lwork);

Include Files
• mkl_scalapack.h

Description
The p?laconsb function looks for two consecutive small subdiagonal elements by analyzing the effect of starting a double shift QR iteration given by \( h_{44}, h_{33}, \) and \( h_{43}h_{34} \) to see if this process makes a subdiagonal negligible.

Input Parameters

\( a \) (local)
Array of size \( lld_a*LOCc(n_a) \). On entry, the Hessenberg matrix whose tridiagonal part is being scanned. Unchanged on exit.

\( \text{desca} \) (global and local)
Array of size \( dlen_\). The array descriptor for the distributed matrix \( A \).

\( i \) (global)
The global location of the bottom of the unreduced submatrix of \( A \). Unchanged on exit.

\( l \) (global)
The global location of the top of the unreduced submatrix of \( A \). Unchanged on exit.

\( h_{44}, h_{33}, h_{43}h_{34} \) (global).
These three values are for the double shift QR iteration.

\( lwork \) (local)
This must be at least \( 7*\text{ceil}(\text{ceil}(i-l)/\text{mb_a})/\text{lcm} (\text{nprow}, \text{npcol}) \). Here \( \text{lcm} \) is the least common multiple and \( \text{nprow}*\text{npcol} \) is the logical grid size.

Output Parameters

\( m \) (global). On exit, this yields the starting location of the QR double shift.
This will satisfy:

\[ l \leq m \leq i-2. \]

\( \text{buf} \) (local).
Array of size \( lwork \).

\textbf{p?lacp2}

\textit{Copies all or part of a distributed matrix to another distributed matrix.}

\textbf{Syntax}

\begin{verbatim}
void pslacp2 (char *uplo, MKL_INT *m, MKL_INT *n, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *b, MKL_INT *ib, MKL_INT *jb, MKL_INT *descb);
void pdlacp2 (char *uplo, MKL_INT *m, MKL_INT *n, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *b, MKL_INT *ib, MKL_INT *jb, MKL_INT *descb);
void pclacp2 (char *uplo, MKL_INT *m, MKL_INT *n, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_Complex8 *b, MKL_INT *ib, MKL_INT *jb, MKL_INT *descb);
void pzlacp2 (char *uplo, MKL_INT *m, MKL_INT *n, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_Complex16 *b, MKL_INT *ib, MKL_INT *jb, MKL_INT *descb);
\end{verbatim}

\textit{Include Files}

- mkl_scalapack.h

\textbf{Description}

The \texttt{p?lacp2} function copies all or part of a distributed matrix $A$ to another distributed matrix $B$. No communication is performed, \texttt{p?lacp2} performs a local copy sub($A$):= sub($B$), where sub($A$) denotes $A(ia:ia+m-1,a:ja+n-1)$ and sub($B$) denotes $B(ib:ib+m-1,jb:jb+n-1)$.

\texttt{p?lacp2} requires that only dimension of the matrix operands is distributed.

\textbf{Input Parameters}

\begin{itemize}
  \item \texttt{uplo} (global) Specifies the part of the distributed matrix sub($A$) to be copied:
    \begin{itemize}
      \item = \text{'U'}: Upper triangular part is copied; the strictly lower triangular part of sub($A$) is not referenced;
      \item = \text{'L'}: Lower triangular part is copied; the strictly upper triangular part of sub($A$) is not referenced.
    \end{itemize}
  \item \texttt{m} (global)
The number of rows in the distributed matrix sub($A$). ($m \geq 0$).
  \item \texttt{n} (global)
The number of columns in the distributed matrix sub($A$). ($n \geq 0$).
  \item \texttt{a} (local).
Point into the local memory to an array of size $\text{lld}_a * \text{LOCc}(ja+n-1)$.
\end{itemize}

On entry, this array contains the local pieces of the $m$-by-$n$ distributed matrix sub($A$).
**ia, ja**
(global) The row and column indices in the global matrix A indicating the first row and the first column of sub(A), respectively.

**desca**
(global and local) array of size dlen_. The array descriptor for the distributed matrix A.

**ib, jb**
(global) The row and column indices in the global matrix B indicating the first row and the first column of sub(B), respectively.

**descb**
(global and local) array of size dlen_. The array descriptor for the distributed matrix B.

**Output Parameters**

**b**
(local).

Pointer into the local memory to an array of size lld_b * LOCc(jb+n-1). This array contains on exit the local pieces of the distributed matrix sub(B) set as follows:

- if uplo = 'U', \(B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1), 1 \leq i \leq j, 1 \leq j \leq n;\)
- if uplo = 'L', \(B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1), j \leq i \leq m, 1 \leq j \leq n;\)
- otherwise, \(B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1), 1 \leq i \leq m, 1 \leq j \leq n.\)

**See Also**

Overview for details of ScaLAPACK array descriptor structures and related notations.

**p?lacp3**

Copies from a global parallel array into a local replicated array or vice versa.

**Syntax**

```c
void pslacp3 (const MKL_INT *m, const MKL_INT *i, float *a, const MKL_INT *desca, float *b, const MKL_INT *ldb, const MKL_INT *ii, const MKL_INT *jj, const MKL_INT *rev);
void pdlacp3 (const MKL_INT *m, const MKL_INT *i, double *a, const MKL_INT *desca, double *b, const MKL_INT *ldb, const MKL_INT *ii, const MKL_INT *jj, const MKL_INT *rev);
void pclacp3 (const MKL_INT *m, const MKL_INT *i, MKL_Complex8 *a, const MKL_INT *desca, MKL_Complex8 *b, const MKL_INT *ldb, const MKL_INT *ii, const MKL_INT *jj, const MKL_INT *rev);
void pzlacp3 (const MKL_INT *m, const MKL_INT *i, MKL_Complex16 *a, const MKL_INT *desca, MKL_Complex16 *b, const MKL_INT *ldb, const MKL_INT *ii, const MKL_INT *jj, const MKL_INT *rev);
```

**Include Files**

- mkl_scalapack.h

**Description**

This is an auxiliary function that copies from a global parallel array into a local replicated array or vice versa. Note that the entire submatrix that is copied gets placed on one node or more. The receiving node can be specified precisely, or all nodes can receive, or just one row or column of nodes.
Optimization Notice

Intel’s compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

$m$ (global)

$m$ is the order of the square submatrix that is copied.

$m \geq 0$. Unchanged on exit.

$i$ (global)
The matrix element $A(i, i)$ is the global location that the copying starts from. Unchanged on exit.

$a$ (local)

Array of size $lld_a \times LOCc(n_a)$. On entry, the parallel matrix to be copied into or from.

$desca$ (global and local) array of size $dlen_\_$. The array descriptor for the distributed matrix $A$.

$b$ (local)

Array of size $ldb \times LOCc(m)$. If $rev = 0$, this is the global portion of the matrix $A(i:i+m-1, i:i+m-1)$. If $rev = 1$, this is unchanged on exit.

$ldb$ (local)
The leading dimension of $B$.

$ii, jj$ (global) By using $rev$ 0 and 1, data can be sent out and returned again. If $rev = 0$, then $ii$ is destination row index and $jj$ is destination column index for the node(s) receiving the replicated matrix$B$. If $ii \geq 0$, $jj \geq 0$, then node $(ii, jj)$ receives the data. If $ii = -1$, $jj \geq 0$, then all rows in column $jj$ receive the data. If $ii \geq 0$, $jj = -1$, then all cols in row $ii$ receive the data. If $ii = -1$, $jj = -1$, then all nodes receive the data. If $rev != 0$, then $ii$ is the source row index for the node(s) sending the replicated $B$.

$rev$ (global) Use $rev = 0$ to send global matrix$A$ into locally replicated matrix$B$ (on node $(ii, jj)$). Use $rev != 0$ to send locally replicated $B$ from node $(ii, jj)$ to its owner (which changes depending on its location in $A$) into the global $A$.

Output Parameters

$a$

On exit, if $rev = 1$, the copied data. Unchanged on exit if $rev = 0$.

$b$

If $rev = 1$, this is unchanged on exit.

p?lacpy
Copies all or part of one two-dimensional array to another.

Syntax
void pslacpy (char *uplo , MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb );
void pdlacpy (char *uplo , MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb );
void pclacpy (char *uplo , MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb );
void pzlacpy (char *uplo , MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb );

Include Files
• mkl_scalapack.h

Description
The p?lacpy function copies all or part of a distributed matrix \( A \) to another distributed matrix \( B \). No communication is performed, \( \texttt{p?lacpy} \) performs a local copy sub(\( B \)) := sub(\( A \)), where sub(\( A \)) denotes \( A(ia:ia+m-1, ja:ja+n-1) \) and sub(\( B \)) denotes \( B(ib:ib+m-1, jb:jb+n-1) \).

Input Parameters

uplo
(global) Specifies the part of the distributed matrix sub(\( A \)) to be copied:
\begin{itemize}
  \item = 'U': Upper triangular part; the strictly lower triangular part of sub(\( A \)) is not referenced;
  \item = 'L': Lower triangular part; the strictly upper triangular part of sub(\( A \)) is not referenced.
\end{itemize}
Otherwise: all of the matrix sub(\( A \)) is copied.

m
(global)
The number of rows in the distributed matrix sub(\( A \)). \((m\geq0)\).

n
(global)
The number of columns in the distributed matrix sub(\( A \)). \((n\geq0)\).

a
(local).
Pointer into the local memory to an array of size \( lld_a * LOCc(ja+n-1) \).

On entry, this array contains the local pieces of the distributed matrix sub(\( A \)).
ia, ja  (global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the matrix $\text{sub}(A)$, respectively.

desca  (global and local) array of size $\text{dlen}_a$. The array descriptor for the distributed matrix $A$.

ib, jb  (global) The row and column indices in the global matrix $B$ indicating the first row and the first column of $\text{sub}(B)$ respectively.

descb  (global and local) array of size $\text{dlen}_b$. The array descriptor for the distributed matrix $B$.

Output Parameters

b  (local).

 Pointer into the local memory to an array of size $\text{lld}_b * \text{LOCc}(\text{jb}+\text{n}-1)$. This array contains on exit the local pieces of the distributed matrix $\text{sub}(B)$ set as follows:

if $\text{uplo} = 'U'$, $B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1)$, $1 \leq i \leq j$, $1 \leq j \leq n$;

if $\text{uplo} = 'L'$, $B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1)$, $j \leq i \leq m$, $1 \leq j \leq n$;

otherwise, $B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1)$, $1 \leq i \leq m$, $1 \leq j \leq n$.

p?laevswp

Moves the eigenvectors from where they are computed to ScaLAPACK standard block cyclic array.

Syntax

void pslaevswp (MKL_INT *n, float *zin, MKL_INT *ldzi, float *z, MKL_INT *iz, MKL_INT *jz, MKL_INT *descz, MKL_INT *nvs, MKL_INT *key, float *work, MKL_INT *lwork);

void pdlaevswp (MKL_INT *n, double *zin, MKL_INT *ldzi, double *z, MKL_INT *iz, MKL_INT *jz, MKL_INT *descz, MKL_INT *nvs, MKL_INT *key, double *work, MKL_INT *lwork);

void pclaevswp (MKL_INT *n, float *zin, MKL_INT *ldzi, MKL_Complex8 *z, MKL_INT *iz, MKL_INT *jz, MKL_INT *descz, MKL_INT *nvs, MKL_INT *key, float *rwork, MKL_INT *lrwork);

void pzlaevswp (MKL_INT *n, double *zin, MKL_INT *ldzi, MKL_Complex16 *z, MKL_INT *iz, MKL_INT *jz, MKL_INT *descz, MKL_INT *nvs, MKL_INT *key, double *rwork, MKL_INT *lrwork);

Include Files

• mkl_scalapack.h

Description

The p?laevswp function moves the eigenvectors (potentially unsorted) from where they are computed, to a ScaLAPACK standard block cyclic array, sorted so that the corresponding eigenvalues are sorted.
**Input Parameters**

\( np \) = the number of rows local to a given process.

\( nq \) = the number of columns local to a given process.

\( n \)  

The order of the matrix \( A \). \( n \geq 0 \).

\( zin \)  

Array of size \( ldzi \times nvs[iam+1] \). The eigenvectors on input. \( iam \) is a process rank from \([0, nprocs)\) interval. Each eigenvector resides entirely in one process. Each process holds a contiguous set of \( nvs[iam+1] \) eigenvectors. The global number of the first eigenvector that the process holds is: \((\text{sum for } i=[0, iam] \text{ of } nvs[i]) + 1\).

\( ldzi \)  

The leading dimension of the \( zin \) array.

\( iz, jz \)  

The row and column indices in the global matrix \( Z \) indicating the first row and the first column of the submatrix \( Z \), respectively.

\( descz \)  

Array of size \( dlen_\cdot \). The array descriptor for the distributed matrix \( Z \).

\( nvs \)  

Array of size \( nprocs+1 \)

\( nvs[i] = \text{number of eigenvectors held by processes } [0, i) \)

\( nvs[0] = \text{number of eigenvectors held by processes } [0, 0) = 0 \)

\( nvs[nprocs] = \text{number of eigenvectors held by } [0, nprocs) = \text{total number of eigenvectors.} \)

\( key \)  

Array of size \( n \). Indicates the actual index (after sorting) for each of the eigenvectors.

\( rwork \)  

Array of size \( lrwork \).

\( lrwork \)  

Size of \( work \).

**Output Parameters**

\( z \)  

Array of global size \( n \times n \) and of local size \( lld_z \times nq \). The eigenvectors on output. The eigenvectors are distributed in a block cyclic manner in both dimensions, with a block size of \( nb \).

**See Also**

Overview for details of ScaLAPACK array descriptor structures and related notations.
**p?lahrd**

Reduces the first \( nb \) columns of a general rectangular matrix \( A \) so that elements below the \( k \)-th subdiagonal are zero, by an orthogonal/unitary transformation, and returns auxiliary matrices that are needed to apply the transformation to the unreduced part of \( A \).

**Syntax**

```c
void pslahrd (MKL_INT *n, MKL_INT *k, MKL_INT *nb, float *a, MKL_INT *ia, MKL_INT *desca, float *tau, float *t, float *y, MKL_INT *iy, MKL_INT *jy, MKL_INT *descy, float *work);

void pdlahrd (MKL_INT *n, MKL_INT *k, MKL_INT *nb, double *a, MKL_INT *ia, MKL_INT *desca, double *tau, double *t, double *y, MKL_INT *iy, MKL_INT *jy, MKL_INT *descy, double *work);

void pclahrd (MKL_INT *n, MKL_INT *k, MKL_INT *nb, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *desca, MKL_Complex8 *tau, MKL_Complex8 *t, MKL_Complex8 *y, MKL_INT *iy, MKL_INT *jy, MKL_INT *descy, MKL_Complex8 *work);

void pzlahrd (MKL_INT *n, MKL_INT *k, MKL_INT *nb, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *desca, MKL_Complex16 *tau, MKL_Complex16 *t, MKL_Complex16 *y, MKL_INT *iy, MKL_INT *jy, MKL_INT *descy, MKL_Complex16 *work);
```

**Include Files**

- mkl_scalapack.h

**Description**

The \( p?lahrd \) function reduces the first \( nb \) columns of a real general \( n \)-by-\((n-k+1) \) distributed matrix \( A(ia:ia+n-1, ja:ja+n-k) \) so that elements below the \( k \)-th subdiagonal are zero. The reduction is performed by an orthogonal/unitary similarity transformation \( Q^*A*Q \). The function returns the matrices \( V \) and \( T \) which determine \( Q \) as a block reflector \( I-V*T*V^* \), and also the matrix \( Y = A*V*T \).

This is an auxiliary function called by \( p?gehrd \). In the following comments \( \text{sub}(A) \) denotes \( A(ia:ia+n-1, ja:ja+n-1) \).

**Input Parameters**

- \( n \)
  
  (global)
  
  The order of the distributed matrix \( \text{sub}(A) \). \( n \geq 0 \).

- \( k \)
  
  (global)
  
  The offset for the reduction. Elements below the \( k \)-th subdiagonal in the first \( nb \) columns are reduced to zero.

- \( nb \)
  
  (global)
  
  The number of columns to be reduced.

- \( a \)
  
  (local)
  
  Pointer into the local memory to an array of size \( lld_a \ast LOCC(ja+n-k) \). On entry, this array contains the local pieces of the \( n \)-by-\((n-k+1) \) general distributed matrix \( A(ia:ia+n-1, ja:ja+n-k) \).
\( ia, ja \) (global) The row and column indices in the global matrix \( A \) indicating the first row and the first column of the matrix \( \text{sub}(A) \), respectively.

\( \text{desca} \) (global and local) array of size \( dlen_\cdot \). The array descriptor for the distributed matrix \( A \).

\( iy, jy \) (global) The row and column indices in the global matrix \( Y \) indicating the first row and the first column of the matrix \( \text{sub}(Y) \), respectively.

\( \text{descy} \) (global and local) array of size \( dlen_\cdot \). The array descriptor for the distributed matrix \( Y \).

\( \text{work} \) (local). Array of size \( nb \).

**Output Parameters**

\( a \) (local).

On exit, the elements on and above the \( k \)-th subdiagonal in the first \( nb \) columns are overwritten with the corresponding elements of the reduced distributed matrix; the elements below the \( k \)-th subdiagonal, with the array \( \tau \), represent the matrix \( Q \) as a product of elementary reflectors. The other columns of the matrix \( A(ia:ia+n-1, ja:ja+n-k) \) are unchanged. (See **Application Notes** below.)

\( \tau \) (local)

Array of size \( \text{LOCc}(ja+n-2) \). The scalar factors of the elementary reflectors (see **Application Notes** below). \( \tau \) is tied to the distributed matrix \( A \).

\( t \) (local)

Array of size \( nb_a * nb_a \). The upper triangular matrix \( T \).

\( y \) (local).

Pointer into the local memory to an array of size \( lld_y * nb_a \). On exit, this array contains the local pieces of the \( n \)-by-\( nb \) distributed matrix \( Y \). \( lld_y \geq \text{LOCr}(ia+n-1) \).

**Application Notes**

The matrix \( Q \) is represented as a product of \( nb \) elementary reflectors

\[ Q = H(1)^*H(2)^*...*H(nb)^*. \]

Each \( H(i) \) has the form

\[ H(i) = i-\tau*v*v^\prime, \]

where \( \tau \) is a real/complex scalar, and \( v \) is a real/complex vector with \( v(1:i+k-1)=0, v(i+k)=1; v(i+k+1:n) \) is stored on exit in \( A(a+i+k:ia+n-1, ja+i-1) \), and \( \tau \) in \( \tau[ja+i-2] \).

The elements of the vectors \( v \) together form the \( (n-k+1) \)-by-\( nb \) matrix \( V \) which is needed, with \( T \) and \( Y \), to apply the transformation to the unreduced part of the matrix, using an update of the form: \( A(ia:ia+n-1, ja:ja+n-k) := (I-V^*T^*V)*(A(ia:ia+n-1, ja:ja+n-k)-Y^*V) \). The contents of \( A(ia:ia+n-1, ja:ja+n-k) \) on exit are illustrated by the following example with \( n = 7, k = 3 \), and \( nb = 2 \):
where $a$ denotes an element of the original matrix $A(ia:ia+n-1, ja:ja+n-k)$, $h$ denotes a modified element of the upper Hessenberg matrix $H$, and $v_i$ denotes an element of the vector defining $H(i)$.

**See Also**

Overview for details of ScaLAPACK array descriptor structures and related notations.

### p?laiect

*Exploits IEEE arithmetic to accelerate the computations of eigenvalues.*

#### Syntax

```c
void pslaiect (float *sigma, MKL_INT *n, float *d, MKL_INT *count);
void pdlaiectb (float *sigma, MKL_INT *n, float *d, MKL_INT *count);
void pdlaiectl (float *sigma, MKL_INT *n, float *d, MKL_INT *count);
```

#### Include Files

- mkl_scalapack.h

#### Description

The p?laiect function computes the number of negative eigenvalues of $(A-\sigma I)$. This implementation of the Sturm Sequence loop exploits IEEE arithmetic and has no conditionals in the innermost loop. The signbit for real function pslaiect is assumed to be bit 32. Double-precision functions pdlaiectb and pdlaiectl differ in the order of the double precision word storage and, consequently, in the signbit location. For pdlaiectb, the double precision word is stored in the big-endian word order and the signbit is assumed to be bit 32. For pdlaiectl, the double precision word is stored in the little-endian word order and the signbit is assumed to be bit 64.

This is a ScaLAPACK internal function and arguments are not checked for unreasonable values.

#### Input Parameters

- **sigma**
  
  The shift. p?laiect finds the number of eigenvalues less than equal to $\sigma$.

- **n**
  
  The order of the tridiagonal matrix $T$. $n \geq 1$.

- **d**
  
  Array of size $2n-1$.

  On entry, this array contains the diagonals and the squares of the off-diagonal elements of the tridiagonal matrix $T$. These elements are assumed to be interleaved in memory for better cache performance. The diagonal entries of $T$ are in the entries $d[0]$, $d[2]$, ..., $d[2n-2]$, while the squares of the off-diagonal entries are $d[1]$, $d[3]$, ..., $d[2n-3]$. To
avoid overflow, the matrix must be scaled so that its largest entry is no
greater than $\text{overflow}^{(1/2)} \ast \text{underflow}^{(1/4)}$ in absolute value, and for
greatest accuracy, it should not be much smaller than that.

**Output Parameters**

\(n\)  
The count of the number of eigenvalues of \(T\) less than or equal to \(sigma\).

**See Also**

Overview for details of ScaLAPACK array descriptor structures and related notations.

### p?lamve

*Copies all or part of one two-dimensional distributed array to another.*

#### Syntax

```c
void pslamve(char* uplo, MKL_INT* m, MKL_INT* n, float* a, MKL_INT* ia, MKL_INT* ja,
MKL_INT* desca, float* b, MKL_INT* ib, MKL_INT* jb, MKL_INT* descb, float* dwork);
void pdlamve(char* uplo, MKL_INT* m, MKL_INT* n, double* a, MKL_INT* ia, MKL_INT* ja,
MKL_INT* desca, double* b, MKL_INT* ib, MKL_INT* jb, MKL_INT* descb, double* dwork);
```

#### Include Files

- mkl_scalapack.h

**Description**

\(p?lamve\) copies all or part of a distributed matrix \(A\) to another distributed matrix \(B\). There is no alignment assumptions at all except that \(A\) and \(B\) are of the same size.

### Optimization Notice

Intel’s compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

**Input Parameters**

\(uplo\)  
*(global )*

Specifies the part of the distributed matrix \(\text{sub}(A)\) to be copied:

- If \(= 'U'\): Upper triangular part is copied; the strictly lower triangular part of \(\text{sub}(A)\) is not referenced;
- If \(= 'L'\): Lower triangular part is copied; the strictly upper triangular part of \(\text{sub}(A)\) is not referenced;

Otherwise: All of the matrix \(\text{sub}(A)\) is copied.
The number of rows to be operated on, which is the number of rows of the distributed matrix \( \text{sub}(A) \). \( m \geq 0 \).

The number of columns to be operated on, which is the number of columns of the distributed matrix \( \text{sub}(A) \). \( n \geq 0 \).

(\text{local} ) pointer into the local memory to an array of size \( lld_a \times LOC_c(ja + n - 1) \). This array contains the local pieces of the distributed matrix \( \text{sub}(A) \) to be copied from.

The row index in the global matrix \( A \) indicating the first row of \( \text{sub}(A) \).

The column index in the global matrix \( A \) indicating the first column of \( \text{sub}(A) \).

(global and local) array of size \( dlen_\). The array descriptor for the distributed matrix \( A \).

The row index in the global matrix \( B \) indicating the first row of \( \text{sub}(B) \).

The column index in the global matrix \( B \) indicating the first column of \( \text{sub}(B) \).

(global and local) array of size \( dlen_\). The array descriptor for the distributed matrix \( B \).

(\text{local workspace} ) array

If \( \text{uplo} = 'U' \) or \( \text{uplo} = 'L' \) and number of processors > 1, the length of \( dwork \) is at least as large as the length of \( b \). Otherwise, \( dwork \) is not referenced.

(\text{local} ) pointer into the local memory to an array of size \( lld_b \times LOC_c(jb + n - 1) \). This array contains on exit the local pieces of the distributed matrix \( \text{sub}(B) \).

\textbf{See Also}

\textbf{Overview} for details of ScaLAPACK array descriptor structures and related notations.

\textbf{p?lange}

\textit{Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of a general rectangular matrix.}
Syntax

```c
float pslange (char *norm, MKL_INT *m, MKL_INT *n, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *work);
double pdlange (char *norm, MKL_INT *m, MKL_INT *n, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *work);
float pclange (char *norm, MKL_INT *m, MKL_INT *n, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *work);
double pzlange (char *norm, MKL_INT *m, MKL_INT *n, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *work);
```

Include Files

- mkl_scalapack.h

Description

The `p?lange` function returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a distributed matrix \( \text{sub}(A) = A(\text{ia:ia+m-1, ja:ja+n-1}) \).

Input Parameters

- **norm**
  (global) Specifies what value is returned by the function:
  - 'M' or 'm': \( \text{val} = \max(|A_{ij}|) \), largest absolute value of the matrix \( A \), it is not a matrix norm.
  - '1' or 'O' or 'o': \( \text{val} = \text{norm}_1(A) \), 1-norm of the matrix \( A \) (maximum column sum),
  - 'I' or 'i': \( \text{val} = \text{norm}_\infty(A) \), infinity norm of the matrix \( A \) (maximum row sum),
  - 'F', 'f', 'E' or 'e': \( \text{val} = \text{norm}_F(A) \), Frobenius norm of the matrix \( A \) (square root of sum of squares).

- **m**
  (global)
  The number of rows in the distributed matrix \( \text{sub}(A) \). When \( m = 0 \), `p?lange` is set to zero. \( m \geq 0 \).

- **n**
  (global)
  The number of columns in the distributed matrix \( \text{sub}(A) \). When \( n = 0 \), `p?lange` is set to zero. \( n \geq 0 \).

- **a**
  (local).
  Pointer into the local memory to an array of size \( \text{lld}_a \times \text{LOCc}(ja+n-1) \) containing the local pieces of the distributed matrix \( A \).

- **ia, ja**
  (global) The row and column indices in the global matrix \( A \) indicating the first row and the first column of the matrix \( \text{sub}(A) \), respectively.

- **desca**
  (global and local) array of size \( dlen_\_) \). The array descriptor for the distributed matrix \( A \).

- **work**
  (local).
  Array size \( lwork \).
\( l_{\text{work}} \geq 0 \) if \( \text{norm} = 'M' \) or \( 'm' \) (not referenced),
\( n_{\text{q}}0 \) if \( \text{norm} = '1', 'O' \) or \( 'o' \),
\( m_{\text{p}}0 \) if \( \text{norm} = 'I' \) or \( 'i' \),
\( 0 \) if \( \text{norm} = 'F', 'f', 'E' \) or \( 'e' \) (not referenced),

where
\[ i_{\text{roffa}} = \text{mod}(ia-1, mb_a), \quad i_{\text{coffa}} = \text{mod}(ja-1, nb_a), \]
\[ i_{\text{arow}} = \text{indxg2p}(ia, mb_a, myrow, rsrca_n, nprow), \]
\[ i_{\text{icol}} = \text{indxg2p}(ja, nb_a, mycol, csrca_n, npcol), \]
\[ m_{\text{p}}0 = \text{numroc}(m+i_{\text{roffa}}, mb_a, myrow, i_{\text{arow}}, nprow), \]
\[ n_{\text{q}}0 = \text{numroc}(n+i_{\text{coffa}}, nb_a, mycol, i_{\text{icol}}, npcol), \]

\text{indxg2p} \text{ and } \text{numroc} \text{ are ScaLAPACK tool functions; } myrow, mycol, nprow, \text{ and } npcol \text{ can be determined by calling the function } \text{blacs_gridinfo}. 

Output Parameters

\text{val} \\
\text{The value returned by the function.}

See Also

Overview \text{ for details of ScaLAPACK array descriptor structures and related notations.}

\text{p?lanhs} \\
\text{Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of an upper Hessenberg matrix.}

Syntax

\text{float pslanhs (char *norm, MKL_INT *n, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *work);} \\
\text{double pdlanhs (char *norm, MKL_INT *n, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *work);} \\
\text{float pclanhs (char *norm, MKL_INT *n, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *work);} \\
\text{double pzlanhs (char *norm, MKL_INT *n, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *work);} \\

Include Files

\text{• mkl_scalapack.h}

Description

The \text{p?lanhs} function returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of an upper Hessenberg distributed matrix \( \text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1) \).
Input Parameters

**norm**
Specifies the value to be returned by the function:
- `'M'` or `'m'`: \( \text{val} = \max(\text{abs}(A_{ij})) \), largest absolute value of the matrix \( A \).
- `'1'` or `'O'` or `'o'`: \( \text{val} = \text{norml}(A) \), 1-norm of the matrix \( A \) (maximum column sum),
- `'I'` or `'i'`: \( \text{val} = \text{normI}(A) \), infinity norm of the matrix \( A \) (maximum row sum),
- `'F'`, `'f'`, `'E'` or `'e'`: \( \text{val} = \text{normF}(A) \), Frobenius norm of the matrix \( A \) (square root of sum of squares).

**n**
The number of columns in the distributed matrix \( \text{sub}(A) \). When \( n = 0 \), \( p?lanhs \) is set to zero. \( n \geq 0 \).

**a**
Pointer into the local memory to an array of size \( \text{lld}_a \ast \text{LOCc}(ja+n-1) \) containing the local pieces of the distributed matrix \( \text{sub}(A) \).

**ia, ja**
The row and column indices in the global matrix \( A \) indicating the first row and the first column of the matrix \( \text{sub}(A) \), respectively.

**desca**
(global and local) array of size \( dlen_ \). The array descriptor for the distributed matrix \( A \).

**work**
(local).

Array of size \( lwork \).
- \( lwork \geq 0 \) if \( \text{norm} = 'M' \) or `'m'` (not referenced),
- \( nq0 \) if \( \text{norm} = '1', 'O' \) or `'o'`,
- \( mp0 \) if \( \text{norm} = 'I' \) or `'i'`,
- 0 if \( \text{norm} = 'F', 'f', 'E' \) or `'e'` (not referenced),

where
- \( iroffa = \text{mod}(ia-1, mb_a) \), \( icoffa = \text{mod}(ja-1, nb_a) \),
- \( iarow = \text{indxg2p}(ia, mb_a, myrow, rsrc_a, nprow) \),
- \( iacol = \text{indxg2p}(ja, nb_a, mycol, csrca, npcol) \),
- \( mp0 = \text{numroc}(m+iroffa, mb_a, myrow, iarow, nq0) \),
- \( nq0 = \text{numroc}(n+icoffa, nb_a, mycol, iacol, npcol) \).

\( \text{indxg2p} \) and \( \text{numroc} \) are ScaLAPACK tool functions; \( myrow, imycol, nprow, \) and \( npcol \) can be determined by calling the function \( \text{blacs_gridinfo} \).

Output Parameters

**val**
The value returned by the function.
See Also
Overview for details of ScaLAPACK array descriptor structures and related notations.

**p?lansy, p?lanhe**

*Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of a real symmetric or a complex Hermitian matrix.*

**Syntax**

```c
float pslansy (char *norm, char *uplo, MKL_INT *n, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *work);
double pdlansy (char *norm, char *uplo, MKL_INT *n, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *work);
float pclansy (char *norm, char *uplo, MKL_INT *n, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *work);
double pzlansy (char *norm, char *uplo, MKL_INT *n, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *work);
float pclanhe (char *norm, char *uplo, MKL_INT *n, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *work);
double pzlanhe (char *norm, char *uplo, MKL_INT *n, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *work);
```

**Include Files**

- mkl_scalapack.h

**Description**

The `p?lansy` and `p?lanhe` functions return the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a distributed matrix `sub(A) = A(ia:ia+m-1, ja:ja +n-1)`.

**Input Parameters**

- **norm**
  
  (global) Specifies what value is returned by the function:
  
  - '=M' or 'm': `val = max(abs(A_{ij}))`, largest absolute value of the matrix `A`, it is not a matrix norm.
  - '=1' or 'O' or 'o': `val = norm1(A)`, 1-norm of the matrix `A` (maximum column sum),
  - '=I' or 'i': `val = normI(A)`, infinity norm of the matrix `A` (maximum row sum),
  - '=F', 'f', 'E' or 'e': `val = normF(A)`, Frobenius norm of the matrix `A` (square root of sum of squares).

- **uplo**
  
  (global) Specifies whether the upper or lower triangular part of the symmetric matrix `sub(A)` is to be referenced.
  
  - '=U': Upper triangular part of `sub(A)` is referenced,
  - '=L': Lower triangular part of `sub(A)` is referenced.
The number of columns in the distributed matrix \( \text{sub}(A) \). When \( n = 0 \), \( \text{p?lansy} \) is set to zero. \( n \geq 0 \).

\( \text{a} \)

Pointer into the local memory to an array of size \( \text{lld}_a \times \text{LOCc}(ja+n-1) \) containing the local pieces of the distributed matrix \( \text{sub}(A) \).

If \( \text{uplo} = 'U' \), the leading \( n \)-by-\( n \) upper triangular part of \( \text{sub}(A) \) contains the upper triangular matrix whose norm is to be computed, and the strictly lower triangular part of this matrix is not referenced. If \( \text{uplo} = 'L' \), the leading \( n \)-by-\( n \) lower triangular part of \( \text{sub}(A) \) contains the lower triangular matrix whose norm is to be computed, and the strictly upper triangular part of \( \text{sub}(A) \) is not referenced.

\( \text{ia, ja} \)

The row and column indices in the global matrix \( A \) indicating the first row and the first column of the matrix \( \text{sub}(A) \), respectively.

\( \text{desca} \)

Array descriptor for the distributed matrix \( A \).

\( \text{work} \)

Array of size \( lwork \).

\( lwork \geq 0 \) if \( \text{norm} = 'M' \) or \( 'm' \) (not referenced),

\( 2 \times nq0 + mp0 + ldw \) if \( \text{norm} = '1', 'O', 'o', 'I', 'i', 'E', 'e' \),

where \( ldw \) is given by:

\[
\begin{align*}
\text{if} ( \text{nprov} \neq \text{npcol} ) \text{ then} \\
\text{ldw} &= \text{mb}_a \times \text{ceil}(\text{ceil}(np0, mb_a), (\text{lcm}/\text{nprov})) \\
\text{else} \\
\text{ldw} &= 0
\end{align*}
\]

0 if \( \text{norm} = 'F', 'f', 'E', 'e' \) (not referenced),

where \( \text{lcm} \) is the least common multiple of \( \text{nprov} \) and \( \text{npcol} \), \( \text{lcm} = \text{iilcm}(\text{nprov, npcol}) \) and \( \text{ceil}(x, y) \) is a \( \text{Scalapack} \) function that returns ceiling \( (x/y) \).

\( \text{iroffa} = \text{mod}(\text{ia} - 1, \text{mb}_a) \), \( \text{icoffa} = \text{mod}(\text{ja} - 1, \text{nb}_a) \),

\( \text{iarow} = \text{indxg2p}(\text{ia}, \text{mb}_a, \text{myrow}, \text{rsrc}_a, \text{nprow}) \),

\( \text{iacol} = \text{indxg2p}(\text{ja}, \text{nb}_a, \text{mycol}, \text{csrc}_a, \text{npcol}) \),

\( \text{mp0} = \text{numroc}(\text{m} + \text{iroffa}, \text{mb}_a, \text{myrow}, \text{iarow}, \text{nprow}) \),

\( \text{nq0} = \text{numroc}(\text{n} + \text{icoffa}, \text{nb}_a, \text{mycol}, \text{iacol}, \text{npcol}) \),

\( \text{iilcm}, \text{iceil}, \text{indxg2p}, \text{and} \text{numroc} \) are \( \text{Scalapack} \) tool functions; \( \text{myrow}, \text{mycol}, \text{nprow}, \text{and} \text{npcol} \) can be determined by calling the function \( \text{blacs_gridinfo} \).
Output Parameters

val  
The value returned by the function.

See Also
Overview for details of ScaLAPACK array descriptor structures and related notations.

p?lantr
Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of a triangular matrix.

Syntax

float pslantr (char *norm, char *uplo, char *diag, MKL_INT *m, MKL_INT *n, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *work);
double pdlantr (char *norm, char *uplo, char *diag, MKL_INT *m, MKL_INT *n, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *work);
float pclantr (char *norm, char *uplo, char *diag, MKL_INT *m, MKL_INT *n, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *work);
double pzlantr (char *norm, char *uplo, char *diag, MKL_INT *m, MKL_INT *n, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *work);

Include Files

• mkl_scalapack.h

Description

The p?lantr function returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a trapezoidal or triangular distributed matrix sub(A) = A(ia:ia+m-1, ja:ja+n-1).

Input Parameters

norm  
(global) Specifies what value is returned by the function:

= 'M' or 'm': val = max(abs(Aij)), largest absolute value of the matrix A, it is not a matrix norm.
= '1' or 'O' or 'o': val = norm1(A), 1-norm of the matrix A (maximum column sum),
= 'I' or 'i': val = normI(A), infinity norm of the matrix A (maximum row sum),
= 'F', 'f', 'E' or 'e': val = normF(A), Frobenius norm of the matrix A (square root of sum of squares).

uplo  
(global)
Specifies whether the upper or lower triangular part of the symmetric matrix sub(A) is to be referenced.

= 'U': Upper trapezoidal,
= 'L': Lower trapezoidal.
Note that sub(A) is triangular instead of trapezoidal if \( m = n \).

\[ \text{diag} \]

(global)

Specifies whether the distributed matrix sub(A) has unit diagonal.

- \( \text{='N'} \): Non-unit diagonal.
- \( \text{='U'} \): Unit diagonal.

\[ m \]

(global)

The number of rows in the distributed matrix sub(A). When \( m = 0 \), `p?lantr` is set to zero. \( m \geq 0 \).

\[ n \]

(global)

The number of columns in the distributed matrix sub(A). When \( n = 0 \), `p?lantr` is set to zero. \( n \geq 0 \).

\[ a \]

(local)

Pointer into the local memory to an array of size \( lld_a * \text{LOCc}(ja+n-1) \) containing the local pieces of the distributed matrix sub(A).

\[ ia, ja \]

(global)

The row and column indices in the global matrix A indicating the first row and the first column of the matrix sub(A), respectively.

\[ \text{desca} \]

(global and local) array of size \( dlen_\). The array descriptor for the distributed matrix A.

\[ \text{work} \]

(local)

Array size \( lwork \).

- \( lwork \geq 0 \) if \( \text{norm} = \text{'M'} \) or \( \text{'m'} \) (not referenced),
- \( nq0 \) if \( \text{norm} = \text{'1'} \), \( \text{'O'} \) or \( \text{'o'} \),
- \( mp0 \) if \( \text{norm} = \text{'I'} \) or \( \text{'i'} \),
- \( 0 \) if \( \text{norm} = \text{'F'} \), \( \text{'F'} \), \( \text{'E'} \) or \( \text{'e'} \) (not referenced),

\( iroffa = \text{mod}(ia-1, mb_a) \), \( icoffa = \text{mod}(ja-1, nb_a) \),

\( \text{iarow} = \text{indxg2p}(ia, mb_a, myrow, rsrc_a, nprow) \),

\( \text{iacol} = \text{indxg2p}(ja, nb_a, mycol, csrc_a, npcol) \),

\( mp0 = \text{numroc}(m+iroffa, mb_a, myrow, iarow, nprow) \),

\( nq0 = \text{numroc}(n+icoffa, nb_a, mycol, iacol, npcol) \).

\( \text{indxg2p} \) and \( \text{numroc} \) are ScaLAPACK tool functions; \( \text{myrow} \), \( \text{mycol} \), \( \text{nprow} \), and \( \text{npcol} \) can be determined by calling the function \( \text{blacs_gridinfo} \).

**Output Parameters**

\[ \text{val} \]

The value returned by the function.

**See Also**

**Overview** for details of ScaLAPACK array descriptor structures and related notations.
Applies a permutation matrix to a general distributed matrix, resulting in row or column pivoting.

Syntax

void pslapiv (char *direc, char *rowcol, char *pivroc, MKL_INT *m, MKL_INT *n, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_INT *ipiv, MKL_INT *ip, MKL_INT *jp, MKL_INT *descip, MKL_INT *iwork);

void pdlapiv (char *direc, char *rowcol, char *pivroc, MKL_INT *m, MKL_INT *n, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_INT *ipiv, MKL_INT *ip, MKL_INT *jp, MKL_INT *descip, MKL_INT *iwork);

void pclapiv (char *direc, char *rowcol, char *pivroc, MKL_INT *m, MKL_INT *n, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_INT *ipiv, MKL_INT *ip, MKL_INT *jp, MKL_INT *descip, MKL_INT *iwork);

void pzlapiv (char *direc, char *rowcol, char *pivroc, MKL_INT *m, MKL_INT *n, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_INT *ipiv, MKL_INT *ip, MKL_INT *jp, MKL_INT *descip, MKL_INT *iwork);

Include Files

- mkl_scalapack.h

Description

The p?lapiv function applies either $P$ (permutation matrix indicated by $ipiv$) or $\text{inv}(P)$ to a general $m$-by-$n$ distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$, resulting in row or column pivoting. The pivot vector may be distributed across a process row or a column. The pivot vector should be aligned with the distributed matrix $A$. This function will transpose the pivot vector, if necessary.

For example, if the row pivots should be applied to the columns of $\text{sub}(A)$, pass $\text{rowcol} = 'C'$ and $\text{pivroc} = 'C'$.

Input Parameters

direc  (global)
Specifies in which order the permutation is applied:

= 'F' (Forward): Applies pivots forward from top of matrix. Computes $P \cdot \text{sub}(A)$.
= 'B' (Backward): Applies pivots backward from bottom of matrix. Computes $\text{inv}(P) \cdot \text{sub}(A)$.

rowcol  (global)
Specifies if the rows or columns are to be permuted:

= 'R': Rows will be permuted,
= 'C': Columns will be permuted.

pivroc  (global)
Specifies whether $ipiv$ is distributed over a process row or column:

= 'R': $ipiv$ is distributed over a process row,
The number of rows in the distributed matrix sub(A). When \( m = 0 \), `p?lapiv` is set to zero. \( m \geq 0 \).

\( n \) (global)

The number of columns in the distributed matrix sub(A). When \( n = 0 \), `p?lapiv` is set to zero. \( n \geq 0 \).

\( a \) (local)

Pointer into the local memory to an array of size \( lld_a \times \text{LOCc}(ja+n-1) \) containing the local pieces of the distributed matrix sub(A).

\( ia, ja \) (global)

The row and column indices in the global matrix A indicating the first row and the first column of the matrix sub(A), respectively.

\( \text{desca} \) (global and local) array of size \( dlen_\). The array descriptor for the distributed matrix A.

\( \text{ipiv} \) (local)

Array of size \( \text{lipiv} \);

when \( \text{rowcol} = 'R' \) or 'r':

\[ \text{lipiv} \geq \text{LOCr}(ia+m-1) + mb_a \text{ if } \text{pivroc} = 'C' \text{ or } 'c', \]
\[ \text{lipiv} \geq \text{LOCc}(m + \text{mod}(jp-1, nb_p)) \text{ if } \text{pivroc} = 'R' \text{ or } 'r', \text{ and,} \]

when \( \text{rowcol} = 'C' \) or 'c':

\[ \text{lipiv} \geq \text{LOCr}(n + \text{mod}(ip-1, mb_p)) \text{ if } \text{pivroc} = 'C' \text{ or } 'c', \]
\[ \text{lipiv} \geq \text{LOCc}(ja+n-1) + nb_a \text{ if } \text{pivroc} = 'R' \text{ or } 'r'. \]

This array contains the pivoting information. \( \text{ipiv}(i) \) is the global row (column), local row (column) \( i \) was swapped with. When \( \text{rowcol} = 'R' \) or 'r' and \( \text{pivroc} = 'C' \text{ or } 'c' \), or \( \text{rowcol} = 'C' \text{ or } 'c' \text{ and } \text{pivroc} = 'R' \text{ or } 'r' \), the last piece of this array of size \( mb_a \) (resp. \( nb_a \)) is used as workspace. In those cases, this array is tied to the distributed matrix A.

\( \text{ip}, \text{jp} \) (global) The row and column indices in the global matrix \( P \) indicating the first row and the first column of the matrix sub(\( P \)), respectively.

\( \text{descip} \) (global and local) array of size \( dlen_\). The array descriptor for the distributed vector \( \text{ipiv} \).

\( \text{iwork} \) (local).

Array of size \( ldw \), where \( ldw \) is equal to the workspace necessary for transposition, and the storage of the transposed \( \text{ipiv} \): Let \( lcm \) be the least common multiple of \( nprow \) and \( npcol \).

```c
if( *rowcol == 'r' && *pivroc == 'r') {
    if( nprow == npcol) {
        ldw = LOCr( n_p + (*jp-1)%nb_p ) + nb_p;
    } else {
        ...
    }
}
```
Output Parameters

\( a \)

(local).

On exit, the local pieces of the permuted distributed submatrix.

```

Include Files

• mkl_scalapack.h

Description

p?lapv2 applies either \( P \) (permutation matrix indicated by \( ipiv \)) or \( \text{inv}(P) \) to an \( m \)-by-\( n \) distributed matrix \( \text{sub}(A) \) denoting \( A(ia:ia+m-1,ja:ja+n-1) \), resulting in row or column pivoting. The pivot vector should be aligned with the distributed matrix \( A \). For pivoting the rows of \( \text{sub}(A) \), \( ipiv \) should be distributed along a process column and replicated over all process rows. Similarly, \( ipiv \) should be distributed along a process row and replicated over all process columns for column pivoting.
Input Parameters

direc (global)
Specifies in which order the permutation is applied:
= 'F' (Forward) Applies pivots Forward from top of matrix. Computes \( P \) sub(\( A \));
= 'B' (Backward) Applies pivots Backward from bottom of matrix. Computes \( \text{inv}( P ) \) * sub(\( A \)).

direct (global)

rowcol (global)
Specifies if the rows or columns are to be permuted:
= 'R' Rows will be permuted,
= 'C' Columns will be permuted.

rowcol (global)

m (global)
The number of rows to be operated on, i.e. the number of rows of the distributed submatrix sub(\( A \)). \( m \geq 0 \).

n (global)
The number of columns to be operated on, i.e. the number of columns of the distributed submatrix sub(\( A \)). \( n \geq 0 \).

a Pointer into local memory to an array of size \( lld_a*LOCc(ja+n-1) \).
On entry, this local array contains the local pieces of the distributed matrix sub(\( A \)) to which the row or columns interchanges will be applied.

ia (global)
The row index in the global array \( a \) indicating the first row of sub(\( A \)).

ja (global)
The column index in the global array \( a \) indicating the first column of sub(\( A \)).

desca (global and local)
Array of size \( dlen_\). The array descriptor for the distributed matrix \( A \).

ipiv Array, size \( \geq \text{LOCr}(m_a)+mb_a \) if \( \text{rowcol} = 'R' \), \( \text{LOCc}(n_a)+nb_a \) otherwise.
It contains the pivoting information. \( \text{ipiv}[i-1] \) is the global row (column), local row (column) \( i \) was swapped with. The last piece of the array of size \( mb_a \) or \( nb_a \) is used as workspace. \( \text{ipiv} \) is tied to the distributed matrix \( A \).

ip (global)
The global row index of \( \text{ipiv} \), which points to the beginning of the submatrix on which to operate.

jp (global)
The global column index of \textit{ipiv}, which points to the beginning of the submatrix on which to operate.

\texttt{descip} \\
\text{(global and local)}

Array of size 8.

The array descriptor for the distributed matrix \textit{ipiv}.

\textbf{Output Parameters}

\texttt{a} \\
On exit, this array contains the local pieces of the permuted distributed matrix.

\textbf{p?laqge}

\textit{Scales a general rectangular matrix, using row and column scaling factors computed by \texttt{p?geequ}.}

\textbf{Syntax}

\begin{verbatim}
void pslaqge (MKL_INT *m, MKL_INT *n, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *r, float *c, float *rowcnd, float *colcnd, float *amax, char *equed);
void pdlaqge (MKL_INT *m, MKL_INT *n, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *r, double *c, double *rowcnd, double *colcnd, double *amax, char *equed);
void pclaqge (MKL_INT *m, MKL_INT *n, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *r, float *c, float *rowcnd, float *colcnd, float *amax, char *equed);
void pzlaqge (MKL_INT *m, MKL_INT *n, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *r, double *c, double *rowcnd, double *colcnd, double *amax, char *equed);
\end{verbatim}

\textbf{Include Files}

- \texttt{mkl_scalapack.h}

\textbf{Description}

The \texttt{p?laqge} function equilibrates a general \textit{m}-by-\textit{n} distributed matrix \texttt{sub(A)} = \texttt{A(ia:ia+m-1, ja:ja+n-1)} using the row and scaling factors in the vectors \texttt{r} and \texttt{c} computed by \texttt{p?geequ}.

\textbf{Input Parameters}

\texttt{m} \\
\text{(global)}

The number of rows in the distributed matrix \texttt{sub(A)}. (\textit{m} \geq 0).

\texttt{n} \\
\text{(global)}

The number of columns in the distributed matrix \texttt{sub(A)}. (\textit{n} \geq 0).

\texttt{a} \\
\text{(local)}

Pointer into the local memory to an array of size \texttt{lld_a * LOCc(ja+n-1)}.

On entry, this array contains the distributed matrix \texttt{sub(A)}.
\textit{ia, ja} \hspace{1cm} (global) The row and column indices in the global matrix \( A \) indicating the first row and the first column of the matrix \( \text{sub}(A) \), respectively.

\textit{desca} \hspace{1cm} (global and local) array of size \textit{dlen\_}. The array descriptor for the distributed matrix \( A \).

\textit{r} \hspace{1cm} (local).
Array of size \( \text{LOCr}(m_a) \). The row scale factors for \( \text{sub}(A) \). \( r \) is aligned with the distributed matrix \( A \), and replicated across every process column. \( r \) is tied to the distributed matrix \( A \).

\textit{c} \hspace{1cm} (local).
Array of size \( \text{LOCc}(n_a) \). The row scale factors for \( \text{sub}(A) \). \( c \) is aligned with the distributed matrix \( A \), and replicated across every process column. \( c \) is tied to the distributed matrix \( A \).

\textit{rowcnd} \hspace{1cm} (local).
The global ratio of the smallest \( r[i] \) to the largest \( r[i] \), \( ia-1 \leq i \leq ia+m-2 \).

\textit{colcnd} \hspace{1cm} (local).
The global ratio of the smallest \( c[i] \) to the largest \( c[i] \), \( ia-1 \leq i \leq ia+n-2 \).

\textit{amax} \hspace{1cm} (global).
Absolute value of largest distributed submatrix entry.

**Output Parameters**

\textit{a} \hspace{1cm} (local).
On exit, the equilibrated distributed matrix. See \textit{equed} for the form of the equilibrated distributed submatrix.

\textit{equed} \hspace{1cm} (global)
Specifies the form of equilibration that was done.

- 'N': No equilibration
- 'R': Row equilibration, that is, \( \text{sub}(A) \) has been pre-multiplied by \( \text{diag}(r[ia-1:ia+m-2]) \),
- 'C': column equilibration, that is, \( \text{sub}(A) \) has been post-multiplied by \( \text{diag}(c[ja-1:ja+n-2]) \),
- 'B': Both row and column equilibration, that is, \( \text{sub}(A) \) has been replaced by \( \text{diag}(r[ia-1:ia+m-2])* \text{sub}(A) * \text{diag}(c[ja-1:ja+n-2]) \).

**See Also**

Overview for details of ScalAPACK array descriptor structures and related notations.

\textit{p?laqr0}
Computes the eigenvalues of a Hessenberg matrix and optionally returns the matrices from the Schur decomposition.
Syntax
void pslaqr0(MKL_INT* wantt, MKL_INT* wantz, MKL_INT* n, MKL_INT* ilo, MKL_INT* ihi, float* h, MKL_INT* desch, float* wr, float* wi, MKL_INT* iloz, MKL_INT* ihiz, float* z, MKL_INT* descz, float* work, MKL_INT* lwork, MKL_INT* iwork, MKL_INT* liwork, MKL_INT* info, MKL_INT* reclevel);
void pdlaqr0(MKL_INT* wantt, MKL_INT* wantz, MKL_INT* n, MKL_INT* ilo, MKL_INT* ihi, double* h, MKL_INT* desch, double* wr, double* wi, MKL_INT* iloz, MKL_INT* ihiz, double* z, MKL_INT* descz, double* work, MKL_INT* lwork, MKL_INT* iwork, MKL_INT* liwork, MKL_INT* info, MKL_INT* reclevel);

Include Files
• mkl_scalapack.h

Description
p?laqr0 computes the eigenvalues of a Hessenberg matrix \( H \) and, optionally, the matrices \( T \) and \( Z \) from the Schur decomposition \( H = Z*T*Z^T \), where \( T \) is an upper quasi-triangular matrix (the Schur form), and \( Z \) is the orthogonal matrix of Schur vectors.

Optionally \( Z \) may be postmultiplied into an input orthogonal matrix \( Q \) so that this function can give the Schur factorization of a matrix \( A \) which has been reduced to the Hessenberg form \( H \) by the orthogonal matrix \( Q \): \( A = Q*H*Q^T = (QZ)*T*(QZ)^T \).

Input Parameters
wantt (global )
Non-zero : the full Schur form \( T \) is required;
Zero : only eigenvalues are required.

wantz (global )
Non-zero : the matrix of Schur vectors \( Z \) is required;
Zero : Schur vectors are not required.

n (global )
The order of the Hessenberg matrix \( H \) (and \( Z \) if wantz is non-zero). \( n \geq 0 \).

ilo, ihi (global )
It is assumed that the matrix \( H \) is already upper triangular in rows and columns \( 1:ilo-1 \) and \( ihi+1:n \). ilo and ihi are normally set by a previous call to p?gebal, and then passed to p?gehrd when the matrix output by ihi is reduced to Hessenberg form. Otherwise ilo and ihi should be set to 1 and \( n \), respectively. If \( n > 0 \), then \( 1 \leq ilo \leq ihi \leq n \).
If \( n = 0 \), then \( ilo = 1 \) and \( ihi = 0 \).

h (global ) array of size \( ld_h * LOC_c(n) \)
The upper Hessenberg matrix \( H \).

desch (global and local )
Array of size \( dlen_\) .
The array descriptor for the distributed matrix \( H \).
**Specify the rows of the matrix** $Z$ **to which transformations must be applied if** $\text{wantz}$ **is non-zero,** $1 \leq \text{ilo} \leq \text{iloz} \leq \text{ihi} \leq \text{ihiz} \leq n.$

**Array of size** $\text{lda}_z \times \text{LOC}(n)$.

If $\text{wantz}$ **is non-zero,** contains the matrix $Z$.

If $\text{wantz}$ **equals zero,** $z$ is not referenced.

**(global and local)** array of size $\text{dlen}_z$.

The array descriptor for the distributed matrix $Z$.

**(local workspace)** array of size $\text{lwork}$

The length of the workspace array $\text{work}$.

**Output Parameters**

On exit, if $\text{wantt}$ **is non-zero,** the matrix $H$ is upper quasi-triangular in rows and columns $\text{ilo}$: $\text{ihi}$, with 1-by-1 and 2-by-2 blocks on the main diagonal. The 2-by-2 diagonal blocks (corresponding to complex conjugate pairs of eigenvalues) are returned in standard form, with $H(i,i) = H(i+1,i+1)$ and $H(i+1,i)^*H(i,i+1) < 0$. If $\text{info} = 0$ and $\text{wantt}$ **equals zero,** the contents of $h$ are unspecified on exit.

The real and imaginary parts, respectively, of the computed eigenvalues $\text{ilo}$ to $\text{ihi}$ are stored in the corresponding elements of $\text{wr}$ and $\text{wi}$. If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of $\text{wr}$ and $\text{wi}$, say the $i$-th and $(i+1)$-th, with $\text{wi}[i-1] > 0$ and $\text{wi}[i] < 0$. If $\text{wantt}$ **is non-zero,** the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in $h$.

Updated matrix with transformations applied only to the submatrix $Z(\text{ilo}:\text{ihi},\text{ilo}:\text{ihi})$.

If $\text{COMPZ} = 'I'$, on exit, if $\text{info} = 0$, $z$ contains the orthogonal matrix $Z$ of the Schur vectors of $H$.

If $\text{wantz}$ **is non-zero,** then $Z(\text{ilo}:\text{ihi},\text{iloz}:\text{ihiz})$ is replaced by $Z(\text{ilo}:\text{ihi},\text{iloz}:\text{ihiz})^*U$, when $U$ is the orthogonal/unitary Schur factor of $H(\text{ilo}:\text{ihi},\text{ilo}:\text{ihi})$.

If $\text{wantz}$ **equals zero,** then $z$ is not defined.

On exit, if $\text{info} = 0$, $\text{work}[0]$ **returns the optimal** $\text{lwork}$.

On exit, if $\text{info} = 0$, $\text{iwork}[0]$ **returns the optimal** $\text{liwork}$. 
info

> 0: if info = i, then the function failed to compute all the eigenvalues.
Elements 0:ilo-2 and i:n-1 of wr and wi contain those eigenvalues which have been successfully computed.

> 0: if wantt equals zero, then the remaining unconverged eigenvalues are the eigenvalues of the upper Hessenberg matrix rows and columns ilo through ihi of the final output value of H.

> 0: if wantt is non-zero, then (initial value of H)*U = U*(final value of H), where U is an orthogonal/unitary matrix. The final value of H is upper Hessenberg and quasi-triangular/triangular in rows and columns info+1 through ihi.

> 0: if wantz is non-zero, then (final value of Z(ilo:ihi,iloz:ihi))=U*(initial value of Z(ilo:ihi,iloz:ihi)), where U is the orthogonal/unitary matrix in the previous expression (regardless of the value of wantt).

> 0: if wantz equals zero, then z is not accessed.

Include Files

• mkl_scalapack.h

Description

p?laqr1 is an auxiliary function used to find the Schur decomposition and/or eigenvalues of a matrix already in Hessenberg form from columns ilo to ihi.

This is a modified version of p?lahqr from ScaLAPACK version 1.7.3. The following modifications were made:

• Workspace query functionality was added.
• Aggressive early deflation is implemented.
• Aggressive deflation (looking for two consecutive small subdiagonal elements by PSLACONSB) is abandoned.
• The returned Schur form is now in canonical form, i.e., the returned 2-by-2 blocks really correspond to complex conjugate pairs of eigenvalues.
• For some reason, the original version of p?lahqr sometimes did not read out the converged eigenvalues correctly. This is now fixed.

**Optimization Notice**

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. </tr>
</tbody>
</table>
descz (global and local) array of size dlen_.
The array descriptor for the distributed matrix Z.

work (local output) array of size lwork

lwork (local)
The size of the work array (lwork≥1).
If lwork=-1, then a workspace query is assumed.

iwork (global and local) array of size ilwork
This holds the some of the IBLK integer arrays.
ilwork (local)
The size of the iwork array (ilwork≥3).

OUTPUT Parameters

a If wantt is non-zero, the matrix A is upper quasi-triangular in rows and columns ilo:ihi, with any 2-by-2 or larger diagonal blocks not yet in standard form. If wantt equals zero, the contents of a are unspecified on exit.

wr, wi (global replicated) array of size n
The real and imaginary parts, respectively, of the computed eigenvalues ilo to ihi are stored in the corresponding elements of wr and wi. If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of wr and wi, say the i-th and (i+1)th, with wi[i-1] > 0 and wi[i] < 0. If wantt is non-zero, the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in a. a may be returned with larger diagonal blocks until the next release.

z On exit z is updated; transformations are applied only to the submatrix Z(ilo:ihiz,ilo:ihi).
If wantz equals zero, z is not referenced.

work[0] On exit, if info = 0, work[0] returns the optimal lwork.

info (global)
< 0: parameter number -info incorrect or inconsistent
= 0: successful exit
> 0: p?laqr1 failed to compute all the eigenvalues ilo to ihi in a total of 30*(ihi-ilo+1) iterations; if info = i, elements i:ihi-1 of wr and wi contain those eigenvalues which have been successfully computed.

Application Notes
This algorithm is very similar to p?ahqr. Unlike p?lahqr, instead of sending one double shift through the largest unreduced submatrix, this algorithm sends multiple double shifts and spaces them apart so that there can be parallelism across several processor row/columns. Another critical difference is that this algorithm aggregates multiple transforms together in order to apply them in a block fashion.

Current Notes and/or Restrictions:
• This code requires the distributed block size to be square and at least six (6); unlike simpler codes like LU, this algorithm is extremely sensitive to block size. Unwise choices of too small a block size can lead to bad performance.
• This code requires \(a\) and \(z\) to be distributed identically and have identical contexts.
• This release currently does not have a function for resolving the Schur blocks into regular 2x2 form after this code is completed. Because of this, a significant performance impact is required while the deflation is done by sometimes a single column of processors.
• This code does not currently block the initial transforms so that none of the rows or columns for any bulge are completed until all are started. To offset pipeline start-up it is recommended that at least \(2 \times \text{LCM}(\text{NPROW}, \text{NPCOL})\) bulges are used (if possible)
• The maximum number of bulges currently supported is fixed at 32. In future versions this will be limited only by the incoming work array.
• The matrix \(A\) must be in upper Hessenberg form. If elements below the subdiagonal are nonzero, the resulting transforms may be nonsimilar. This is also true with the LAPACK function.
• For this release, it is assumed \(rsrc_ = csrc_ = 0\)
• Currently, all the eigenvalues are distributed to all the nodes. Future releases will probably distribute the eigenvalues by the column partitioning.
• The internals of this function are subject to change.

\end{verbatim}

Include Files

• mkl_scalapack.h

Description

\texttt{p?laqr2} accepts as input an upper Hessenberg matrix \(A\) and performs an orthogonal similarity transformation designed to detect and deflate fully converged eigenvalues from a trailing principal submatrix. On output \(A\) is overwritten by a new Hessenberg matrix that is a perturbation of an orthogonal similarity transformation of \(A\). It is to be hoped that the final version of \(A\) has many zero subdiagonal entries.

This function handles small deflation windows which is affordable by one processor. Normally, it is called by \texttt{p?laqr1}. All the inputs are assumed to be valid without checking.
Optimization Notice

Intel’s compilers may or may not optimize to the same degree for non-Intel microprocessors for
optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and
SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or
effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-
dependent optimizations in this product are intended for use with Intel microprocessors. Certain
optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to
the applicable product User and Reference Guides for more information regarding the specific instruction
sets covered by this notice.

Notice revision #20110804

Input Parameters

wantt  (global )
If wantt is non-zero, then the Hessenberg matrix \( A \) is fully updated so that
the quasi-triangular Schur factor may be computed (in cooperation with the
calling function).
If wantt equals zero, then only enough of \( A \) is updated to preserve the
eigenvalues.

wantz  (global )
If wantz is non-zero, then the orthogonal matrix \( Z \) is updated so that the
orthogonal Schur factor may be computed (in cooperation with the calling
function).
If wantz equals zero, then \( z \) is not referenced.

n  (global )
The order of the matrix \( A \) and (if wantz is non-zero) the order of the
orthogonal matrix \( Z \).

ktop, kbot  (global )
It is assumed without a check that either \( kbot = n \) or \( A(kbot+1,kbot)=0 \).
kbot and ktop together determine an isolated block along the diagonal of
the Hessenberg matrix. However, \( A(ktop,ktop-1)=0 \) is not essentially
necessary if wantt is non-zero.

nw  (global )
Deflation window size. \( 1 \leq nw \leq (kbot-ktop+1) \). Normally \( nw \geq 3 \) if p?laqr2 is
called by p?laqr1.

a  (local ) array of size \( ld_a \times LOC(c(n)) \)
The initial \( n \)-by-\( n \) section of \( a \) stores the Hessenberg matrix undergoing
aggressive early deflation.

desca  (global and local) array of size \( dlen_\).
The array descriptor for the distributed matrix \( A \).

iloz, ihiz  (global )
Specify the rows of the matrix \( Z \) to which transformations must be applied if \( \text{wantz} \) is non-zero. \( 1 \leq \text{iloz} \leq \text{ihiz} \leq n \).

\[ z \]

Array of size \( \text{ldd}_z \times \text{LOC}(n) \)

If \( \text{wantz} \) is non-zero, then on output, the orthogonal similarity transformation mentioned above has been accumulated into the matrix \( Z(\text{iloz}:\text{ihiz}, \ kbot: \text{ktop}) \), stored in \( z \), from the right.

If \( \text{wantz} \) is zero, then \( z \) is unreferenced.

\[ \text{descz} \]

(global and local) array of size \( \text{dlen}_z \).

The array descriptor for the distributed matrix \( Z \).

\[ t \]

(local workspace) array of size \( \text{ldt} \times \text{nw} \).

\[ \text{ldt} \]

(local)

The leading dimension of the array \( t \). \( \text{ldt} \geq \text{nw} \).

\[ v \]

(local workspace) array of size \( \text{ldv} \times \text{nw} \).

\[ \text{ldv} \]

(local)

The leading dimension of the array \( v \). \( \text{ldv} \geq \text{nw} \).

\[ \text{wr, wi} \]

(local workspace) array of size \( \text{kbot} \).

\[ \text{work} \]

(local workspace) array of size \( \text{lwork} \).

\[ \text{lwork} \]

(local)

\( \text{work(} \text{lwork} \text{)} \) is a local array and \( \text{lwork} \) is assumed big enough so that \( \text{lwork} \geq \text{nw} \times \text{nw} \).

**OUTPUT Parameters**

\[ a \]

On output \( a \) has been transformed by an orthogonal similarity transformation, perturbed, and returned to Hessenberg form that (it is to be hoped) has some zero subdiagonal entries.

\[ z \]

(global)

The number of unconverged (that is, approximate) eigenvalues returned in \( \text{sr} \) and \( \text{si} \) that may be used as shifts by the calling function.

\[ \text{nd} \]

(global)

The number of converged eigenvalues uncovered by this function.

\[ \text{sr, si} \]

(global) array of size \( \text{kbot} \)

On output, the real and imaginary parts of approximate eigenvalues that may be used for shifts are stored in \( \text{sr}[\text{kbot}-\text{nd}-\text{ns}] \) through \( \text{sr}[\text{kbot}-\text{nd}-1] \) and \( \text{si}[\text{kbot}-\text{nd}-\text{ns}] \) through \( \text{si}[\text{kbot}-\text{nd}-1] \), respectively.
On processor #0, the real and imaginary parts of converged eigenvalues are stored in $sr[kbot-nd]$ through $sr[kbot-1]$ and $si[kbot-nd]$ through $si[kbot-1]$, respectively. On other processors, these entries are set to zero.

p?laqr3
Performs the orthogonal/unitary similarity transformation of a Hessenberg matrix to detect and deflate fully converged eigenvalues from a trailing principal submatrix (aggressive early deflation).

Syntax
void pslaqr3(MKL_INT* wantt, MKL_INT* wantz, MKL_INT* n, MKL_INT* ktop, MKL_INT* kbot, MKL_INT* nw, float* h, MKL_INT* desch, MKL_INT* iloz, MKL_INT* ihiz, float* z, MKL_INT* descz, MKL_INT* ns, MKL_INT* nd, float* sr, float* si, float* v, MKL_INT* descv, MKL_INT* nh, float* t, MKL_INT* desct, MKL_INT* nv, float* wv, MKL_INT* descw, float* work, MKL_INT* lwork, MKL_INT* iwork, MKL_INT* liwork, MKL_INT* reclevel);

void pdlaqr3(MKL_INT* wantt, MKL_INT* wantz, MKL_INT* n, MKL_INT* ktop, MKL_INT* kbot, MKL_INT* nw, double* h, MKL_INT* desch, MKL_INT* iloz, MKL_INT* ihiz, double* z, MKL_INT* descz, MKL_INT* ns, MKL_INT* nd, double* sr, double* si, double* v, MKL_INT* descv, MKL_INT* nh, double* t, MKL_INT* desct, MKL_INT* nv, double* wv, MKL_INT* descw, double* work, MKL_INT* lwork, MKL_INT* iwork, MKL_INT* liwork, MKL_INT* reclevel);

Include Files
• mkl_scalapack.h

Description
This function accepts as input an upper Hessenberg matrix $H$ and performs an orthogonal similarity transformation designed to detect and deflate fully converged eigenvalues from a trailing principal submatrix. On output $H$ is overwritten by a new Hessenberg matrix that is a perturbation of an orthogonal similarity transformation of $H$. It is to be hoped that the final version of $H$ has many zero subdiagonal entries.

Input Parameters
wantt

(global )

If wantt is non-zero, then the Hessenberg matrix $H$ is fully updated so that the quasi-triangular Schur factor may be computed (in cooperation with the calling function).

If wantt equals zero, then only enough of $H$ is updated to preserve the eigenvalues.

wantz

(global )

If wantz is non-zero, then the orthogonal matrix $Z$ is updated so that the orthogonal Schur factor may be computed (in cooperation with the calling function).

If wantz equals zero, then $Z$ is not referenced.
The order of the matrix $H$ and (if $\text{wantz}$ is non-zero), the order of the orthogonal matrix $Z$.

It is assumed that either $k\text{top} = 1$ or $H(k\text{top},k\text{top}-1)=0$. $k\text{bot}$ and $k\text{top}$ together determine an isolated block along the diagonal of the Hessenberg matrix.

It is assumed without a check that either $k\text{bot} = n$ or $H(k\text{bot}+1,k\text{bot})=0$. $k\text{bot}$ and $k\text{top}$ together determine an isolated block along the diagonal of the Hessenberg matrix.

Deflation window size. $1 \leq nw \leq (k\text{bot}-k\text{top}+1)$.

The initial $n$-by-$n$ section of $H$ stores the Hessenberg matrix undergoing aggressive early deflation.

The array descriptor for the distributed matrix $H$.

Specify the rows of the matrix $Z$ to which transformations must be applied if $\text{wantz}$ is non-zero. $1 \leq \text{iloz}\leq \text{ihiz}\leq n$.

Array of size $lld_z \ast LOC_c(n)$

If $\text{wantz}$ is non-zero, then on output, the orthogonal similarity transformation mentioned above has been accumulated into the matrix $Z(\text{iloz}:\text{ihiz},k\text{bot}:k\text{top})$ from the right.

If $\text{wantz}$ is zero, then $z$ is unreferenced.

The array descriptor for the distributed matrix $Z$.

An $nw$-by-$nw$ distributed work array.

The array descriptor for the distributed matrix $V$.

The number of columns of $t$. $nh \geq nw$.

The array descriptor for the distributed matrix $T$. 

The array descriptor for the distributed matrix $V$. 

The array descriptor for the distributed matrix $T$. 

The number of rows of work array `wv` available for workspace. `nv\geq nw`.

`wv`  
(global workspace) array of size `lld_w*LOC_\_`(`nw`)  

`descw`  
(global and local) array of size `dlen_`_.  
The array descriptor for the distributed matrix `wv`.  

`work`  
(local workspace) array of size `lwork`.  

`lwork`  
(local)  
The size of the work array `work (lwork\geq 1)`. `lwork = 2* nw` suffices, but greater efficiency may result from larger values of `lwork`. If `lwork = -1`, then a workspace query is assumed; `p?laqr3` only estimates the optimal workspace size for the given values of `n`, `nw`, `ktop` and `kbot`. The estimate is returned in `work[0]`. No error message related to `lwork` is issued by `xerbla`. Neither `h` nor `z` are accessed.  

`iwork`  
(local workspace) array of size `liwork` 

`liwork`  
(local)  
The length of the workspace array `iwork (liwork\geq 1)`. If `liwork=-1`, then a workspace query is assumed. 

**OUTPUT Parameters**

`h`  
On output `h` has been transformed by an orthogonal similarity transformation, perturbed, and the returned to Hessenberg form that (it is to be hoped) has some zero subdiagonal entries.  

`z`  
IF `wantz` is non-zero, then on output, the orthogonal similarity transformation mentioned above has been accumulated into the matrix `Z (iloz:ihiz, kbot:ktop)` from the right. If `wantz` is zero, then `z` is unreferenced.  

`ns`  
(global)  
The number of unconverged (that is, approximate) eigenvalues returned in `sr` and `si` that may be used as shifts by the calling function.  

`nd`  
(global)  
The number of converged eigenvalues uncovered by this function.  

`sr`, `si`  
(global) array of size `kbot`. The real and imaginary parts of approximate eigenvalues that may be used for shifts are stored in `sr[kbot-nd-ns]` through `sr[kbot-nd-1]` and `si[kbot-nd-ns]` through `si[kbot-nd-1]`, respectively. The real and imaginary parts of converged eigenvalues are stored in `sr[kbot-nd]` through `sr[kbot-1]` and `si[kbot-nd]` through `si[kbot-1]`, respectively.  

`work[0]`  
On exit, if `info = 0`, `work[0]` returns the optimal `lwork`  

`iwork[0]`  
On exit, if `info = 0`, `iwork[0]` returns the optimal `liwork`
See Also for details of ScaLAPACK array descriptor structures and related notations.

p?laqr5
Performs a single small-bulge multi-shift QR sweep.

Syntax

void pslaqr5(mkl_int* wantt, mkl_int* wantz, mkl_int* kacc22, mkl_int* n, mkl_int* ktop, mkl_int* kbot, mkl_int* nshfts, float* sr, float* si, float* h, mkl_int* desch, mkl_int* iloz, mkl_int* ihiz, float* z, mkl_int* descz, float* work, mkl_int* lwork, mkl_int* iwork, mkl_int* liwork);

void pdlaqr5(mkl_int* wantt, mkl_int* wantz, mkl_int* kacc22, mkl_int* n, mkl_int* ktop, mkl_int* kbot, mkl_int* nshfts, double* sr, double* si, double* h, mkl_int* desch, mkl_int* iloz, mkl_int* ihiz, double* z, mkl_int* descz, double* work, mkl_int* lwork, mkl_int* iwork, mkl_int* liwork);

Include Files

• mkl_scalapack.h

Description

This auxiliary function called by p?laqr0 performs a single small-bulge multi-shift QR sweep by chasing separated groups of bulges along the main block diagonal of a Hessenberg matrix $H$.

Input Parameters

wantt

(global) scalar

wantt is non-zero if the quasi-triangular Schur factor is being computed. wantt is set to zero otherwise.

wantz

(global) scalar

wantz is non-zero if the orthogonal Schur factor is being computed. wantz is set to zero otherwise.

kacc22

(global)

Value 0, 1, or 2. Specifies the computation mode of far-from-diagonal orthogonal updates.

= 0: p?laqr5 does not accumulate reflections and does not use matrix-matrix multiply to update far-from-diagonal matrix entries.

= 1: p?laqr5 accumulates reflections and uses matrix-matrix multiply to update the far-from-diagonal matrix entries.

= 2: p?laqr5 accumulates reflections, uses matrix-matrix multiply to update the far-from-diagonal matrix entries, and takes advantage of 2-by-2 block structure during matrix multiplies.

n

(global) scalar

The order of the Hessenberg matrix $H$ and, if wantz is non-zero, the order of the orthogonal matrix $Z$.

ktop, kbot

(global) scalar
These are the first and last rows and columns of an isolated diagonal block upon which the QR sweep is to be applied. It is assumed without a check that either $ktop = 1$ or $H(ktop,ktop-1) = 0$ and either $kbot = n$ or $H(kbot+1,kbot) = 0$.

$nshfts$ (global) scalar

$nshfts$ gives the number of simultaneous shifts. $nshfts$ must be positive and even.

$sr, si$ (global) Array of size $nshfts$

$sr$ contains the real parts and $si$ contains the imaginary parts of the $nshfts$ shifts of origin that define the multi-shift QR sweep.

$h$ (local) Array of size $lld_h * LOC_c(n)$

On input $h$ contains a Hessenberg matrix $H$.

$desc$ (global and local)

array of size $dlen_$. The array descriptor for the distributed matrix $H$.

$iloz, ihiz$ (global)

Specify the rows of the matrix $Z$ to which transformations must be applied if $wantz$ is non-zero. $1 \leq iloz \leq ihiz \leq n$

$z$ (local) array of size $lld_z * LOC_c(n)$

If $wantz$ is non-zero, then the QR Sweep orthogonal similarity transformation is accumulated into the matrix $Z(iloz:ihiz,kbot:ktop)$ from the right. If $wantz$ equals zero, then $z$ is unreferenced.

$descz$ (global and local) array of size $dlen_$. The array descriptor for the distributed matrix $Z$.

$work$ (local workspace) array of size $lwork$

$lwork$ (local)

The size of the $work$ array ($lwork \geq 1$). If $lwork=-1$, then a workspace query is assumed.

$liwork$ (local)

The size of the $iwork$ array ($liwork \geq 1$). If $liwork=-1$, then a workspace query is assumed.

Output Parameters

$h$ A multi-shift QR sweep with shifts $sr(j)+i*si(j)$ is applied to the isolated diagonal block in rows and columns $ktop$ through $kbot$ of the matrix $H$. 

ScaLAPACK Routines
If `wantz` is non-zero, `z` is updated with transformations applied only to the submatrix $Z(ilo:ihiz,kbot:ktop)$.

On exit, if $\text{info} = 0$, `work[0]` returns the optimal $lwork$.

On exit, if $\text{info} = 0$, `iwork[0]` returns the optimal $liwork$.

**p?laqsy**

Scales a symmetric/Hermitian matrix, using scaling factors computed by `p?poequ`.

**Syntax**

```c
void pslaqsy(char *uplo, MKL_INT *n, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *sr, float *sc, float *scond, float *amax, char *equed);
void pdlaqsy(char *uplo, MKL_INT *n, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *sr, double *sc, double *scond, double *amax, char *equed);
void pclaqsy(char *uplo, MKL_INT *n, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *sr, float *sc, float *scond, float *amax, char *equed);
void pzlaqsy(char *uplo, MKL_INT *n, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *sr, double *sc, double *scond, double *amax, char *equed);
```

**Include Files**

- mkl_scalapack.h

**Description**

The `p?laqsy` function equilibrates a symmetric distributed matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ using the scaling factors in the vectors $sr$ and $sc$. The scaling factors are computed by `p?poequ`.

**Input Parameters**

- `uplo`
  (global) Specifies the upper or lower triangular part of the symmetric distributed matrix $\text{sub}(A)$ to be referenced:
  - 'U': Upper triangular part;
  - 'L': Lower triangular part.

- `n`
  (global)
  The order of the distributed matrix $\text{sub}(A)$. $n \geq 0$.

- `a`
  (local).
  Pointer into the local memory to an array of size $lld_a * LOCc(ja+n-1)$.
  On entry, this array contains the local pieces of the distributed matrix $\text{sub}(A)$. On entry, the local pieces of the distributed symmetric matrix $\text{sub}(A)$.
If \( \text{uplo} = 'U' \), the leading \( n \)-by-\( n \) upper triangular part of \( \text{sub}(A) \) contains the upper triangular part of the matrix, and the strictly lower triangular part of \( \text{sub}(A) \) is not referenced.

If \( \text{uplo} = 'L' \), the leading \( n \)-by-\( n \) lower triangular part of \( \text{sub}(A) \) contains the lower triangular part of the matrix, and the strictly upper triangular part of \( \text{sub}(A) \) is not referenced.

\( \text{ia}, \text{ja} \)

(globally)

The row and column indices in the global matrix \( A \) indicating the first row and the first column of the matrix \( \text{sub}(A) \), respectively.

\( \text{desca} \)

(globally and locally) array of size \( \text{dlen}_\cdot \). The array descriptor for the distributed matrix \( A \).

\( \text{sr} \)

(local)

Array of size \( \text{LOCr}(m_a) \). The scale factors for the matrix \( A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+n-1) \). \( \text{sr} \) is aligned with the distributed matrix \( A \), and replicated across every process column. \( \text{sr} \) is tied to the distributed matrix \( A \).

\( \text{sc} \)

(local)

Array of size \( \text{LOCc}(m_a) \). The scale factors for the matrix \( A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+n-1) \). \( \text{sc} \) is aligned with the distributed matrix \( A \), and replicated across every process column. \( \text{sc} \) is tied to the distributed matrix \( A \).

\( \text{scond} \)

(global)

Ratio of the smallest \( \text{sr}[i] \) (respectively \( \text{sc}[j] \)) to the largest \( \text{sr}[i] \) (respectively \( \text{sc}[j] \)), with \( \text{ia} - 1 \leq i < \text{ia} + \text{m} - 1 \) and \( \text{ja} - 1 \leq j < \text{ja} + \text{n} - 1 \).

\( \text{amax} \)

(global)

Absolute value of largest distributed submatrix entry.

**Output Parameters**

\( \text{a} \)

On exit,

if \( \text{equed} = 'Y' \), the equilibrated matrix:

\[
\text{diag}\left(\text{sr}_{\text{ia}}, \ldots, \text{sr}_{\text{ia}+\text{n}-1}\right) \times \text{sub}(A) \times \text{diag}\left(\text{sc}_{\text{ja}}, \ldots, \text{sc}_{\text{ja}+\text{n}-1}\right).
\]

\( \text{equed} \)

(global)

Specifies whether or not equilibration was done.

\( = 'N' \): No equilibration.

\( = 'Y' \): Equilibration was done, that is, \( \text{sub}(A) \) has been replaced by:

\[
\text{diag}\left(\text{sr}_{\text{ia}}, \ldots, \text{sr}_{\text{ia}+\text{n}-1}\right) \times \text{sub}(A) \times \text{diag}\left(\text{sc}_{\text{ja}}, \ldots, \text{sc}_{\text{ja}+\text{n}-1}\right).
\]

**See Also**

Overview for details of ScaLAPACK array descriptor structures and related notations.
p?lared1d
Redistributes an array assuming that the input array, bycol, is distributed across rows and that all process columns contain the same copy of bycol.

Syntax

void pslared1d (MKL_INT *n, MKL_INT *ia, MKL_INT *ja, MKL_INT *desc, float *bycol, float *byall, float *work, MKL_INT *lwork);
void pdlared1d (MKL_INT *n, MKL_INT *ia, MKL_INT *ja, MKL_INT *desc, double *bycol, double *byall, double *work, MKL_INT *lwork);

Include Files

- mkl_scalapack.h

Description

The p?lared1d function redistributes a 1D array. It assumes that the input array bycol is distributed across rows and that all process column contain the same copy of bycol. The output array byall is identical on all processes and contains the entire array.

Input Parameters

np = Number of local rows in bycol()

\( n \) (global)
The number of elements to be redistributed. \( n \geq 0 \).

\( ia, ja \) (global) \( ia, ja \) must be equal to 1.

desc (local) array of size 9. A 2D array descriptor, which describes bycol.

bycol (local).
Distributed block cyclic array of global size \( n \) and of local size \( np \). bycol is distributed across the process rows. All process columns are assumed to contain the same value.

work (local).
size \( lwork \). Used to hold the buffers sent from one process to another.

lwork (local)
The size of the work array. \( lwork \geq \text{numroc}(n, \text{desc}[nb_], 0, 0, npcol) \).

Output Parameters

byall (global).
Global size \( n \), local size \( n \). byall is exactly duplicated on all processes. It contains the same values as bycol, but it is replicated across all processes rather than being distributed.

See Also
Overview for details of ScaLAPACK array descriptor structures and related notations.
p?lared2d
Redistributes an array assuming that the input array
byrow is distributed across columns and that all
process rows contain the same copy of byrow.

Syntax
void pslared2d (MKL_INT *n, MKL_INT *ia, MKL_INT *ja, MKL_INT *desc, float *byrow, 
float *byall, float *work, MKL_INT *lwork);
void pdlared2d (MKL_INT *n, MKL_INT *ia, MKL_INT *ja, MKL_INT *desc, double *byrow, double *byall, double *work, MKL_INT *lwork);

Include Files
• mkl_scalapack.h

Description
The p?lared2d function redistributes a 1D array. It assumes that the input array byrow is distributed across
columns and that all process rows contain the same copy of byrow. The output array byall will be identical
on all processes and will contain the entire array.

Input Parameters
np = Number of local rows in byrow()

  n (global)
  The number of elements to be redistributed. \( n \geq 0 \).

  ia, ja (global) ia, ja must be equal to 1.

  desc (local) array of size dlen_. A 2D array descriptor, which describes byrow.

  byrow (local).
  Distributed block cyclic array of global size \( n \) and of local size \( np \).
  byrow is distributed across the process columns. All process rows are assumed to contain the same value.

  work (local).
  size lwork. Used to hold the buffers sent from one process to another.

  lwork (local) The size of the work array. \( lwork \geq \text{numroc}(n, \text{desc}[\text{nb}], 0, 0, \text{npcol}) \).

Output Parameters
byall (global).
Global size \( n \), local size \( n \). byall is exactly duplicated on all processes. It contains the same values as byrow, but it is replicated across all processes rather than being distributed.

See Also
Overview for details of ScaLAPACK array descriptor structures and related notations.
**p?larf**

Applies an elementary reflector to a general rectangular matrix.

**Syntax**

```c
void pslarf (char *side, MKL_INT *m, MKL_INT *n, float *v, MKL_INT *iv, MKL_INT *jc, MKL_INT *descv, float *incv, float *tau, float *c, MKL_INT *ic, MKL_INT *jc, MKL_INT *descc, float *work);

void pdlarf (char *side, MKL_INT *m, MKL_INT *n, double *v, MKL_INT *iv, MKL_INT *jc, MKL_INT *descv, MKL_INT *incv, double *tau, double *c, MKL_INT *ic, MKL_INT *jc, MKL_INT *descc, double *work);

void pclarf (char *side, MKL_INT *m, MKL_INT *n, MKL_Complex8 *v, MKL_INT *iv, MKL_INT *incv, MKL_Complex8 *tau, MKL_Complex8 *c, MKL_INT *ic, MKL_INT *jc, MKL_INT *descc, MKL_Complex8 *work);

void pzlarf (char *side, MKL_INT *m, MKL_INT *n, MKL_Complex16 *v, MKL_INT *iv, MKL_INT *jc, MKL_INT *descv, MKL_INT *incv, MKL_Complex16 *tau, MKL_Complex16 *c, MKL_INT *ic, MKL_INT *jc, MKL_INT *descc, MKL_Complex16 *work);
```

**Include Files**

- mkl_scalapack.h

**Description**

The p?larf function applies a real/complex elementary reflector $Q$ (or $Q^T$) to a real/complex $m$-by-$n$ distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$, from either the left or the right. $Q$ is represented in the form

$$Q = I - \tau * v * v',$$

where $\tau$ is a real/complex scalar and $v$ is a real/complex vector.

If $\tau = 0$, then $Q$ is taken to be the unit matrix.

**Input Parameters**

- **side**
  - (global).
  - = 'L': form $Q^{*}\text{sub}(C)$,
  - = 'R': form $\text{sub}(C)^{*}Q$, $Q=Q^{T}$.

- **m**
  - (global)
  - The number of rows in the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).

- **n**
  - (global)
  - The number of columns in the distributed submatrix $\text{sub}(A)$. ($n \geq 0$).

- **v**
  - (local).
  - Pointer into the local memory to an array of size $\text{ld}_v * \text{LOC}(n, v)$, containing the local pieces of the global distributed matrix $V$ representing the Householder transformation $Q$,
  - $V(iv:iv+m-1, jv)$ if $\text{side} = 'L$ and $\text{incv} = 1$,
The array \( V \) is the representation of \( Q \). \( V \) is not used if \( \tau = 0 \).

**iv, jv**  
(global) The row and column indices in the global matrix \( V \) indicating the first row and the first column of the matrix sub(\( V \)), respectively.

**descv**  
(global and local) array of size \( dlen_\)_. The array descriptor for the distributed matrix \( V \).

**incv**  
(global)  
The global increment for the elements of \( V \). Only two values of \( incv \) are supported in this version, namely 1 and \( m_v \).

\( incv \) must not be zero.

**tau**  
(local).  
Array of size \( LOCc(jv) \) if \( incv = 1 \), and \( LOCr(iv) \) otherwise. This array contains the Householder scalars related to the Householder vectors.  
\( tau \) is tied to the distributed matrix \( V \).

**c**  
(local).  
Pointer into the local memory to an array of size \( lld_c * LOCc(jc+n-1) \), containing the local pieces of sub(\( C \)).

**ic, jc**  
(global)  
The row and column indices in the global matrix \( C \) indicating the first row and the first column of the matrix sub(\( C \)), respectively.

**descc**  
(global and local) array of size \( dlen_ \)_. The array descriptor for the distributed matrix \( C \).

**work**  
(local).  
Array of size \( lwork \).

If \( incv = 1 \),  
if \( side = 'L' \),  
if \( ivcol = iccol \),  
\( lwork \geq nqc0 \) else  
\( lwork \geq mpc0 + \max(1, nqc0) \) end if  
else if \( side = 'R' \),  
\( lwork \geq nqc0 + \max(\max(1, mpc0), numroc(numroc(n+icoffc,nb_v,0,0,npc0),nb_v,0,0,lcmq)) \) end if  
else if \( incv = m_v \),
if \( \text{side} = 'L', \)

\[
\text{lwork} \geq \text{mpc} 0 + \max\left( \max(1, nqc 0 ), \text{numroc}\left( \text{numroc}(m + \text{iroffc}, \text{mb}_v, 0, 0, \text{nprow}), \text{mb}_v, 0, 0, \text{lcmp}) \right) \right)
\]

else if \( \text{side} = 'R', \)

if \( \text{ivrow} = \text{icrow}, \)

\[
\text{lwork} \geq \text{mpc} 0
\]

else

\[
\text{lwork} \geq nqc 0 + \max(1, \text{mpc} 0 )
\]

end if

end if

end if,

Include Files
- mkl_scalapack.h

Description
The p?larfb function applies a real/complex block reflector $Q$ or its transpose $Q^T$/conjugate transpose $Q^H$ to a real/complex distributed $m$-by-$n$ matrix sub($C$) = $C(ic:ic+m-1, jc:jc+n-1)$ from the left or the right.

Input Parameters

side (global)
- If $side$ = 'L': apply $Q$ or $Q^T$ for real flavors ($Q^H$ for complex flavors) from the Left;
- If $side$ = 'R': apply $Q$ or $Q^T$ for real flavors ($Q^H$ for complex flavors) from the Right.

trans (global)
- If $trans$ = 'N': no transpose, apply $Q$;
  - For real flavors, if $trans$='T': transpose, apply $Q^T$;
  - For complex flavors, if $trans$ = 'C': conjugate transpose, apply $Q^H$;

direct (global) Indicates how $Q$ is formed from a product of elementary reflectors.
- If $direct$ = 'F': $Q = H(1)*H(2)*...*H(k)$ (Forward)
- If $direct$ = 'B': $Q = H(k)*...*H(2)*H(1)$ (Backward)

storev (global)
- Indicates how the vectors that define the elementary reflectors are stored:
  - If $storev$ = 'C': Columnwise
  - If $storev$ = 'R': Rowwise.

m (global)
The number of rows in the distributed matrix sub($C$). ($m \geq 0$).

n (global)
The number of columns in the distributed matrix sub($C$). ($n \geq 0$).

k (global)
The order of the matrix $T$.

v (local).
Pointer into the local memory to an array of size
It contains the local pieces of the distributed vectors $V$ representing the Householder transformation.

If $storev = 'C'$ and $\text{side} = 'L'$,
$$\text{lld}_v \geq \max(1, \text{LOCr}(iv+m-1))$$
if $storev = 'C'$ and $\text{side} = 'R'$,
$$\text{lld}_v \geq \max(1, \text{LOCr}(iv+n-1))$$
if $storev = 'R'$, $\text{lld}_v \geq \text{LOCr}(jv+k-1)$.

($iv, jv$)
The row and column indices in the global matrix $V$ indicating the first row and the first column of the matrix sub($V$), respectively.

($\text{descv}$)
(global and local) array of size $dlen_\cdot$. The array descriptor for the distributed matrix $V$.

($c$)
(local).

Pointer into the local memory to an array of size $\text{lld}_c \ast \text{LOCc}(jc+n-1)$, containing the local pieces of sub($C$).

($ic, jc$)
(global) The row and column indices in the global matrix $C$ indicating the first row and the first column of the matrix sub($C$), respectively.

($\text{descc}$)
(global and local) array of size $dlen_\cdot$. The array descriptor for the distributed matrix $C$.

($\text{work}$)
(local).
Workspace array of size $lwork$.
If $storev = 'C'$,
if $\text{side} = 'L'$,
$$lwork \geq ( nqc0 + mpc0 ) \ast k$$
else if $\text{side} = 'R'$,
$$lwork \geq ( nqc0 + \max( npv0 + \text{numroc}( numroc( n + icoffc, nb_v, 0, 0, npcol ), nb_v, 0, 0, lcmq ), mpc0 ) ) \ast k$$
end if
else if $\text{storev} = 'R'$,
if $\text{side} = 'L'$,
$$lwork \geq ( mpc0 + \max( mqv0 + \text{numroc}( numroc( m + iroffc, mb_v, 0, 0, nprow ), mb_v, 0, 0, lcm ) ), nqc0 ) ) \ast k$$
else if $\text{side} = 'R'$,
$$lwork \geq ( mpc0 + nqc0 ) \ast k$$
end if
end if,

where

\[ \text{lcmq} = \frac{lcm}{ncol} \] with \[ lcm = \text{iclm}(nprow, ncol) \],

\[ \text{iroffv} = \text{mod}(iv-1, mb_v), \text{icoffv} = \text{mod}(jv-1, nb_v), \]

**p?larfc**

Applies the conjugate transpose of an elementary reflector to a general matrix.

**Syntax**

```c
void pclarfc (char *side, MKL_INT *m, MKL_INT *n, MKL_Complex8 *v, MKL_INT *iv, MKL_INT *jv, MKL_INT *descv, MKL_INT *incv, MKL_Complex8 *tau, MKL_Complex8 *c, MKL_INT *ic, MKL_INT *jic, MKL_INT *descic, MKL_Complex8 *work);
void pzlarfc (char *side, MKL_INT *m, MKL_INT *n, MKL_Complex16 *v, MKL_INT *iv, MKL_INT *jv, MKL_INT *descv, MKL_INT *incv, MKL_Complex16 *tau, MKL_Complex16 *c, MKL_INT *ic, MKL_INT *jic, MKL_INT *descic, MKL_Complex16 *work);
```
Include Files
• mkl_scalapack.h

Description
The `p?larfc` function applies a complex elementary reflector $QH$ to a complex $m$-by-$n$ distributed matrix $\text{sub}(C) = C(\text{ic:ic+m-1, jc:jc+n-1})$, from either the left or the right. $Q$ is represented in the form

$$Q = i - \tau v^*v',$$

where $\tau$ is a complex scalar and $v$ is a complex vector.

If $\tau = 0$, then $Q$ is taken to be the unit matrix.

Input Parameters

- **side** (global)
  - if `side = 'L'`: form $QH*\text{sub}(C)$;
  - if `side = 'R'`: form $\text{sub}(C)*QH$.

- **m** (global)
  The number of rows in the distributed matrix $\text{sub}(C)$. ($m \geq 0$).

- **n** (global)
  The number of columns in the distributed matrix $\text{sub}(C)$. ($n \geq 0$).

- **v** (local)
  Pointer into the local memory to an array of size $\text{lld}_v * \text{LOCc}(n_v)$, containing the local pieces of the global distributed matrix $V$ representing the Householder transformation $Q$,

  - $V(\text{iv:iv+m-1, jv})$ if `side = 'L' and incv = 1`,
  - $V(\text{iv, jv:iv+m-1})$ if `side = 'L' and incv = $m_v$,
  - $V(\text{iv:iv+n-1, jv})$ if `side = 'R' and incv = 1`,
  - $V(\text{iv, jv:jv+n-1})$ if `side = 'R' and incv = $m_v$.

  The array $v$ is the representation of $Q$. $v$ is not used if $\tau = 0$.

- **iv, jv** (global)
  The row and column indices in the global matrix $V$ indicating the first row and the first column of the matrix $\text{sub}(V)$, respectively.

- **descv** (global and local) array of size $\text{dlen}_v$. The array descriptor for the distributed matrix $V$.

- **incv** (global)
  The global increment for the elements of $v$. Only two values of $\text{incv}$ are supported in this version, namely 1 and $m_v$.

  $\text{incv}$ must not be zero.

- **tau** (local)
  Array of size $\text{LOCc}(jv)$ if $\text{incv} = 1$, and $\text{LOCr}(iv)$ otherwise. This array contains the Householder scalars related to the Householder vectors.
\( \tau \) is tied to the distributed matrix \( V \).

\( \mathbf{c} \) (local).

Pointer into the local memory to an array of size \( \text{lld}_\mathbf{c} * \text{LOC}c(j+c+n-1) \), containing the local pieces of \( \text{sub}(C) \).

\( \mathbf{ic}, \mathbf{jc} \) (global)

The row and column indices in the global matrix \( C \) indicating the first row and the first column of the matrix \( \text{sub}(C) \), respectively.

\( \text{descc} \) (global and local) array of size \( \text{dlen}_\mathbf{c} \). The array descriptor for the distributed matrix \( C \).

\( \text{work} \) (local).

Workspace array of size \( \text{lwork} \).

If \( \text{incv} = 1 \),

if \( \text{side} = \text{`L'} \),

if \( \text{ivcol} = \text{icc} \),

\( \text{lwork} \geq nqc0 \)

p?larfg
Generates an elementary reflector (Householder matrix).

Syntax
void pslarfg (MKL_INT *n, float *alpha, MKL_INT *iax, MKL_INT *jax, float *x, MKL_INT *ix, MKL_INT *jx, MKL_INT *descx, MKL_INT *incx, float *tau);
void pdlarfg (MKL_INT *n, double *alpha, MKL_INT *iax, MKL_INT *jax, double *x, MKL_INT *ix, MKL_INT *jx, MKL_INT *descx, MKL_INT *incx, double *tau);
void pclarfg (MKL_INT *n, MKL_Complex8 *alpha, MKL_INT *iax, MKL_INT *jax, MKL_Complex8 *x, MKL_INT *ix, MKL_INT *jx, MKL_INT *descx, MKL_INT *incx, MKL_Complex8 *tau);
void pzlarfg (MKL_INT *n, MKL_Complex16 *alpha, MKL_INT *iax, MKL_INT *jax, MKL_Complex16 *x, MKL_INT *ix, MKL_INT *jx, MKL_INT *descx, MKL_INT *incx, MKL_Complex16 *tau);

Include Files
• mkl_scalapack.h

Description
The p?larfg function generates a real/complex elementary reflector $H$ of order $n$, such that

$$H \cdot sub(X) = H \cdot \begin{pmatrix} x(ix, jx) \\ \alpha \end{pmatrix} = \begin{pmatrix} \alpha \\ 0 \end{pmatrix}, \quad H^* \cdot H = I,$$

where $\alpha$ is a scalar (a real scalar - for complex flavors), and sub(X) is an $(n-1)$-element real/complex distributed vector $X(ix:ix+n-2, jx)$ if incx = 1 and $X(ix, jx:jx+n-2)$ if incx = m_x. $H$ is represented in the form
where \( \tau \) is a real/complex scalar and \( v \) is a real/complex \((n-1)\)-element vector. Note that \( H \) is not Hermitian.

If the elements of \( \text{sub}(X) \) are all zero (and \( X(iax, jax) \) is real for complex flavors), then \( \tau = 0 \) and \( H \) is taken to be the unit matrix.

Otherwise \( 1 \leq \text{real}(\tau) \leq 2 \) and \( \text{abs}(\tau-1) \leq 1 \).

**Input Parameters**

\( n \)  
(global)  
The global order of the elementary reflector. \( n \geq 0 \).

\( iax, jax \)  
(global)  
The global row and column indices of \( X(iax, jax) \) in the global matrix \( X \).

\( x \)  
(local).  
Pointer into the local memory to an array of size \( lld_x * \text{LOCc}(n_x) \). This array contains the local pieces of the distributed vector \( \text{sub}(X) \). Before entry, the incremented array \( \text{sub}(X) \) must contain vector \( x \).

\( ix, jx \)  
(global)  
The row and column indices in the global matrix \( X \) indicating the first row and the first column of \( \text{sub}(X) \), respectively.

\( \text{descx} \)  
(global and local)  
Array of size \( dlen_\_ \). The array descriptor for the distributed matrix \( X \).

\( incx \)  
(global)  
The global increment for the elements of \( x \). Only two values of \( incx \) are supported in this version, namely 1 and \( m_\_x \). \( incx \) must not be zero.

**Output Parameters**

\( \alpha \)  
(local)  
On exit, \( \alpha \) is computed in the process scope having the vector \( \text{sub}(X) \).

\( x \)  
(local).  
On exit, it is overwritten with the vector \( v \).

\( \tau \)  
(local).  
Array of size \( \text{LOCc}(jx) \) if \( incx = 1 \), and \( \text{LOCr}(ix) \) otherwise. This array contains the Householder scalars related to the Householder vectors. \( \tau \) is tied to the distributed matrix \( X \).

**See Also**

Overview for details of ScaLAPACK array descriptor structures and related notations.
**p?larft**

Forms the triangular vector $T$ of a block reflector $H=I-V^*TV$. 

**Syntax**

```c
void pslarft (char *direct, char *storev, MKL_INT *n, MKL_INT *k, float *v, MKL_INT *iv, MKL_INT *jv, MKL_INT *descv, float *tau, float *t, float *work);
void pdlarft (char *direct, char *storev, MKL_INT *n, MKL_INT *k, double *v, MKL_INT *iv, MKL_INT *jv, MKL_INT *descv, double *tau, double *t, double *work);
void pclarft (char *direct, char *storev, MKL_INT *n, MKL_INT *k, MKL_Complex8 *v, MKL_INT *iv, MKL_INT *jv, MKL_INT *descv, MKL_Complex8 *tau, MKL_Complex8 *t, MKL_Complex8 *work);
void pzlarft (char *direct, char *storev, MKL_INT *n, MKL_INT *k, MKL_Complex16 *v, MKL_INT *iv, MKL_INT *jv, MKL_INT *descv, MKL_Complex16 *tau, MKL_Complex16 *t, MKL_Complex16 *work);
```

**Include Files**

- mkl_scalapack.h

**Description**

The p?larft function forms the triangular factor $T$ of a real/complex block reflector $H$ of order $n$, which is defined as a product of $k$ elementary reflectors.

If `direct = 'F'`, $H = H(1)H(2)\ldots H(k)$, and $T$ is upper triangular;

If `direct = 'B'`, $H = H(k)H(2)H(1)$, and $T$ is lower triangular.

If `storev = 'C'`, the vector which defines the elementary reflector $H(i)$ is stored in the $i$-th column of the distributed matrix $V$, and $H = I-V^*TV$.

If `storev = 'R'`, the vector which defines the elementary reflector $H(i)$ is stored in the $i$-th row of the distributed matrix $V$, and $H = I-V^*TV$.

**Input Parameters**

- **direct**
  
  Specifies the order in which the elementary reflectors are multiplied to form the block reflector:
  
  - if `direct = 'F'`: $H = H(1)H(2)\ldots H(k)$ (forward)
  - if `direct = 'B'`: $H = H(k)\ldots H(2)H(1)$ (backward).

- **storev**
  
  Specifies how the vectors that define the elementary reflectors are stored (See Application Notes below):
  
  - if `storev = 'C'`: columnwise;
  - if `storev = 'R'`: rowwise.
The order of the block reflector $H$. $n \geq 0$.

The order of the triangular factor $T_i$ is equal to the number of elementary reflectors.

$1 \leq k \leq mb_v (= nb_v)$.

Pointer into the local memory to an array of local size

$\text{LOCr}(iv+n-1) \times \text{LOCc}(jv+k-1)$ if $\text{storev} = 'C'$, and

$\text{LOCr}(iv+k-1) \times \text{LOCc}(jv+n-1)$ if $\text{storev} = 'R'$.

The distributed matrix $V$ contains the Householder vectors. (See Application Notes below).

The row and column indices in the global matrix $V$ indicating the first row and the first column of the matrix $\text{sub}(V)$, respectively.

Array of size $\text{LOCr}(iv+k-1)$ if $\text{incv} = m_v$, and $\text{LOCc}(jv+k-1)$ otherwise. This array contains the Householder scalars related to the Householder vectors.

$\text{tau}$ is tied to the distributed matrix $V$.

Workspace array of size $k^*(k -1)/2$.

Array of size $nb_v \times nb_v$ if $\text{storev} = 'C'$, and $mb_v \times mb_v$ otherwise. It contains the $k$-by-$k$ triangular factor of the block reflector associated with $v$.

If $\text{direct} = 'F'$, $\text{t}$ is upper triangular;

if $\text{direct} = 'B'$, $\text{t}$ is lower triangular.

The shape of the matrix $V$ and the storage of the vectors that define the $H(i)$ is best illustrated by the following example with $n = 5$ and $k = 3$. The elements equal to 1 are not stored; the corresponding array elements are modified but restored on exit. The rest of the array is not used.
See Also
Overview for details of ScaLAPACK array descriptor structures and related notations.

**p?larz**

 Applies an elementary reflector as returned by **p?tzrzf** to a general matrix.

**Syntax**

```c
void pslarz (char *side, MKL_INT *m, MKL_INT *n, MKL_INT *l,
            float *v, MKL_INT *iv, MKL_INT *jv, MKL_INT *descv,

            MKL_INT *jc, MKL_INT *descc, float *work);

void pdlarz (char *side, MKL_INT *m, MKL_INT *n, MKL_INT *l,
            double *v, MKL_INT *iv, MKL_INT *jv, MKL_INT *descv,
            MKL_INT *incv, double *tau, double *c, MKL_INT *ic,
            MKL_INT *jc, MKL_INT *descc, double *work);

void pclarz (char *side, MKL_INT *m, MKL_INT *n, MKL_INT *l,
            MKL_Complex8 *v, MKL_INT *iv, MKL_INT *jv,
            MKL_INT *descv, MKL_INT *incv, MKL_Complex8 *tau,
            MKL_Complex8 *c, MKL_INT *ic, MKL_INT *jc,
            MKL_INT *descc, MKL_Complex8 *work);

void pzlarz (char *side, MKL_INT *m, MKL_INT *n, MKL_INT *l,
            MKL_Complex16 *v, MKL_INT *iv, MKL_INT *jv,
            MKL_INT *descv, MKL_INT *incv, MKL_Complex16 *tau,
            MKL_Complex16 *c, MKL_INT *ic, MKL_INT *jc,
            MKL_INT *descc, MKL_Complex16 *work);
```

**Include Files**

- mkl_scalapack.h

**Description**

The **p?larz** function applies a real/complex elementary reflector $Q$ (or $Q^T$) to a real/complex $m$-by-$n$ distributed matrix $\text{sub}(C) = C(\text{ic:ic+m-1}, \text{jc:jc+n-1})$, from either the left or the right. $Q$ is represented in the form

$$Q = I - \tau v v^\top,$$

where $\tau$ is a real/complex scalar and $v$ is a real/complex vector.

If $\tau = 0$, then $Q$ is taken to be the unit matrix.

$Q$ is a product of $k$ elementary reflectors as returned by **p?tzrzf**.
Input Parameters

\( \text{side} \) (global)

if \( \text{side} = 'L' \): form \( Q^* \text{sub}(C) \),
if \( \text{side} = 'R' \): form \( \text{sub}(C)^*Q \), \( Q = Q^* \) (for real flavors).

\( m \) (global)

The number of rows in the distributed matrix \( \text{sub}(C) \). \( m \geq 0 \).

\( n \) (global)

The number of columns in the distributed matrix \( \text{sub}(C) \). \( n \geq 0 \).

\( l \) (global)

The columns of the distributed matrix \( \text{sub}(A) \) containing the meaningful part of the Householder reflectors. If \( \text{side} = 'L' \), \( m \geq l \geq 0 \), if \( \text{side} = 'R' \), \( n \geq l \geq 0 \).

\( v \) (local).

Pointer into the local memory to an array of size \( \text{ld}_d \times \text{LOCc}(n_v) \) containing the local pieces of the global distributed matrix \( V \) representing the Householder transformation \( Q \),
\( V(iv:iv+l-1, jv) \) if \( \text{side} = 'L' \) and \( \text{incv} = 1 \),
\( V(iv, jv:jv+l-1) \) if \( \text{side} = 'L' \) and \( \text{incv} = m_v \),
\( V(iv:iv+l-1, jv) \) if \( \text{side} = 'R' \) and \( \text{incv} = 1 \),
\( V(iv, jv:jv+l-1) \) if \( \text{side} = 'R' \) and \( \text{incv} = m_v \).

The vector \( v \) in the representation of \( Q \). \( v \) is not used if \( \tau = 0 \).

\( iv, jv \) (global) The row and column indices in the global distributed matrix \( V \) indicating the first row and the first column of the matrix \( \text{sub}(V) \), respectively.

descv (global and local) array of size \( dlen_\). The array descriptor for the distributed matrix \( V \).

\( \text{incv} \) (global)

The global increment for the elements of \( V \). Only two values of \( \text{incv} \) are supported in this version, namely 1 and \( m_v \).

\( \text{incv} \) must not be zero.

\( \tau \) (local)

Array of size \( \text{LOCc}(jv) \) if \( \text{incv} = 1 \), and \( \text{LOCr}(iv) \) otherwise. This array contains the Householder scalars related to the Householder vectors. \( \tau \) is tied to the distributed matrix \( V \).

\( c \) (local).

Pointer into the local memory to an array of size \( \text{ld}_c \times \text{LOCc}(j_c+n-1) \), containing the local pieces of \( \text{sub}(C) \).

\( ic, j_c \) (global)
The row and column indices in the global matrix $C$ indicating the first row and the first column of the matrix sub($C$), respectively.

$\text{descC}$

global and local) array of size $\text{dlen}_\epsilon$. The array descriptor for the distributed matrix $C$.

$\text{work}$

(local).

Array of size $\text{lw}_{\text{ork}}$

If $\text{inc}_{\text{v}} = 1$,

if $\text{side} = 'L$',

if $\text{iv}_{\text{col}} = \text{ic}_{\text{col}}$,

$\text{lw}_{\text{ork}} \geq Nq_{C0}$

else

$\text{lw}_{\text{ork}} \geq Mp_{C0} + \text{max}(1, Nq_{C0})$

end if

else if $\text{side} = 'R$',

$\text{lw}_{\text{ork}} \geq Nq_{C0} + \text{max}(\text{max}(1, Mp_{C0}), \text{numroc}(\text{numroc}(n+ico_{ffc}, nb_{v}, 0,0,npc_{ol}), nb_{v}, 0,0,lcmq))$

end if

else if $\text{inc}_{\text{v}} = m_{v}$,

if $\text{side} = 'L$',

$\text{lw}_{\text{ork}} \geq Mp_{C0} + \text{max}(\text{max}(1, Nq_{C0}), \text{numroc}(\text{numroc}(m+iro_{ffc}, mb_{v}, 0,0,npw_{r}, mb_{v}, 0,0,lcmp)))$

else if $\text{side} = 'R$',

if $\text{iv}_{\text{row}} = \text{ic}_{\text{row}}$,

$\text{lw}_{\text{ork}} \geq Mp_{C0}$

else

$\text{lw}_{\text{ork}} \geq Nq_{C0} + \text{max}(1, Mp_{C0})$

end if

end if

end if.

Here $lcm$ is the least common multiple of $\text{npro}_{w}$ and $\text{npc}_{ol}$ and

$lcm = \text{ilcm}(\text{npro}_{w}, \text{npc}_{ol}), lcm_{\text{p}} = lcm / \text{npro}_{w},$

$lcmq = lcm / \text{npc}_{ol},$

$iro_{ffc} = \text{mod}(ic-1, mb_{c}), ico_{ffc} = \text{mod}(jc-1, nb_{c})$, $ic_{\text{row}} = \text{indxg2p}(ic, mb_{c}, \text{my}_{\text{row}}, rsr_{c}_{c}, npw_{r})$, $ic_{\text{col}} = \text{indxg2p}(jc, nb_{c}, \text{my}_{\text{col}}, csr_{c}_{c}, npc_{ol})$, $mpc_{0} = \text{numroc}(m+iro_{ffc}, mb_{c}, \text{my}_{\text{row}}, ic_{\text{row}}, npw_{r})$, $nqc_{0} = \text{numroc}(n+ico_{ffc}, nb_{c}, \text{my}_{\text{col}}, ic_{\text{col}}, npc_{ol})$,
ilcm, indxg2p, and numroc are ScaLAPACK tool functions; *myrow, *mycol, *nprow, and *npcol can be determined by calling the function blacs_gridinfo.

Output Parameters

\( c \)  

(local).

On exit, sub(\( C \)) is overwritten by the \( Q^{*} \) sub(\( C \)) if \( \text{side} = 'L' \), or sub(\( C \)) * \( Q \) if \( \text{side} = 'R' \).

**p?larzb**

Applies a block reflector or its transpose/conjugate-transpose as returned by **p?tzrzf** to a general matrix.

Syntax

```c
void pslarzb (char *side, char *trans, char *direct, char *storev, MKL_INT *m, MKL_INT *n, MKL_INT *k, MKL_INT *l, float *v, MKL_INT *iv, MKL_INT *jv, MKL_INT *descv, float *t, float *c, MKL_INT *ic, MKL_INT *jc, MKL_INT *descc, float *work );
void pdlarzb (char *side, char *trans, char *direct, char *storev, MKL_INT *m, MKL_INT *n, MKL_INT *k, MKL_INT *l, double *v, MKL_INT *iv, MKL_INT *jv, MKL_INT *descv, double *t, double *c, MKL_INT *ic, MKL_INT *jc, MKL_INT *descc, double *work );
void pclarzb (char *side, char *trans, char *direct, char *storev, MKL_INT *m, MKL_INT *n, MKL_INT *k, MKL_INT *l, MKL_Complex8 *v, MKL_INT *iv, MKL_INT *jv, MKL_INT *descv, MKL_Complex8 *t, MKL_Complex8 *c, MKL_INT *ic, MKL_INT *jc, MKL_INT *descc, MKL_Complex8 *work );
void pzlarzb (char *side, char *trans, char *direct, char *storev, MKL_INT *m, MKL_INT *n, MKL_INT *k, MKL_INT *l, MKL_Complex16 *v, MKL_INT *iv, MKL_INT *jv, MKL_INT *descv, MKL_Complex16 *t, MKL_Complex16 *c, MKL_INT *ic, MKL_INT *jc, MKL_INT *descc, MKL_Complex16 *work );
```

Include Files

- mkl_scalapack.h

Description

The **p?larzb** function applies a real/complex block reflector \( Q \) or its transpose \( Q^T \) (conjugate transpose \( Q^H \) for complex flavors) to a real/complex distributed \( m \)-by-\( n \) matrix sub(\( C \)) = \( C(ic:ic+m-1, jc:jc+n-1) \) from the left or the right.

\( Q \) is a product of \( k \) elementary reflectors as returned by **p?tzrzf**.

Currently, only \( \text{storev} = 'R' \) and \( \text{direct} = 'B' \) are supported.
Input Parameters

side  
(if global)
if side = 'L': apply Q or $Q^T$ ($Q^H$ for complex flavors) from the Left;
if side = 'R': apply Q or $Q^T$ ($Q^H$ for complex flavors) from the Right.

trans  
(if global)
if trans = 'N': No transpose, apply Q;
If trans='T': Transpose, apply $Q^T$ (real flavors);
If trans='C': Conjugate transpose, apply $Q^H$ (complex flavors).

direct  
(if global)
Indicates how $H$ is formed from a product of elementary reflectors.
if direct = 'F': $H = H(1)*H(2)*...*H(k) - forward (not supported) ;
if direct = 'B': $H = H(k)*...*H(2)*H(1) - backward.$

storev  
(if global)
Indicates how the vectors that define the elementary reflectors are stored:
if storev = 'C': columnwise (not supported ).
if storev = 'R': rowwise.

m  
(if global)
The number of rows in the distributed submatrix sub(C). ($m \geq 0$).

n  
(if global)
The number of columns in the distributed submatrix sub(C). ($n \geq 0$).

k  
(if global)
The order of the matrix $T$. (= the number of elementary reflectors whose product defines the block reflector).

l  
(if global)
The columns of the distributed submatrix sub(A) containing the meaningful part of the Householder reflectors.
If side = 'L', $m \geq l \geq 0$,
if side = 'R', $n \geq l \geq 0$.

v  
(if local).
Pointer into the local memory to an array of size $lld_v * LOCr(jv+m-1)$ if side = 'L', $lld_v * LOCC(jv+m-1)$ if side = 'R'.
It contains the local pieces of the distributed vectors $V$ representing the Householder transformation as returned by p?tzrzf.

$lld_v \geq LOCr(iv+k-1)$.

iv, jv  
(if global)
The row and column indices in the global matrix $V$ indicating the first row and the first column of the submatrix sub($V$), respectively.

$\text{descv}$ (global and local) array of size $dlen_$. The array descriptor for the distributed matrix $V$.

$t$ (local)

Array of size $mb_v*mb_v$.

The lower triangular matrix $T$ in the representation of the block reflector.

$c$ (local).

Pointer into the local memory to an array of size $lld_c * \text{LOCc}(jc+n-1)$.

On entry, the $m$-by-$n$ distributed matrix sub(C).

$ic, jc$ (global)

The row and column indices in the global matrix $C$ indicating the first row and the first column of the submatrix sub(C), respectively.

$\text{descc}$ (global and local) array of size $dlen_$. The array descriptor for the distributed matrix $C$.

$\text{work}$ (local).

Array of size $lwork$.

If $\text{storev} = 'C'$,

if $\text{side} = 'L'$,

$lwork \geq (nqc0 + mpc0) * k$

else if $\text{side} = 'R'$,

$lwork \geq (nqc0 + \max(npv0 + \text{numroc}(n+icoffc, nb_v, 0, 0, npcol), nb_v, 0, 0, lcmq), mpc0)) * k$

end if

else if $\text{storev} = 'R'$,

if $\text{side} = 'L'$,

$lwork \geq (mpc0 + \max(mqv0 + \text{numroc}(m+iroffc, mb_v, 0, 0, nprow), mb_v, 0, 0, lcmq), nqc0)) * k$

else if $\text{side} = 'R'$,

$lwork \geq (mpc0 + nqc0) * k$

end if

end if.

Here $lcmq = lcm/npcol$ with $lcm = iclm(nprow, npc0)$,

$\text{iroffv} = \text{mod}(iv-1, mb_v), \text{icoffv} = \text{mod}(jv-1, nb_v)$,

$\text{ivrow} = \text{indxg2p}(iv, mb_v, myrow, rsrc_v, nprow),$. 

1605
ivcol = indxg2p(jv, nb_v, mycol, csrcc_v, npcol),
mqv0 = numroc(m+icoffv, nb_v, mycol, ivcol, npcol),
npv0 = numroc(n+iroffv, mb_v, myrow, ivrow, nprow),
iroffc = mod(ic-1, mb_c), icoffc = mod(jc-1, nb_c),
icrow = indxg2p(ic, mb_c, myrow, rsrcc_c, nprow),
iccol = indxg2p(jc, nb_c, mycol, csrcc_c, npcol),
mpc0 = numroc(m+iroffc, mb_c, myrow, icrow, nprow),
npc0 = numroc(n+icoffc, mb_c, myrow, icrow, nprow),
nqc0 = numroc(n+icoffc, nb_c, mycol, iccol, npcol),
ilcm, indxg2p, and numroc are ScaLAPACK tool functions; myrow, mycol, nprow, and npcol can be determined by calling the function blacs_gridinfo.

Output Parameters

\( c \) (local).
On exit, sub(C) is overwritten by the \( Q^*\text{sub(C)} \), or \( Q'^*\text{sub(C)} \), or \( \text{sub(C)}*Q \), or \( \text{sub(C)}*Q' \), where \( Q' \) is the transpose (conjugate transpose) of \( Q \).

\texttt{p?larzc}
Applies (multiplies by) the conjugate transpose of an elementary reflector as returned by \texttt{p?tzrzf} to a general matrix.

Syntax

\begin{verbatim}
void pclarzc (char *side, MKL_INT *m, MKL_INT *n, MKL_INT *l, MKL_Complex8 *v, MKL_INT *iv, MKL_INT *jv, MKL_INT *descv, MKL_INT *incv, MKL_Complex8 *tau, MKL_Complex8 *c, MKL_INT *ic, MKL_INT *jc, MKL_INT *descc, MKL_Complex8 *work);
\end{verbatim}

\begin{verbatim}
void pzlarzc (char *side, MKL_INT *m, MKL_INT *n, MKL_INT *l, MKL_Complex16 *v, MKL_INT *iv, MKL_INT *jv, MKL_INT *descv, MKL_INT *incv, MKL_Complex16 *tau, MKL_Complex16 *c, MKL_INT *ic, MKL_INT *jc, MKL_INT *descc, MKL_Complex16 *work);
\end{verbatim}

Include Files

- mkl_scalapack.h

Description

The \texttt{p?larzc} function applies a complex elementary reflector \( Q^H \) to a complex \( m \)-by-\( n \) distributed matrix \( \text{sub}(C) = C(\text{ic}:\text{ic}+m-1, \text{jc}:\text{jc}+n-1) \), from either the left or the right. \( Q \) is represented in the form
\[ Q = i - \tau \cdot v^Ho, \]
where \( \tau \) is a complex scalar and \( v \) is a complex vector.
If \( \tau = 0 \), then \( Q \) is taken to be the unit matrix.
Q is a product of \( k \) elementary reflectors as returned by \( \text{p?tzrf} \).

**Input Parameters**

\( \text{side} \) (global)

- if \( \text{side} = 'L' \): form \( Q^H \text{sub}(C) \);
- if \( \text{side} = 'R' \): form \( \text{sub}(C)Q^H \).

\( m \) (global)

The number of rows in the distributed matrix \( \text{sub}(C) \). \( (m \geq 0) \).

\( n \) (global)

The number of columns in the distributed matrix \( \text{sub}(C) \). \( (n \geq 0) \).

\( l \) (global)

The columns of the distributed matrix \( \text{sub}(A) \) containing the meaningful part of the Householder reflectors.

- If \( \text{side} = 'L' \), \( m \geq l \geq 0 \),
- if \( \text{side} = 'R' \), \( n \geq l \geq 0 \).

\( v \) (local).

Pointer into the local memory to an array of size \( \text{ld}_v \times \text{LOCc}(n_v) \) containing the local pieces of the global distributed matrix \( V \) representing the Householder transformation \( Q \),

- \( V(\text{iv:iv}+l-1, \text{jv}) \) if \( \text{side} = 'L' \) and \( \text{incv} = 1 \),
- \( V(\text{iv}, \text{jv:jv}+l-1) \) if \( \text{side} = 'L' \) and \( \text{incv} = m_v \),
- \( V(\text{iv:iv}+l-1, \text{jv}) \) if \( \text{side} = 'R' \) and \( \text{incv} = 1 \),
- \( V(\text{iv}, \text{jv:jv}+l-1) \) if \( \text{side} = 'R' \) and \( \text{incv} = m_v \).

The vector \( v \) in the representation of \( Q \). \( v \) is not used if \( \tau = 0 \).

\( \text{iv}, \text{jv} \) (global)

The row and column indices in the global matrix \( V \) indicating the first row and the first column of the matrix \( \text{sub}(V) \), respectively.

\( \text{descv} \) (global and local) array of size \( dlen_\)_. The array descriptor for the distributed matrix \( V \).

\( \text{incv} \) (global)

The global increment for the elements of \( V \). Only two values of \( \text{incv} \) are supported in this version, namely 1 and \( m_v \).

\( \text{incv} \) must not be zero.

\( \tau \) (local)

Array of size \( \text{LOCc}(jv) \) if \( \text{incv} = 1 \), and \( \text{LOCr}(iv) \) otherwise. This array contains the Householder scalars related to the Householder vectors.

\( \tau \) is tied to the distributed matrix \( V \).

\( c \) (local).
Pointer into the local memory to an array of size $\text{lld}_c \times \text{LOCc}(\text{jc} + n - 1)$, containing the local pieces of sub($C$).

$ic, jc$

The row and column indices in the global matrix $C$ indicating the first row and the first column of the matrix sub($C$), respectively.

$\text{descc}$ (global and local) array of size $dlen_\text{c}$. The array descriptor for the distributed matrix $C$.

$work$ (local).

If $incv = 1$,
if $side = 'L'$,
if $ivcol = iccol$,
$\text{lwork} \geq nqc0$
else
$\text{lwork} \geq mpc0 + \max(1, nqc0)$
end if
else if $side = 'R'$,
$\text{lwork} \geq nqc0 + \max(1, mpc0), \text{numroc(numroc} (n+icoffc, nb_v, 0, 0, npcol), nb_v, 0, 0, lcmq))$  end if
else if $incv = m_v$,
if $side = 'L'$,
$\text{lwork} \geq mpc0 + \max(1, nqc0), \text{numroc(numroc} (m+iroffc, mb_v, 0, 0, nprow), mb_v, 0, 0, lcm))$
else if $side = 'R'$,
if $ivrow = icrow$,
$\text{lwork} \geq mpc0$
else
$\text{lwork} \geq nqc0 + \max(1, mpc0)$
end if
end if
end if

Here $lcm$ is the least common multiple of $nprow$ and $npcol$;

$lcm = \text{ilcm}(nprow, npcol), lcm = lcm/nprow, lcmq = lcm/npcol,$
$\text{iroffc} = \text{mod}(ic-1, mb_c), \text{icoffc} = \text{mod}(jc-1, nb_c),$ 
$\text{icrow} = \text{indxg2p}(ic, mb_c, myrow, rsrcc_c, nprow),$ 
$\text{iccol} = \text{indxg2p}(jc, nb_c, mycol, csrrc_c, npcol),$ 
$\text{mpc0} = \text{numroc}(m+iroffc, mb_c, myrow, icrow, nprow),$ 
$nqc0 = \text{numroc}(n+icoffc, nb_c, mycol, iccol, npcol),$ 
$\text{lcm}, \text{indxg2p}, \text{and \ numroc are ScaLAPACK tool functions;}$

$myrow, mycol, nprow, \text{ and npcol can be determined by calling the function blacs_gridinfo}.$

Output Parameters

$c$ (local).
On exit, sub(C) is overwritten by the $Q^H \times \text{sub(C)}$ if side = 'L', or $\text{sub(C)} \times Q^H$ if side = 'R'.

See Also
Overview for details of ScaLAPACK array descriptor structures and related notations.

p?larzt
Forms the triangular factor $T$ of a block reflector $H = I - V^T \times T \times V^H$ as returned by p?tzrzf.

Syntax

```c
void pslarzt (char *direct , char *storev , MKL_INT *n , MKL_INT *k , float *v , MKL_INT *iv , MKL_INT *descv , float *tau , float *t , float *work );
void pdlarzt (char *direct , char *storev , MKL_INT *n , MKL_INT *k , double *v , MKL_INT *iv , MKL_INT *descv , double *tau , double *t , double *work );
void pclarzt (char *direct , char *storev , MKL_INT *n , MKL_INT *k , MKL_Complex8 *v , MKL_INT *iv , MKL_INT *descv , MKL_Complex8 *tau , MKL_Complex8 *t , MKL_Complex8 *work );
void pzlarzt (char *direct , char *storev , MKL_INT *n , MKL_INT *k , MKL_Complex16 *v , MKL_INT *iv , MKL_INT *descv , MKL_Complex16 *tau , MKL_Complex16 *t , MKL_Complex16 *work );
```

Include Files

- mkl_scalapack.h

Description
The p?larzt function forms the triangular factor $T$ of a real/complex block reflector $H$ of order greater than $n$, which is defined as a product of $k$ elementary reflectors as returned by p?tzrzf.

If direct = 'F', $H = H(1) \times H(2) \times \ldots \times H(k)$, and $T$ is upper triangular;
If direct = 'B', $H = H(k) \times \ldots \times H(2) \times H(1)$, and $T$ is lower triangular.

If storev = 'C', the vector which defines the elementary reflector $H(i)$, is stored in the $i$-th column of the array $v$, and $H = i-v \times t \times v'$.
If storev = 'R', the vector, which defines the elementary reflector $H(i)$, is stored in the $i$-th row of the array $v$, and $H = i-v^T \times t \times v$

Currently, only storev = 'R' and direct = 'B' are supported.

Input Parameters

direct
(global)
Specifies the order in which the elementary reflectors are multiplied to form the block reflector:
if direct = 'F': $H = H(1) \times H(2) \times \ldots \times H(k)$ (Forward, not supported)
if direct = 'B': $H = H(k) \times \ldots \times H(2) \times H(1)$ (Backward).
storev (global)
Specifies how the vectors which defines the elementary reflectors are stored:
if storev = 'C': columnwise (not supported);
if storev = 'R': rowwise.

n (global)
The order of the block reflector $H$. $n \geq 0$.

k (global)
The order of the triangular factor $T$ (= the number of elementary reflectors).
$1 \leq k \leq mb_v (= nb_v)$.

v Pointer into the local memory to an array of local size $\text{LOCr}(iv+k-1) \times \text{LOCc}(jv+n-1)$.
The distributed matrix $V$ contains the Householder vectors. See Application Notes below.

iv, jv (global) The row and column indices in the global matrix $V$ indicating the first row and the first column of the matrix sub($V$), respectively.

descv (local) array of size $dlen_v$. The array descriptor for the distributed matrix $V$.

tau (local)
Array of size $\text{LOCr}(iv+k-1)$ if $\text{incv} = m_v$, and $\text{LOCc}(jv+k-1)$ otherwise. This array contains the Householder scalars related to the Householder vectors.
$\tau$ is tied to the distributed matrix $V$.

work (local).
Workspace array of size $(k*(k-1)/2)$.

Output Parameters

v (local)

Array of size $mb_v*mb_v$. It contains the $k$-by-$k$ triangular factor of the block reflector associated with $v$. $t$ is lower triangular.

Application Notes
The shape of the matrix $V$ and the storage of the vectors which define the $H(i)$ is best illustrated by the following example with $n = 5$ and $k = 3$. The elements equal to 1 are not stored; the corresponding array elements are modified but restored on exit. The rest of the array is not used.
See Also
Overview for details of ScaLAPACK array descriptor structures and related notations.

p?lascl

Multiplies a general rectangular matrix by a real scalar defined as \( C_{to}/C_{from} \).

Syntax

void pslascl (char *type, float *cfrom, float *cto, MKL_INT *m, MKL_INT *n, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_INT *info);

void pdlascl (char *type, double *cfrom, double *cto, MKL_INT *m, MKL_INT *n, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_INT *info);

void pclascl (char *type, float *cfrom, float *cto, MKL_INT *m, MKL_INT *n, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_INT *info);

void pzlascl (char *type, double *cfrom, double *cto, MKL_INT *m, MKL_INT *n, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_INT *info);
Include Files

- mkl_scalapack.h

Description

The p?lascl function multiplies the $m$-by-$n$ real/complex distributed matrix sub($A$) denoting $A(ia:ia+m-1, ja:ja+n-1)$ by the real/complex scalar $cto/cfrom$. This is done without over/underflow as long as the final result $cto*A(i,j)/cfrom$ does not over/underflow. $type$ specifies that sub($A$) may be full, upper triangular, lower triangular or upper Hessenberg.

Input Parameters

$\textit{type}$  
*(global)*  
$\textit{type}$ indicates the storage type of the input distributed matrix.  
if $\textit{type} = 'G'$: sub($A$) is a full matrix,  
if $\textit{type} = 'L'$: sub($A$) is a lower triangular matrix,  
if $\textit{type} = 'U'$: sub($A$) is an upper triangular matrix,  
if $\textit{type} = 'H'$: sub($A$) is an upper Hessenberg matrix.

$\textit{cfrom, cto}$  
*(global)*  
The distributed matrix sub($A$) is multiplied by $cto/cfrom$. $A(i,j)$ is computed without over/underflow if the final result $cto*A(i,j)/cfrom$ can be represented without over/underflow. $cfrom$ must be nonzero.

$m$  
*(global)*  
The number of rows in the distributed matrix sub($A$). ($m \geq 0$).

$n$  
*(global)*  
The number of columns in the distributed matrix sub($A$). ($n \geq 0$).

$a$  
*(local input/local output)*  
Pointer into the local memory to an array of size $lld_a * LOCc(ja+n-1)$. This array contains the local pieces of the distributed matrix sub($A$).

$\textit{ia, ja}$  
*(global)*  
The column and row indices in the global matrix $A$ indicating the first row and column of the matrix sub($A$), respectively.

$\textit{desca}$  
*(global and local)*  
Array of size $dlen_$. The array descriptor for the distributed matrix $A$.

Output Parameters

$a$  
*(local)*  
On exit, this array contains the local pieces of the distributed matrix multiplied by $cto/cfrom$.

$\textit{info}$  
*(local)*  
if $\textit{info} = 0$: the execution is successful.
if $info < 0$: If the $i$-th argument is an array and the $j$-th entry, indexed
$j-1$, had an illegal value, then $info = -(i*100+j)$,
if the $i$-th argument is a scalar and had an illegal value, then $info = -i$.

p?lase2

Initializes an $m$-by-$n$ distributed matrix.

Syntax
void pslase2 (const char* uplo, const MKL_INT* m, const MKL_INT* n, const float* alpha,
const float* beta, float* a, const MKL_INT* ia, const MKL_INT* ja, const MKL_INT* desca);
void pdlase2 (const char* uplo, const MKL_INT* m, const MKL_INT* n, const double* alpha,
const double* beta, double* a, const MKL_INT* ia, const MKL_INT* ja, const MKL_INT* desca);
void pclase2 (const char* uplo, const MKL_INT* m, const MKL_INT* n, const MKL_Complex8* alpha,
const MKL_Complex8* beta, MKL_Complex8* a, const MKL_INT* ia, const MKL_INT* ja, const MKL_INT* desca);
void pzlase2 (const char* uplo, const MKL_INT* m, const MKL_INT* n, const MKL_Complex16* alpha,
const MKL_Complex16* beta, MKL_Complex16* a, const MKL_INT* ia, const MKL_INT* ja, const MKL_INT* desca);

Include Files
• mkl_scalapack.h

Description
p?lase2 initializes an $m$-by-$n$ distributed matrix sub( $A$ ) denoting $A(ia:ia+m-1,ja:ja+n-1)$ to $beta$ on the
diagonal and $alpha$ on the off-diagonals. p?lase2 requires that only the dimension of the matrix operand is
distributed.

Input Parameters

$uplo$ (global)
Specifies the part of the distributed matrix sub( $A$ ) to be set:
= 'U': Upper triangular part is set; the strictly lower triangular part of
sub( $A$ ) is not changed;
= 'L': Lower triangular part is set; the strictly upper triangular part of
sub( $A$ ) is not changed;
Otherwise: All of the matrix sub( $A$ ) is set.

$m$ (global)
The number of rows to be operated on i.e the number of rows of the
distributed submatrix sub( $A$ ). $m >= 0$.

$n$ (global)
The number of columns to be operated on i.e the number of columns of the distributed submatrix sub( A ). \( n \geq 0 \).

\textbf{alpha} (global)
The constant to which the off-diagonal elements are to be set.

\textbf{beta} (global)
The constant to which the diagonal elements are to be set.

\textbf{ia} (global)
The row index in the global array \( a \) indicating the first row of sub( A ).

\textbf{ja} (global)
The column index in the global array \( a \) indicating the first column of sub( A ).

\textbf{desca} (global and local)
Array of size \( dlen_\_ \).
The array descriptor for the distributed matrix \( A \).

**Output Parameters**

\textbf{a} (local)
Pointer into the local memory to an array of size \( lld_a \* \text{LOCc(ja+}n-1) \).
This array contains the local pieces of the distributed matrix sub( A ) to be set.

On exit, the leading \( m \)-by-\( n \) submatrix sub( A ) is set as follows:
if \( uplo = 'U' \), \( A(ia+i-1,ja+j-1) = alpha, 1\leq i\leq j-1, 1\leq j\leq n \),
if \( uplo = 'L' \), \( A(ia+i-1,ja+j-1) = alpha, j+1\leq i\leq m, 1\leq j\leq n \),
otherwise, \( A(ia+i-1,ja+j-1) = alpha, 1\leq i\leq m, 1\leq j\leq n, ia+i \neq ja+j \),
and, for all \( uplo \), \( A(ia+i-1,ja+j-1) = beta, 1\leq i\leq \min(m,n) \).

\textbf{p?laset}
Initializes the offdiagonal elements of a matrix to \textit{alpha} and the diagonal elements to \textit{beta}.

**Syntax**

```c
void pslaset (char *uplo, MKL_INT *m, MKL_INT *n, float *alpha, float *beta, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca );
void pdlaset (char *uplo, MKL_INT *m, MKL_INT *n, double *alpha, double *beta, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca );
void pclaset (char *uplo, MKL_INT *m, MKL_INT *n, MKL_Complex8 *alpha, MKL_Complex8 *beta, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca );
void pzlaset (char *uplo, MKL_INT *m, MKL_INT *n, MKL_Complex16 *alpha, MKL_Complex16 *beta, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca );
```
Include Files

- mkl_scalapack.h

Description

The `p?laset` function initializes an \( m \)-by-\( n \) distributed matrix \( A(ia:ia+m-1, ja:ja+n-1) \) to \( beta \) on the diagonal and \( alpha \) on the offdiagonals.

Input Parameters

\( \text{uplo} \) (global)

Specifies the part of the distributed matrix \( A(ia:ia+m-1, ja:ja+n-1) \) to be set:

- if \( \text{uplo} = 'U' \): upper triangular part; the strictly lower triangular part of \( A(ia:ia+m-1, ja:ja+n-1) \) is not changed;
- if \( \text{uplo} = 'L' \): lower triangular part; the strictly upper triangular part of \( A(ia:ia+m-1, ja:ja+n-1) \) is not changed.

Otherwise: all of the matrix \( A(ia:ia+m-1, ja:ja+n-1) \) is set.

\( m \) (global)

The number of rows in the distributed matrix \( A(ia:ia+m-1, ja:ja+n-1) \). \((m \geq 0)\).

\( n \) (global)

The number of columns in the distributed matrix \( A(ia:ia+m-1, ja:ja+n-1) \). \((n \geq 0)\).

\( \alpha \) (global).

The constant to which the offdiagonal elements are to be set.

\( \beta \) (global).

The constant to which the diagonal elements are to be set.

Output Parameters

\( a \) (local).

Pointer into the local memory to an array of size \( \text{lld}_{a} \times \text{LOCc}(ja+n-1) \).

This array contains the local pieces of the distributed matrix \( A(ia:ia+m-1, ja:ja+n-1) \) to be set. On exit, the leading \( m \)-by-\( n \) matrix \( A(ia:ia+m-1, ja:ja+n-1) \) is set as follows:

- if \( \text{uplo} = 'U' \), \( A(ia+i-1, ja+j-1) = \alpha, 1 \leq i \leq j-1, 1 \leq j \leq n \),
- if \( \text{uplo} = 'L' \), \( A(ia+i-1, ja+j-1) = \alpha, j+1 \leq i \leq m, 1 \leq j \leq n \),

otherwise, \( A(ia+i-1, ja+j-1) = \alpha, 1 \leq i \leq m, 1 \leq j \leq n, ia+i \neq ja+j \), and, for all \( \text{uplo}, A(ia+i-1, ja+i-1) = \beta, 1 \leq i \leq \min(m,n) \).

\( \text{ia}, \text{ja} \) (global)

The column and row indices in the distributed matrix \( A(ia:ia+m-1, ja:ja+n-1) \) indicating the first row and column of the matrix \( A(ia:ia+m-1, ja:ja+n-1) \), respectively.

\( \text{desca} \) (global and local)

Array of size \( \text{dlen}_\_ \). The array descriptor for the distributed matrix \( A(ia:ia+m-1, ja:ja+n-1) \).

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.
p?lasmsub
Looks for a small subdiagonal element from the bottom of the matrix that it can safely set to zero.

Syntax

```c
void pslasmsub (const float *a, const MKL_INT *desca, const MKL_INT *i, const MKL_INT *l, MKL_INT *k, const float *smlnum, float *buf, const MKL_INT *lwork);
void pdlasmsub (const double *a, const MKL_INT *desca, const MKL_INT *i, const MKL_INT *l, MKL_INT *k, const double *smlnum, double *buf, const MKL_INT *lwork);
void pclasmsub (const MKL_Complex8 *a, const MKL_INT *desca, const MKL_INT *i, const MKL_INT *l, MKL_INT *k, const float *smlnum, MKL_Complex8 *buf, const MKL_INT *lwork);
void pzlasmsub (const MKL_Complex16 *a, const MKL_INT *desca, const MKL_INT *i, const MKL_INT *l, MKL_INT *k, const double *smlnum, MKL_Complex16 *buf, const MKL_INT *lwork);
```

Include Files

- mkl_scalapack.h

Description

The p?lasmsub function looks for a small subdiagonal element from the bottom of the matrix that it can safely set to zero. This function performs a global maximum and must be called by all processes.

Input Parameters

- **a**  
  (local)  
  Array of size lld_a*LOCc(n_a).  
  On entry, the Hessenberg matrix whose tridiagonal part is being scanned. Unchanged on exit.

- **desca**  
  (global and local)  
  Array of size dlen_. The array descriptor for the distributed matrix A.

- **i**  
  (global)  
  The global location of the bottom of the unreduced submatrix of A. Unchanged on exit.

- **l**  
  (global)  
  The global location of the top of the unreduced submatrix of A. Unchanged on exit.

- **smlnum**  
  (global)  
  On entry, a "small number" for the given matrix. Unchanged on exit. The machine-dependent constants for the stopping criterion.

- **lwork**  
  (local)  
  This must be at least 2*ceil(ceil((i-l)/mb_a )/ lcm(nprow,npcol)). Here lcm is least common multiple and nprowxnpcol is the logical grid size.
Output Parameters

\( k \) (global)

On exit, this yields the bottom portion of the unreduced submatrix. This will satisfy: \( l \leq k \leq i-1 \).

\( buf \) (local)

Array of size \( lwork \).

Application Notes

This routine parallelizes the code from \( ?lahqr \) that looks for a single small subdiagonal element.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

\( p?lasrt \)

Sorts the numbers in an array and the corresponding vectors in increasing order.

Syntax

```c
void pslasrt (const char* id, const MKL_INT* n, float* d, const float* q, const MKL_INT* iq, const MKL_INT* jq, const MKL_INT* descq, float* work, const MKL_INT* lwork, MKL_INT* iwork, MKL_INT* info);
void pdlasrt (const char* id, const MKL_INT* n, double* d, const double* q, const MKL_INT* iq, const MKL_INT* jq, const MKL_INT* descq, double* work, const MKL_INT* lwork, MKL_INT* iwork, MKL_INT* info);
```

Include Files

- mkl_scalapack.h

Description

\( p?lasrt \) sorts the numbers in \( d \) and the corresponding vectors in \( q \) in increasing order.

Input Parameters

\( id \) (global)

= 'I': sort \( d \) in increasing order;

= 'D': sort \( d \) in decreasing order. (NOT IMPLEMENTED YET)

\( n \) (global)

The number of columns to be operated on i.e the number of columns of the distributed submatrix \( \text{sub}(Q) \). \( n \geq 0 \).

\( d \) (global)

Array, size \( (n) \)

\( q \) (local)

Pointer into the local memory to an array of size \( lld_q*LOCc(jq+n-1) \).
This array contains the local pieces of the distributed matrix \( A \) to be copied from.

\( \text{iq} \) (global)
The row index in the global array \( A \) indicating the first row of sub( \( Q \) ).

\( \text{jq} \) (global)
The column index in the global array \( A \) indicating the first column of sub( \( Q \) ).

\( \text{descq} \) (global and local)
Array of size \( \text{dien}_- \).
The array descriptor for the distributed matrix \( A \).

\( \text{work} \) (local)
Array, size (\( lwork \))

\( \text{lwork} \) (local)
The size of the array \( \text{work} \).
\[
\text{lwork} = \text{MAX}( n, \text{NP} \times (\text{NB} + \text{NQ}) ), \quad \text{where} \quad \text{NP} = \text{numroc}( n, \text{NB}, \text{MYROW}, \text{IAROW}, \text{NPROW} ), \quad \text{NQ} = \text{numroc}( n, \text{NB}, \text{MYCOL}, \text{DESCQ}(\text{csrc}_-), \text{NPCOL} ).
\]
\( \text{numroc} \) is a ScaLAPACK tool function.

\( \text{iwork} \) (local)
Array, size (\( liwork \))

\( \text{liwork} \) (local)
The size of the array \( \text{iwork} \).
\[
\text{liwork} = n + 2 \times \text{NB} + 2 \times \text{NPCOL}
\]

**Output Parameters**

\( d \)
On exit, the numbers in \( d \) are sorted in increasing order.

\( \text{info} \) (global)
\[
\text{info} = 0: \text{successful exit}
\]
\[
\text{info} < 0: \text{If the } i\text{-th argument is an array and the } j\text{-th entry had an illegal value, then } \text{info} = -((i \times 100 + j)), \text{if the } i\text{-th argument is a scalar and had an illegal value, then } \text{info} = -i.
\]

**plassq**
*Updates a sum of squares represented in scaled form.*

**Syntax**

void pslassq (MKL_INT *n, float *x, MKL_INT *ix, MKL_INT *jx, MKL_INT *descx, MKL_INT *incx, float *scale, float *sumsq);
void pdlassq (MKL_INT *n, double *x, MKL_INT *ix, MKL_INT *jx, MKL_INT *descx, MKL_INT *incx, double *scale, double *sumsq);
void pclassq (MKL_INT *n, MKL_Complex8 *x, MKL_INT *ix, MKL_INT *jx, MKL_INT *descx, MKL_INT *incx, float *scale, float *sumsq);
void pzlassq (MKL_INT *n, MKL_Complex16 *x, MKL_INT *ix, MKL_INT *jx, MKL_INT *descx, MKL_INT *incx, double *scale, double *sumsq);

Include Files
• mkl_scalapack.h

Description
The plassq function returns the values scl and smsq such that
scl^2 * smsq = x_1^2 + ... + x_n^2 + scale^2 * sumsq,
where
x_i = sub(X) = \text{sub}(X) = X[ix + (jx-1)*m_x + (i-1)*incx] for pslassq/pdlassq,
x_i = sub(X) = \text{abs}(X) = \text{abs}(X[ix + (jx-1)*m_x + (i-1)*incx]) for pclassq/pzlassq.

For real functions pslassq/pdlassq the value of sumsq is assumed to be non-negative and scl returns the value
scl = max(scale, abs(x_i)).

For complex functions pclassq/pzlassq the value of sumsq is assumed to be at least unity and the value of ssq will then satisfy
1.0 \leq ssq \leq sumsq + 2n

Value scale is assumed to be non-negative and scl returns the value
\textbf{scl = max} (scale, abs(\text{real}(x_i)), abs(\text{imag}(x_i)))

For all functions plassq values scale and sumsq must be supplied in scale and sumsq respectively, and scale and sumsq are overwritten by scl and ssq respectively.

All functions plassq make only one pass through the vector sub(X).

Input Parameters

n (global)
The length of the distributed vector sub(x).

x
The array that stores the vector for which a scaled sum of squares is computed:
x[ix + (jx-1)*m_x + i*incx], 0 \leq i < n.

ix (global)
The row index in the global matrix X indicating the first row of sub(X).

jx (global)
The column index in the global matrix X indicating the first column of sub(X).

descx (global and local) array of size dlen_.
The array descriptor for the distributed matrix X.
incx

(global)
The global increment for the elements of $X$. Only two values of $incx$ are supported in this version, namely 1 and $m_x$. The argument $incx$ must not equal zero.

scale

(local).
On entry, the value $scale$ in the equation above.

sumsq

(local)
On entry, the value $sumsq$ in the equation above.

Output Parameters

scale

(local).
On exit, $scale$ is overwritten with $scl$, the scaling factor for the sum of squares.

sumsq

(local).
On exit, $sumsq$ is overwritten with the value $smsq$, the basic sum of squares from which $scl$ has been factored out.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?laswp

Performs a series of row interchanges on a general rectangular matrix.

Syntax

void pslaswp (char *direc, char *rowcol, MKL_INT *n, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_INT *k1, MKL_INT *k2, MKL_INT *ipiv);
void pdlaswp (char *direc, char *rowcol, MKL_INT *n, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_INT *k1, MKL_INT *k2, MKL_INT *ipiv);
void pclaswp (char *direc, char *rowcol, MKL_INT *n, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_INT *k1, MKL_INT *k2, MKL_INT *ipiv);
void pzlaswp (char *direc, char *rowcol, MKL_INT *n, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_INT *k1, MKL_INT *k2, MKL_INT *ipiv);

Include Files

• mkl_scalapack.h

Description

The p?laswp function performs a series of row or column interchanges on the distributed matrix $sub(A)=A(ia:ia+n-1, ja:ja+n-1)$. One interchange is initiated for each of rows or columns $k1$ through $k2$ of $sub(A)$. This function assumes that the pivoting information has already been broadcast along the process row or column. Also note that this function will only work for $k1$-$k2$ being in the same $mb$ (or $nb$) block. If you want to pivot a full matrix, use p?lapiv.
Input Parameters

direc (global)
Specifies in which order the permutation is applied:
= 'F' - forward,
= 'B' - backward.

rowcol (global)
Specifies if the rows or columns are permuted:
= 'R' - rows,
= 'C' - columns.

n (global)
If rowcol='R', the length of the rows of the distributed matrix A(*, ja:ja+n-1) to be permuted;
If rowcol='C', the length of the columns of the distributed matrix A(ia:ia +n-1 , *) to be permuted;

a (local)
Pointer into the local memory to an array of size lld_a * LOCC(n_a). On entry, this array contains the local pieces of the distributed matrix to which the row/columns interchanges will be applied.

ia (global)
The row index in the global matrix A indicating the first row of sub(A).

ja (global)
The column index in the global matrix A indicating the first column of sub(A).

desca (global and local) array of size dlen_.
The array descriptor for the distributed matrix A.

k1 (global)
The first element of ipiv for which a row or column interchange will be done.

k2 (global)
The last element of ipiv for which a row or column interchange will be done.

ipiv (local)
Array of size LOCr(m_a)+mb_a for row pivoting and LOCr(n_a)+nb_a for column pivoting. This array is tied to the matrix A, ipiv[k]=l implies rows (or columns) k+1 and l are to be interchanged, k = 0, 1, ..., size (ipiv) -1.

Output Parameters

A (local)
On exit, the permuted distributed matrix.
p?latra
Computes the trace of a general square distributed matrix.

Syntax
float pslatra (MKL_INT *n, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca);
double pdlatra (MKL_INT *n, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca);
void pclatra (MKL_Complex8 *, MKL_INT *n, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca);
void pzlatra (MKL_Complex16 *, MKL_INT *n, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca);

Include Files
• mkl_scalapack.h

Description
This function computes the trace of an n-by-n distributed matrix sub(A) denoting $A(ia:ia+n-1, ja:ja+n-1)$. The result is left on every process of the grid.

Input Parameters
n (global)
The number of rows and columns to be operated on, that is, the order of the distributed matrix sub(A). $n \geq 0$.
a (local).
Pointer into the local memory to an array of size $lld_a \ast LOCc(ja+n-1)$ containing the local pieces of the distributed matrix, the trace of which is to be computed.
ia, ja (global) The row and column indices respectively in the global matrix A indicating the first row and the first column of the matrix sub(A), respectively.
desca (global and local) array of size $dlen_\_$. The array descriptor for the distributed matrix A.

Output Parameters
val
The value returned by the function.

See Also
Overview for details of ScaLAPACK array descriptor structures and related notations.
**p?latrd**

Reduces the first nb rows and columns of a symmetric/Hermitian matrix A to real tridiagonal form by an orthogonal/unitary similarity transformation.

**Syntax**

```c
void pslatrd (char *uplo, MKL_INT *n, MKL_INT *nb, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *d, float *e, float *tau, float *w, MKL_INT *iw, MKL_INT *jw, MKL_INT *descw, float *work);
```

```c
void pdlatrd (char *uplo, MKL_INT *n, MKL_INT *nb, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *d, double *e, double *tau, double *w, MKL_INT *iw, MKL_INT *jw, MKL_INT *descw, double *work);
```

```c
void pclatrd (char *uplo, MKL_INT *n, MKL_INT *nb, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *d, float *e, MKL_Complex8 *tau, MKL_Complex8 *w, MKL_INT *iw, MKL_INT *jw, MKL_INT *descw, MKL_Complex8 *work);
```

```c
void pzlatrd (char *uplo, MKL_INT *n, MKL_INT *nb, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *d, double *e, MKL_Complex16 *tau, MKL_Complex16 *w, MKL_INT *iw, MKL_INT *jw, MKL_INT *descw, MKL_Complex16 *work);
```

**Include Files**

- mkl_scalapack.h

**Description**

The p?latrd function reduces nb rows and columns of a real symmetric or complex Hermitian matrix sub(A) = A(ia:ia+n-1, ja:ja+n-1) to symmetric/complex tridiagonal form by an orthogonal/unitary similarity transformation Q'*sub(A)*Q, and returns the matrices V and W, which are needed to apply the transformation to the unreduced part of sub(A).

If uplo = U, p?latrd reduces the last nb rows and columns of a matrix, of which the upper triangle is supplied;

if uplo = L, p?latrd reduces the first nb rows and columns of a matrix, of which the lower triangle is supplied.

This is an auxiliary function called by p?sytrd/p?hetrd.

**Input Parameters**

- **uplo**

  (global)

  Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix sub(A) is stored:

  = 'U': Upper triangular

  = L: Lower triangular.

- **n**

  (global)

  The number of rows and columns to be operated on, that is, the order of the distributed matrix sub(A). n ≥ 0.

- **nb**

  (global)

  The number of rows and columns to be reduced.
**a**
Pointer into the local memory to an array of size \( lld_a \ast LOCc(ja+n-1) \).

On entry, this array contains the local pieces of the symmetric/Hermitian distributed matrix sub(\( A \)).

If \( uplo = 'U' \), the leading \( n \)-by-\( n \) upper triangular part of sub(\( A \)) contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced.

If \( uplo = 'L' \), the leading \( n \)-by-\( n \) lower triangular part of sub(\( A \)) contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced.

**ia**
(global)
The row index in the global matrix \( A \) indicating the first row of sub(\( A \)).

**ja**
(global)
The column index in the global matrix \( A \) indicating the first column of sub(\( A \)).

**desca**
(global and local) array of size \( dlen_\). The array descriptor for the distributed matrix \( A \).

**iw**
(global)
The row index in the global matrix \( W \) indicating the first row of sub(\( W \)).

**jw**
(global)
The column index in the global matrix \( W \) indicating the first column of sub(\( W \)).

**descw**
(global and local) array of size \( dlen_\). The array descriptor for the distributed matrix \( W \).

**work**
(local)
Workspace array of size \( nb_a \).

**Output Parameters**

**a**
(local)
On exit, if \( uplo = 'U' \), the last \( nb \) columns have been reduced to tridiagonal form, with the diagonal elements overwriting the diagonal elements of sub(\( A \)); the elements above the diagonal with the array \( tau \) represent the orthogonal/unitary matrix \( Q \) as a product of elementary reflectors;

if \( uplo = 'L' \), the first \( nb \) columns have been reduced to tridiagonal form, with the diagonal elements overwriting the diagonal elements of sub(\( A \)); the elements below the diagonal with the array \( tau \) represent the orthogonal/unitary matrix \( Q \) as a product of elementary reflectors.

**d**
(local)
Array of size \( LOCc(ja+n-1) \).

The diagonal elements of the tridiagonal matrix \( T \): \( d[i] = A(i+1,i+1), i = 0, 1, ..., LOCc(ja+n-1)-1 \). \( d \) is tied to the distributed matrix \( A \).
The off-diagonal elements of the tridiagonal matrix $T$:

- $e[i] = A(i+1, i+2)$ if $uplo = 'U'$,
- $e[i] = A(i+2, i+1)$ if $uplo = 'L'$,

$i = 0, 1, ..., LOCc(ja+n-1) - 1$.

$e$ is tied to the distributed matrix $A$.

**Application Notes**

If $uplo = 'U'$, the matrix $Q$ is represented as a product of elementary reflectors

$$Q = H(n) \times H(n-1) \times ... \times H(n-nb+1)$$

Each $H(i)$ has the form

$$H(i) = I - \tau \cdot v \cdot v'$$

where $\tau$ is a real/complex scalar, and $v$ is a real/complex vector with $v(i:n) = 0$ and $v(i-1) = 1$; $v(1:i-1)$ is stored on exit in $A(ia:ia-i+1, ja+i)$, and $\tau$ in $tau[ja+i-2]$.

If $uplo = 'L'$, the matrix $Q$ is represented as a product of elementary reflectors

$$Q = H(1) \times H(2) \times ... \times H(nb)$$

Each $H(i)$ has the form

$$H(i) = I - \tau \cdot v \cdot v'$$

where $\tau$ is a real/complex scalar, and $v$ is a real/complex vector with $v(1:i) = 0$ and $v(i+1) = 1$; $v(i+2: n)$ is stored on exit in $A(ia+i+1: ia+n-1, ja+i-1)$, and $\tau$ in $tau[ja+i-2]$.

The elements of the vectors $v$ together form the $n$-by-$nb$ matrix $V$ which is needed, with $W$, to apply the transformation to the unreduced part of the matrix, using a symmetric/Hermitian rank-2k update of the form:

$\mathsf{sub}(A) := \mathsf{sub}(A) - vw' - wv'$.

The contents of $a$ on exit are illustrated by the following examples with

$n = 5$ and $nb = 2$: 

$$
\begin{array}{cccc}
\vdots & \vdots & \vdots & \vdots \\

\tau_1 & \vdots & \vdots & \vdots \\
\vdots & \vdots & \vdots & \vdots \\
\vdots & \vdots & \vdots & \vdots \\
\vdots & \vdots & \vdots & \vdots \\
\tau_2 & \vdots & \vdots & \vdots \\
\vdots & \vdots & \vdots & \vdots \\
\vdots & \vdots & \vdots & \vdots \\
\vdots & \vdots & \vdots & \vdots \\
\tau_3 & \vdots & \vdots & \vdots \\
\vdots & \vdots & \vdots & \vdots \\
\vdots & \vdots & \vdots & \vdots \\
\vdots & \vdots & \vdots & \vdots \\
\tau_4 & \vdots & \vdots & \vdots \\
\vdots & \vdots & \vdots & \vdots \\
\vdots & \vdots & \vdots & \vdots \\
\vdots & \vdots & \vdots & \vdots \\
\tau_5 & \vdots & \vdots & \vdots \\
\end{array}
$$
where \( d \) denotes a diagonal element of the reduced matrix, \( a \) denotes an element of the original matrix that is unchanged, and \( v_i \) denotes an element of the vector defining \( H(i) \).

### p?latrs

Solves a triangular system of equations with the scale factor set to prevent overflow.

**Syntax**

```c
void pslatrs (char *uplo, char *trans, char *diag, char *normin, MKL_INT *n, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *x, MKL_INT *ix, MKL_INT *jx, MKL_INT *descx, float *scale, float *cnorm, float *work);

void pdlatrs (char *uplo, char *trans, char *diag, char *normin, MKL_INT *n, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *x, MKL_INT *ix, MKL_INT *jx, MKL_INT *descx, double *scale, double *cnorm, double *work);

void pclatrs (char *uplo, char *trans, char *diag, char *normin, MKL_INT *n, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_Complex8 *x, MKL_INT *ix, MKL_INT *jx, MKL_INT *descx, float *scale, float *cnorm, MKL_Complex8 *work);

void pzlatrs (char *uplo, char *trans, char *diag, char *normin, MKL_INT *n, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_Complex16 *x, MKL_INT *ix, MKL_INT *jx, MKL_INT *descx, double *scale, double *cnorm, MKL_Complex16 *work);
```

**Include Files**

- mkl_scalapack.h

**Description**

The p?latrs function solves a triangular system of equations \( Ax = sb \), \( A^T x = sb \) or \( A^H x = sb \), where \( s \) is a scale factor set to prevent overflow. The description of the function will be extended in the future releases.

**Input Parameters**

- **uplo**

  Specifies whether the matrix \( A \) is upper or lower triangular.
= 'U': Upper triangular
= 'L': Lower triangular

\textit{trans}

Specifies the operation applied to $Ax$.
= 'N': Solve $Ax = s*b$ (no transpose)
= 'T': Solve $A^\top x = s*b$ (transpose)
= 'C': Solve $A^H x = s*b$ (conjugate transpose),

where $s$ - is a scale factor

\textit{diag}

Specifies whether or not the matrix $A$ is unit triangular.
= 'N': Non-unit triangular
= 'U': Unit triangular

\textit{normin}

Specifies whether $cnorm$ has been set or not.
= 'Y': $cnorm$ contains the column norms on entry;
= 'N': $cnorm$ is not set on entry. On exit, the norms will be computed and stored in $cnorm$.

\textbf{n}

The order of the matrix $A$. $n \geq 0$

\textbf{a}

Array of size $lda* n$. Contains the triangular matrix $A$.

If $\text{uplo} = \text{U}$, the leading $n$-by-$n$ upper triangular part of the array $a$ contains the upper triangular matrix, and the strictly lower triangular part of $a$ is not referenced.

If $\text{uplo} = \text{L}$, the leading $n$-by-$n$ lower triangular part of the array $a$ contains the lower triangular matrix, and the strictly upper triangular part of $a$ is not referenced.

If $\text{diag} = \text{U}$, the diagonal elements of $a$ are also not referenced and are assumed to be 1.

\textbf{ia, ja}

(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the submatrix $A$, respectively.

\textbf{desca}

(global and local) array of size $dlen_\text{a}$. The array descriptor for the distributed matrix $A$.

\textbf{x}

Array of size $n$. On entry, the right hand side $b$ of the triangular system.

\textbf{ix}

(global).The row index in the global matrix $X$ indicating the first row of sub($X$).

\textbf{jx}

(global)

The column index in the global matrix $X$ indicating the first column of sub($X$).

\textbf{descx}

(global and local)

Array of size $dlen_\text{x}$. The array descriptor for the distributed matrix $X$. 
cnorm

Array of size n. If normin = 'Y', cnorm is an input argument and cnorm[j]
contains the norm of the off-diagonal part of the (j+1)-th column of the
matrix A, j=0, 1, ..., n-1. If trans = 'N', cnorm[j] must be greater than or
equal to the infinity-norm, and if trans = 'T' or 'C', cnorm[j] must be
greater than or equal to the 1-norm.

work

(local).
Temporary workspace.

Output Parameters

x

On exit, x is overwritten by the solution vector x.

scale

Array of size lda* n. The scaling factor s for the triangular system as
described above.

If scale = 0, the matrix A is singular or badly scaled, and the vector x is
an exact or approximate solution to Ax = 0.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?latrz

Reduces an upper trapezoidal matrix to upper
triangular form by means of orthogonal/unitary
transformations.

Syntax

void pslatrz (MKL_INT *m, MKL_INT *n, MKL_INT *l, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *tau, float *work);
void pdlatrz (MKL_INT *m, MKL_INT *n, MKL_INT *l, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *tau, double *work);
void pclatrz (MKL_INT *m, MKL_INT *n, MKL_INT *l, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_Complex8 *tau, MKL_Complex8 *work);
void pzlatrz (MKL_INT *m, MKL_INT *n, MKL_INT *l, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_Complex16 *tau, MKL_Complex16 *work);

Include Files

• mkl_scalapack.h

Description

The p?latrz function reduces the m-by-n (m ≤ n) real/complex upper trapezoidal matrix sub(A) =
[A(ia:ia+m-1, ja:ja+m-1)A(ia:ia+m-1, ja+n-l:ja+n-l)] to upper triangular form by means of
orthogonal/unitary transformations.

The upper trapezoidal matrix sub(A) is factored as
sub(A) = ( R 0 )*Z,

where Z is an n-by-n orthogonal/unitary matrix and R is an m-by-m upper triangular matrix.
Input Parameters

\( m \) (global)
The number of rows in the distributed matrix \( \text{sub}(A) \). \( m \geq 0 \).

\( n \) (global)
The number of columns in the distributed matrix \( \text{sub}(A) \). \( n \geq 0 \).

\( l \) (global)
The number of columns of the distributed matrix \( \text{sub}(A) \) containing the meaningful part of the Householder reflectors. \( l > 0 \).

\( a \) (local)
Pointer into the local memory to an array of size \( \text{lld}_a \ast \text{LOCc}(ja+n-1) \). On entry, the local pieces of the \( m \)-by-\( n \) distributed matrix \( \text{sub}(A) \), which is to be factored.

\( ia \) (global)
The row index in the global matrix \( A \) indicating the first row of \( \text{sub}(A) \).

\( ja \) (global)
The column index in the global matrix \( A \) indicating the first column of \( \text{sub}(A) \).

\( \text{desca} \) (global and local) array of size \( \text{dlen}_a \).
The array descriptor for the distributed matrix \( A \).

\( \text{work} \) (local)
Workspace array of size \( \text{lwork} \).
\( \text{lwork} \geq \text{nq0} + \max(1, \text{mp0}) \), where
\( \text{iroff} = \text{mod}(ia-1, \text{mb}_a) \),
\( \text{icoff} = \text{mod}(ja-1, \text{nb}_a) \),
\( \text{iarow} = \text{indxg2p}(ia, \text{mb}_a, \text{myrow}, \text{rsr}_c_a, \text{npro}_w) \),
\( \text{iacol} = \text{indxg2p}(ja, \text{nb}_a, \text{mycol}, \text{csr}_c_a, \text{npcol}) \),
\( \text{mp0} = \text{numroc}(m+\text{iroff}, \text{mb}_a, \text{myrow}, \text{iarow}, \text{npro}_w) \),
\( \text{nq0} = \text{numroc}(n+\text{icoff}, \text{nb}_a, \text{mycol}, \text{iacol}, \text{npcol}) \),
\( \text{numroc}, \text{indxg2p}, \text{and numroc} \) are ScaLAPACK tool functions; \( \text{myrow}, \text{mycol}, \text{npro}_w, \text{andnpcol} \) can be determined by calling the function \( \text{blacs_gridinfo} \).

Output Parameters

\( a \)
On exit, the leading \( m \)-by-\( m \) upper triangular part of \( \text{sub}(A) \) contains the upper triangular matrix \( R \), and elements \( n-l+1 \) to \( n \) of the first \( m \) rows of \( \text{sub}(A) \), with the array \( \text{tau} \), represent the orthogonal/unitary matrix \( Z \) as a product of \( m \) elementary reflectors.

\( \text{tau} \) (local)
Array of size $\text{LOCr}(ja+m-1)$. This array contains the scalar factors of the elementary reflectors. $\tau$ is tied to the distributed matrix $A$.

**Application Notes**

The factorization is obtained by Householder's method. The $k$-th transformation matrix, $Z(k)$, which is used (or, in case of complex functions, whose conjugate transpose is used) to introduce zeros into the $(m - k + 1)$-th row of $\text{sub}(A)$, is given in the form

$$Z(k) = \begin{bmatrix} I & 0 \\ 0 & T(k) \end{bmatrix},$$

where

$$T(k) = I - \tau u(k) u(k)^\dagger,$$ $$u(k) = \begin{bmatrix} 1 \\ 0 \\ z(k) \end{bmatrix}$$

$\tau$ is a scalar and $z(k)$ is an $(n-m)$-element vector. $\tau$ and $z(k)$ are chosen to annihilate the elements of the $k$-th row of $\text{sub}(A)$. The scalar $\tau$ is returned in the $k$-th element of $\tau$, indexed $k-1$, and the vector $u(k)$ in the $k$-th row of $\text{sub}(A)$, such that the elements of $z(k)$ are in $A(k, m+1), \ldots, A(k, n)$. The elements of $R$ are returned in the upper triangular part of $\text{sub}(A)$.

$Z$ is given by

$$Z = Z(1)Z(2)\ldots Z(m).$$

**See Also**

Overview for details of ScaLAPACK array descriptor structures and related notations.

**p?lauu2**

*Computes the product $U^*U'$ or $L'*L$, where $U$ and $L$ are upper or lower triangular matrices (local unblocked algorithm).*

**Syntax**

```c
void pslauu2 (char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
void pdlauu2 (char *uplo , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
void pclauu2 (char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
void pzlauu2 (char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
```

**Include Files**

- mkl_scalapack.h

**Description**

The p?lauu2 function computes the product $U^*U'$ or $L'*L$, where the triangular factor $U$ or $L$ is stored in the upper or lower triangular part of the distributed matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$.

If $\text{uplo} = 'U'$ or '$u'$, then the upper triangle of the result is stored, overwriting the factor $U$ in $\text{sub}(A)$.
If \( uplo = 'L' \) or \( 'l' \), then the lower triangle of the result is stored, overwriting the factor \( L \) in \( \text{sub}(A) \).

This is the unblocked form of the algorithm, calling BLAS Level 2 Routines. No communication is performed by this function, the matrix to operate on should be strictly local to one process.

**Input Parameters**

- \( \text{uplo} \) (global)
  
  Specifies whether the triangular factor stored in the matrix \( \text{sub}(A) \) is upper or lower triangular:
  
  \( = 'U' \): upper triangular

  \( = 'L' \): lower triangular.

- \( n \) (global)
  
  The number of rows and columns to be operated on, that is, the order of the triangular factor \( U \) or \( L \). \( n \geq 0 \).

- \( a \) (local)
  
  Pointer into the local memory to an array of size \( \text{lld}_a * \text{LOCc}(ja+n-1) \). On entry, the local pieces of the triangular factor \( U \) or \( L \).

- \( \text{ia} \) (global)
  
  The row index in the global matrix \( A \) indicating the first row of \( \text{sub}(A) \).

- \( \text{ja} \) (global)
  
  The column index in the global matrix \( A \) indicating the first column of \( \text{sub}(A) \).

- \( \text{desca} \) (global and local) array of size \( \text{dlen}_a \). The array descriptor for the distributed matrix \( A \).

**Output Parameters**

- \( a \) (local)
  
  On exit, if \( \text{uplo} = 'U' \), the upper triangle of the distributed matrix \( \text{sub}(A) \) is overwritten with the upper triangle of the product \( U^*U \); if \( \text{uplo} = 'L' \), the lower triangle of \( \text{sub}(A) \) is overwritten with the lower triangle of the product \( L^*L \).

**See Also**

**Overview** for details of ScaLAPACK array descriptor structures and related notations.

**p?lauum**

*Computes the product \( U^*U \) or \( L^*L \), where \( U \) and \( L \) are upper or lower triangular matrices.*

**Syntax**

```c
void pslauum (char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
void pdlauum (char *uplo , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
```
void pclauum (char *uplo, MKL_INT *n, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca);

void pzlauum (char *uplo, MKL_INT *n, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca);

Include Files
• mkl_scalapack.h

Description
The p?lauum function computes the product $U^*U'$ or $L'^*L$, where the triangular factor $U$ or $L$ is stored in the upper or lower triangular part of the matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$.

If $\text{uplo} = 'U'$ or 'u', then the upper triangle of the result is stored, overwriting the factor $U$ in $\text{sub}(A)$. If $\text{uplo} = 'L'$ or 'l', then the lower triangle of the result is stored, overwriting the factor $L$ in $\text{sub}(A)$.

This is the blocked form of the algorithm, calling Level 3 PBLAS.

Input Parameters

$\text{uplo}$ (global)
Specifies whether the triangular factor stored in the matrix $\text{sub}(A)$ is upper or lower triangular:

= 'U': upper triangular
= 'L': lower triangular.

$n$ (global)
The number of rows and columns to be operated on, that is, the order of the triangular factor $U$ or $L$. $n \geq 0$.

$a$ (local)
Pointer into the local memory to an array of size $\text{lld}_a \ast \text{LOCc}(ja+n-1)$. On entry, the local pieces of the triangular factor $U$ or $L$.

$\text{ia}$ (global)
The row index in the global matrix $A$ indicating the first row of $\text{sub}(A)$.

$\text{ja}$ (global)
The column index in the global matrix $A$ indicating the first column of $\text{sub}(A)$.

$\text{desca}$ (global and local) array of size $\text{dlen}_$. The array descriptor for the distributed matrix $A$.

Output Parameters

$a$ (local)
On exit, if $\text{uplo} = 'U'$, the upper triangle of the distributed matrix $\text{sub}(A)$ is overwritten with the upper triangle of the product $U^*U'$; if $\text{uplo} = 'L'$, the lower triangle of $\text{sub}(A)$ is overwritten with the lower triangle of the product $L'^*L$.

p?lawil
Forms the Wilkinson transform.

Syntax

void pslawil (const MKL_INT *ii, const MKL_INT *jj, const MKL_INT *m, const float *a, const MKL_INT *desca, const float *h44, const float *h33, const float *h43h34, float *v);

void pdlawil (const MKL_INT *ii, const MKL_INT *jj, const MKL_INT *m, const double *a, const MKL_INT *desca, const double *h44, const double *h33, const double *h43h34, double *v);

void pclawil (const MKL_INT *ii, const MKL_INT *jj, const MKL_INT *m, const MKL_Complex8 *a, const MKL_INT *desca, const MKL_Complex8 *h44, const MKL_Complex8 *h33, const MKL_Complex8 *h43h34, MKL_Complex8 *v);

void pzlawil (const MKL_INT *ii, const MKL_INT *jj, const MKL_INT *m, const MKL_Complex16 *a, const MKL_INT *desca, const MKL_Complex16 *h44, const MKL_Complex16 *h33, const MKL_Complex16 *h43h34, MKL_Complex16 *v);

Include Files
• mkl_scalapack.h

Description
The p?lawil function gets the transform given by $h_{44}$, $h_{33}$, and $h_{43}h_{34}$ into $v$ starting at row $m$.

Input Parameters

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>

</tbody>
</table>
Output Parameters

\( v \)  
\( (\text{global}) \)  
Array of size 3 that contains the transform on output.

See Also
Overview for details of ScaLAPACK array descriptor structures and related notations.

**p?org2l/p?ung2l**

Generates all or part of the orthogonal/unitary matrix \( Q \) from a QL factorization determined by \( p?geqlf \) (unblocked algorithm).

**Syntax**

```c
void psorg2l (MKL_INT *m, MKL_INT *n, MKL_INT *k, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *tau, float *work, MKL_INT *lwork, MKL_INT *info);
void pdorg2l (MKL_INT *m, MKL_INT *n, MKL_INT *k, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *tau, double *work, MKL_INT *lwork, MKL_INT *info);
void pcung2l (MKL_INT *m, MKL_INT *n, MKL_INT *k, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_Complex8 *tau, MKL_Complex8 *work, MKL_INT *lwork, MKL_INT *info);
void pzung2l (MKL_INT *m, MKL_INT *n, MKL_INT *k, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_Complex16 *tau, MKL_Complex16 *work, MKL_INT *lwork, MKL_INT *info);
```

**Include Files**

- mkl_scalapack.h

**Description**

The \( p?org2l/p?ung2l \) function generates an \( m \)-by-\( n \) real/complex distributed matrix \( Q \) denoting \( A(ia:ia+m-1, ja:ja+n-1) \) with orthonormal columns, which is defined as the last \( n \) columns of a product of \( k \) elementary reflectors of order \( m \):

\[
Q = H(k)*...*H(2)*H(1)
\]

as returned by \( p?geqlf \).

**Input Parameters**

\( m \)  
\( (\text{global}) \)  
The number of rows in the distributed submatrix \( Q \). \( m \geq 0 \).

\( n \)  
\( (\text{global}) \)  
The number of columns in the distributed submatrix \( Q \). \( m \geq n \geq 0 \).

\( k \)  
\( (\text{global}) \)  
The number of elementary reflectors whose product defines the matrix \( Q \). \( n \geq k \geq 0 \).

\( a \)  
Pointer into the local memory to an array of size \( lld_a \times LOCC(ja+n-1) \).
On entry, the $j$-th column of the matrix stored in $a$ must contain the vector that defines the elementary reflector $H(j)$, $ja+n-k \leq j \leq ja+n-k$, as returned by p?geqlf in the $k$ columns of its distributed matrix argument $A(ia:,ja+n-k:ja+n-1)$.

$ia$ (global)
The row index in the global matrix $A$ indicating the first row of sub($A$).

$ja$ (global)
The column index in the global matrix $A$ indicating the first column of sub($A$).

desca (global and local) array of size $dlen_\$. The array descriptor for the distributed matrix $A$.

tau (local)
Array of size $\text{LOCc}(ja+n-1)$.
$\tau[j]$ contains the scalar factor of the elementary reflector $H(j+1)$, $j = 0, 1, \ldots, \text{LOCc}(ja+n-1)-1$, as returned by p?geqlf.

work (local)
Workspace array of size $lwork$.

lwork (local or global)
The size of the array work.
$lwork$ is local input and must be at least $lwork \geq mpa_0 + \max(1, nqa_0)$, where

\begin{align*}
ipa & = \text{mod}(ia-1, mb_a), \\
ic & = \text{mod}(ja-1, nb_a), \\
\text{irow} & = \text{indxg2p}(ia, mb_a, myrow, rsrch_a, nprow), \\
\text{icol} & = \text{indxg2p}(ja, nb_a, mycol, csrch_a, npcol), \\
mpa_0 & = \text{numroc}(m+iroffa, mb_a, myrow, iarow, nprow), \\
nqa_0 & = \text{numroc}(n+icoffa, nb_a, mycol, iacol, npcol).
\end{align*}

indxg2p and numroc are ScaLAPACK tool functions; myrow, mycol, nprow, and npcol can be determined by calling the function blacs_gridinfo.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

$a$
On exit, this array contains the local pieces of the $m$-by-$n$ distributed matrix $Q$.

work
On exit, $\text{work}[0]$ returns the minimal and optimal $lwork$.

info (local)
= 0: successful exit
< 0: if the i-th argument is an array and the j-th entry, indexed j-1, had an illegal value,
then info = -(i*100 +j),

Include Files
• mkl_scalapack.h

Description
The p?org2r/p?ung2r function generates an m-by-n real/complex matrix Q denoting A(ia:ia+m-1, ja:ja+n-1) with orthonormal columns, which is defined as the first n columns of a product of k elementary reflectors of order m:
Q = H(1)*H(2)*...*H(k)
as returned by p?geqrf.

Input Parameters

m (global)
The number of rows in the distributed submatrix Q. m≥ 0.

n (global)
The number of columns in the distributed submatrix Q. m≥ n ≥ 0.
The number of elementary reflectors whose product defines the matrix $Q$. $n \geq k \geq 0$.

$a$

Pointer into the local memory to an array of size $lld_a \cdot \text{LOCc}(ja+n-1)$.

On entry, the $j$-th column of the matrix stored in $a$ must contain the vector that defines the elementary reflector $H(j)$, $ja \leq j \leq ja+k-1$, as returned by $p?geqrf$ in the $k$ columns of its distributed matrix argument $A(ia:*,ja:ja+k-1)$.

$ia$

(global)

The row index in the global matrix $A$ indicating the first row of sub($A$).

$ja$

(global)

The column index in the global matrix $A$ indicating the first column of sub($A$).

$desca$

(global and local) array of size $dlen_\_$. The array descriptor for the distributed matrix $A$.

$tau$

(local)

Array of size $\text{LOCc}(ja+k-1)$.

$tau[j]$ contains the scalar factor of the elementary reflector $H(j+1)$, $j = 0, 1, \ldots, \text{LOCc}(ja+k-1)-1$, as returned by $p?geqrf$. This array is tied to the distributed matrix $A$.

$work$

(local)

Workspace array of size $lwork$.

$lwork$

(local or global)

The size of the array $work$.

$lwork$ is local input and must be at least $lwork \geq mpa0 + \max(1, nqa0)$, where

- $iroffa = \text{mod}(ia-1, mb_a)$, $icoffa = \text{mod}(ja-1, nb_a)$,
- $iarow = \text{indxg2p}(ia, mb_a, myrow, rsra_a, nprow)$,
- $iacol = \text{indxg2p}(ja, nb_a, mycol, rsca_a, npcol)$,
- $mpa0 = \text{numroc}(m+iroffa, mb_a, myrow, iarow, nprow)$,
- $nqa0 = \text{numroc}(n+icoffa, nb_a, mycol, iacol, npcol)$.

$\text{indxg2p}$ and $\text{numroc}$ are ScaLAPACK tool functions; $myrow$, $mycol$, $nprow$, and $npcol$ can be determined by calling the function $\text{blacs_gridinfo}$.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by $pxerbla$. 

---

*ScaLAPACK Routines* 4
Output Parameters

- **a**
  - On exit, this array contains the local pieces of the $m$-by-$n$ distributed matrix $Q$.

- **work**
  - On exit, `work[0]` returns the minimal and optimal `lwork`

- **info**
  - $= 0$: successful exit
  - $< 0$: if the $i$-th argument is an array and the $j$-th entry, indexed $j-1$, had an illegal value,
  - then $info = - (i*100 + j)$,
  - if the $i$-th argument is a scalar and had an illegal value,
  - then $info = -i$.

**p?orgl2/p?ungl2**
Generates all or part of the orthogonal/unitary matrix $Q$ from an LQ factorization determined by `p?gelqf` (unblocked algorithm).

### Syntax

```c
void psorgl2 (MKL_INT *m, MKL_INT *n, MKL_INT *k, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *tau, float *work, MKL_INT *lwork, MKL_INT *info);
void pdorgl2 (MKL_INT *m, MKL_INT *n, MKL_INT *k, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *tau, double *work, MKL_INT *lwork, MKL_INT *info);
void pcungl2 (MKL_INT *m, MKL_INT *n, MKL_INT *k, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_Complex8 *tau, MKL_Complex8 *work, MKL_INT *lwork, MKL_INT *info);
void pzungl2 (MKL_INT *m, MKL_INT *n, MKL_INT *k, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_Complex16 *tau, MKL_Complex16 *work, MKL_INT *lwork, MKL_INT *info);
```

**Include Files**

- `mkl_scalapack.h`

**Description**

The `p?orgl2/p?ungl2` function generates a $m$-by-$n$ real/complex matrix $Q$ denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal rows, which is defined as the first $m$ rows of a product of $k$ elementary reflectors of order $n$

- $Q = H(k)*...*H(2)*H(1)$ (for real flavors),
- $Q = (H(k))^H*...*(H(2))^H*(H(1))^H$ (for complex flavors) as returned by `p?gelqf`.

**Input Parameters**

- **m**
  - (global)
The number of rows in the distributed submatrix $Q. m \geq 0$.

$n$

The number of columns in the distributed submatrix $Q. n \geq m \geq 0$.

$k$

The number of elementary reflectors whose product defines the matrix $Q. m \geq k \geq 0$.

$a$

Pointer into the local memory to an array of size $lld_a \times \text{LOCc}(ja+n-1)$.

On entry, the $i$-th row of the matrix stored in $a$ must contain the vector that defines the elementary reflector $H(i), ia \leq i \leq ia+k-1$, as returned by $p?gelqf$ in the $k$ rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$.

$ia$

The row index in the global matrix $A$ indicating the first row of sub($A$).

$ja$

The column index in the global matrix $A$ indicating the first column of sub($A$).

desca

(global and local) array of size $dlen_. The array descriptor for the distributed matrix $A$.

tau

(local)

Array of size $\text{LOCr}(ja+k-1). \tau[j]$ contains the scalar factor of the elementary reflectors $H(j+1), j = 0, 1, ..., \text{LOCr}(ja+k-1)-1$, as returned by $p?gelqf$. This array is tied to the distributed matrix $A$.

$work$

(local)

Workspace array of size $lwork$.

$lwork$

(local or global)

The size of the array $work$.

$lwork$ is local input and must be at least $lwork \geq nqa0 + \max(1, mpa0)$, where

\[
\begin{align*}
  iroffa &= \text{mod}(ia-1, mb_a), \\
  icoffa &= \text{mod}(ja-1, nb_a), \\
  iarow &= \text{indxg2p}(ia, mb_a, myrow, rsrc_a, nprow), \\
  iacol &= \text{indxg2p}(ja, nb_a, mycol, csrc_a, npcol), \\
  mpa0 &= \text{numroc}(m+iroffa, mb_a, myrow, iarow, nprow), \\
  nqa0 &= \text{numroc}(n+icoffa, nb_a, mycol, iacol, npcol).
\end{align*}
\]

$\text{indxg2p}$ and $\text{numroc}$ are ScaLAPACK tool functions; $myrow, mycol, nprow,$ and $npcol$ can be determined by calling the function $\text{blacs\_gridinfo}$. 

ScaLAPACK Routines
If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

**Output Parameters**

$a$

On exit, this array contains the local pieces of the $m$-by-$n$ distributed matrix $Q$.

$work$

On exit, $work[0]$ returns the minimal and optimal $lwork$.

$info$

(local)

- $0$: successful exit
- $< 0$: if the $i$-th argument is an array and the $j$-th entry, indexed $j-1$, had an illegal value, then $info = -(i*100 +j)$.
- if the $i$-th argument is a scalar and had an illegal value, then $info = -i$.

void pcungr2 (MKL_INT *m, MKL_INT *n, MKL_INT *k, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_Complex8 *tau, MKL_Complex8 *work, MKL_INT *lwork, MKL_INT *info );
void pzungr2 (MKL_INT *m, MKL_INT *n, MKL_INT *k, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_Complex16 *tau, MKL_Complex16 *work, MKL_INT *lwork, MKL_INT *info );
```

**Include Files**

- mkl_scalapack.h

**Description**

The $p?orgr2/p?ungr2$ function generates an $m$-by-$n$ real/complex matrix $Q$ denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal rows, which is defined as the last $m$ rows of a product of $k$ elementary reflectors of order $n$:

$$Q = H(1)H(2)*...*H(k)$$

(for real flavors);
\[ Q = (H(1))^{H}*(H(2))^{H}...*(H(k))^{H} \text{ (for complex flavors) as returned by } \text{pgerqf}. \]

**Input Parameters**

\( m \) (global)

The number of rows in the distributed submatrix \( Q \). \( m \geq 0 \).

\( n \) (global)

The number of columns in the distributed submatrix \( Q \). \( n \geq m \geq 0 \).

\( k \) (global)

The number of elementary reflectors whose product defines the matrix \( Q \). \( m \geq k \geq 0 \).

\( a \)

Point into the local memory to an array of size \( lld_a \times LOCc(ja+n-1) \).

On entry, the \( i \)-th row of the matrix stored in \( a \) must contain the vector that defines the elementary reflector \( H(i) \), \( ia+m-k \leq i \leq ia+m-1 \), as returned by \text{pgerqf} in the \( k \) rows of its distributed matrix argument \( A(ia+m-k:ia+m-1, ja:*). \)

\( ia \) (global)

The row index in the global matrix \( A \) indicating the first row of \( \text{sub}(A) \).

\( ja \) (global)

The column index in the global matrix \( A \) indicating the first column of \( \text{sub}(A) \).

\( \text{desca} \) (global and local) array of size \( dlen_\). The array descriptor for the distributed matrix \( A \).

\( \text{tau} \) (local)

Array of size \( \text{LOCr}(ja+m-1) \). \( \text{tau}[j] \) contains the scalar factor of the elementary reflectors \( H(j+1), j = 0, 1, \ldots, \text{LOCr}(ja+m-1)-1 \), as returned by \text{pgerqf}. This array is tied to the distributed matrix \( A \).

\( \text{work} \) (local)

Workspace array of size \( lwork \).

\( lwork \) (local or global)

The size of the array \( \text{work} \).

\( lwork \) is local input and must be at least \( lwork \geq nqa0 + \max(1, mpa0) \), where \( iroff = \text{mod}(ia-1, mb_a) \), \( icoff = \text{mod}(ja-1, nb_a) \),

\( iarow = \text{indxg2p}(ia, mb_a, myrow, rsrc_a, nprow) \),

\( iacol = \text{indxg2p}(ja, nb_a, mycol, csrc_a, npcol) \),

\( mpa0 = \text{numroc}(m+iroff, mb_a, myrow, iarow, nprow) \),

\( nqa0 = \text{numroc}(n+icoff, nb_a, mycol, iacol, npcol) \).

\text{indxg2p} and \text{numroc} are \text{ScaLAPACK} tool functions; \( \text{myrow, mycol, nprow, and npcol} \) can be determined by calling the function \text{blacs_gridinfo}. 

---

**ScaLAPACK Routines**

4 1641
If \( lwork = -1 \), then \( lwork \) is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by \texttt{pxerbla}.

**Output Parameters**

\( a \)

On exit, this array contains the local pieces of the \( m \)-by-\( n \) distributed matrix \( Q \).

\( \text{work} \)

On exit, \( \text{work}[0] \) returns the minimal and optimal \( lwork \).

\( \text{info} \)

(local)

\[ = 0: \text{successful exit} \]

\[ < 0: \text{if the} \ i\text{-th argument is an array and the} \ j\text{-th entry, indexed} \ j-1, \text{had an illegal value, then} \text{info} = - (i*100 + j) , \]

if the \( i\text{-th argument is a scalar and had an illegal value, then} \text{info} = -i. \]

1642
Description
The function overwrites the general real/complex $m$-by-$n$ distributed matrix sub
\[
(C) = C(\text{ic:ic+m-1,jc:jc+n-1})
\]
with
\[
Q\text{*sub}(C) \text{ if } \text{side} = 'L' \text{ and } \text{trans} = 'N', \text{ or}
\]
\[
Q^T\text{*sub}(C) / Q^H\text{*sub}(C) \text{ if } \text{side} = 'L' \text{ and } \text{trans} = 'T' \text{ (for real flavors) or } \text{trans} = 'C' \text{ (for complex flavors)}, \text{ or}
\]
\[
\text{sub}(C)\text{*}Q \text{ if } \text{side} = 'R' \text{ and } \text{trans} = 'N', \text{ or}
\]
\[
\text{sub}(C)\text{*}Q^T / \text{sub}(C)\text{*}Q^H \text{ if } \text{side} = 'R' \text{ and } \text{trans} = 'T' \text{ (for real flavors) or } \text{trans} = 'C' \text{ (for complex flavors)},
\]
where $Q$ is a real orthogonal or complex unitary distributed matrix defined as the product of $k$ elementary reflectors
\[
Q = H(k)*...*H(2)*H(1)
\]
as returned by \texttt{pgeqlf}. $Q$ is of order $m$ if $\text{side} = 'L'$ and of order $n$ if $\text{side} = 'R'$.

Input Parameters

- \textit{side} (global)
  - $'L'$: apply $Q$ or $Q^T$ for real flavors ($Q^H$ for complex flavors) from the left,
  - $'R'$: apply $Q$ or $Q^T$ for real flavors ($Q^H$ for complex flavors) from the right.

- \textit{trans} (global)
  - $'N'$: apply $Q$ (no transpose)
  - $'T'$: apply $Q^T$ (transpose, for real flavors)
  - $'C'$: apply $Q^H$ (conjugate transpose, for complex flavors)

- \textit{m} (global)
The number of rows in the distributed matrix sub($C$). $m \geq 0$.

- \textit{n} (global)
The number of columns in the distributed matrix sub($C$). $n \geq 0$.

- \textit{k} (global)
The number of elementary reflectors whose product defines the matrix $Q$.
  If $\text{side} = 'L'$, $m \geq k \geq 0$;
  if $\text{side} = 'R'$, $n \geq k \geq 0$.

- \textit{a} (local)
  Pointer into the local memory to an array of size $\text{lld}_a \ast \text{LOCc}(ja+k-1)$.
  On entry, the $j$-th row of the matrix stored in $a$ must contain the vector that defines the elementary reflector $H(j)$, $ja \leq j \leq ja+k-1$, as returned by \texttt{pgeqlf} in the $k$ columns of its distributed matrix argument $A(ia:*,ja:ja+k-1)$. The argument $A(ia:*,ja:ja+k-1)$ is modified by the function but restored on exit.
  If $\text{side} = 'L'$, $\text{lld}_a \geq \max(1, \text{LOCr}(ia+m-1))$,
if side = 'R', lld_a ≥ max(1, LOCr(ia+n-1)).

ia (global)
The row index in the global matrix A indicating the first row of sub(A).

ja (global)
The column index in the global matrix A indicating the first column of sub(A).

desca (global and local) array of size dlen_. The array descriptor for the distributed matrix A.

tau (local)
Array of size LOCC(ja+n-1). tau[j] contains the scalar factor of the elementary reflector H(j+1), j = 0, 1, ..., LOCC(ja+n-1)-1, as returned by pgeqlf. This array is tied to the distributed matrix A.

c (local)
Pointer into the local memory to an array of size lld_c * LOCC(jc+n-1). On entry, the local pieces of the distributed matrix sub (C).

ic (global)
The row index in the global matrix C indicating the first row of sub(C).

jc (global)
The column index in the global matrix C indicating the first column of sub(C).

descc (global and local) array of size dlen_. The array descriptor for the distributed matrix C.

work (local)
Workspace array of size lwork.

On exit, work(1) returns the minimal and optimal lwork.

lwork (local or global)
The size of the array work.

lwork is local input and must be at least

if side = 'L', lwork ≥ mpc0 + max(1, nqc0),

if side = 'R', lwork ≥ nqc0 + max(max(1, mpc0), numroc(numroc(n + icoffc, nb_a, 0, 0, npcol), nb_a, 0, 0, lcmq)),

where

lcmq = lcm/npcol,

lcm = iclm(nprow, npcol),

iwoffc = mod(ic-1, mb_c),

icoffc = mod(jc-1, nb_c),

icrow = indxg2p(ic, mb_c, myrow, rsr_c, nprow),

iccol = indxg2p(jc, nb_c, mycol, csr_c, npcol),
Output Parameters

c
On exit, c is overwritten by \( Q \cdot \text{sub}(C) \), or \( Q^T \cdot \text{sub}(C) \), or \( Q^H \cdot \text{sub}(C) \).

work
On exit, work[0] returns the minimal and optimal lwork.

info
(local)
= 0: successful exit
< 0: if the i-th argument is an array and the j-th entry, indexed j-1, had an illegal value,
then info = - (i*100 +j),
if the i-th argument is a scalar and had an illegal value,
then info = -i.

NOTE
The distributed submatrices \( A(ia:*, ja:* \) and \( C(ic:ic+m-1, jc:ic+n-1) \) must verify some alignment properties, namely the following expressions should be true:

If side = 'L', \( (mb_a == mb_c && iroff_a == iroff_c && iarow == icrow) \)
If side = 'R', \( (mb_a == nb_c && iroff_a == iroff_c) \).

\[ \text{sub}(C) \cdot Q \] if side = 'R' and trans = 'N', or
\[ \text{sub}(C) \cdot Q^T / \; \text{sub}(C) \cdot Q^H \] if side = 'R' and trans = 'T' (for real flavors) or trans = 'C' (for complex flavors).

where \( Q \) is a real orthogonal or complex unitary matrix defined as the product of \( k \) elementary reflectors
\[ Q = H(k) \cdots H(2) \cdot H(1) \] as returned by p?geqrf. \( Q \) is of order \( m \) if side = 'L' and of order \( n \) if side = 'R'.

Input Parameters

side

(global)
= 'L': apply \( Q \) or \( Q^T \) for real flavors (\( Q^H \) for complex flavors) from the left,
= 'R': apply \( Q \) or \( Q^T \) for real flavors (\( Q^H \) for complex flavors) from the right.

trans

(global)
= 'N': apply \( Q \) (no transpose)
= 'T': apply \( Q^T \) (transpose, for real flavors)
= 'C': apply \( Q^H \) (conjugate transpose, for complex flavors)

m

(global)
The number of rows in the distributed matrix sub(C). \( m \geq 0 \).

n

(global)
The number of columns in the distributed matrix sub(C). \( n \geq 0 \).

k

(global)
The number of elementary reflectors whose product defines the matrix \( Q \).
If \( side = 'L', m \geq k \geq 0 \);
if side = 'R', n ≥ k ≥ 0.

a
(local)
Pointer into the local memory to an array of size lld_a * LOCc(ja+k-1).

On entry, the j-th column of the matrix stored in a must contain the vector
that defines the elementary reflector H(j), ja ≤ j ≤ ja + k - 1, as returned by
pgeqrf in the k columns of its distributed matrix argument A(ia:*, ja:ja + k-1).
The argument A(ia:*, ja:ja+k-1) is modified by the function but
restored on exit.

If side = 'L', lld_a ≥ max(1, LOCr(ia+m-1)),
If side = 'R', lld_a ≥ max(1, LOCr(ia+n-1)).

ia
(global)
The row index in the global matrix A indicating the first row of sub(A).

ja
(global)
The column index in the global matrix A indicating the first column of
sub(A).

desca
(global and local) array of size dlen_. The array descriptor for the
distributed matrix A.

tau
(local)
Array of size LOCc(ja+k-1). tau[j] contains the scalar factor of the
elementary reflector H(j+1), j = 0, 1, ..., LOCc(ja+k-1)-1, as returned by
pgeqrf. This array is tied to the distributed matrix A.

c
(local)
Pointer into the local memory to an array of size lld_c * LOCc(jc+n-1).

On entry, the local pieces of the distributed matrix sub (C).

ic
(global)
The row index in the global matrix C indicating the first row of sub(C).

jc
(global)
The column index in the global matrix C indicating the first column of
sub(C).

descc
(global and local) array of size dlen_.
The array descriptor for the distributed matrix C.

work
(local)
Workspace array of size lwork.

lwork
(local or global)
The size of the array work.
lwork is local input and must be at least
if side = 'L', lwork ≥ mpc0 + max(1, nqc0),
if side = 'R', lwork ≥ nqc0 + max(max(1, mpc0), numroc(numroc(n + icoffc, nb_a, 0, 0, npcol), nb_a, 0, 0, lcmq)),

where
lcmq = lcm/npcol,
lcm = iclm(nprow, npcol),
iero = mod(ic-1, mb_c),
icoffc = mod(jc-1, nb_c),
icrow = indxg2p(ic, mb_c, myrow, rsrc_c, nprow),
iccol = indxg2p(jc, nb_c, mycol, csr_c, npcol),
Mqc0 = numroc(m+icoffc, nb_c, mycol, icrow, nprow),
Npc0 = numroc(n+icoffc, mb_c, myrow, iccol, npcol),
ilcm, indx2p and numroc are ScaLAPACK tool functions; myrow, mycol, nprow, and npcol can be determined by calling the function blacs_gridinfo.

If lwork = -1, then lwork is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

**Output Parameters**

**c**

On exit, c is overwritten by Q*sub(C), or Q^T*sub(C)/ Q'*sub(C), or sub(C)*Q, or sub(C)*Q^T / sub(C)*Q'

**work**

On exit, work[0] returns the minimal and optimal lwork.

**info**

(local)

= 0: successful exit
< 0: if the i-th argument is an array and the j-th entry, indexed j-1, had an illegal value,
then info = -(i*100 +j),
if the i-th argument is a scalar and had an illegal value,
then info = -i.

**NOTE**
The distributed submatrices A(ia:*, ja:*) and C(ic:ic+m-1, jc:jc+n-1) must verify some alignment properties, namely the following expressions should be true:

If side = 'L', (mb_a == mb_c) && (iero == icoffc) && (iarow == icrow).

If side = 'R', (mb_a == nb_c) && (iero == icoffc).

**See Also**

Overview for details of ScaLAPACK array descriptor structures and related notations.
**p?orml2/p?unml2**

Multiplies a general matrix by the orthogonal/unitary matrix from an LQ factorization determined by p?gelqf (unblocked algorithm).

**Syntax**

```c
void psorml2 (char *side, char *trans, MKL_INT *m, MKL_INT *n, MKL_INT *k, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *tau, float *c, MKL_INT *ic, MKL_INT *jc, MKL_INT *descc, float *work, MKL_INT *lwork, MKL_INT *info);

void pdorml2 (char *side, char *trans, MKL_INT *m, MKL_INT *n, MKL_INT *k, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *tau, double *c, MKL_INT *ic, MKL_INT *jc, MKL_INT *descc, double *work, MKL_INT *lwork, MKL_INT *info);

```

**Include Files**

- mkl_scalapack.h

**Description**

The p?orml2/p?unml2 function overwrites the general real/complex \( m \times n \) distributed matrix sub

\[ C = C(ia:ic+m-1, ja:jc+n-1) \]

with

\[ Q^*C \text{ if } side = 'L' \text{ and } trans = 'N', \text{ or} \]

\[ Q^*C / Q^H C \text{ if } side = 'L' \text{ and } trans = 'T' \text{ (for real flavors) or } trans = 'C' \text{ (for complex flavors), or} \]

\[ \text{sub}(C)Q \text{ if } side = 'R' \text{ and } trans = 'N', \text{ or} \]

\[ \text{sub}(C)Q^T / \text{sub}(C)Q^H \text{ if } side = 'R' \text{ and } trans = 'T' \text{ (for real flavors) or } trans = 'C' \text{ (for complex flavors).} \]

Where \( Q \) is a real orthogonal or complex unitary distributed matrix defined as the product of \( k \) elementary reflectors

\[ Q = H(k)^*...*H(2)^*H(1) \] (for real flavors)

\[ Q = (H(k))^H...*(H(2))^H*(H(1))^H \] (for complex flavors)

As returned by p?gelqf. \( Q \) is of order \( m \) if \( side = 'L' \) and of order \( n \) if \( side = 'R'. \)

**Input Parameters**

- **side** (global)
  - \( 'L' \): apply \( Q \) or \( Q^T \) for real flavors (\( Q^H \) for complex flavors) from the left,
  - \( 'R' \): apply \( Q \) or \( Q^T \) for real flavors (\( Q^H \) for complex flavors) from the right.
**trans**
- 'N': apply $Q$ (no transpose)
- 'T': apply $Q^T$ (transpose, for real flavors)
- 'C': apply $Q^H$ (conjugate transpose, for complex flavors)

**m**
(global)
The number of rows in the distributed matrix sub($C$). $m \geq 0$.

**n**
(global)
The number of columns in the distributed matrix sub($C$). $n \geq 0$.

**k**
(global)
The number of elementary reflectors whose product defines the matrix $Q$.

If $side = 'L'$, $m \geq k \geq 0$;
if $side = 'R'$, $n \geq k \geq 0$.

**a**
(local)
Pointer into the local memory to an array of size 

\[ \text{ldd}_a \times \text{LOCc}(ja+m-1) \] if $side = 'L'$,

\[ \text{ldd}_a \times \text{LOCc}(ja+n-1) \] if $side = 'R'$,

where $\text{ldd}_a \geq \max(1, \text{LOCr}(ia+k-1))$.

On entry, the $i$-th row of the matrix stored in $a$ must contain the vector that defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by p?gelqf in the $k$ rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$. The argument $A(ia:ia+k-1, ja:*)$ is modified by the function but restored on exit.

**ia**
(global)
The row index in the global matrix $A$ indicating the first row of sub($A$).

**ja**
(global)
The column index in the global matrix $A$ indicating the first column of sub($A$).

**desca**
(global and local) array of size $dlen_\_$. The array descriptor for the distributed matrix $A$.

**tau**
(local)
Array of size $\text{LOCc}(ia+k-1)$. $\tau[i]$ contains the scalar factor of the elementary reflector $H(i+1)$, $i = 0, 1, ..., \text{LOCc}(ja+k-1)-1$, as returned by p?gelqf. This array is tied to the distributed matrix $A$.

**c**
(local)
Pointer into the local memory to an array of size $\text{ldd}_c \times \text{LOCc}(jc+n-1)$. On entry, the local pieces of the distributed matrix sub ($C$).

**ic**
(global)
The row index in the global matrix $C$ indicating the first row of sub($C$).
The column index in the global matrix $C$ indicating the first column of $\text{sub}(C)$.

descC

(global and local) array of size $dlen_\cdot$. The array descriptor for the distributed matrix $C$.

work

(local)

Workspace array of size $lwork$.

lwork

(local or global)

The size of the array $work$.

$lwork$ is local input and must be at least

if $side = 'L'$, $lwork \geq mqc_0 + \max(\max(1, n{pc}_0), \text{numroc}(\text{numroc}(m + \text{icoffc}, mb_\cdot, 0, 0, np{row}), mb_\cdot, 0, 0, lcmp))$,

if $side = 'R'$, $lwork \geq n{pc}_0 + \max(1, mqc_0)$,

where

$lcmp = lcm / np{row},$

$lcm = ilcm(np{row}, np{col}),$

$\text{iroffc} = \text{mod}(ic-1, mb_\cdot),$

$\text{icoffc} = \text{mod}(jc-1, nb_\cdot),$

$\text{icrow} = \text{indxg2p}(ic, mb_\cdot, my{row}, rsr{c}_\cdot, np{row}),$

$\text{iccol} = \text{indxg2p}(jc, nb_\cdot, my{col}, csr{c}_\cdot, np{col}),$

$Mpc_0 = \text{numroc}(m+\text{icoffc}, mb_\cdot, my{col}, \text{icrow}, np{row}),$

$Nqc_0 = \text{numroc}(n+\text{iroffc}, nb_\cdot, my{row}, \text{iccol}, np{col}),$

$ilcm, \text{indxg2p}$ and $\text{numroc}$ are ScaLAPACK tool functions; $my{row}$, $my{col}$, $np{row}$, and $np{col}$ can be determined by calling the function $\text{blacs_gridinfo}$.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by $\text{pxerbla}$.

Output Parameters

c

On exit, $c$ is overwritten by $Q\cdot \text{sub}(C)$, or $Q^T\cdot \text{sub}(C)\cdot Q^H\cdot \text{sub}(C)$, or $\text{sub}(C)\cdot Q$, or $\text{sub}(C)\cdot Q^T / \text{sub}(C)\cdot Q^H$.

work

On exit, $work[0]$ returns the minimal and optimal $lwork$.

info

(local)

$= 0$: successful exit

$< 0$: if the $i$-th argument is an array and the $j$-th entry, indexed $j-1$, had an illegal value,

then $info = - (i*100 + j)$,
if the \( i \)-th argument is a scalar and had an illegal value, then \( info = -i \).

**NOTE**
The distributed submatrices \( A(ia:*, ja:* \) and \( C(ic:ic+m-1, jc:jc+n-1) \) must verify some alignment properties, namely the following expressions should be true:

If \( side = 'L' \), \((nb_a == mb_c && icoffa == iroffc)\)
If \( side = 'R' \), \((nb_a == nb_c && icoffa == icoffc && icol == icol)\).

**See Also**
Overview for details of ScaLAPACK array descriptor structures and related notations.

\texttt{pormr2/punmr2}

Multiplies a general matrix by the orthogonal/unitary matrix from an RQ factorization determined by \texttt{pgerqf} (unblocked algorithm).

**Syntax**

```c
void psormr2 (char *side, char *trans, MKL_INT *m, MKL_INT *n, MKL_INT *k, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *tau, float *c, MKL_INT *ic, MKL_INT *jc, MKL_INT *descc, float *work, MKL_INT *lwork, MKL_INT *info);
void pdormr2 (char *side, char *trans, MKL_INT *m, MKL_INT *n, MKL_INT *k, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *tau, double *c, MKL_INT *ic, MKL_INT *jc, MKL_INT *descc, double *work, MKL_INT *lwork, MKL_INT *info);
void pcunmr2 (char *side, char *trans, MKL_INT *m, MKL_INT *n, MKL_INT *k, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_Complex8 *tau, MKL_Complex8 *c, MKL_INT *ic, MKL_INT *jc, MKL_INT *descc, MKL_Complex8 *work, MKL_INT *lwork, MKL_INT *info);
void pzunmr2 (char *side, char *trans, MKL_INT *m, MKL_INT *n, MKL_INT *k, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_Complex16 *tau, MKL_Complex16 *c, MKL_INT *ic, MKL_INT *jc, MKL_INT *descc, MKL_Complex16 *work, MKL_INT *lwork, MKL_INT *info);
```

**Include Files**
- \texttt{mkl_scalapack.h}

**Description**
The \texttt{pormr2/punmr2} function overwrites the general real/complex \( m \)-by-\( n \) distributed matrix sub
(C)\(=C(ic:ic+m-1, jc:jc+n-1) \) with

\( Q^*\text{sub}(C) \) if \( side = 'L' \) and \( trans = 'N' \), or
\( Q^T\text{sub}(C) / Q^H\text{sub}(C) \) if \( side = 'L' \) and \( trans = 'T' \) (for real flavors) or \( trans = 'C' \) (for complex flavors), or

\( \text{sub}(C)Q \) if \( side = 'R' \) and \( trans = 'N' \), or

\( \text{sub}(C)Q^T / \text{sub}(C)Q^H \) if \( side = 'R' \) and \( trans = 'T' \) (for real flavors) or \( trans = 'C' \) (for complex flavors).
where $Q$ is a real orthogonal or complex unitary distributed matrix defined as the product of $k$ elementary reflectors

$Q = H(1)^*H(2)^*...*H(k)$ (for real flavors)

$Q = (H(1))^H(H(2))^H...*(H(k))^H$ (for complex flavors)

as returned by \texttt{pgerqf}. $Q$ is of order $m$ if $\text{side} = 'L'$ and of order $n$ if $\text{side} = 'R'$.

**Input Parameters**

- \textit{side} (global)
  - $'L'$: apply $Q$ or $Q^T$ for real flavors ($Q^H$ for complex flavors) from the left,
  - $'R'$: apply $Q$ or $Q^T$ for real flavors ($Q^H$ for complex flavors) from the right.

- \textit{trans} (global)
  - $'N'$: apply $Q$ (no transpose)
  - $'T'$: apply $Q^T$ (transpose, for real flavors)
  - $'C'$: apply $Q^H$ (conjugate transpose, for complex flavors)

- \textit{m} (global)
  The number of rows in the distributed matrix \texttt{sub(C)}. $m \geq 0$.

- \textit{n} (global)
  The number of columns in the distributed matrix \texttt{sub(C)}. $n \geq 0$.

- \textit{k} (global)
  The number of elementary reflectors whose product defines the matrix $Q$.
  If $\text{side} = 'L'$, $m \geq k \geq 0$;
  if $\text{side} = 'R'$, $n \geq k \geq 0$.

- \textit{a} (local)
  Pointer into the local memory to an array of size
  
  $\text{lld}_a \cdot \text{LOCc}(ja+m-1)$ if $\text{side} = 'L'$,
  
  $\text{lld}_a \cdot \text{LOCc}(ja+n-1)$ if $\text{side} = 'R'$,

  where $\text{lld}_a \geq \max (1, \text{LOCr}(ia+k-1))$.

  On entry, the $i$-th row of the matrix stored in $a$ must contain the vector that defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by \texttt{pgerqf} in the $k$ rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$.

  The argument $A(ia:ia+k-1, ja:*)$ is modified by the function but restored on exit.

- \textit{ia} (global)
  The row index in the global matrix $A$ indicating the first row of \texttt{sub(A)}.

- \textit{ja} (global)
The column index in the global matrix $A$ indicating the first column of sub($A$).

$\text{desca}$

(global and local) array of size $dlen_\_$. The array descriptor for the distributed matrix $A$.

$\tau$

(local)

Array of size $\text{LOCc}(ia+k-1)$. $\tau[j]$ contains the scalar factor of the elementary reflector $H(j+1)$, $j = 0, 1, \ldots$, $\text{LOCc}(ja+k-1)-1$, as returned by $\text{pgerqf}$. This array is tied to the distributed matrix $A$.

$c$

(local)

Pointer into the local memory to an array of size $lld_c \times \text{LOCc}(jc+n-1)$. On entry, the local pieces of the distributed matrix sub ($C$).

$ic$

(global)

The row index in the global matrix $C$ indicating the first row of sub($C$).

$jc$

(global)

The column index in the global matrix $C$ indicating the first column of sub($C$).

$\text{descc}$

(global and local) array of size $dlen_\_$. The array descriptor for the distributed matrix $C$.

$\text{work}$

(local)

Workspace array of size $lwork$.

$lwork$

(local or global)

The size of the array $\text{work}$.

$lwork$ is local input and must be at least

if $side = 'L'$, $lwork \geq \text{mpc0} + \max(\max(1, nqc0), \text{numroc}(\text{numroc}(m + iroffc, mb_a, 0, 0, nprow), mb_a, 0, 0, lcmp))$,

if $side = 'R'$, $lwork \geq nqc0 + \max(1, \text{mpc0})$,

where $lcmp = \text{lcm}/\text{nprow}$,

$lcm = i\text{icl}(\text{nprow}, \text{ncol})$,

$\text{iroffc} = \text{mod}(ic-1, \text{mb}_c)$,

$\text{icoffc} = \text{mod}(jc-1, \text{nb}_c)$,

$\text{icrow} = \text{indxg2p}(ic, \text{mb}_c, \text{myrow}, \text{rsrc}_c, \text{nprow})$,

$\text{iccol} = \text{indxg2p}(jc, \text{nb}_c, \text{mycol}, \text{csrc}_c, \text{ncol})$,

$\text{Mpc0} = \text{numroc}(m + \text{iroffc}, \text{mb}_a, \text{myrow}, \text{icrow}, \text{nprow})$,

$\text{Nqc0} = \text{numroc}(n + \text{icoffc}, \text{nb}_c, \text{mycol}, \text{iccol}, \text{ncol})$,

$l\text{lcm}$, $\text{indxg2p}$ and $\text{numroc}$ are ScaLAPACK tool functions; $\text{myrow}$, $\text{mycol}$, $\text{nprow}$, and $\text{ncol}$ can be determined by calling the function $\text{blacs_gridinfo}$.
If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

### Output Parameters

- **$c$**
  
  On exit, $c$ is overwritten by $Q^*_{\text{sub}(C)}$, or $Q^T_{\text{sub}(C)}/Q^*_{\text{sub}(C)}$, or $\text{sub}(C)*Q$, or $\text{sub}(C)*Q^T/\text{sub}(C)*Q^H$

- **$work$**

- **$info$**
  
  (local)
  
  - $= 0$: successful exit
  - $< 0$: if the $i$-th argument is an array and the $j$-th entry, indexed $j-1$, had an illegal value,
    then $info = - (i*100 + j)$,
  - if the $i$-th argument is a scalar and had an illegal value,
    then $info = -i$.

### NOTE

The distributed submatrices $A(ia:*, ja:*)$ and $C(ic:ic+m-1,jc:jc+n-1)$ must verify some alignment properties, namely the following expressions should be true:

- If $side = 'L'$, $(nb_a == mb_c) \&\& (icoffa == iroffc)$.
- If $side = 'R'$, $(nb_a == nb_c) \&\& (icoffa == icoffc) \&\& (iacol == iccol)$.

### `p?pbtrsv`

Solves a single triangular linear system via frontsolve or backsolve where the triangular matrix is a factor of a banded matrix computed by `p?pbtf`.  

### Syntax

```c
void pspbtrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *bw , MKL_INT *nrhs ,
    float *a , MKL_INT *ja , MKL_INT *desca , float *b , MKL_INT *ib , MKL_INT *descb ,
    float *af , MKL_INT *laf , float *work , MKL_INT *lwork , MKL_INT *info );
void pdpbtrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *bw , MKL_INT *nrhs ,
    double *a , MKL_INT *ja , MKL_INT *desca , double *b , MKL_INT *ib , MKL_INT *descb ,
    double *af , MKL_INT *laf , double *work , MKL_INT *lwork , MKL_INT *info );
void pcpbtrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *bw , MKL_INT *nrhs ,
    MKL_Complex8 *a , MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *b , MKL_INT *ib ,
    MKL_INT *descb , MKL_Complex8 *af , MKL_INT *laf , MKL_Complex8 *work , MKL_INT *
    lwork , MKL_INT *info );
```
void pzpbtrsv(char *uplo, char *trans, MKL_INT *n, MKL_INT *bw, MKL_INT *nrhs, MKL_Complex16 *a, MKL_INT *ja, MKL_INT *desca, MKL_Complex16 *b, MKL_INT *ib, MKL_INT *descb, MKL_Complex16 *af, MKL_INT *laf, MKL_Complex16 *work, MKL_INT *lwork, MKL_INT *info);

Include Files
• mkl_scalapack.h

Description
The \texttt{p?pbtrsv} function solves a banded triangular system of linear equations
\[ A(1:n, ja:ja+n-1)X = B(jb:jb+n-1, 1:nrhs) \]
or
\[ A(1:n, ja:ja+n-1)^T X = B(jb:jb+n-1, 1:nrhs) \]
for real flavors,
\[ A(1:n, ja:ja+n-1)^H X = B(jb:jb+n-1, 1:nrhs) \]
for complex flavors,
where \( A(1:n, ja:ja+n-1) \) is a banded triangular matrix factor produced by the Cholesky factorization code \texttt{p?pbtrf} and is stored in \( A(1:n, ja:ja+n-1) \) and \( af \). The matrix stored in \( A(1:n, ja:ja+n-1) \) is either upper or lower triangular according to \( uplo \).

The function \texttt{p?pbtrf} must be called first.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

\begin{itemize}
\item \textbf{uplo} (global) Must be 'U' or 'L'.
\begin{itemize}
\item If \texttt{uplo} = 'U', upper triangle of \( A(1:n, ja:ja+n-1) \) is stored;
\item If \texttt{uplo} = 'L', lower triangle of \( A(1:n, ja:ja+n-1) \) is stored.
\end{itemize}
\end{itemize}

\item \textbf{trans} (global) Must be 'N' or 'T' or 'C'.
\begin{itemize}
\item If \texttt{trans} = 'N', solve with \( A(1:n, ja:ja+n-1) \);
\item If \texttt{trans} = 'T' or 'C' for real flavors, solve with \( A(1:n, ja:ja+n-1)^T \).
\item If \texttt{trans} = 'C' for complex flavors, solve with conjugate transpose \( (A(1:n, ja:ja+n-1))^H \).
\end{itemize}

\item \textbf{n} (global) The number of rows and columns to be operated on, that is, the order of the distributed submatrix \( A(1:n, ja:ja+n-1) \). \( n \geq 0 \).

\item \textbf{bw} (global)
The number of subdiagonals in 'L' or 'U', $0 \leq bw \leq n-1$.

$nrhs$ (global)
The number of right hand sides; the number of columns of the distributed submatrix $B(jb:jb+n-1, 1:nrhs); nrhs \geq 0$.

$a$ (local)
Pointer into the local memory to an array with the first size $lld_a \geq (bw +1)$, stored in desca.

On entry, this array contains the local pieces of the $n$-by-$n$ symmetric banded distributed Cholesky factor $L$ or $L^*A(1:n, ja:ja+n-1)$.

This local portion is stored in the packed banded format used in LAPACK. See the Application Notes below and the ScaLAPACK manual for more detail on the format of distributed matrices.

$ja$ (global) The index in the global in the global matrix $A$ that points to the start of the matrix to be operated on (which may be either all of $A$ or a submatrix of $A$).

desca (global and local) array of size $dlen_\_$. The array descriptor for the distributed matrix $A$.

If 1D type ($dtype_a = 501$), then $dlen \geq 7$;

If 2D type ($dtype_a = 1$), then $dlen \geq 9$.

Contains information on mapping of $A$ to memory. (See ScaLAPACK manual for full description and options.)

$b$ (local)
Pointer into the local memory to an array of local lead size $lld_b \geq nb$.

On entry, this array contains the local pieces of the right hand sides $B(jb:jb+n-1, 1:nrhs)$.

$ib$ (global) The row index in the global matrix $B$ that points to the first row of the matrix to be operated on (which may be either all of $B$ or a submatrix of $B$).

descb (global and local) array of size $dlen_\_$. The array descriptor for the distributed matrix $B$.

If 1D type ($dtype_b = 502$), then $dlen \geq 7$;

If 2D type ($dtype_b = 1$), then $dlen \geq 9$.

Contains information on mapping of $B$ to memory. Please, see ScaLAPACK manual for full description and options.

$laf$ (local)
The size of user-input auxiliary fill-in space $af$. Must be $laf \geq (nb +2* bw) * bw$. If $laf$ is not large enough, an error code will be returned and the minimum acceptable size will be returned in $af[0]$.

$work$ (local)
The array \textit{work} is a temporary workspace array of size \textit{lwork}. This space may be overwritten in between function calls.

\textit{lwork} (local or global) The size of the user-input workspace \textit{work}, must be at least \textit{lwork} \geq \textit{bw} \times \textit{nrhs}. If \textit{lwork} is too small, the minimal acceptable size will be returned in \textit{work[0]} and an error code is returned.

**Output Parameters**

\textit{af} (local)

The array \textit{af} is of size \textit{laf}. It contains auxiliary fill-in space. The fill-in space is created in a call to the factorization function \texttt{p?pbtrf} and is stored in \textit{af}. If a linear system is to be solved using \texttt{p?pbtrs} after the factorization function, \textit{af} must not be altered after the factorization.

\textit{b}

On exit, this array contains the local piece of the solutions distributed matrix \(X\).

\textit{work[0]}

On exit, \textit{work[0]} contains the minimum value of \textit{lwork}.

\textit{info} (local)

\[ \begin{align*}
\text{info} = 0 : & \text{ successful exit} \\
\text{< 0} : & \text{ if the } i\text{-th argument is an array and the } j\text{-th entry, indexed } j-1, \text{ had an illegal value,} \\
& \text{ then } info = -(i \times 100 + j), \\
\text{ if the } i\text{-th argument is a scalar and had an illegal value,} \\
& \text{ then } info = -i.
\end{align*} \]

**Application Notes**

If the factorization function and the solve function are to be called separately to solve various sets of right-hand sides using the same coefficient matrix, the auxiliary space \textit{af} must not be altered between calls to the factorization function and the solve function.

The best algorithm for solving banded and tridiagonal linear systems depends on a variety of parameters, especially the bandwidth. Currently, only algorithms designed for the case \(N/P \gg \text{bw}\) are implemented. These algorithms go by many names, including Divide and Conquer, Partitioning, domain decomposition-type, etc.

The Divide and Conquer algorithm assumes the matrix is narrowly banded compared with the number of equations. In this situation, it is best to distribute the input matrix \(A\) one-dimensionally, with columns atomic and rows divided amongst the processes. The basic algorithm divides the banded matrix up into \(P\) pieces with one stored on each processor, and then proceeds in 2 phases for the factorization or 3 for the solution of a linear system.

1. **Local Phase**: The individual pieces are factored independently and in parallel. These factors are applied to the matrix creating fill-in, which is stored in a non-inspectable way in auxiliary space \textit{af}. Mathematically, this is equivalent to reordering the matrix \(A\) as \(P\text{AT}\) and then factoring the principal leading submatrix of size equal to the sum of the sizes of the matrices factored on each processor. The factors of these submatrices overwrite the corresponding parts of \(A\) in memory.

2. **Reduced System Phase**: A small \((\text{bw} \times (P-1))\) system is formed representing interaction of the larger blocks and is stored (as are its factors) in the space \textit{af}. A parallel Block Cyclic Reduction algorithm is used. For a linear system, a parallel front solve followed by an analogous backsolve, both using the structure of the factored matrix, are performed.
3. **Back Substitution Phase**: For a linear system, a local backsubstitution is performed on each processor in parallel.

**See Also**

**Overview** for details of ScaLAPACK array descriptor structures and related notations.

**p?pttrsv**

Solves a single triangular linear system via frontsolve or backsolve where the triangular matrix is a factor of a tridiagonal matrix computed by **p?pttrf**.

**Syntax**

```c
void pspttrsv (char *uplo, MKL_INT *n, MKL_INT *nrhs, float *d, float *e, MKL_INT *ja, MKL_INT *desca, float *b, MKL_INT *ib, MKL_INT *descb, float *af, MKL_INT *laf, float *work, MKL_INT *lwork, MKL_INT *info);

void pdpttrsv (char *uplo, MKL_INT *n, MKL_INT *nrhs, double *d, double *e, MKL_INT *ja, MKL_INT *desca, double *b, MKL_INT *ib, MKL_INT *descb, double *af, MKL_INT *laf, double *work, MKL_INT *lwork, MKL_INT *info);

void pcpttrsv (char *uplo, char *trans, MKL_INT *n, MKL_INT *nrhs, float *d, MKL_Complex8 *e, MKL_INT *ja, MKL_INT *desca, MKL_Complex8 *b, MKL_INT *ib, MKL_INT *descb, MKL_Complex8 *af, MKL_INT *laf, MKL_Complex8 *work, MKL_INT *lwork, MKL_INT *info);

void pzpttrsv (char *uplo, char *trans, MKL_INT *n, MKL_INT *nrhs, double *d, MKL_Complex16 *e, MKL_INT *ja, MKL_INT *desca, MKL_Complex16 *b, MKL_INT *ib, MKL_INT *descb, MKL_Complex16 *af, MKL_INT *laf, MKL_Complex16 *work, MKL_INT *lwork, MKL_INT *info);
```

**Include Files**

- mkl_scalapack.h

**Description**

The **p?pttrsv** function solves a tridiagonal triangular system of linear equations

\[ A(1:n, ja:ja+n-1)X = B(jb:jb+n-1, 1:nrhs) \]

or

\[ A(1:n, ja:ja+n-1)^T X = B(jb:jb+n-1, 1:nrhs) \] for real flavors,

\[ A(1:n, ja:ja+n-1)^H X = B(jb:jb+n-1, 1:nrhs) \] for complex flavors,

where \( A(1:n, ja:ja+n-1) \) is a tridiagonal triangular matrix factor produced by the Cholesky factorization code **p?pttrf** and is stored in \( A(1:n, ja:ja+n-1) \) and \( af \). The matrix stored in \( A(1:n, ja:ja+n-1) \) is either upper or lower triangular according to \( uplo \).

The function **p?pttrf** must be called first.

**Input Parameters**

- **uplo** (global) Must be 'U' or 'L'.
  - If **uplo** = 'U', upper triangle of \( A(1:n, ja:ja+n-1) \) is stored;
  - If **uplo** = 'L', lower triangle of \( A(1:n, ja:ja+n-1) \) is stored.
trans

(global) Must be 'N' or 'C'.

If \( \text{trans} = 'N' \), solve with \( A(1:n, ja:ja+n-1) \); 

If \( \text{trans} = 'C' \) (for complex flavors), solve with conjugate transpose 
\( (A(1:n, ja:ja+n-1))^H \).

\( n \)

(global)

The number of rows and columns to be operated on, that is, the order of 
the distributed submatrix \( A(1:n, ja:ja+n-1) \). \( n \geq 0 \).

\( nrhs \)

(global)

The number of right hand sides; the number of columns of the distributed 
submatrix \( B(jb:jb+n-1, 1:nrhs) \); \( nrhs \geq 0 \).

\( d \)

(local)

Pointer to the local part of the global vector storing the main diagonal of the 
matrix; must be of size \( \geq nb_a \).

\( e \)

(local)

Pointer to the local part of the global vector \( du \) storing the upper diagonal of 
the matrix; must be of size \( \geq nb_a \). Globally, \( du(n) \) is not referenced, and \( du \) 
must be aligned with \( d \).

\( ja \)

(global) The index in the global matrix \( A \) that points to the start of the 
matrix to be operated on (which may be either all of \( A \) or a submatrix of \( A \)).

\( desca \)

(global and local) array of size \( dlen_\). The array descriptor for the 
distributed matrix \( A \).

If 1D type (\( dtype_a = 501 \) or 502), then \( dlen \geq 7 \); 

If 2D type (\( dtype_a = 1 \)), then \( dlen \geq 9 \).

Contains information on mapping of \( A \) to memory. See ScaLAPACK manual 
for full description and options.

\( b \)

(local)

Pointer into the local memory to an array of local lead size \( lld_b \geq nb \).

On entry, this array contains the local pieces of the right hand sides 
\( B(jb:jb+n-1, 1:nrhs) \).

\( ib \)

(global) The row index in the global matrix \( B \) that points to the first row of 
the matrix to be operated on (which may be either all of \( B \) or a submatrix of 
\( B \)).

\( descb \)

(global and local) array of size \( dlen_\). The array descriptor for the 
distributed matrix \( B \).

If 1D type (\( dtype_b = 502 \)), then \( dlen \geq 7 \); 

If 2D type (\( dtype_b = 1 \)), then \( dlen \geq 9 \).

Contains information on mapping of \( B \) to memory. See ScaLAPACK manual 
for full description and options.

\( laf \)

(local)
The size of user-input auxiliary fill-in space \( af \). Must be \( laf \geq (nb + 2 * bw) * bw \).

If \( laf \) is not large enough, an error code will be returned and the minimum acceptable size will be returned in \( af[0] \).

\( \text{work} \)

(local)

The array \( \text{work} \) is a temporary workspace array of size \( lwork \). This space may be overwritten in between function calls.

\( lwork \)

(local or global) The size of the user-input workspace \( \text{work} \), must be at least \( lwork \geq (10 + 2 \times \min(100, nrhs)) \times npcol + 4 \times nrhs \). If \( lwork \) is too small, the minimal acceptable size will be returned in \( \text{work}[0] \) and an error code is returned.

Output Parameters

\( d, e \)

(local).

On exit, these arrays contain information on the factors of the matrix.

\( af \)

(local)

The array \( af \) is of size \( laf \). It contains auxiliary fill-in space. The fill-in space is created in a call to the factorization function \( p?pbtrf \) and is stored in \( af \). If a linear system is to be solved using \( p?pttrs \) after the factorization function, \( af \) must not be altered after the factorization.

\( b \)

On exit, this array contains the local piece of the solutions distributed matrix \( X \).

\( \text{work}[0] \)

On exit, \( \text{work}[0] \) contains the minimum value of \( lwork \).

\( \text{info} \)

(local)

\( = 0 \): successful exit
\( < 0 \): if the \( i \)-th argument is an array and the \( j \)-th entry, indexed \( j-1 \), had an illegal value,
then \( \text{info} = -(i*100 + j) \),
if the \( i \)-th argument is a scalar and had an illegal value,
then \( \text{info} = -i \).

See Also

\( p?potf2 \)

Computes the Cholesky factorization of a symmetric/Hermitian positive definite matrix (local unblocked algorithm).

Syntax

```c
void pspotf2 (char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
```
void pdpotf2 (char *uplo, MKL_INT *n, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_INT *info);
void pcpotf2 (char *uplo, MKL_INT *n, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_INT *info);
void pzpotf2 (char *uplo, MKL_INT *n, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_INT *info);

Include Files
- mkl_scalapack.h

Description
The p?potf2 function computes the Cholesky factorization of a real symmetric or complex Hermitian positive definite distributed matrix sub(A) = A(ia:ia+n-1, ja:ja+n-1).

The factorization has the form
sub(A) = U'*U, if uplo = 'U', or sub(A) = L*L', if uplo = 'L',
where U is an upper triangular matrix, L is lower triangular. X' denotes transpose (conjugate transpose) of X.

Input Parameters

uplo
   (global)
   Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix A is stored.
   = 'U': upper triangle of sub(A) is stored;
   = 'L': lower triangle of sub(A) is stored.

n
   (global)
   The number of rows and columns to be operated on, that is, the order of the distributed matrix sub(A). n ≥ 0.

a
   (local)
   Pointer into the local memory to an array of size lld_a * LOCc(ja+n-1) containing the local pieces of the n-by-n symmetric distributed matrix sub(A) to be factored.
   If uplo = 'U', the leading n-by-n upper triangular part of sub(A) contains the upper triangular matrix and the strictly lower triangular part of this matrix is not referenced.
   If uplo = 'L', the leading n-by-n lower triangular part of sub(A) contains the lower triangular matrix and the strictly upper triangular part of sub(A) is not referenced.

ia, ja
   (global)
   The row and column indices in the global matrix A indicating the first row and the first column of the sub(A), respectively.

desca
   (global and local) array of size dlen_. The array descriptor for the distributed matrix A.
Output Parameters

a
(local)
On exit,
if uplo = 'U', the upper triangular part of the distributed matrix contains
the Cholesky factor U;
if uplo = 'L', the lower triangular part of the distributed matrix contains
the Cholesky factor L.

info
(local)
= 0: successful exit
< 0: if the i-th argument is an array and the j-th entry, indexed j-1, had an
illegal value,
then info = - (i*100 +j),
if the i-th argument is a scalar and had an illegal value,
then info = -i.
> 0: if info = k, the leading minor of order k is not positive definite, and
the factorization could not be completed.

Overview for details of ScaLAPACK array descriptor structures and related notations.

p?rot
Applies a planar rotation to two distributed vectors.

Syntax
void psrot(MKL_INT* n, float* x, MKL_INT* ix, MKL_INT* jx, MKL_INT* descx, MKL_INT*
inx, float* y, MKL_INT* iy, MKL_INT* jy, MKL_INT* descy, MKL_INT* incy, float* cs,
float* sn, float* work, MKL_INT* lwork, MKL_INT* info);
void pdrot(MKL_INT* n, double* x, MKL_INT* ix, MKL_INT* jx, MKL_INT* descx, MKL_INT*
inx, double* y, MKL_INT* iy, MKL_INT* jy, MKL_INT* descy, MKL_INT* incy, double* cs,
double* sn, double* work, MKL_INT* lwork, MKL_INT* info);

Include Files
• mkl_scalapack.h

Description
p?rot applies a planar rotation defined by cs and sn to the two distributed vectors sub(x) and sub(y).

Input Parameters

n (global )
The number of elements to operate on when applying the planar rotation to
x and y (n≥0).

x (local) array of size ( (jx-1)*m_x + ix + ( n - 1 )*abs( incx ))
This array contains the entries of the distributed vector sub( x ).

ix (global )
The global row index of the submatrix of the distributed matrix x to operate on. If incx = 1, then it is required that ix = iy. 1 ≤ ix ≤ m_x.

jx (global )
The global column index of the submatrix of the distributed matrix x to operate on. If incx = m_x, then it is required that jx = jy. 1 ≤ jx ≤ n_x.

descx (global and local) array of size 9
The array descriptor of the distributed matrix x.

incx (global )
The global increment for the elements of x. Only two values of incx are supported in this version, namely 1 and m_x. Moreover, it must hold that incx = m_x if incy = m_y and that incx = 1 if incy = 1.

y (local) array of size ( (jy-1)*m_y + iy + (n - 1)*abs( incy ) )
This array contains the entries of the distributed vector sub( y ).

iy (global )
The global row index of the submatrix of the distributed matrix y to operate on. If incy = 1, then it is required that iy = ix. 1 ≤ iy ≤ m_y.

jy (global )
The global column index of the submatrix of the distributed matrix y to operate on. If incy = m_x, then it is required that jy = jx. 1 ≤ jy ≤ m_y.

descy (global and local) array of size 9
The array descriptor of the distributed matrix y.

incy (global )
The global increment for the elements of y. Only two values of incy are supported in this version, namely 1 and m_y. Moreover, it must hold that incy = m_y if incx = m_x and that incy = 1 if incx = 1.

cs, sn (global)
The parameters defining the properties of the planar rotation. It must hold that 0 ≤ cs, sn ≤ 1 and that sn^2 + cs^2 = 1. The latter is hardly checked in finite precision arithmetics.

work (local workspace) array of size lwork

lwork (local )
The length of the workspace array work.
If incx = 1 and incy = 1, then lwork = 2*m_x
If \( lwork = -1 \), then a workspace query is assumed; the function only calculates the optimal size of the \( work \) array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by \texttt{pxerbla}.

**OUTPUT Parameters**

\( x \)
\( y \)
\( work[0] \)
\( info \)

On exit, if \( info = 0 \), \( work[0] \) returns the optimal \( lwork \) (global).

\( = 0 \): successful exit
\( < 0 \): if \( info = -i \), the \( i \)-th argument had an illegal value.

If the \( i \)-th argument is an array and the \( j \)-th entry, indexed \( j-1 \), had an illegal value, then \( info = -(i*100+j) \), if the \( i \)-th argument is a scalar and had an illegal value, then \( info = -i \).

**See Also**

Overview for details of ScaLAPACK array descriptor structures and related notations.

**p?rscl**

*Multiplies a vector by the reciprocal of a real scalar.*

**Syntax**

```c
void psrscl (MKL_INT *n, float *sa, float *sx, MKL_INT *ix, MKL_INT *jx, MKL_INT *descx, MKL_INT *incx);
void pdrscl (MKL_INT *n, double *sa, double *sx, MKL_INT *ix, MKL_INT *jx, MKL_INT *descx, MKL_INT *incx);
void pcsrscl (MKL_INT *n, float *sa, MKL_Complex8 *sx, MKL_INT *ix, MKL_INT *jx, MKL_INT *descx, MKL_INT *incx);
void pzdrscl (MKL_INT *n, double *sa, MKL_Complex16 *sx, MKL_INT *ix, MKL_INT *jx, MKL_INT *descx, MKL_INT *incx);
```

**Include Files**

- \texttt{mkl_scalapack.h}

**Description**

The \( p?rscl \) function multiplies an \( n \)-element real/complex vector \( \text{sub}(X) \) by the real scalar \( 1/a \). This is done without overflow or underflow as long as the final result \( \text{sub}(X)/a \) does not overflow or underflow.

\( \text{sub}(X) \) denotes \( X(ix:ix+n-1, jx:jx) \), if \( incx = 1 \),
and \( X(ix:ix, jx:jx+n-1) \), if \( incx = m_x \).

**Input Parameters**

\( n \) (global)
The number of components of the distributed vector \( sub(X) \). \( n \geq 0 \).

\( sa \)
The scalar \( a \) that is used to divide each component of the vector \( sub(X) \). This parameter must be \( \geq 0 \).

\( sx \)
Array containing the local pieces of a distributed matrix of size of at least 
\(((jx-1)*m_x + ix + (n-1)*abs(incx)). This array contains the entries 
of the distributed vector \( sub(X) \).

\( ix \)
(global) The row index of the submatrix of the distributed matrix \( X \) to 
operate on.

\( jx \)
(global)
The column index of the submatrix of the distributed matrix \( X \) to operate 
on.

\( descx \)
(global and local)
Array of size 9. The array descriptor for the distributed matrix \( X \).

\( incx \)
(global)
The increment for the elements of \( X \). This version supports only two values 
of \( incx \), namely 1 and \( m_x \).

**Output Parameters**

\( sx \)
On exit, the result \( x/a \).

**See Also**

Overview for details of ScaLAPACK array descriptor structures and related notations.

**p?sygs2/p?hegs2**

Reduces a symmetric/Hermitian positive-definite 
generalized eigenproblem to standard form, using the 
factorization results obtained from p?potrf (local 
unblocked algorithm).

**Syntax**

```c
void pssygs2 (MKL_INT *ibtype, char *uplo, MKL_INT *n, float *a, MKL_INT *ia, 
MKL_INT *ja, MKL_INT *desca, float *b, MKL_INT *ib, MKL_INT *jb, MKL_INT *descb, 
MKL_INT *info );
void pdsygs2 (MKL_INT *ibtype, char *uplo, MKL_INT *n, double *a, MKL_INT *ia, 
MKL_INT *ja, MKL_INT *desca, double *b, MKL_INT *ib, MKL_INT *jb, MKL_INT *descb, 
MKL_INT *info );
void pchegs2 (MKL_INT *ibtype, char *uplo, MKL_INT *n, MKL_Complex8 *a, MKL_INT 
*ia, MKL_INT *ja, MKL_INT *desca, MKL_Complex8 *b, MKL_INT *ib, MKL_INT *jb, 
MKL_INT *descb, MKL_INT *info );
void pzhegs2 (MKL_INT *ibtype, char *uplo, MKL_INT *n, MKL_Complex16 *a, MKL_INT 
*ia, MKL_INT *ja, MKL_INT *desca, MKL_Complex16 *b, MKL_INT *ib, MKL_INT *jb, 
MKL_INT *descb, MKL_INT *info );
```
Include Files

- mkl_scalapack.h

Description

The `p?sygs2/ p?hegs2` function reduces a real symmetric-definite or a complex Hermitian positive-definite generalized eigenproblem to standard form.

Here `sub(A)` denotes `A(ia:ia+n-1, ja:ja+n-1)`, and `sub(B)` denotes `B(ib:ib+n-1, jb:jb+n-1)`.

If `ibtype = 1`, the problem is

\[
\text{sub}(A)*x = \lambda*\text{sub}(B)*x
\]

and `sub(A)` is overwritten by

\[
\text{inv}(U^T)*\text{sub}(A)*\text{inv}(U) \quad \text{or} \quad \text{inv}(L)*\text{sub}(A)*\text{inv}(L^T)
\]

- for real flavors, and

\[
\text{inv}(U^H)*\text{sub}(A)*\text{inv}(U) \quad \text{or} \quad \text{inv}(L)*\text{sub}(A)*\text{inv}(L^H)
\]

- for complex flavors.

If `ibtype = 2` or `3`, the problem is

\[
\text{sub}(A)*\text{sub}(B)*x = \lambda*x \quad \text{or} \quad \text{sub}(B)*\text{sub}(A)*x = \lambda*x
\]

and `sub(A)` is overwritten by

\[
U*\text{sub}(A)*U^T \quad \text{or} \quad L*L^T*\text{sub}(A)*L
\]

- for real flavors and

\[
U*\text{sub}(A)*U^H \quad \text{or} \quad L*L^H*\text{sub}(A)*L
\]

- for complex flavors.

The matrix `sub(B)` must have been previously factorized as `U^T*U` or `L*L^T` (for real flavors), or as `U^H*U` or `L*L^H` (for complex flavors) by `p?potrf`.

Input Parameters

- `ibtype` (global)
  
  `= 1:`
  
  compute `inv(U^T)*sub(A)*inv(U)`, or `inv(L)*sub(A)*inv(L^T)` for real functions,
  
  and `inv(U^H)*sub(A)*inv(U)`, or `inv(L)*sub(A)*inv(L^H)` for complex functions;
  
  `= 2` or `3`:
  
  compute `U*sub(A)*U^T`, or `L*L^T*sub(A)*L` for real functions,
  
  and `U*sub(A)*U^H` or `L*L^H*sub(A)*L` for complex functions.

- `uplo` (global)

  Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix `sub(A)` is stored, and how `sub(B)` is factorized.

  `= 'U'`: Upper triangular of `sub(A)` is stored and `sub(B)` is factorized as `U^T*U` (for real functions) or as `U^H*U` (for complex functions).

  `= 'L'`: Lower triangular of `sub(A)` is stored and `sub(B)` is factorized as `L*L^T` (for real functions) or as `L*L^H` (for complex functions)

- `n` (global)

  The order of the matrices `sub(A)` and `sub(B)`. \( n \geq 0 \).
**Input Parameters**

\( a \) (local)

Pointer into the local memory to an array of size \( lld_a \ast LOCc(ja+n-1) \).

On entry, this array contains the local pieces of the \( n \)-by-\( n \) symmetric/Hermitian distributed matrix sub(\( A \)).

If \( uplo = 'U' \), the leading \( n \)-by-\( n \) upper triangular part of sub(\( A \)) contains the upper triangular part of the matrix, and the strictly lower triangular part of sub(\( A \)) is not referenced.

If \( uplo = 'L' \), the leading \( n \)-by-\( n \) lower triangular part of sub(\( A \)) contains the lower triangular part of the matrix, and the strictly upper triangular part of sub(\( A \)) is not referenced.

\( ia, ja \) (global)

The row and column indices in the global matrix \( A \) indicating the first row and the first column of the sub(\( A \)), respectively.

\( desca \) (global and local) array of size \( dlen_\ast \). The array descriptor for the distributed matrix \( A \).

\( B \) (local)

Pointer into the local memory to an array of size \( lld_b \ast LOCc(jb+n-1) \).

On entry, this array contains the local pieces of the triangular factor from the Cholesky factorization of sub(\( B \)) as returned by \( p?potrf \).

\( ib, jb \) (global)

The row and column indices in the global matrix \( B \) indicating the first row and the first column of the sub(\( B \)), respectively.

\( descb \) (global and local) array of size \( dlen_\ast \). The array descriptor for the distributed matrix \( B \).

**Output Parameters**

\( a \) (local)

On exit, if \( info = 0 \), the transformed matrix is stored in the same format as sub(\( A \)).

\( info \)

\( = 0 \): successful exit.

\(< 0 \): if the \( i \)-th argument is an array and the \( j \)-th entry, indexed \( j-1 \), had an illegal value,

then \( info = - (i \ast 100 + j) \),

if the \( i \)-th argument is a scalar and had an illegal value,

then \( info = -i \).

void pzhetd2 (char *uplo, MKL_INT *n, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *d, double *e, MKL_Complex16 *tau, MKL_Complex16 *work, MKL_INT *lwork, MKL_INT *info);
```

**Include Files**

- mkl_scalapack.h

**Description**

The `p?sytd2/p?hetd2` function reduces a real symmetric/complex Hermitian matrix `sub(A)` to symmetric/Hermitian tridiagonal form `T` by an orthogonal/unitary similarity transformation:

\[ Q^* sub(A) Q = T, \]

where `sub(A) = A(ia:ia+n-1, ja:ja+n-1)`.

**Input Parameters**

- `uplo` (global)
  
  Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix `sub(A)` is stored:
  
  - `'U'`: upper triangular
  - `'L'`: lower triangular

- `n` (global)
  
  The number of rows and columns to be operated on, that is, the order of the distributed matrix `sub(A)`. \( n \geq 0 \).

- `a` (local)
  
  Pointer into the local memory to an array of size \( lld_a \times LOC_c(ja+n-1) \).
  
  On entry, this array contains the local pieces of the \( n \)-by-\( n \) symmetric/Hermitian distributed matrix `sub(A)`.
  
  If `uplo = 'U'`, the leading \( n \)-by-\( n \) upper triangular part of `sub(A)` contains the upper triangular part of the matrix, and the strictly lower triangular part of `sub(A)` is not referenced.
If \( uplo = 'L' \), the leading \( n \)-by-\( n \) lower triangular part of \( sub(A) \) contains the lower triangular part of the matrix, and the strictly upper triangular part of \( sub(A) \) is not referenced.

\( ia, ja \)  
(global)  
The row and column indices in the global matrix \( A \) indicating the first row and the first column of the \( sub(A) \), respectively.

\( desca \)  
(global and local) array of size \( dlen_\). The array descriptor for the distributed matrix \( A \).

\( work \)  
(local)  
The array \( work \) is a temporary workspace array of size \( lwork \).

**Output Parameters**

\( a \)  
On exit, if \( uplo = 'U' \), the diagonal and first superdiagonal of \( sub(A) \) are overwritten by the corresponding elements of the tridiagonal matrix \( T \), and the elements above the first superdiagonal, with the array \( tau \), represent the orthogonal/unitary matrix \( Q \) as a product of elementary reflectors; if \( uplo = 'L' \), the diagonal and first subdiagonal of \( A \) are overwritten by the corresponding elements of the tridiagonal matrix \( T \), and the elements below the first subdiagonal, with the array \( tau \), represent the orthogonal/unitary matrix \( Q \) as a product of elementary reflectors. See the Application Notes below.

\( d \)  
(local)  
Array of size \( LOCc(ja+n-1) \). The diagonal elements of the tridiagonal matrix \( T \):

\[
d[i] = A(i+1,i+1), \text{ where } i=0,1,..., LOCc(ja+n-1)-1 ; \ d \text{ is tied to the distributed matrix } A.
\]

\( e \)  
(local)  
Array of size \( LOCc(ja+n-1) \),

\[
e[i] = A(i+1,i+2) \text{ if } uplo = 'U',
\]

\[
e[i] = A(i+2,i+1) \text{ if } uplo = 'L',
\]

where \( i=0,1,..., LOCc(ja+n-1)-1 \). \( e \) is tied to the distributed matrix \( A \).

\( tau \)  
(local)  
Array of size \( LOCc(ja+n-1) \).

The scalar factors of the elementary reflectors. \( tau \) is tied to the distributed matrix \( A \).

\( work[0] \)  
On exit, \( work[0] \) returns the minimal and optimal value of \( lwork \).

\( lwork \)  
(local or global)
The size of the workspace array \textit{work}.

\textit{lwork} is local input and must be at least \textit{lwork} \geq 3n.

If \textit{lwork} = -1, then \textit{lwork} is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by \texttt{pxerbla}.

\textit{info} (local)
= 0: successful exit
< 0: if the \textit{i}-th argument, indexed \textit{i-1}, is an array and the \textit{j}-th entry had an illegal value,
then \textit{info} = -(\textit{i}*100+\textit{j}),
if the \textit{i}-th argument is a scalar and had an illegal value,
then \textit{info} = -\textit{i}.

\textbf{Application Notes}

If \textit{uplo} = 'U', the matrix \(Q\) is represented as a product of elementary reflectors

\(Q = H(n-1)\ldots H(2)H(1)\)

Each \(H(i)\) has the form

\(H(i) = I - \tau v v'\),

where \(\tau\) is a real/complex scalar, and \(v\) is a real/complex vector with \(v(i+1:n) = 0\) and \(v(i) = 1\);

\(v(1:i-1)\) is stored on exit in \(A(ia:ia+i-2, ja+i)\), and \(\tau\) in \(\tau[ja+i-2]\).

If \textit{uplo} = 'L', the matrix \(Q\) is represented as a product of elementary reflectors

\(Q = H(1)H(2)\ldots H(n-1)\).

Each \(H(i)\) has the form

\(H(i) = I - \tau v v'\),

where \(\tau\) is a real/complex scalar, and \(v\) is a real/complex vector with \(v(1:i) = 0\) and \(v(i+1) = 1\); \(v(i+2:n)\) is stored on exit in \(A(ia+i+1:ia+n-1, ja+i-1)\), and \(\tau\) in \(\tau[ja+i-2]\).

The contents of sub \((A)\) on exit are illustrated by the following examples with \(n = 5\):

\[ \begin{bmatrix} d & e & v_2 & v_3 & v_4 \\ d & e & v_3 & v_4 \\ d & e & v_4 \\ d & e \\ e \end{bmatrix} \quad \begin{bmatrix} d \\ e \\ v_1 & e & d \\ v_1 & v_2 & e & d \\ v_1 & v_2 & v_3 & e & d \end{bmatrix} \]

where \(d\) and \(e\) denotes diagonal and off-diagonal elements of \(T\), and \(v_i\) denotes an element of the vector defining \(H(i)\).
NOTE
The distributed matrix sub(A) must verify some alignment properties, namely the following expression should be true:

\[(mb_a==nb_a && iroffa==icoffa)\]

where \(iroffa = \text{mod}(ia - 1, mb_a)\) and \(icoffa = \text{mod}(ja -1, nb_a)\).

**p?trord**
*Reorders the Schur factorization of a general matrix.*

**Syntax**

```c
void pstrord(char* compq, MKL_INT* select, MKL_INT* para, MKL_INT* n, float* t, MKL_INT* it, MKL_INT* jt, MKL_INT* desct, float* q, MKL_INT* iq, MKL_INT* jq, MKL_INT* descq, float* wr, float* wi, MKL_INT* m, float* work, MKL_INT* iwork, MKL_INT* liwork, MKL_INT* info);
void pdtrord(char* compq, MKL_INT* select, MKL_INT* para, MKL_INT* n, double* t, MKL_INT* it, MKL_INT* jt, MKL_INT* desct, double* q, MKL_INT* iq, MKL_INT* jq, MKL_INT* descq, double* wr, double* wi, MKL_INT* m, double* work, MKL_INT* lwork, MKL_INT* iwork, MKL_INT* liwork, MKL_INT* info);
```

**Include Files**

- mkl_scalapack.h

**Description**

`p?trord` reorders the real Schur factorization of a real matrix \(A = Q^*TQ^\top\), so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix \(T\), and the leading columns of \(Q\) form an orthonormal basis of the corresponding right invariant subspace.

\(T\) must be in Schur form (as returned by `p?lahqr`), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks.

This function uses a delay and accumulate procedure for performing the off-diagonal updates.

**Optimization Notice**

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

**Input Parameters**

- `compq` (global)
= 'V': update the matrix q of Schur vectors;
= 'N': do not update q.

select (global) array of size n

select specifies the eigenvalues in the selected cluster. To select a real eigenvalue \( w(j) \), select[\( j-1 \)] must be set to 1. To select a complex conjugate pair of eigenvalues \( w(j) \) and \( w(j+1) \), corresponding to a 2-by-2 diagonal block, either select[\( j-1 \)] or select[\( j \)] or both must be set to 1; a complex conjugate pair of eigenvalues must be either both included in the cluster or both excluded.

para (global)

Block parameters:

\( para[0] \) maximum number of concurrent computational windows allowed in the algorithm; \( 0 < para[0] \leq \min(nprow, ncol) \) must hold;

\( para[1] \) number of eigenvalues in each window; \( 0 < para[1] < para[2] \) must hold;

\( para[3] \) minimal percentage of FLOPS required for performing matrix-matrix multiplications instead of pipelined orthogonal transformations; \( 0 \leq para[3] \leq 100 \) must hold;

\( para[4] \) width of block column slabs for row-wise application of pipelined orthogonal transformations in their factorized form; \( 0 < para[4] \leq mb_t \) must hold.

\( para[5] \) the maximum number of eigenvalues moved together over a process border; in practice, this will be approximately half of the cross border window size; \( 0 < para[5] \leq para[1] \) must hold.

n (global)
The order of the globally distributed matrix \( t \). \( n \geq 0 \).

t (local) array of size \( lld_t \times LOC_c(n) \).
The local pieces of the global distributed upper quasi-triangular matrix \( T \), in Schur form.

it, jt (global)
The row and column index in the global matrix \( T \) indicating the first column of \( T \). \( it = jt = 1 \) must hold (see Application Notes).

desct (global and local) array of size \( dlen_\_ \).
The array descriptor for the global distributed matrix \( T \).

q (local) array of size \( lld_q \times LOC_c(n) \).
On entry, if \( \text{compq} = 'V' \), the local pieces of the global distributed matrix \( Q \) of Schur vectors.

If \( \text{compq} = 'N' \), \( q \) is not referenced.

\( iq, jq \)  
(global)  
The column index in the global matrix \( Q \) indicating the first column of \( Q \). \( iq = jq = 1 \) must hold (see Application Notes).

\( \text{descq} \)  
(global and local) array of size \( dlen_\).  
The array descriptor for the global distributed matrix \( Q \).

\( \text{work} \)  
(local workspace) array of size \( lwork \)

\( lwork \)  
(local)  
The size of the array \( \text{work} \).

If \( lwork = -1 \), then a workspace query is assumed; the function only calculates the optimal size of the \( \text{work} \) array, returns this value as the first entry of the \( \text{work} \) array, and no error message related to \( lwork \) is issued by \text{pxerbla}.

\( iwork \)  
(local workspace) array of size \( liwork \)

\( liwork \)  
(local)  
The size of the array \( iwork \).

If \( liwork = -1 \), then a workspace query is assumed; the function only calculates the optimal size of the \( iwork \) array, returns this value as the first entry of the \( iwork \) array, and no error message related to \( liwork \) is issued by \text{pxerbla}.

**OUTPUT Parameters**

\( \text{select} \)  
(global) array of size \( n \)  
The (partial) reordering is displayed.

\( t \)  
On exit, \( t \) is overwritten by the local pieces of the reordered matrix \( T \), again in Schur form, with the selected eigenvalues in the globally leading diagonal blocks.

\( q \)  
On exit, if \( \text{compq} = 'V' \), \( q \) has been postmultiplied by the global orthogonal transformation matrix which reorders \( t \); the leading \( m \) columns of \( q \) form an orthonormal basis for the specified invariant subspace.

If \( \text{compq} = 'N' \), \( q \) is not referenced.

\( \text{wr, wi} \)  
(global) array of size \( n \)  
The real and imaginary parts, respectively, of the reordered eigenvalues of the matrix \( T \). The eigenvalues are in principle stored in the same order as on the diagonal of \( T \), with \( \text{wr}[i] = T(i+i+1) \) and, if \( T(i+i+1,:i+i+1) \) is a 2-by-2 diagonal block, \( \text{wi}[i-1] > 0 \) and \( \text{wi}[i] = -\text{wi}[i-1] \).

Note also that if a complex eigenvalue is sufficiently ill-conditioned, then its value may differ significantly from its value before reordering.
The size of the specified invariant subspace.

\[ 0 \leq m \leq n. \]

\texttt{work[0]}  

On exit, if \( info = 0 \), \texttt{work[0]} returns the optimal \( lwork \).

\texttt{iwork[0]}  

On exit, if \( info = 0 \), \texttt{iwork[0]} returns the optimal \( liwork \).

\texttt{info}  

(general)  

\( = 0 \): successful exit

\( < 0 \): if \( info = -i \), the \( i \)-th argument had an illegal value. If the \( i \)-th argument is an array and the \( j \)-th entry, indexed \( j-1 \), had an illegal value, then \( info = -(i*1000+j) \), if the \( i \)-th argument is a scalar and had an illegal value, then \( info = -i \).

\( > 0 \): here we have several possibilities

- Reordering of \( t \) failed because some eigenvalues are too close to separate (the problem is very ill-conditioned); \( t \) may have been partially reordered, and \( wr \) and \( wi \) contain the eigenvalues in the same order as in \( t \).
  
  On exit, \( info = \{ \text{the index of } t \text{ where the swap failed (indexing starts at 1)} \} \).

- A 2-by-2 block to be reordered split into two 1-by-1 blocks and the second block failed to swap with an adjacent block.
  
  On exit, \( info = \{ \text{the index of } t \text{ where the swap failed}\} \).

- If \( info = n+1 \), there is no valid BLACS context (see the BLACS documentation for details).

\textbf{Application Notes}

The following alignment requirements must hold:

- \( mb_t = nb_t = mb_q = nb_q \)
- \( rsrct_t = rsrct_q \)
- \( csrct_t = csrct_q \)

All matrices must be blocked by a block factor larger than or equal to two (3). This is to simplify reordering across processor borders in the presence of 2-by-2 blocks.

This algorithm cannot work on submatrices of \( t \) and \( q \), i.e., \( it = jt = iq = jq = 1 \) must hold. This is however no limitation since \texttt{p?lahqr} does not compute Schur forms of submatrices anyway.

Parallel execution recommendations:

- Use a square grid, if possible, for maximum performance. The block parameters in \texttt{para} should be kept well below the data distribution block size.
- In general, the parallel algorithm strives to perform as much work as possible without crossing the block borders on the main block diagonal.

\textbf{See Also}

\textbf{Overview} for details of ScaLAPACK array descriptor structures and related notations.
p?trsen
Reorders the Schur factorization of a matrix and (optionally) computes the reciprocal condition numbers and invariant subspace for the selected cluster of eigenvalues.

Syntax

Input Parameters

job

Specifies whether condition numbers are required for the cluster of eigenvalues (s) or the invariant subspace (sep):
= 'N': no condition numbers are required;
= 'E': only the condition number for the cluster of eigenvalues is computed (s);
= 'V': only the condition number for the invariant subspace is computed
(sep);
= 'B': condition numbers for both the cluster and the invariant subspace are
computed (s and sep).

compq

(global )

= 'V': update the matrix q of Schur vectors;
= 'N': do not update q.

select

(global ) array of size n

select specifies the eigenvalues in the selected cluster. To select a real
eigenvalue \( w(j) \), \( select[j-1] \) must be set to a non-zero number. To select a
complex conjugate pair of eigenvalues \( w(j) \) and \( w(j+1) \), corresponding to a
2-by-2 diagonal block, either \( select[j-1] \) or \( select[j] \) or both must be set
to a non-zero number; a complex conjugate pair of eigenvalues must be
either both included in the cluster or both excluded.

para

(global )

Block parameters:

\[ para[0] \]
maximum number of concurrent computational
windows allowed in the algorithm; \( 0 < para[0] \leq \min(NPROW,NPCOL) \) must hold;

\[ para[1] \]
number of eigenvalues in each window; \( 0 < para[1] < para[2] \) must hold;

\[ para[2] \]
window size; \( para[1] < para[2] < mb_t \) must hold;

\[ para[3] \]
minimal percentage of flops required for
performing matrix-matrix multiplications instead
of pipelined orthogonal transformations; \( 0 \leq para[3] \leq 100 \) must hold;

\[ para[4] \]
width of block column slabs for row-wise
application of pipelined orthogonal
transformations in their factorized form; \( 0 < para[4] \leq mb_t \) must hold.

\[ para[5] \]
the maximum number of eigenvalues moved
together over a process border; in practice, this
will be approximately half of the cross border
window size \( 0 < para[5] \leq para[1] \) must hold;

n

(global )
The order of the globally distributed matrix \( t \). \( n \geq 0 \).

t

(local ) array of size \( lld_t \times LOC_c(n) \).
The local pieces of the global distributed upper quasi-triangular matrix \( T \), in
Schur form.

it, jt

(global )
The row and column index in the global matrix $T$ indicating the first column of $T$. $it = jt = 1$ must hold (see Application Notes).

$\text{desct}$

(global and local) array of size $\text{dlen}_\cdot$.

The array descriptor for the global distributed matrix $T$.

$q$

(local ) array of size $\text{lld}_q \times \text{LOC}_c(n)$.

On entry, if $\text{compq} = \text{'V'}$, the local pieces of the global distributed matrix $Q$ of Schur vectors.

If $\text{compq} = \text{'N'}$, $q$ is not referenced.

$iq, jq$

(global )

The column index in the global matrix $Q$ indicating the first column of $Q$. $iq = jq = 1$ must hold (see Application Notes).

$\text{descq}$

(global and local) array of size $\text{dlen}_\cdot$.

The array descriptor for the global distributed matrix $Q$.

$\text{work}$

(local workspace) array of size $\text{lwork}$

The size of the array $\text{work}$.

If $\text{lwork} = -1$, then a workspace query is assumed; the function only calculates the optimal size of the $\text{work}$ array, returns this value as the first entry of the $\text{work}$ array, and no error message related to $\text{lwork}$ is issued by $\text{pxerbla}$.

$i\text{work}$

(local workspace) array of size $\text{liwork}$

(local )

The size of the array $\text{iwork}$.

If $\text{liwork} = -1$, then a workspace query is assumed; the function only calculates the optimal size of the $\text{iwork}$ array, returns this value as the first entry of the $\text{iwork}$ array, and no error message related to $\text{liwork}$ is issued by $\text{pxerbla}$.

**OUTPUT Parameters**

$t$

$t$ is overwritten by the local pieces of the reordered matrix $T$, again in Schur form, with the selected eigenvalues in the globally leading diagonal blocks.

$q$

On exit, if $\text{compq} = \text{'V'}$, $q$ has been postmultiplied by the global orthogonal transformation matrix which reorders $t$; the leading $m$ columns of $q$ form an orthonormal basis for the specified invariant subspace.

If $\text{compq} = \text{'N'}$, $q$ is not referenced.

$wr, wi$

(global ) array of size $n$
The real and imaginary parts, respectively, of the reordered eigenvalues of the matrix $T$. The eigenvalues are in principle stored in the same order as on the diagonal of $T$, with $w_{r}[i] = T(i+1,i+1)$ and, if $T(i:i+1,i:i+1)$ is a 2-by-2 diagonal block, $w_{i}[i-1] > 0$ and $w_{i}[i] = -w_{i}[i-1]$.

Note also that if a complex eigenvalue is sufficiently ill-conditioned, then its value may differ significantly from its value before reordering.

$m$  
(global )

The size of the specified invariant subspace. $0 \leq m \leq n$.

$s$  
(global )

If $job = 'E'$ or 'B', $s$ is a lower bound on the reciprocal condition number for the selected cluster of eigenvalues. $s$ cannot underestimate the true reciprocal condition number by more than a factor of $\sqrt{n}$. If $m = 0$ or $n$, $s = 1$.

If $job = 'N'$ or 'V', $s$ is not referenced.

$sep$  
(global )

If $job = 'V'$ or 'B', $sep$ is the estimated reciprocal condition number of the specified invariant subspace. If $m = 0$ or $n$, $sep = \text{norm}(t)$.

If $job = 'N'$ or 'E', $sep$ is not referenced.

$work[0]$  
On exit, if $info = 0$, $work[0]$ returns the optimal $lwork$.

$iwork[0]$  
On exit, if $info = 0$, $iwork[0]$ returns the optimal $liwork$.

$info$  
(global )

= 0: successful exit

< 0: if $info = -i$, the $i$-th argument had an illegal value.

If the $i$-th argument is an array and the $j$-th entry, indexed $j-1$, had an illegal value, then $info = -(i*1000+j)$, if the $i$-th argument is a scalar and had an illegal value, then $info = -i$.

> 0: here we have several possibilities

- Reordering of $t$ failed because some eigenvalues are too close to separate (the problem is very ill-conditioned); $t$ may have been partially reordered, and $w_{r}$ and $w_{i}$ contain the eigenvalues in the same order as in $t$.

  On exit, $info = \{\text{the index of } t \text{ where the swap failed (indexing starts at 1)}\}$.

- A 2-by-2 block to be reordered split into two 1-by-1 blocks and the second block failed to swap with an adjacent block.

  On exit, $info = \{\text{the index of } t \text{ where the swap failed}\}$.

- If $info = n+1$, there is no valid BLACS context (see the BLACS documentation for details).

**Application Notes**

The following alignment requirements must hold:
All matrices must be blocked by a block factor larger than or equal to two (3). This to simplify reordering across processor borders in the presence of 2-by-2 blocks.

This algorithm cannot work on submatrices of \( t \) and \( q \), i.e., \( it = jt = iq = jq = 1 \) must hold. This is however no limitation since \( \text{plahqr} \) does not compute Schur forms of submatrices anyway.

For parallel execution, use a square grid, if possible, for maximum performance. The block parameters in \( \text{para} \) should be kept well below the data distribution block size.

In general, the parallel algorithm strives to perform as much work as possible without crossing the block borders on the main block diagonal.

\textbf{p?trti2}

\textit{Computes the inverse of a triangular matrix (local unblocked algorithm).}

\textbf{Syntax}

\begin{verbatim}
void pstrti2 (char *uplo, char *diag, MKL_INT *n, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_INT *info);
void pdtrti2 (char *uplo, char *diag, MKL_INT *n, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_INT *info);
void pctrti2 (char *uplo, char *diag, MKL_INT *n, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_INT *info);
void pztrti2 (char *uplo, char *diag, MKL_INT *n, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_INT *info);
\end{verbatim}

\textbf{Include Files}

- mkl_scalapack.h

\textbf{Description}

The \texttt{p?trti2} function computes the inverse of a real/complex upper or lower triangular block matrix sub \( (A) = A(ia:ia+n-1, ja:ja+n-1). \)

This matrix should be contained in one and only one process memory space (local operation).

\textbf{Input Parameters}

\begin{itemize}
  \item \texttt{uplo} (global)
    \text{Specifies whether the matrix sub \( (A) \) is upper or lower triangular.}
    \begin{itemize}
      \item = `'U'`: sub \( (A) \) is upper triangular
      \item = `'L'`: sub \( (A) \) is lower triangular.
    \end{itemize}

  \item \texttt{diag} (global)
    \text{Specifies whether or not the matrix \( A \) is unit triangular.}
    \begin{itemize}
      \item = `'N'`: sub \( (A) \) is non-unit triangular
    \end{itemize}
\end{itemize}
= 'U': sub (A) is unit triangular.

\( n \) (global)
The number of rows and columns to be operated on, i.e., the order of the distributed submatrix \( \text{sub}(A) \). \( n \geq 0 \).

\( a \) (local)
Pointer into the local memory to an array, \( \text{size llda} \ast \text{LOCc}(ja+n-1) \).
On entry, this array contains the local pieces of the triangular matrix \( \text{sub}(A) \).
If \( \text{uplo} = 'U' \), the leading \( n \)-by-\( n \) upper triangular part of the matrix \( \text{sub}(A) \) contains the upper triangular part of the matrix, and the strictly lower triangular part of \( \text{sub}(A) \) is not referenced.
If \( \text{uplo} = 'L' \), the leading \( n \)-by-\( n \) lower triangular part of the matrix \( \text{sub}(A) \) contains the lower triangular part of the matrix, and the strictly upper triangular part of \( \text{sub}(A) \) is not referenced. If \( \text{diag} = 'U' \), the diagonal elements of \( \text{sub}(A) \) are not referenced either and are assumed to be 1.

\( ia, ja \) (global)
The row and column indices in the global matrix \( A \) indicating the first row and the first column of the \( \text{sub}(A) \), respectively.

\( \text{desca} \) (global and local) array of size \( dlen_ \). The array descriptor for the distributed matrix \( A \).

**Output Parameters**

\( a \) On exit, the (triangular) inverse of the original matrix, in the same storage format.

\( \text{info} \)

\( = 0 \): successful exit
\(< 0 \): if the \( i \)-th argument is an array and the \( j \)-th entry, indexed \( j-1 \), had an illegal value,
then \( \text{info} = -(i*100+j) \),
if the \( i \)-th argument is a scalar and had an illegal value,
then \( \text{info} = -i \).

**See Also**

**?lahqr2**

*Updates the eigenvalues and Schur decomposition.*

**Syntax**

```c
void clahqr2 (const MKL_INT* wantt, const MKL_INT* wantz, const MKL_INT* n, const MKL_INT* ilo, const MKL_INT* ihi, MKL_Complex8* h, const MKL_INT* ldh, MKL_Complex8* w, const MKL_INT* iloz, const MKL_INT* ihiz, MKL_Complex8* z, const MKL_INT* ldz, MKL_INT* info);
```
void zlahqr2 (const MKL_INT* wantt, const MKL_INT* wantz, const MKL_INT* n, const MKL_INT* ilo, const MKL_INT* ihi, MKL_Complex16* h, const MKL_INT* ldh, MKL_Complex16* w, const MKL_INT* iloz, const MKL_INT* ihiz, MKL_Complex16* z, const MKL_INT* ldz, MKL_INT* info);

**Include Files**
- mkl_scalapack.h

**Description**
?lahqr2 is an auxiliary routine called by ?hseqr to update the eigenvalues and Schur decomposition already computed by ?hseqr, by dealing with the Hessenberg submatrix in rows and columns ilo to ihi. This version of ?lahqr (not the standard LAPACK version) uses a double-shift algorithm (like LAPACK’s ?lahqr). Unlike the standard LAPACK convention, this does not assume the subdiagonal is real, nor does it work to preserve this quality if given.

**Input Parameters**

**wantt**
- ≠ 0: the full Schur form T is required;
- = 0: only eigenvalues are required.

**wantz**
- ≠ 0: the matrix of Schur vectors Z is required;
- = 0: Schur vectors are not required.

**n**
The order of the matrix H. n >= 0.

**ilo, ihi**
It is assumed that the matrix H is upper triangular in rows and columns ihi +1 : n, and that matrix element H(ilo, ilo-1) = 0 (unless ilo = 1). ?lahqr works primarily with the Hessenberg submatrix in rows and columns ilo to ihi, but applies transformations to all of h if wantt is nonzero.
- 1 <= ilo <= max(1, ihi); ihi <= n.

**h**
Array, size ldh*n.
On entry, the upper Hessenberg matrix H.

**ldh**
The leading dimension of the array h. ldh >= max(1, n).

**iloz, ihiz**
Specify the rows of Z to which transformations must be applied if wantz ≠ 0.
- 1 <= iloz <= ilo; ihi <= ihiz <= n.

**z**
Array, size ldz*n.
If wantz ≠ 0, on entry z must contain the current matrix Z of transformations. If wantz = 0, z is not referenced.

**ldz**
The leading dimension of the array z. ldz >= max(1, n).
### Output Parameters

- **h**: On exit, if `wantt ≠ 0`, `h` is upper triangular in rows and columns `ilo` to `ihi`. If `wantt = 0`, the contents of `h` are unspecified on exit.

- **w**: Array, size (`n`)
  The computed eigenvalues `ilo` to `ihi` are stored in the corresponding elements of `w`. If `wantt ≠ 0`, the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in `h`, with `w[i] = H(i, i)`.

- **z**: If `wantz ≠ 0`, on exit `z` has been updated; transformations are applied only to the submatrix `Z(ilo:ihiz, ilo:ihi)`. If `wantz = 0`, `z` is not referenced.

- **info**: 
  - `info = 0`: successful exit
  - `info > 0`: if `info = i`, `?lahqr` failed to compute all the eigenvalues `ilo` to `ihi` in a total of `30*(ihi-ilo+1)` iterations; elements `w[i:ihi - 1]` contain those eigenvalues which have been successfully computed.

---

**?lamsh**

*Sends multiple shifts through a small (single node) matrix to maximize the number of bulges that can be sent through.*

#### Syntax

```c
void slamsh (float *s, const MKL_INT *lds, MKL_INT *nbulge, const MKL_INT *jblk, float *h, const MKL_INT *ldh, const MKL_INT *n, const float *ulp);
void dlamsh (double *s, const MKL_INT *lds, MKL_INT *nbulge, const MKL_INT *jblk, double *h, const MKL_INT *ldh, const MKL_INT *n, const double *ulp);
void clamsh (MKL_Complex8 *s, const MKL_INT *lds, MKL_INT *nbulge, const MKL_INT *jblk, MKL_Complex8 *h, const MKL_INT *ldh, const MKL_INT *n, const float *ulp);
void zlamsh (MKL_Complex16 *s, const MKL_INT *lds, MKL_INT *nbulge, const MKL_INT *jblk, MKL_Complex16 *h, const MKL_INT *ldh, const MKL_INT *n, const double *ulp);
```

#### Include Files

- mkl_scalapack.h

#### Description

The `?lamsh` function sends multiple shifts through a small (single node) matrix to see how small consecutive subdiagonal elements are modified by subsequent shifts in an effort to maximize the number of bulges that can be sent through. The function should only be called when there are multiple shifts/bulges (`nbulge > 1`) and the first shift is starting in the middle of an unreduced Hessenberg matrix because of two or more small consecutive subdiagonal elements.

#### Input Parameters

- **s**: (local)
  Array of size `lds*2*jblk`. 
On entry, the matrix of shifts. Only the 2x2 diagonal of \( s \) is referenced. It is assumed that \( s \) has \( jblk \) double shifts (size 2).

\( lds \) (local)

On entry, the leading dimension of \( S \); unchanged on exit. \( 1 < nbulge \leq jblk \leq lds/2 \).

\( nbulge \) (local)

On entry, the number of bulges to send through \( h \) \((>1)\). \( nbulge \) should be less than the maximum determined \( (jblk) \). \( 1 < nbulge \leq jblk \leq lds/2 \).

\( jblk \) (local)

On entry, the number of double shifts determined for \( S \); unchanged on exit.

\( h \) (local)

Array of size \( ldh \times n \).

On entry, the local matrix to apply the shifts on. \( h \) should be aligned so that the starting row is 2.

\( ldh \) (local)

On entry, the leading dimension of \( H \); unchanged on exit.

\( n \) (local)

On entry, the size of \( H \). If all the bulges are expected to go through, \( n \) should be at least \( 4nbulge+2 \). Otherwise, \( nbulge \) may be reduced by this function.

\( ulp \) (local)

On entry, machine precision. Unchanged on exit.

**Output Parameters**

\( s \)

On exit, the data is rearranged in the best order for applying.

\( nbulge \)

On exit, the maximum number of bulges that can be sent through.

\( h \)

On exit, the data is destroyed.

**See Also**

Overview for details of ScaLAPACK array descriptor structures and related notations.

?lapst

_Sorts the numbers in increasing or decreasing order._

**Syntax**

```c
void slapst (const char* id, const MKL_INT* n, const float* d, MKL_INT* indx, MKL_INT* info);
void dlapst (const char* id, const MKL_INT* n, const double* d, MKL_INT* indx, MKL_INT* info);
```
Include Files

- mkl_scalapack.h

Description

?lapst is a modified version of the LAPACK routine ?lasrt. Define a permutation indx that sorts the numbers in d in increasing order (if id = 'I') or in decreasing order (if id = 'D').

Use Quick Sort, reverting to Insertion sort on arrays of size <= 20. Dimension of STACK limits n to about $2^{32}$.

Input Parameters

- id
  - = 'I': sort d in increasing order;
  - = 'D': sort d in decreasing order.
- n
  - The length of the array d.
- d
  - Array, size (n)
  - The array to be sorted.

Output Parameters

- indx
  - Array, size (n).
  - The permutation which sorts the array d.
- info
  - = 0: successful exit
  - < 0: if info = -i, the i-th argument had an illegal value

?laqr6

Performs a single small-bulge multi-shift QR sweep collecting the transformations.

Syntax

void slaqr6(char* job, MKL_INT* wantt, MKL_INT* wantz, MKL_INT* kacc22, MKL_INT* n, MKL_INT* ktop, MKL_INT* kbot, MKL_INT* nshfts, float* sr, float* si, float* h, MKL_INT* ldh, MKL_INT* iloz, MKL_INT* ihiz, float* z, MKL_INT* ldz, float* v, MKL_INT* ldv, float* u, MKL_INT* ldu, MKL_INT* nv, float* wv, MKL_INT* ldwv, MKL_INT* nh, float* wh, MKL_INT* ldwh);

void dlaqr6(char* job, MKL_INT* wantt, MKL_INT* wantz, MKL_INT* kacc22, MKL_INT* n, MKL_INT* ktop, MKL_INT* kbot, MKL_INT* nshfts, double* sr, double* si, double* h, MKL_INT* ldh, MKL_INT* iloz, MKL_INT* ihiz, double* z, MKL_INT* ldz, double* v, MKL_INT* ldv, double* u, MKL_INT* ldu, MKL_INT* nv, double* wv, MKL_INT* ldwv, MKL_INT* nh, double* wh, MKL_INT* ldwh);

Include Files

- mkl_scalapack.h
Description

This auxiliary function performs a single small-bulge multi-shift QR sweep, moving the chain of bulges from top to bottom in the submatrix $H(ktop:kbot, ktop:kbot)$, collecting the transformations in the matrix $V$ or accumulating the transformations in the matrix $Z$ (see below).

This is a modified version of ?laqr5 from LAPACK 3.1.

Input Parameters

$job$

Set the kind of job to do in ?laqr6, as follows:

- $job = 'I'$: Introduce and chase bulges in submatrix
- $job = 'C'$: Chase bulges from top to bottom of submatrix
- $job = 'O'$: Chase bulges off submatrix

$wantt$

$wantt$ is non-zero if the quasi-triangular Schur factor is being computed. $wantt$ is set to zero otherwise.

$wantz$

$wantz$ is non-zero if the orthogonal Schur factor is being computed. $wantz$ is set to zero otherwise.

$kacc22$

Specifies the computation mode of far-from-diagonal orthogonal updates.

- $kacc22 = 0$: ?laqr6 does not accumulate reflections and does not use matrix-matrix multiply to update far-from-diagonal matrix entries.
- $kacc22 = 1$: ?laqr6 accumulates reflections and uses matrix-matrix multiply to update the far-from-diagonal matrix entries.

$n$

$n$ is the order of the Hessenberg matrix $H$ upon which this function operates.

$ktop, kbot$

These are the first and last rows and columns of an isolated diagonal block upon which the QR sweep is to be applied. It is assumed without a check that either $ktop = 1$ or $H(ktop, ktop-1) = 0$ and either $kbot = n$ or $H(kbot+1, kbot) = 0$.

$nshfts$

$nshfts$ gives the number of simultaneous shifts. $nshfts$ must be positive and even.

$sr, si$

Array of size $nshfts$

$sr$ contains the real parts and $si$ contains the imaginary parts of the $nshfts$ shifts of origin that define the multi-shift QR sweep.

$h$

Array of size $ldh * n$

On input $h$ contains a Hessenberg matrix $H$.

$ldh$

$ldh$ is the leading dimension of $H$ just as declared in the calling function. $ldh \geq \max(1, n)$.

$iloz, ihiz$

Specify the rows of the matrix $Z$ to which transformations must be applied if $wantz$ is non-zero. $1 \leq iloz, ihiz \leq n$. 
**Array of size** $ldz \times ktop$

If $\text{wantz}$ is non-zero, then the QR sweep orthogonal similarity transformation is accumulated into the matrix $Z(iloz:ihiz,kbot:ktop)$, stored in the array $z$, from the right.

If $\text{wantz}$ equals zero, then $z$ is unreferenced.

$ldz$

$ldz$ is the leading dimension of $z$ just as declared in the calling function. $ldz \geq n$.

$v$

(workspace) array of size $ldv \times nshfts/2$

$ldv$

$ldv$ is the leading dimension of $v$ as declared in the calling function. $ldv \geq 3$.

$u$

(workspace) array of size $ldu \times (3 \times nshfts - 3)$

$ldu$

$ldu$ is the leading dimension of $u$ just as declared in the calling function. $ldu \geq 3 \times nshfts - 3$.

$nh$

$nh$ is the number of columns in array $wh$ available for workspace. $nh \geq 1$ is required for usage of this workspace, otherwise the updates of the far-from-diagonal elements will be updated without level 3 BLAS.

$wh$

(workspace) array of size $ldwh \times nh$

$ldwh$

Leading dimension of $wh$ just as declared in the calling function. $ldwh \geq 3 \times nshfts - 3$.

$nv$

$nv$ is the number of rows in $wv$ available for workspace. $nv \geq 1$ is required for usage of this workspace, otherwise the updates of the far-from-diagonal elements will be updated without level 3 BLAS.

$wv$

(workspace) array of size $ldwv \times 3 \times nshfts$

$ldwv$

Scalar

$ldwv$ is the leading dimension of $wv$ as declared in the in the calling function. $ldwv \geq nv$.

**OUTPUT Parameters**

$h$

A multi-shift QR sweep with shifts $si[j]+i*si[j]$ is applied to the isolated diagonal block in matrix rows and columns $ktop$ through $kbot$.

$z$

If $\text{wantz}$ is non-zero, then the QR sweep orthogonal/unitary similarity transformation is accumulated into the matrix $Z(iloz:ihiz,kbot:ktop)$ from the right.

If $\text{wantz}$ equals zero, then $z$ is unreferenced.

**Application Notes**

**Notes**

Based on contributions by Karen Braman and Ralph Byers, Department of Mathematics, University of Kansas, USA Robert Granat, Department of Computing Science and HPC2N, Umea University, Sweden

**See Also**

Overview for details of ScaLAPACK array descriptor structures and related notations.
?lar1va
Computes scaled eigenvector corresponding to given eigenvalue.

Syntax
void slar1va (MKL_INT* n, MKL_INT* b1, MKL_INT* bn, float* lambda, float* d, float* l, float* ld, float* lld, float* pivmin, float* gaptol, float* z, MKL_INT* wantnc, MKL_INT* negcnt, float* ztz, float* mingma, MKL_INT* r, MKL_INT* isuppz, float* nrminv, float* resid, float* rqcorr, float* work);
void dlar1va (MKL_INT* n, MKL_INT* b1, MKL_INT* bn, double* lambda, double* d, double* l, double* ld, double* lld, double* pivmin, double* gaptol, double* z, MKL_INT* wantnc, MKL_INT* negcnt, double* ztz, double* mingma, MKL_INT* r, MKL_INT* isuppz, double* nrminv, double* resid, double* rqcorr, double* work);

Include Files
• mkl_scalapack.h

Description
?lar1va computes the (scaled) r-th column of the inverse of the submatrix in rows b1 through bn of the tridiagonal matrix \( LDL^T - \lambda I \). When \( \lambda \) is close to an eigenvalue, the computed vector is an accurate eigenvector. Usually, \( r \) corresponds to the index where the eigenvector is largest in magnitude. The following steps accomplish this computation:

1. Stationary qd transform, \( LDL^T - \lambda I = L_1 D_1 L_1^T \).
2. Progressive qd transform, \( LDL^T - \lambda I = U D U^T \).
3. Computation of the diagonal elements of the inverse of \( LDL^T - \lambda I \) by combining the above transforms, and choosing \( r \) as the index where the diagonal of the inverse is (one of the) largest in magnitude.
4. Computation of the (scaled) r-th column of the inverse using the twisted factorization obtained by combining the top part of the stationary and the bottom part of the progressive transform.

Input Parameters

n
The order of the matrix \( LDL^T \).

b1
First index of the submatrix of \( LDL^T \).

bn
Last index of the submatrix of \( LDL^T \).

lambda
The shift \( \lambda \). In order to compute an accurate eigenvector, \( \lambda \) should be a good approximation to an eigenvalue of \( LDL^T \).

l
Array of size \( n-1 \)

The \( (n-1) \) subdiagonal elements of the unit bidiagonal matrix \( L \), in elements 0 to \( n-2 \).

d
Array of size \( n \)

The \( n \) diagonal elements of the diagonal matrix \( D \).

ld
Array of size \( n-1 \)

The \( n-1 \) elements \( l[i]*d[i], i=0,\ldots,n-2 \).

lld
Array of size \( n-1 \)
The \( n-1 \) elements \( l[i,i] \cdot d[i], i=0, \ldots, n-2 \).

**pivmin**
The minimum pivot in the Sturm sequence.

**gaptol**
Tolerance that indicates when eigenvector entries are negligible with respect to their contribution to the residual.

**z**
Array of size \( n \)

On input, all entries of \( z \) must be set to 0.

**wantnc**
Specifies whether \( \text{negcnt} \) has to be computed.

**r**
The twist index for the twisted factorization used to compute \( z \).

On input, \( 0 \leq r \leq n \). If \( r \) is input as 0, \( r \) is set to the index where \((LDL^T - \sigma I)^{-1}\) is largest in magnitude. If \( 1 \leq r \leq n \), \( r \) is unchanged.

Ideally, \( r \) designates the position of the maximum entry in the eigenvector.

**work**
(Workspace) array of size \( 4 \times n \)

**OUTPUT Parameters**

**z**
On output, \( z \) contains the (scaled) \( r \)-th column of the inverse. The scaling is such that \( z[r-1] \) equals 1.

**negcnt**
If \( \text{wantncis non-zero} \) then \( \text{negcnt} = \text{the number of pivots} < \text{pivmin} \) in the matrix factorization \( LDL^T \), and \( \text{negcnt} = -1 \) otherwise.

**ztz**
The square of the 2-norm of \( z \).

**mingma**
The reciprocal of the largest (in magnitude) diagonal element of the inverse of \( LDL^T - \sigma I \).

**r**
On output, \( r \) contains the twist index used to compute \( z \).

**isuppz**
array of size 2

The support of the vector in \( z \), i.e., the vector \( z \) is non-zero only in elements \( \text{isuppz}[0] \) and \( \text{isuppz}[1] \).

**nrminv**
\( nrminv = 1/\text{SQRT}(ztz) \)

**resid**
The residual of the FP vector.

\( resid = \text{ABS}(mingma)/\text{SQRT}(ztz) \)

**rqcorr**
The Rayleigh Quotient correction to \( \lambda \).

**See Also**
**Overview** for details of ScaLAPACK array descriptor structures and related notations.

**?laref**
Applies Householder reflectors to matrices on their rows or columns.
Syntax

void slaref (const char* type, float* a, const MKL_INT* lda, const MKL_INT* wantz, float* z, const MKL_INT* ldz, const MKL_INT* block, MKL_INT* irow1, MKL_INT* icoll, const MKL_INT* istart, const MKL_INT* istop, const MKL_INT* itmp1, const MKL_INT* itmp2, const MKL_INT* liloz, const MKL_INT* lihiz, const float* vecs, float* v2, float* v3, float* t1, float* t2, float* t3);

void dlaref (const char* type, double* a, const MKL_INT* lda, const MKL_INT* wantz, double* z, const MKL_INT* ldz, const MKL_INT* block, MKL_INT* irow1, MKL_INT* icoll, const MKL_INT* istart, const MKL_INT* istop, const MKL_INT* itmp1, const MKL_INT* itmp2, const MKL_INT* liloz, const MKL_INT* lihiz, const double* vecs, double* v2, double* v3, double* t1, double* t2, double* t3);

void claref (const char* type, MKL_Complex8* a, const MKL_INT* lda, const MKL_INT* wantz, MKL_Complex8* z, const MKL_INT* ldz, const MKL_INT* block, MKL_INT* irow1, MKL_INT* icoll, const MKL_INT* istart, const MKL_INT* istop, const MKL_INT* itmp1, const MKL_INT* itmp2, const MKL_INT* liloz, const MKL_INT* lihiz, const MKL_Complex8* vecs, MKL_Complex8* v2, MKL_Complex8* v3, MKL_Complex8* t1, MKL_Complex8* t2, MKL_Complex8* t3);

void zlaref (const char* type, MKL_Complex16* a, const MKL_INT* lda, const MKL_INT* wantz, MKL_Complex16* z, const MKL_INT* ldz, const MKL_INT* block, MKL_INT* irow1, MKL_INT* icoll, const MKL_INT* istart, const MKL_INT* istop, const MKL_INT* itmp1, const MKL_INT* itmp2, const MKL_INT* liloz, const MKL_INT* lihiz, const MKL_Complex16* vecs, MKL_Complex16* v2, MKL_Complex16* v3, MKL_Complex16* t1, MKL_Complex16* t2, MKL_Complex16* t3);

Include Files

• mkl_scalapack.h

Description

?laref applies one or several Householder reflectors of size 3 to one or two matrices (if column is specified) on either their rows or columns.

Input Parameters

type
(local)

If 'R': Apply reflectors to the rows of the matrix (apply from left)
Otherwise: Apply reflectors to the columns of the matrix
Unchanged on exit.

a
(local)

Array, lda*LOCc(ja+n-1)

On entry, the matrix to receive the reflections.

lda
(local)

On entry, the leading dimension of a.

Unchanged on exit.

wantz
(local)
If \( \text{want} z \neq 0 \), then apply any column reflections to \( z \) as well.

If \( \text{want} z = 0 \), then do no additional work on \( z \).

\( z \)

(local)

Array, \( ldz * ncols \), where the value \( ncols \) depends on other arguments. If \( \text{want} z \text{want} z \neq 0 \) and \( \text{type} \neq 'R' \) then \( ncols = icoil + 3*(lihiz - liloz + 1) \). Otherwise, \( ncols \) is unused.

On entry, the second matrix to receive column reflections.

This is changed only if \( \text{want} z \) is set.

\( ldz \)

(local)

On entry, the leading dimension of \( z \).

Unchanged on exit.

\( \text{block} \)

(local)

If nonzero, then apply several reflectors at once and read their data from the \( \text{vecs} \) array.

If zero, apply the single reflector given by \( v2, v3, t1, t2, \) and \( t3 \).

\( irow1 \)

(local)

On entry, the local row element of \( a \).

\( icol1 \)

(local)

On entry, the local column element of \( a \).

\( \text{istart} \)

(local)

Specifies the "number" of the first reflector. This is used as an index into \( \text{vecs} \) if \( \text{block} \) is set. \( \text{istart} \) is ignored if \( \text{block} \) is zero.

\( \text{istop} \)

(local)

Specifies the "number" of the last reflector. This is used as an index into \( \text{vecs} \) if \( \text{block} \) is set. \( \text{istop} \) is ignored if \( \text{block} \) is zero.

\( \text{itmp1} \)

(local)

Starting range into \( a \). For rows, this is the local first column. For columns, this is the local first row.

\( \text{itmp2} \)

(local)

Ending range into \( a \). For rows, this is the local last column. For columns, this is the local last row.

\( \text{liloz, lihiz} \)

(local)

These serve the same purpose as \( \text{itmp1, itmp2} \) but for \( z \) when \( \text{want} z \) is set.

\( \text{vecs} \)

(local)
Array of size $3\times N$ (matrix size)
This holds the size 3 reflectors one after another and this is only accessed when block is nonzero

$v_2, v_3, t_1, t_2, t_3$ (local)
This holds information on a single size 3 Householder reflector and is read when block is zero, and overwritten when block is nonzero

**Output Parameters**

*a*
The updated matrix on exit.

*z*
This is changed only if wantz is set.

*irow1*
Undefined on output.

*icol1*
Undefined on output.

$v_2, v_3, t_1, t_2, t_3$ Overwritten when block is nonzero.

---

**slarrb2**
*Provides limited bisection to locate eigenvalues for more accuracy.*

**Syntax**

```c
void slarrb2(MKL_INT* n, float* d, float* lld, MKL_INT* ifirst, MKL_INT* ilast, float* rtol1, float* rtol2, MKL_INT* offset, float* w, float* wgap, float* werr, float* work, MKL_INT* iwork, float* pivmin, float* lgpvmn, float* lgspdm, MKL_INT* twist, MKL_INT* info);
```

```c
void dlarrb2(MKL_INT* n, double* d, double* lld, MKL_INT* ifirst, MKL_INT* ilast, double* rtol1, double* rtol2, MKL_INT* offset, double* w, double* wgap, double* werr, double* work, MKL_INT* iwork, double* pivmin, double* lgpvmn, double* lgspdm, MKL_INT* twist, MKL_INT* info);
```

**Include Files**

- mkl_scalapack.h

**Description**

Given the relatively robust representation (RRR) $LDL^T$, ?larrb2 does "limited" bisection to refine the eigenvalues of $LDL^T$ with indices in a given range to more accuracy. Initial guesses for these eigenvalues are input in $w$, the corresponding estimate of the error in these guesses and their gaps are input in $werr$ and $wgap$, respectively. During bisection, intervals $[left, right]$ are maintained by storing their mid-points and semi-widths in the arrays $w$ and $werr$ respectively. The range of indices is specified by the $ifirst$, $ilast$, and $offset$ parameters, as explained in Input Parameters.
NOTE
There are very few minor differences between larrb from LAPACK and this current function ?larrb2. The most important reason for creating this nearly identical copy is profiling: in the ScaLAPACK MRRR algorithm, eigenvalue computation using ?larrb2 is used for refinement in the construction of the representation tree, as opposed to the initial computation of the eigenvalues for the root RRR which uses ?larrb. When profiling, this allows an easy quantification of refinement work vs. computing eigenvalues of the root.

Input Parameters

\( n \)

The order of the matrix.

\( d \)

Array of size \( n \).

The \( n \) diagonal elements of the diagonal matrix \( D \).

\( lld \)

Array of size \( n-1 \).

The \((n-1)\) elements \( l_{i+1} \cdot l_{i+1} \cdot d[i] \), \( i=0, ..., n-2 \).

\( ifirst \)

The index of the first eigenvalue to be computed.

\( ilast \)

The index of the last eigenvalue to be computed.

\( rtol1, rtol2 \)

Tolerance for the convergence of the bisection intervals.

An interval \([left, right]\) has converged if \( right - left < \max (rtol1 \cdot \text{gap}, rtol2 \cdot \max (|left|, |right|)) \) where \( \text{gap} \) is the (estimated) distance to the nearest eigenvalue.

\( offset \)

Offset for the arrays \( w, \text{wgap and werr} \), i.e., the elements indexed \( ifirst - offset - 1 \) through \( ilast - offset - 1 \) of these arrays are to be used.

\( w \)

Array of size \( n \).

On input, \( w[ifirst - offset - 1] \) through \( w[ilast - offset - 1] \) are estimates of the eigenvalues of \( LDL^T \) indexed \( ifirst \) through \( ilast \).

\( wgap \)

Array of size \( n-1 \).

On input, the (estimated) gaps between consecutive eigenvalues of \( LDL^T \), i.e., \( wgap[I - offset - 1] \) is the gap between eigenvalues \( I \) and \( I + 1 \). Note that if \( ifirst = ilast \) then \( wgap[ifirst - offset - 1] \) must be set to zero.

\( werr \)

Array of size \( n \).

On input, \( werr[ifirst - offset - 1] \) through \( werr[ilast - offset - 1] \) are the errors in the estimates of the corresponding elements in \( w \).

\( work \)

(workspace) array of size \( 4 \cdot n \).

Workspace.

\( iwork \)

(workspace) array of size \( 2 \cdot n \).

Workspace.

\( pivmin \)

The minimum pivot in the Sturm sequence.
Logarithm of $\text{pivmin}$, precomputed.

Logarithm of the spectral diameter, precomputed.

The twist index for the twisted factorization that is used for the $\text{negcount}$.

- $\text{twist} = n$: Compute $\text{negcount}$ from $\text{LDL}^T - \lambda I = L_d D_d L_d^T$
- $\text{twist} = 1$: Compute $\text{negcount}$ from $\text{LDL}^T - \lambda I = U_d D_d U_d^T$
- $\text{twist} = r, 1 < r < n$: Compute $\text{negcount}$ from $\text{LDL}^T - \lambda I = N_r \Delta_r N_r^T$

**OUTPUT Parameters**

- $w$: On output, the eigenvalue estimates in $w$ are refined.
- $\text{wgap}$: On output, the eigenvalue gaps in $\text{wgap}$ are refined.
- $\text{werr}$: On output, the errors in $\text{werr}$ are refined.
- $\text{info}$: Error flag.

**See Also**

MKL_INT* iblock, MKL_INT* indexw, float* work, MKL_INT* iwork, MKL_INT* doli,
MKL_INT* dou, MKL_INT* info);

void dlarrd2(char* range, char* order, MKL_INT* n, double* vl, double* vu, MKL_INT* il,
MKL_INT* iu, double* gers, double* reltol, double* d, double* e, double* e2, double* pivmin,
MKL_INT* nsplit, MKL_INT* isplit, MKL_INT* m, double* w, double* werr, double* wl,
double* wu, MKL_INT* iblock, MKL_INT* indexw, double* work, MKL_INT* iwork, MKL_INT* doli,
MKL_INT* dou, MKL_INT* info);
```

**Include Files**

- mkl_scalapack.h

**Description**

?larrd2 computes the eigenvalues of a symmetric tridiagonal matrix $T$ to limited initial accuracy. This is an auxiliary code to be called from larre2a.

?larrd2 has been created using the LAPACK code larrd which itself stems from stebz. The motivation for creating ?larrd2 is efficiency: When computing eigenvalues in parallel and the input tridiagonal matrix splits into blocks, ?larrd2 can skip over blocks which contain none of the eigenvalues from DOL to DOU for which the processor responsible. In extreme cases (such as large matrices consisting of many blocks of small size like $2 \times 2$), the gain can be substantial.
Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for
optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and
SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or
effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-
dependent optimizations in this product are intended for use with Intel microprocessors. Certain
optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to
the applicable product User and Reference Guides for more information regarding the specific instruction
sets covered by this notice.

Notice revision #20110804

Input Parameters

**range**

= 'A': ("All") all eigenvalues will be found.
= 'V': ("Value") all eigenvalues in the half-open interval (vl, vu] will be
found.
= 'I': ("Index") eigenvalues of the entire matrix with the indices in a given
range will be found.

**order**

= 'B': ("By Block") the eigenvalues will be grouped by split-off block (see
iblock, isplit) and ordered from smallest to largest within the block.
= 'E': ("Entire matrix") the eigenvalues for the entire matrix will be ordered
from smallest to largest.

**n**

The order of the tridiagonal matrix \(T\). \(n \geq 0\).

**vl, vu**

If range='V', the lower and upper bounds of the interval to be searched for
eigenvalues. Eigenvalues less than or equal to \(vl\), or greater than \(vu\), will
not be returned. \(vl < vu\).

Not referenced if range = 'A' or 'I'.

**il, iu**

If range='I', the indices (in ascending order) of the smallest eigenvalue, to
be returned in \(w[il-1]\), and largest eigenvalue, to be returned in \(w[iu-1]\).
\(1 \leq il \leq iu \leq n\), if \(n > 0\); \(il = 1\) and \(iu = 0\) if \(n = 0\).

Not referenced if range = 'A' or 'V'.

**gers**

Array of size 2*\(n\)
The \(n\) Gerschgorin intervals (the \(i\)-th Gerschgorin interval is \(gers[2*i-2],
gers[2*i-1])\).

**reltol**

The minimum relative width of an interval. When an interval is narrower
than reltol times the larger (in magnitude) endpoint, then it is considered
to be sufficiently small, i.e., converged. Note: this should always be at least
radix*machine epsilon.

**d**

Array of size \(n\)
The \(n\) diagonal elements of the tridiagonal matrix \(T\).

**e**

Array of size \(n-1\)
The \((n-1)\) off-diagonal elements of the tridiagonal matrix \(T\).
e2

Array of size \( n-1 \)
The \((n-1)\) squared off-diagonal elements of the tridiagonal matrix \( T \).

pivmin

The minimum pivot allowed in the sturm sequence for \( T \).

nsplit

The number of diagonal blocks in the matrix \( T \).
\[ 1 \leq \text{nsplit} \leq n. \]

isplit

Array of size \( n \)
The splitting points, at which \( T \) breaks up into submatrices.
The first submatrix consists of rows/columns 1 to \( \text{isplit}[0] \), the second of rows/columns \( \text{isplit}[0]+1 \) through \( \text{isplit}[1] \), etc., and the \( \text{nsplit} \)-th submatrix consists of rows/columns \( \text{isplit}[\text{nsplit}-2]+1 \) through \( \text{isplit}[\text{nsplit}-1]=n \).
(Only the first \( \text{nsplit} \) elements will actually be used, but since the user cannot know a priori what value \( \text{nsplit} \) will have, \( n \) words must be reserved for \( \text{isplit} \).

work

(workspace) Array of size \( 4*n \)

iwork

(workspace) Array of size \( 3*n \)

Specifying an index range \( \text{dol:dou} \) allows the user to work on only a selected part of the representation tree.
Otherwise, the setting \( \text{dol}=1, \text{dou}=n \) should be applied.
Note that \( \text{dol} \) and \( \text{dou} \) refer to the order in which the eigenvalues are stored in \( W \).

OUTPUT Parameters

\( m \)

The actual number of eigenvalues found. \( 0 \leq m \leq n \).
(See also the description of \( \text{info}=2,3 \).)

\( w \)

Array of size \( n \)
On exit, the first \( m \) elements of \( w \) will contain the eigenvalue approximations. \( \text{?larrd2} \) computes an interval \( I_j = (a_j, b_j) \) that includes eigenvalue \( j \). The eigenvalue approximation is given as the interval midpoint \( w[j-1] = (a_j + b_j)/2 \). The corresponding error is bounded by \( \text{werr}[j-1] = \text{abs}(a_j - b_j)/2 \).

\( \text{werr} \)

Array of size \( n \)
The error bound on the corresponding eigenvalue approximation in \( w \).

\( \text{wl, wu} \)

The interval \( (\text{wl, wu}) \) contains all the wanted eigenvalues.
If \( \text{range}='V' \), then \( \text{wl} = \text{vl} \) and \( \text{wu} = \text{vu} \).
If \( \text{range}='A' \), then \( \text{wl} \) and \( \text{wu} \) are the global Gerschgorin bounds on the spectrum.
If \( \text{range}='I' \), then \( \text{wl} \) and \( \text{wu} \) are computed by \( \text{SLAEBZ} \) from the index range specified.
iblock

Array of size \( n \)

At each row/column \( j \) where \( e[j-1] \) is zero or small, the matrix \( T \) is considered to split into a block diagonal matrix. On exit, if \( \text{info} = 0 \), \( \text{iblock}[i] \) specifies to which block (from 0 to the number of blocks minus one) the eigenvalue \( w[i] \) belongs. (?larrd2 may use the remaining \( n-m \) elements as workspace.)

indexw

Array of size \( n \)

The indices of the eigenvalues within each block (submatrix); for example, \( \text{indexw}[i] = j \) and \( \text{iblock}[i] = k \) imply that the \((i+1)\)-th eigenvalue \( w[i] \) is the \( j \)-th eigenvalue in block \( k \).

info

\( = 0: \) successful exit
\( < 0: \) if \( \text{info} = -i \), the \( i \)-th argument had an illegal value
\( > 0: \) some or all of the eigenvalues failed to converge or were not computed:
  - \( =1 \) or \( 3: \) Bisection failed to converge for some eigenvalues; these eigenvalues are flagged by a negative block number. The effect is that the eigenvalues may not be as accurate as the absolute and relative tolerances.
  - \( =2 \) or \( 3: \) \( \text{range} = 'I' \) only: Not all of the eigenvalues \( il:iu \) were found.
  - \( =4: \) \( \text{range} = 'I', \) and the Gershgorin interval initially used was too small. No eigenvalues were computed.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

?larr2

Given a tridiagonal matrix, sets small off-diagonal elements to zero and for each unreduced block, finds base representations and eigenvalues.

Syntax

```c
void slarr2(char* range, MKL_INT* n, float* vl, float* vu, MKL_INT* il, MKL_INT* iu, 
float* d, float* e, float* e2, float* rto1, float* rto2, float* spltol, MKL_INT* 
nsplit, MKL_INT* isplit, MKL_INT* m, MKL_INT* dol, MKL_INT* dou, float* w, float* werr, 
float* wgap, MKL_INT* iblock, MKL_INT* indexw, float* gers, float* pivmin, float* work, 
MKL_INT* iwork, MKL_INT* info);

void dlarr2(char* range, MKL_INT* n, double* vl, double* vu, MKL_INT* il, MKL_INT* iu, 
double* d, double* e, double* e2, double* rto1, double* rto2, double* spltol, MKL_INT* 
nsplit, MKL_INT* isplit, MKL_INT* m, MKL_INT* dol, MKL_INT* dou, double* w, double* 
werr, double* wgap, MKL_INT* iblock, MKL_INT* indexw, double* gers, double* pivmin, 
double* work, MKL_INT* iwork, MKL_INT* info);
```

Include Files

- `mkl_scalapack.h`
Description
To find the desired eigenvalues of a given real symmetric tridiagonal matrix $T$, \texttt{?larre2} sets, via \texttt{?larra}, "small" off-diagonal elements to zero. For each block $T_i$, it finds

- a suitable shift at one end of the block's spectrum,
- the root RRR, $T_i - \sigma_i L_i D_i L_i^T$, and
- eigenvalues of each $L_i D_i L_i^T$.

The representations and eigenvalues found are then returned to \texttt{?stegr2} to compute the eigenvectors $T$.

\texttt{?larre2} is more suitable for parallel computation than the original LAPACK code for computing the root RRR and its eigenvalues. When computing eigenvalues in parallel and the input tridiagonal matrix splits into blocks, \texttt{?larre2} can skip over blocks which contain none of the eigenvalues from $dol$ to $dou$ for which the processor is responsible. In extreme cases (such as large matrices consisting of many blocks of small size, e.g. 2x2), the gain can be substantial.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

\texttt{range}

- 'A': ("All") all eigenvalues will be found.
- 'V': ("Value") all eigenvalues in the half-open interval $(vl, vu]$ will be found.
- 'I': ("Index") eigenvalues of the entire matrix with the indices in a given range will be found.

\texttt{n}

The order of the matrix. $n > 0$.

\texttt{vl, vu}

If \texttt{range}='V', the lower and upper bounds for the eigenvalues.

Eigenvalues less than or equal to $vl$, or greater than $vu$, will not be returned. $vl < vu$.

\texttt{il, iu}

If \texttt{range}='I', the indices (in ascending order) of the smallest eigenvalue, to be returned in $w[il-1]$, and largest eigenvalue, to be returned in $w[iu-1]$. $1 \leq il \leq iu \leq n$.

\texttt{d}

Array of size $n$

The $n$ diagonal elements of the tridiagonal matrix $T$.

\texttt{e}

Array of size $n$

The first $(n-1)$ entries contain the subdiagonal elements of the tridiagonal matrix $T$; $e[n-1]$ need not be set.
The first \((n-1)\) entries contain the squares of the subdiagonal elements of the tridiagonal matrix \(T\); \(e_2[n-1]\) need not be set.

Parameters for bisection.

An interval \([\text{left}, \text{right}]\) has converged if \(\text{right-left}\leq \max(\text{rtol1}\times\text{gap}, \text{rtol2}\times\max(|\text{left}|,|\text{right}|))\)

The threshold for splitting.

Specifying an index range \(\text{dol: dou}\) allows the user to work on only a selected part of the representation tree. Otherwise, the setting \(\text{dol}=1, \text{dou}=n\) should be applied.

Note that \(\text{dol}\) and \(\text{dou}\) refer to the order in which the eigenvalues are stored in \(w\).

Workspace array of size \(6\times n\)

Workspace array of size \(5\times n\)

If \(\text{range}='I'\) or \(='A'\), \(\text{larrre2}\) contains bounds on the desired part of the spectrum.

The \(n\) diagonal elements of the diagonal matrices \(D_i\).

The entries \(e[\text{isplit}][i]\), \(0\leq\text{isplit}\), contain the base points \(\sigma_{i+1}\) on output.

The entries \(e_2[\text{isplit}][i]\), \(0\leq\text{isplit}\), are set to zero.

The number of blocks \(T\) splits into. \(1\leq\text{nsplit}\leq n\).

Array of size \(n\)

The splitting points, at which \(T\) breaks up into blocks.

The first block consists of rows/columns 1 to \(\text{isplit}[0]\), the second of rows/columns \(\text{isplit}[0]+1\) through \(\text{isplit}[1]\), etc., and the \(\text{nsplit}\)-th block consists of rows/columns \(\text{isplit}[\text{nsplit}-2]+1\) through \(\text{isplit}[\text{nsplit}-1]=n\).

The total number of eigenvalues (of all \(L_iD_iL_i^\top\)) found.

Array of size \(n\)

The first \(m\) elements contain the eigenvalues. The eigenvalues of each of the blocks, \(L_iD_iL_i^\top\), are sorted in ascending order (\(\text{larrre2}\) may use the remaining \(n-m\) elements as workspace).

Note that immediately after exiting this function, only the eigenvalues in \(w\) with indices in range \(\text{dol}-1:\text{dou}-1\) might rely on this processor when the eigenvalue computation is done in parallel.
The error bound on the corresponding eigenvalue in $w$.

Note that immediately after exiting this function, only the uncertainties in $werr$ with indices in range $dol-1:dou-1$ might rely on this processor when the eigenvalue computation is done in parallel.

$w_{gap}$

Array of size $n$

The separation from the right neighbor eigenvalue in $w$.

The gap is only with respect to the eigenvalues of the same block as each block has its own representation tree.

Exception: at the right end of a block we store the left gap

Note that immediately after exiting this function, only the gaps in $w_{gap}$ with indices in range $dol-1:dou-1$ might rely on this processor when the eigenvalue computation is done in parallel.

$iblock$

Array of size $n$

The indices of the blocks (submatrices) associated with the corresponding eigenvalues in $w$; $iblock[i]=1$ if eigenvalue $w[i]$ belongs to the first block from the top, $iblock[i]=2$ if $w[i]$ belongs to the second block, and so on.

$indexw$

Array of size $n$

The indices of the eigenvalues within each block (submatrix); for example, $indexw[i]=10$ and $iblock[i]=2$ imply that the $(i+1)$-th eigenvalue $w[i]$ is the 10th eigenvalue in block 2.

$gers$

Array of size $2*n$

The $n$ Gerschgorin intervals (the $i$-th Gerschgorin interval is $(gers[2*i-2], gers[2*i-1])$).

$pivmin$

The minimum pivot in the sturm sequence for $T$.

$info$

- $= 0$: successful exit
- $> 0$: A problem occurred in $?larrre2$.
- $< 0$: One of the called functions signaled an internal problem.

Needs inspection of the corresponding parameter $info$ for further information.

- $=-1$: Problem in $?larrd$.
- $=-2$: Not enough internal iterations to find the base representation.
- $=-4$: Problem in $?larrb$ when preforming bisection on the desired part of the spectrum.
- $=-5$: Problem in $?lasq2$
- $=-6$: Problem in $?lasq2$

See Also

Overview for details of ScALAPACK array descriptor structures and related notations.
?larre2a
Given a tridiagonal matrix, sets small off-diagonal elements to zero and for each unreduced block, finds base representations and eigenvalues.

Syntax

```c
void slarre2a(char* range, MKL_INT* n, float* vl, float* vu, MKL_INT* il, MKL_INT* iu, float* d, float* e, float* e2, float* rtol1, float* rtol2, float* spltol, MKL_INT* nsplit, MKL_INT* isplit, MKL_INT* m, MKL_INT* dol, MKL_INT* dou, MKL_INT* needil, MKL_INT* neediu, float* w, float* werr, float* wgap, MKL_INT* iblock, MKL_INT* indexw, float* gers, float* sdiam, float* pivmin, float* work, MKL_INT* iwork, float* minrgp, MKL_INT* info);

void dlarre2a(char* range, MKL_INT* n, double* vl, double* vu, MKL_INT* il, MKL_INT* iu, double* d, double* e, double* e2, double* rtol1, double* rtol2, double* spltol, MKL_INT* nsplit, MKL_INT* isplit, MKL_INT* m, MKL_INT* Dol, MKL_INT* dou, MKL_INT* needil, MKL_INT* neediu, double* w, double* werr, double* wgap, MKL_INT* iblock, MKL_INT* indexw, double* gers, double* sdiam, double* pivmin, double* work, MKL_INT* iwork, double* minrgp, MKL_INT* info);
```

Include Files

- mkl_scalapack.h

Description

To find the desired eigenvalues of a given real symmetric tridiagonal matrix $T$, ?larre2a sets any "small" off-diagonal elements to zero, and for each unreduced block $T_i$, it finds

- a suitable shift at one end of the block's spectrum,
- the base representation, $T_i - \sigma_i I = L_i D_i L_i^T$, and
- eigenvalues of each $L_i D_i L_i^T$.

NOTE
The algorithm obtains a crude picture of all the wanted eigenvalues (as selected by range). However, to reduce work and improve scalability, only the eigenvalues $dol$ to $dou$ are refined. Furthermore, if the matrix splits into blocks, RRRs for blocks that do not contain eigenvalues from $dol$ to $dou$ are skipped. The DQDS algorithm (function ?lasq2) is not used, unlike in the sequential case. Instead, eigenvalues are computed in parallel to some figures using bisection.

Optimization Notice

Notice revision #20110804
Input Parameters

range

- 'A': ("All") all eigenvalues will be found.
- 'V': ("Value") all eigenvalues in the half-open interval \((vl, vu]\) will be found.
- 'I': ("Index") eigenvalues of the entire matrix with the indices in a given range will be found.

n

The order of the matrix. \(n > 0\).

vl, vu

If \(range='V'\), the lower and upper bounds for the eigenvalues. Eigenvalues less than or equal to \(vl\), or greater than \(vu\), will not be returned. \(vl < vu\).

If \(range='I'\) or \(='A'\), \(?larre2a\) computes bounds on the desired part of the spectrum.

il, iu

If \(range='I'\), the indices (in ascending order) of the smallest eigenvalue, to be returned in \(w[il-1]\), and largest eigenvalue, to be returned in \(w[iu-1]\). \(1 \leq il \leq iu \leq n\).

d

Array of size \(n\)

On entry, the \(n\) diagonal elements of the tridiagonal matrix \(T\).

e

Array of size \(n\)

The first \((n-1)\) entries contain the subdiagonal elements of the tridiagonal matrix \(T\); \(e[n-1]\) need not be set.

e2

Array of size \(n\)

The first \((n-1)\) entries contain the squares of the subdiagonal elements of the tridiagonal matrix \(T\); \(e2[n-1]\) need not be set.

rtol1, rtol2

Parameters for bisection.

An interval \([left, right]\) has converged if \(right - left < max(\ rtol1*gap, \ rtol2*max(|left|,|right|))\)

spltol

The threshold for splitting.

dol, dou

If the user wants to work on only a selected part of the representation tree, he can specify an index range \(dol:dou\).

Otherwise, the setting \(dol=1, dou=n\) should be applied.

Note that \(dol\) and \(dou\) refer to the order in which the eigenvalues are stored in \(w\).

work

Workspace array of size \(6*n\)

iwork

Workspace array of size \(5*n\)

minrgp

The minimum relative gap threshold to decide whether an eigenvalue or a cluster boundary is reached.
OUTPUT Parameters

vl, vu
If range='V', the lower and upper bounds for the eigenvalues. Eigenvalues
less than or equal to vl, or greater than vu, are not returned. vl < vu.
If range='I' or range='A', ?larr2a computes bounds on the desired part
of the spectrum.

d
The n diagonal elements of the diagonal matrices D_i.
e
contains the subdiagonal elements of the unit bidiagonal matrices L_i. The
entries e[isplit[i]], 0 ≤ isplit, contain the base points σ_i+1 on output.
e2
The entries e2[isplit[i]], 0 ≤ isplit have been set to zero.

nsplit
The number of blocks T splits into. 1 ≤ nsplit ≤ n.
isplit
Array of size n
The splitting points, at which T breaks up into blocks.
The first block consists of rows/columns 1 to isplit[0], the second of
rows/columns isplit[0]+1 through isplit[1], etc., and the nsplit-th
block consists of rows/columns isplit[nsplit-2]+1 through
isplit[nsplit-1]=n.
m
The total number of eigenvalues (of all L_iD_iL^T_i) found.
needil, neediu
The indices of the leftmost and rightmost eigenvalues of the root node RRR
which are needed to accurately compute the relevant part of the
representation tree.
w
Array of size n
The first m elements contain the eigenvalues. The eigenvalues of each of the
blocks, L_iD_iL^T_i, are sorted in ascending order (?larr2a may use the
remaining n-m elements as workspace).
Note that immediately after exiting this function, only the eigenvalues in
w with indices in range dol-1:dou-1 rely on this processor because the
eigenvalue computation is done in parallel.
werr
Array of size n
The error bound on the corresponding eigenvalue in w.
Note that immediately after exiting this function, only the uncertainties in
werr with indices in range dol-1:dou-1 are reliable on this processor because the
eigenvalue computation is done in parallel.
wgap
Array of size n
The separation from the right neighbor eigenvalue in w. The gap is only with
respect to the eigenvalues of the same block as each block has its own
representation tree.
Exception: at the right end of a block we store the left gap
Note that immediately after exiting this function, only the gaps in wgap with
indices in range dol-1:dou-1 are reliable on this processor because the
eigenvalue computation is done in parallel.
iblock

Array of size \( n \)

The indices of the blocks (submatrices) associated with the corresponding eigenvalues in \( w \); \( iblock[i]=1 \) if eigenvalue \( w[i] \) belongs to the first block from the top, \( iblock[i]=2 \) if \( w[i] \) belongs to the second block, and so on.

indexw

Array of size \( n \)

The indices of the eigenvalues within each block (submatrix); for example, \( indexw[i] = 10 \) and \( iblock[i]=2 \) imply that the \((i+1)\)-th eigenvalue \( w[i] \) is the 10th eigenvalue in block 2.

gers

Array of size \( 2*n \)

The \( n \) Gerschgorin intervals (the \( i \)-th Gerschgorin interval is \((gers[2*i-2], gers[2*i-1])\)).

pivmin

The minimum pivot in the sturm sequence for \( T \).

info

= 0: successful exit
> 0: A problem occurred in ?larre2a.
< 0: One of the called functions signaled an internal problem. Needs inspection of the corresponding parameter info for further information.
= -2: Not enough internal iterations to find base representation.
= -3: Problem in ?larrb2 when computing the refined root representation.
= -4: Problem in ?larrb2 when preforming bisection on the desired part of the spectrum.
= -9 Problem: \( m < \text{dou-dol+1} \), that is the code found fewer eigenvalues than it was supposed to.

See Also
Overview for details of ScaLAPACK array descriptor structures and related notations.

?larrf2

Finds a new relatively robust representation such that at least one of the eigenvalues is relatively isolated.

Syntax

void slarrf2(MKL_INT* n, float* d, float* l, float* ld, MKL_INT* clstrt, MKL_INT* clend, MKL_INT* clmid1, MKL_INT* clmid2, float* w, float* wgap, float* werr, MKL_INT* trymid, float* spdiam, float* clgapl, float* clgapr, float* pivmin, float* sigma, float* dplus, float* lplus, float* work, MKL_INT* info);

void dlarrf2(MKL_INT* n, double* d, double* l, double* ld, MKL_INT* clstrt, MKL_INT* clend, MKL_INT* clmid1, MKL_INT* clmid2, double* w, double* wgap, double* werr, MKL_INT* trymid, double* spdiam, double* clgapl, double* clgapr, double* pivmin, double* sigma, double* dplus, double* lplus, double* work, MKL_INT* info);

Include Files

• mkl_scalapack.h
Description

Given the initial representation $LDL^T$ and its cluster of close eigenvalues (in a relative measure), defined by the indices of the first and last eigenvalues in the cluster, ?larrf2 finds a new relatively robust representation $LDL^T - \sigma I = L\_4D\_4L\_4^T$ such that at least one of the eigenvalues of $L\_4D\_4L\_4^T$ is relatively isolated.

This is an enhanced version of ?larrf that also tries shifts in the middle of the cluster, should there be a large gap, in order to break large clusters into at least two pieces.

Input Parameters

- $n$ The order of the matrix (subblock, if the matrix was split).
- $d$ Array of size $n$
  The $n$ diagonal elements of the diagonal matrix $D$.
- $l$ Array of size $n-1$
  The ($n-1$) subdiagonal elements of the unit bidiagonal matrix $L$.
- $ld$ Array of size $n-1$
  The ($n-1$) elements $l[i] * d[i]$.
- $clstrt$ The index of the first eigenvalue in the cluster.
- $clend$ The index of the last eigenvalue in the cluster.
- $clmid1, clmid2$ The index of a middle eigenvalue pair with large gap.
- $w$ Array of size $\geq (clend - clstrt + 1)$
  The eigenvalue approximations of $LDL^T$ in ascending order. $w[clstrt - 1]$ through $w[clend - 1]$ form the cluster of relatively close eigenvalues.
- $wgap$ Array of size $\geq (clend - clstrt + 1)$
  The separation from the right neighbor eigenvalue in $w$.
- $werr$ Array of size $\geq (clend - clstrt + 1)$
  $werr$ contains the semiwidth of the uncertainty interval of the corresponding eigenvalue approximation in $w$.
- $spdiam$ Estimate of the spectral diameter obtained from the Gerschgorin intervals
- $clgapl, clgapr$ Absolute gap on each end of the cluster.
  Set by the calling function to protect against shifts too close to eigenvalues outside the cluster.
- $pivmin$ The minimum pivot allowed in the Sturm sequence.
- $work$ Workspace array of size $2*n$

Output Parameters

- $wgap$ Contains refined values of its input approximations. Very small gaps are unchanged.
- $sigma$ The shift ($\sigma$) used to form $L\_4D\_4L\_4^T$. 
**dplus**

Array of size \( n \)

The \( n \) diagonal elements of the diagonal matrix \( D_+ \).

**lplus**

Array of size \( n-1 \)

The first \((n-1)\) elements of \( lplus \) contain the subdiagonal elements of the unit bidiagonal matrix \( L_+ \).

See Also

MKL_INT* parity, MKL_INT* zoffset, MKL_INT* info);

void dlarrv2(MKL_INT* n, double* vl, double* vu, double* d, double* l,
double* pivmin, MKL_INT* isplit, MKL_INT* m, MKL_INT* dol, MKL_INT* dou,
MKL_INT* needil, MKL_INT* neediu, double* minrgp, double* rtoi1,
double* rtoi2, double* w, double* werr, double* wgap, MKL_INT* iblock,
MKL_INT* indexw, double* gers, double* sdiamp, double* z,
MKL_INT* ldz, MKL_INT* isuppz, double* work, MKL_INT* iwork,
MKL_INT* vstart, MKL_INT* finish, MKL_INT* maxcls, MKL_INT* parity,
MKL_INT* zoffset, MKL_INT* info);
```

Include Files

- mkl_scalapack.h

**Description**

`?larrv2` computes the eigenvectors of the tridiagonal matrix \( T = LDL^T \) given \( L, D \) and approximations to the eigenvalues of \( LDL^T \). The input eigenvalues should have been computed by `larre2a` or by previous calls to `?larrv2`.

The major difference between the parallel and the sequential construction of the representation tree is that in the parallel case, not all eigenvalues of a given cluster might be computed locally. Other processors might "own" and refine part of an eigenvalue cluster. This is crucial for scalability. Thus there might be communication necessary before the current level of the representation tree can be parsed.

Please note:

- The calling sequence has two additional integer parameters, \( dol \) and \( dou \), that should satisfy \( m \geq dou \geq dol \geq 1 \). These parameters are only relevant when both eigenvalues and eigenvectors are computed (stegr2b parameter \( jobz = 'V' \)). `?larrv2` only computes the eigenvectors corresponding to eigenvalues \( dol \) through \( dou \) in \( w \). (That is, instead of computing the eigenvectors belonging to \( w[0] \) through \( w[m-1] \), only the eigenvectors belonging to eigenvalues \( w[dol - 1] \) through \( w[dou -1] \) are computed. In this case, only the eigenvalues \( dol:dou \) are guaranteed to be accurately refined to all figures by Rayleigh-Quotient iteration.
The additional arguments \texttt{vstart}, \texttt{finish}, \texttt{ndepth}, \texttt{parity}, \texttt{zoffset} are included as a thread-safe implementation equivalent to save variables. These variables store details about the local representation tree which is computed layerwise. For scalability reasons, eigenvalues belonging to the locally relevant representation tree might be computed on other processors. These need to be communicated before the inspection of the RRRs can proceed on any given layer. Note that only when the variable \texttt{finish} is non-zero, the computation has ended. All eigenpairs between \texttt{dol} and \texttt{dou} have been computed. \texttt{m} is set to \texttt{dou - dol + 1}.

\texttt{?larrv2} needs more workspace in \texttt{z} than the sequential \texttt{slarrv}. It is used to store the conformal embedding of the local representation tree.

</tbody>
</table>

### Input Parameters

- \texttt{n} 
  The order of the matrix. \( n \geq 0 \).

- \texttt{vl, vu} 
  Lower and upper bounds of the interval that contains the desired eigenvalues. \( vl < vu \). Needed to compute gaps on the left or right end of the extremal eigenvalues in the desired range. \( vu \) is currently not used but kept as parameter in case needed.

- \texttt{d} 
  Array of size \( n \)
  The \( n \) diagonal elements of the diagonal matrix \( d \). On exit, \( d \) is overwritten.

- \texttt{l} 
  Array of size \( n \)
  The \((n-1)\) subdiagonal elements of the unit bidiagonal matrix \( L \) are in elements 0 to \( n-2 \) of \( i \) (if the matrix is not split.) At the end of each block is stored the corresponding shift as given by \texttt{?larre}. On exit, \( l \) is overwritten.

- \texttt{pivmin} 
  The minimum pivot allowed in the sturm sequence.

- \texttt{isplit} 
  Array of size \( n \)
  The splitting points, at which the matrix \( T \) breaks up into blocks. The first block consists of rows/columns 1 to \texttt{isplit[0]}, the second of rows/columns \texttt{isplit[0]} + 1 through \texttt{isplit[1]}, etc.

- \texttt{m} 
  The total number of input eigenvalues. \( 0 \leq m \leq n \).

- \texttt{dol, dou} 
  If you want to compute only selected eigenvectors from all the eigenvalues supplied, you can specify an index range \texttt{dol:dou}. Or else the setting \texttt{dol=1, dou=m} should be applied. Note that \texttt{dol} and \texttt{dou} refer to the order in which the eigenvalues are stored in \texttt{w}. If you want to compute only
selected eigenpairs, the columns $dol-1$ to $dou+1$ of the eigenvector space $Z$ contain the computed eigenvectors. All other columns of $Z$ are set to zero.

If $dol > 1$, then $Z(:,dol-1-zoffset)$ is used.

If $dou < n$, then $Z(:,dou+1-zoffset)$ is used.

$needil, neediu$

Describe which are the left and right outermost eigenvalues that still need to be included in the computation. These indices indicate whether eigenvalues from other processors are needed to correctly compute the conformally embedded representation tree.

When $dol\leq needil\leq neediu\leq dou$, all required eigenvalues are local to the processor and no communication is required to compute its part of the representation tree.

$minrgp$

The minimum relative gap threshold to decide whether an eigenvalue or a cluster boundary is reached.

$rtol1, rtol2$

Parameters for bisection. An interval $[left, right]$ has converged if $right-left < \max( rtol1*gap, rtol2*\max(|left|,|right|) )$.

$w$

Array of size $n$

The first $m$ elements of $w$ contain the approximate eigenvalues for which eigenvectors are to be computed. The eigenvalues should be grouped by split-off block and ordered from smallest to largest within the block. (The output array $w$ from $?stegr2a$ is expected here.) Furthermore, they are with respect to the shift of the corresponding root representation for their block.

$werr$

Array of size $n$

The first $m$ elements contain the semiwidth of the uncertainty interval of the corresponding eigenvalue in $w$.

$wgap$

Array of size $n$

The separation from the right neighbor eigenvalue in $w$.

$iblock$

Array of size $n$

The indices of the blocks (submatrices) associated with the corresponding eigenvalues in $w$; $iblock[i]=1$ if eigenvalue $w[i]$ belongs to the first block from the top, $iblock[i]=2$ if $w[i]$ belongs to the second block, and so on.

$indexw$

Array of size $n$

The indices of the eigenvalues within each block (submatrix). For example: $indexw[i]= 10$ and $iblock[i]=2$ imply that the $(i+1)$-th eigenvalue $w[i]$ is the $10$th eigenvalue in block $2$.

$gers$

Array of size $2*n$

The $n$ Gerschgorin intervals (the $i$-th Gerschgorin interval is $(gers[2*i-2], gers[2*i-1])$). The Gerschgorin intervals should be computed from the original unshifted matrix.

Not used but kept as parameter for possible future use.
sdiam

Array of size \( n \)
The spectral diameters for all unreduced blocks.

ldz

The leading dimension of the array \( z \). \( ldz \geq 1 \), and if stegr2b parameter jobz = 'V', \( ldz \geq \max(1,n) \).

work

(workspace) array of size \( 12*n \)

iwork

(workspace) Array of size \( 7*n \)

vstart

Non-zero on initialization, set to zero afterwards.

finish

A flag that indicates whether all eigenpairs have been computed.

maxcls

The largest cluster worked on by this processor in the representation tree.

ndepth

The current depth of the representation tree. Set to zero on initial pass, changed when the deeper levels of the representation tree are generated.

parity

An internal parameter needed for the storage of the clusters on the current level of the representation tree.

zoffset

Offset for storing the eigenpairs when \( z \) is distributed in 1D-cyclic fashion.

OUTPUT Parameters

needil, neediu

Unshifted eigenvalues for which eigenvectors have already been computed.

w

Contains refined values of its input approximations.

werr

Contains refined values of its input approximations. Very small gaps are changed.

wgap

Array of size \( ldz \times \max(1,m) \)

If info = 0, the first \( m \) columns of the matrix \( Z \), stored in the array \( z \), contain the orthonormal eigenvectors of the matrix \( T \) corresponding to the input eigenvalues, with the \( i \)-th column of \( Z \) holding the eigenvector associated with \( \lambda[i-1] \).

In the distributed version, only a subset of columns is accessed, see dol, dou, and zoffset.

isuppz

Array of size \( 2 \times \max(1,m) \)
The support of the eigenvectors in \( z \), i.e., the indices indicating the non-zero elements in \( z \). The \( i \)-th eigenvector is non-zero only in elements \( isuppz[2*i-2] \) through \( isuppz[2*i-1] \).

vstart

Non-zero on initialization, set to zero afterwards.

finish

A flag that indicates whether all eigenpairs have been computed.

maxcls

The largest cluster worked on by this processor in the representation tree.

ndepth

The current depth of the representation tree. Set to zero on initial pass, changed when the deeper levels of the representation tree are generated.
**parity**

An internal parameter needed for the storage of the clusters on the current level of the representation tree.

**info**

- 0: successful exit
- > 0: A problem occurred in ?larrv2.
- < 0: One of the called functions signaled an internal problem. Needs inspection of the corresponding parameter info for further information.
- -1: Problem in ?larrb2 when refining a child's eigenvalues.
- -2: Problem in ?larrf2 when computing the RRR of a child. When a child is inside a tight cluster, it can be difficult to find an RRR. A partial remedy from the user's point of view is to make the parameter minrgp smaller and recompile. However, as the orthogonality of the computed vectors is proportional to 1/minrgp, be aware that decreasing minrgp might be a reduction in precision.
- -3: Problem in ?larrb2 when refining a single eigenvalue after the Rayleigh correction was rejected.
- 5: The Rayleigh Quotient Iteration failed to converge to full accuracy.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

?lasorte

*Sorts eigenpairs by real and complex data types.*

**Syntax**

```c
void slasorte (float *s, MKL_INT *lds, MKL_INT *j, float *out, MKL_INT *info);
void dlasorte (double *s, MKL_INT *lds, MKL_INT *j, double *out, MKL_INT *info);
```

**Include Files**

- mkl_scalapack.h

**Description**

The ?lasorte function sorts eigenpairs so that real eigenpairs are together and complex eigenpairs are together. This helps to employ 2x2 shifts easily since every second subdiagonal is guaranteed to be zero. This function does no parallel work and makes no calls.

**Optimization Notice**

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804
**Input Parameters**

- **s** (local)
  - Array of size lds.
  - On entry, a matrix already in Schur form.

- **lds** (local)
  - On entry, the leading dimension of the array s; unchanged on exit.

- **j** (local)
  - On entry, the order of the matrix S; unchanged on exit.

- **out** (local)
  - Array of size 2*j. The work buffer required by the function.

- **info** (local)
  - Set, if the input matrix had an odd number of real eigenvalues and things could not be paired or if the input matrix S was not originally in Schur form. 0 indicates successful completion.

**Output Parameters**

- **s**
  - On exit, the diagonal blocks of S have been rewritten to pair the eigenvalues. The resulting matrix is no longer similar to the input.

- **out**
  - Work buffer.

**See Also**

Overview for details of ScaLAPACK array descriptor structures and related notations.

### ?lasrt2

**Sorts numbers in increasing or decreasing order.**

**Syntax**

```c
void slasrt2 (char *id, MKL_INT *n, float *d, MKL_INT *key, MKL_INT *info);
void dlasrt2 (char *id, MKL_INT *n, double *d, MKL_INT *key, MKL_INT *info);
```

**Include Files**

- mkl_scalapack.h

**Description**

The ?lasrt2 function is modified LAPACK function ?lasrt, which sorts the numbers in d in increasing order (if id = 'I') or in decreasing order (if id = 'D'). It uses Quick Sort, reverting to Insertion Sort on arrays of size ≤ 20. The size of STACK limits n to about $2^{32}$.

**Input Parameters**

- **id**
  - = 'I': sort d in increasing order;
  - = 'D': sort d in decreasing order.
The length of the array \( d \).

\( d \)

Array of size \( n \).

On entry, the array to be sorted.

\( key \)

Array of size \( n \).

On entry, \( key \) contains a key to each of the entries in \( d \).

Typically, \( key[i] = i+1 \) for all \( i = 0, ..., n-1 \).

Output Parameters

\( d \)

On exit, \( d \) has been sorted into increasing order

\( (d[0] \leq ... \leq d[n-1]) \)

or into decreasing order

\( (d[0] \geq ... \geq d[n-1]) \),

depending on \( id \).

\( info \)

\( = 0 \): successful exit

\(< 0 \): if \( info = -i \), the \( i \)-th argument had an illegal value.

\( key \)

On exit, \( key \) is permuted in exactly the same manner as \( d \) was permuted from input to output. Therefore, if \( key[i] = i+1 \) for all \( i = 0, ..., n-1 \) on input, \( d[i] \) on output equals \( d[\text{key}[i]-1] \) on input.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.

\(?\text{stegr2}\)

Computes selected eigenvalues and eigenvectors of a real symmetric tridiagonal matrix.

Syntax

\[
\text{void sstegr2}(\text{char* jobz, char* range, MKL_INT* n, float* d, float* e, float* vl, float* vu, MKL_INT* il, MKL_INT* iu, MKL_INT* m, float* w, float* z, MKL_INT* ldz, MKL_INT* nzc, MKL_INT* isuppz, float* work, MKL_INT* lwork, MKL_INT* iwork, MKL_INT* liwork, MKL_INT* dol, MKL_INT* dou, MKL_INT* zoffset, MKL_INT* info});
\]

\[
\text{void dstegr2}(\text{char* jobz, char* range, MKL_INT* n, double* d, double* e, double* vl, double* vu, MKL_INT* il, MKL_INT* iu, MKL_INT* m, double* w, double* z, MKL_INT* ldz, MKL_INT* nzc, MKL_INT* isuppz, double* work, MKL_INT* lwork, MKL_INT* iwork, MKL_INT* liwork, MKL_INT* dol, MKL_INT* dou, MKL_INT* zoffset, MKL_INT* info});
\]

Include Files

- \text{mkl_scalapack.h}

Description

\(?\text{stegr2}\) computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix \( T \). It is invoked in the ScaLAPACK MRRR driver \( p\text{syevr} \) and the corresponding Hermitian version either when only eigenvalues are to be computed, or when only a single processor is used (the sequential-like case).

\(?\text{stegr2}\) has been adapted from LAPACK's \( \text{stegr} \). Please note the following crucial changes.
1. The calling sequence has two additional integer parameters, \( \text{dol} \) and \( \text{dou} \), that should satisfy \( \text{m} \geq \text{dou} \geq \text{dol} \geq 1 \). ?steqr2 only computes the eigenpairs corresponding to eigenvalues \( \text{dol} \) through \( \text{dou} \) in \( w \), indexed \( \text{dol}-1 \) through \( \text{dou}-1 \). (That is, instead of computing the eigenpairs belonging to \( w[0] \) through \( w[m-1] \), only the eigenvectors belonging to eigenvalues \( w[\text{dol}-1] \) through \( w[\text{dou}-1] \) are computed. In this case, only the eigenvalues \( \text{dol} \) through \( \text{dou} \) are guaranteed to be fully accurate.

2. \( m \) is not the number of eigenvalues specified by \( \text{range} \), but is \( m = \text{dou} - \text{dol} + 1 \). This concerns the case where only eigenvalues are computed, but on more than one processor. Thus, in this case \( m \) refers to the number of eigenvalues computed on this processor.

3. The arrays \( w \) and \( z \) might not contain all the wanted eigenpairs locally, instead this information is distributed over other processors.

---

**Optimization Notice**

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

**Input Parameters**

- **jobz**
  - = 'N': Compute eigenvalues only;
  - = 'V': Compute eigenvalues and eigenvectors.

- **range**
  - = 'A': all eigenvalues will be found.
  - = 'V': all eigenvalues in the half-open interval \((vl,vu]\) will be found.
  - = 'I': eigenvalues of the entire matrix with the indices in a given range will be found.

- **n**
  The order of the matrix. \( n \geq 0 \).

- **d**
  Array of size \( n \)
  On entry, the \( n \) diagonal elements of the tridiagonal matrix \( T \). Overwritten on exit.

- **e**
  Array of size \( n \)
  On entry, the \((n-1)\) subdiagonal elements of the tridiagonal matrix \( T \) in elements 0 to \( n-2 \) of \( e[\text{e}-1] \) need not be set on input, but is used internally as workspace. Overwritten on exit.

- **vl**
  - If \( \text{range} = 'V' \), the lower and upper bounds of the interval to be searched for eigenvalues. \( vl < vu \).
  - Not referenced if \( \text{range} = 'A' \) or \( 'I' \).

- **vu**
  - If \( \text{range} = 'V' \), the lower and upper bounds of the interval to be searched for eigenvalues. \( vl < vu \).
  - Not referenced if \( \text{range} = 'A' \) or \( 'I' \).

- **il, iu**
  - If \( \text{range} = 'I' \), the indices (in ascending order) of the smallest eigenvalue, to be returned in \( w[\text{il}-1] \), and largest eigenvalue, to be returned in \( w[\text{iu}-1] \).
$1 \leq i_{ll} \leq i_{ul} \leq n$, if $n > 0$.

Not referenced if range = 'A' or 'V'.

ldz

The leading dimension of the array $z$. $ldz \geq 1$, and if jobz = 'V', then $ldz \geq \text{max}(1,n)$.

nzc

The number of eigenvectors to be held in the array $z$, storing the matrix $Z$.

If range = 'A', then $nzc \geq \text{max}(1,n)$.

If range = 'V', then $nzc \geq$ the number of eigenvalues in $(vl, vu]$.

If range = 'I', then $nzc \geq i_{ul} - i_{ll} + 1$.

If $nzc = -1$, then a workspace query is assumed; the function calculates the number of columns of the matrix $Z$ that are needed to hold the eigenvectors. This value is returned as the first entry of the $z$ array, and no error message related to $nzc$ is issued.

lwork

The size of the array work. $lwork \geq \text{max}(1, 18*n)$ if jobz = 'V', and $lwork \geq \text{max}(1, 12*n)$ if jobz = 'N'. If $lwork = -1$, then a workspace query is assumed; the function only calculates the optimal size of the work array, returns this value as the first entry of the work array, and no error message related to $lwork$ is issued.

liwork

The size of the array liwork. $liwork \geq \text{max}(1, 10*n)$ if the eigenvectors are desired, and $liwork \geq \text{max}(1, 8*n)$ if only the eigenvalues are to be computed.

If $liwork = -1$, then a workspace query is assumed; the function only calculates the optimal size of the liwork array, returns this value as the first entry of the liwork array, and no error message related to liwork is issued.

dol, dou

From the eigenvalues $w[0]$ through $w[n-1]$, only eigenvectors $Z(:,dol)$ to $Z(:,dou)$ are computed.

If $dol > 1$, then $Z(:,dol-1-zoffset)$ is used and overwritten.

If $dou < m$, then $Z(:,dou+1-zoffset)$ is used and overwritten.

zoffset

Offset for storing the eigenpairs when $z$ is distributed in 1D-cyclic fashion

OUTPUT Parameters

m

Globally summed over all processors, $m$ equals the total number of eigenvalues found. $0 \leq m \leq n$. If range = 'A', $m = n$, and if range = 'I', $m = i_{ul} - i_{ll} + 1$. The local output equals $m = dou - dol + 1$.

w

Array of size $n$

The first $m$ elements contain the selected eigenvalues in ascending order. Note that immediately after exiting this function, only the eigenvalues indexed $dol-1$ through $dou-1$ are reliable on this processor because the eigenvalue computation is done in parallel. Other processors will hold reliable information on other parts of the $w$ array. This information is communicated in the ScaLAPACK driver.

z

Array of size $ldz \times \text{max}(1,m)$. 

1714
If $jobz = 'V'$, and if $info = 0$, then the first $m$ columns of the matrix $Z$ stored in $z$ contain some of the orthonormal eigenvectors of the matrix $T$ corresponding to the selected eigenvalues, with the $i$-th column of $Z$ holding the eigenvector associated with $w[i-1]$.

If $jobz = 'N'$, then $z$ is not referenced.

Note: the user must ensure that at least $\max(1, m)$ columns of the matrix are supplied in the array $z$; if $range = 'V'$, the exact value of $m$ is not known in advance and can be computed with a workspace query by setting $nzc = -1$, see below.

$\text{isuppz}$ array of size $2*\max(1, m)$

The support of the eigenvectors in $z$, i.e., the indices indicating the nonzero elements in $z$. The $i$-th computed eigenvector is nonzero only in elements $\text{isuppz}[2*i-2]$ through $\text{isuppz}[2*i-1]$. This is relevant in the case when the matrix is split. $\text{isuppz}$ is only set if $n>2$.

$\text{work}$

On exit, if $info = 0$, $\text{work}[0]$ returns the optimal (and minimal) $lwork$.

$\text{iwork}$

On exit, if $info = 0$, $\text{iwork}[0]$ returns the optimal $liwork$.

$\text{info}$

On exit, $info$

= 0: successful exit
other: if $info = -i$, the $i$-th argument had an illegal value
if $info = 10X$, internal error in $\text{?larre2}$,
if $info = 20X$, internal error in $\text{?larrv}$.

Here, the digit $X = \text{ABS}(iinfo) < 10$, where $iinfo$ is the nonzero error code returned by $\text{?larre2}$ or $\text{?larrv}$, respectively.

See Also
Overview for details of ScaLAPACK array descriptor structures and related notations.

$\text{?stegr2a}$

Computes selected eigenvalues and initial representations needed for eigenvector computations.

Syntax

void $\text{sstegr2a}(\text{char* } jobz, \text{char* } range, \text{MKL_INT* } n, \text{float* } d, \text{float* } e, \text{float* } vl, \text{float* } vu, \text{MKL_INT* } il, \text{MKL_INT* } iu, \text{MKL_INT* } m, \text{float* } w, \text{float* } z, \text{MKL_INT* } ldz, \text{MKL_INT* } nzc, \text{float* } work, \text{MKL_INT* } lwork, \text{MKL_INT* } iwork, \text{MKL_INT* } liwork, \text{MKL_INT* } dol, \text{MKL_INT* } dou, \text{MKL_INT* } needil, \text{MKL_INT* } neediu, \text{MKL_INT* } inderr, \text{MKL_INT* } nsplit, \text{float* } pivmin, \text{float* } scale, \text{float* } wl, \text{float* } wu, \text{MKL_INT* } info);$

Include Files

- mkl_scalapack.h

Description

?stegr2a computes selected eigenvalues and initial representations needed for eigenvector computations in ?stegr2b. It is invoked in the ScaLAPACK MRRR driver ?syevr and the corresponding Hermitian version when both eigenvalues and eigenvectors are computed in parallel on multiple processors. For this case, ?stegr2a implements the first part of the MRRR algorithm, parallel eigenvalue computation and finding the root RRR. At the end of ?stegr2a, other processors might have a part of the spectrum that is needed to continue the computation locally. Once this eigenvalue information has been received by the processor, the computation can then proceed by calling the second part of the parallel MRRR algorithm, ?stegr2b.

Please note:

- The calling sequence has two additional integer parameters, (compared to LAPACK’s ?stegr), these are dol and dou and should satisfy \( m \geq dou \geq dol \geq 1 \). These parameters are only relevant for the case jobz = 'V'.

Globally invoked over all processors, ?stegr2a computes all the eigenvalues specified by range.

?stegr2a locally only computes the eigenvalues corresponding to eigenvalues dol through dou in \( \omega \), indexed \( dol-1 \) through \( dou-1 \). (That is, instead of computing the eigenvectors belonging to \( \omega[m-1] \), only the eigenvectors belonging to eigenvalues \( \omega[dol-1] \) through \( \omega[dou-1] \) are computed. In this case, only the eigenvalues dol through dou are guaranteed to be fully accurate.

- \( m \) is not the number of eigenvalues specified by range, but it is \( m = dou - dol + 1 \). Instead, \( m \) refers to the number of eigenvalues computed on this processor.

- While no eigenvectors are computed in ?stegr2a itself (this is done later in ?stegr2b), the interface

  If jobz = 'V' then, depending on range and dol, dou, ?stegr2a might need more workspace in z then the original ?stegr. In particular, the arrays \( \omega \) and \( z \) might not contain all the wanted eigenpairs locally, instead this information is distributed over other processors.

Optimization Notice

Intel’s compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

- **jobz**
  
  = 'N': Compute eigenvalues only;
  
  = 'V': Compute eigenvalues and eigenvectors.

- **range**
  
  = 'A': all eigenvalues will be found.
  
  = 'V': all eigenvalues in the half-open interval \((vl, vu]\) will be found.
  
  = 'I': eigenvalues of the entire matrix with the indices in a given range will be found.

- **n**
  
  The order of the matrix. \( n \geq 0 \).
**d**

Array of size $n$

The $n$ diagonal elements of the tridiagonal matrix $T$. Overwritten on exit.

**e**

Array of size $n$

On entry, the $(n-1)$ subdiagonal elements of the tridiagonal matrix $T$ in elements 0 to $n-2$ of $e$. $e[n-1]$ need not be set on input, but is used internally as workspace. Overwritten on exit.

**vl, vu**

If $range = 'V'$, the lower and upper bounds of the interval to be searched for eigenvalues. $vl < vu$.

Not referenced if $range = 'A'$ or 'I'.

**il, iu**

If $range = 'I'$, the indices (in ascending order) of the smallest eigenvalue, to be returned in $w[il-1]$, and largest eigenvalue, to be returned in $w[iu-1]$. $1 \leq il \leq iu \leq n$, if $n > 0$.

Not referenced if $range = 'A'$ or 'V'.

**ldz**

The leading dimension of the array $z$. $ldz \geq 1$, and if $jobz = 'V'$, then $ldz \geq \max(1,n)$.

**nzc**

The number of eigenvectors to be held in the array $z$.

If $range = 'A'$, then $nzc \geq \max(1,n)$.

If $range = 'V'$, then $nzc \geq$ the number of eigenvalues in $(vl,vu)$.

If $range = 'I'$, then $nzc \geq iu-il+1$.

If $nzc = -1$, then a workspace query is assumed; the function calculates the number of columns of the matrix stored in array $z$ that are needed to hold the eigenvectors. This value is returned as the first entry of the $z$ array, and no error message related to $nzc$ is issued.

**lwork**

The size of the array $work$. $lwork \geq \max(1,18*n)$ if $jobz = 'V'$, and $lwork \geq \max(1,12*n)$ if $jobz = 'N'$.

If $lwork = -1$, then a workspace query is assumed; the function only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued.

**liwork**

The size of the array $iwork$. $liwork \geq \max(1,10*n)$ if the eigenvectors are desired, and $liwork \geq \max(1,8*n)$ if only the eigenvalues are to be computed.

If $liwork = -1$, then a workspace query is assumed; the function only calculates the optimal size of the $iwork$ array, returns this value as the first entry of the $iwork$ array, and no error message related to $liwork$ is issued.

**dol, dou**

From all the eigenvalues $w[0]$ through $w[m-1]$, only eigenvalues $w[dol-1]$ through $w[dou-1]$ are computed.

**OUTPUT Parameters**

**m**

Globally summed over all processors, $m$ equals the total number of eigenvalues found. $0 \leq m \leq n$. 
If \( \text{range} = 'A' \), \( m = n \), and if \( \text{range} = 'I' \), \( m = iu-il+1 \).

The local output equals \( m = dou-dol+1 \).

\( w \)

Array of size \( n \)

The first \( m \) elements contain approximations to the selected eigenvalues in ascending order. Note that immediately after exiting this function, only the eigenvalues indexed \( dol-1 \) through \( dou-1 \) are reliable on this processor because the eigenvalue computation is done in parallel. The other entries are very crude preliminary approximations. Other processors hold reliable information on these other parts of the \( w \) array.

This information is communicated in the ScaLAPACK driver.

\( z \)

Array of size \( ldz \times \max(1,m) \).

\texttt{?stegr2a} does not compute eigenvectors, this is done in \texttt{?stegr2b}. The argument \( z \) as well as all related other arguments only appear to keep the interface consistent and to signal to the user that this function is meant to be used when eigenvectors are computed.

\( \text{work} \)

On exit, if \( \text{info} = 0 \), \( \text{work}[0] \) returns the optimal (and minimal) \( lwork \).

\( \text{iwork} \)

On exit, if \( \text{info} = 0 \), \( \text{iwork}[0] \) returns the optimal \( liwork \).

\( \text{needil, neediu} \)

The indices of the leftmost and rightmost eigenvalues needed to accurately compute the relevant part of the representation tree. This information can be used to find out which processors have the relevant eigenvalue information needed so that it can be communicated.

\( \text{inderr} \)

\( \text{inderr} \) points to the place in the work space where the eigenvalue uncertainties (errors) are stored.

\( \text{nsplit} \)

The number of blocks into which \( T \) splits. \( 1 \leq \text{nsplit} \leq n \).

\( \text{pivmin} \)

The minimum pivot in the sturm sequence for \( T \).

\( \text{scale} \)

The scaling factor for the tridiagonal \( T \).

\( \text{wl, wu} \)

The interval \((\text{wl}, \text{wu}]\) contains all the wanted eigenvalues.

It is either given by the user or computed in \texttt{?larre2a}.

\( \text{info} \)

On exit, \( \text{info} = 0 \): successful exit

other: if \( \text{info} = -i \), the \( i \)-th argument had an illegal value

if \( \text{info} = 10x \), internal error in \texttt{?larre2a},

Here, the digit \( x = \text{abs} \left( \text{iinfo} \right) < 10 \), where \( \text{iinfo} \) is the nonzero error code returned by \texttt{?larre2a}.

\textbf{See Also}

\textbf{Overview} for details of ScaLAPACK array descriptor structures and related notations.
**ssteqr2b**

From eigenvalues and initial representations computes the selected eigenvalues and eigenvectors of the real symmetric tridiagonal matrix in parallel on multiple processors.

**Syntax**

```c
void sstegr2b(char* jobz, MKL_INT* n, float* d, float* e, MKL_INT* m, float* w, float* z, MKL_INT* ldz, MKL_INT* nzc, MKL_INT* isuppz, float* work, MKL_INT* lwork, MKL_INT* iwork, MKL_INT* liwork, MKL_INT* dol, MKL_INT* dou, MKL_INT* needil, MKL_INT* neediu, MKL_INT* indwlc, float* pivmin, float* scale, float* wI, float* wu, MKL_INT* vstart, MKL_INT* finish, MKL_INT* maxcls, MKL_INT* ndepth, MKL_INT* parity, MKL_INT* zoffset, MKL_INT* info);

void dstegr2b(char* jobz, MKL_INT* n, double* d, double* e, MKL_INT* m, double* w, double* z, MKL_INT* ldz, MKL_INT* nzc, MKL_INT* isuppz, double* work, MKL_INT* lwork, MKL_INT* iwork, MKL_INT* liwork, MKL_INT* dol, MKL_INT* dou, MKL_INT* needil, MKL_INT* neediu, MKL_INT* indwlc, double* pivmin, double* scale, double* wI, double* wu, MKL_INT* vstart, MKL_INT* finish, MKL_INT* maxcls, MKL_INT* ndepth, MKL_INT* parity, MKL_INT* zoffset, MKL_INT* info);
```

**Include Files**

- mkl_scalapack.h

**Description**

`ssteqr2b` should only be called after a call to `ssteqr2a`. From eigenvalues and initial representations computed by `ssteqr2a`, `ssteqr2b` computes the selected eigenvalues and eigenvectors of the real symmetric tridiagonal matrix in parallel on multiple processors. It is potentially invoked multiple times on a given processor because the locally relevant representation tree might depend on spectral information that is "owned" by other processors and might need to be communicated.

Please note:

- The calling sequence has two additional integer parameters, `dol` and `dou`, that should satisfy \( m \geq dou > dol > 1 \). These parameters are only relevant for the case `jobz = 'V'`. `ssteqr2b` only computes the eigenvectors corresponding to eigenvalues `dol` through `dou` in `w`, indexed `dol-1` through `dou-1`. (That is, instead of computing the eigenvectors belonging to `w[0]` through `w[m-1]`, only the eigenvectors belonging to eigenvalues `w[dol-1]` through `w[dou-1]` are computed. In this case, only the eigenvalues `dol` through `dou` are guaranteed to be accurately refined to all figures by Rayleigh-Quotient iteration.

- The additional arguments `vstart`, `finish`, `ndepth`, `parity`, `zoffset` are included as a thread-safe implementation equivalent to save variables. These variables store details about the local representation tree which is computed layerwise. For scalability reasons, eigenvalues belonging to the locally relevant representation tree might be computed on other processors. These need to be communicated before the inspection of the RRRs can proceed on any given layer. Note that only when the variable `finish` is non-zero, the computation has ended. All eigenpairs between `dol` and `dou` have been computed. `m` is set to `dou - dol + 1`.

- `ssteqr2b` needs more workspace in `z` than the sequential `ssteqr`. It is used to store the conformal embedding of the local representation tree.
Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.
Notice revision #20110804

Input Parameters

jobz
- \texttt{='N'}: Compute eigenvalues only;
- \texttt{='V'}: Compute eigenvalues and eigenvectors.

n
The order of the matrix. \( n \geq 0 \).

d
Array of size \( n \)
The \( n \) diagonal elements of the tridiagonal matrix \( T \). Overwritten on exit.
e
Array of size \( n \)
The \((n-1)\) subdiagonal elements of the tridiagonal matrix \( T \) in elements 0 to \( n-2 \) of \( e \). \( e[n-1] \) need not be set on input, but is used internally as workspace. Overwritten on exit.

m
The total number of eigenvalues found in \texttt{?steqr2a}. \( 0 \leq m \leq n \).

w
Array of size \( n \)
The first \( m \) elements contain approximations to the selected eigenvalues in ascending order. Note that only the eigenvalues from the locally relevant part of the representation tree, that is all the clusters that include eigenvalues from \texttt{dol} through \texttt{dou}, are reliable on this processor. (It does not need to know about any others anyway.)

ldz
The leading dimension of the array \( z \). \( ldz \geq 1 \), and if \texttt{jobz = 'V'}, then \( ldz \geq \text{max}(1,n) \).

nzc
The number of eigenvectors to be held in the array \( z \), storing the matrix \( Z \).

lwork
The size of the array \( \text{work} \). \( lwork \geq \text{max}(1,18*n) \)
if \texttt{jobz = 'V'}, and \( lwork \geq \text{max}(1,12*n) \) if \texttt{jobz = 'N'}.

If \texttt{lwork = -1}, then a workspace query is assumed; the function only calculates the optimal size of the \texttt{work} array, returns this value as the first entry of the \texttt{work} array, and no error message related to \texttt{lwork} is issued.

liwork
The size of the array \( \text{liwork} \). \( liwork \geq \text{max}(1,10*n) \) if the eigenvectors are desired, and \( liwork \geq \text{max}(1,8*n) \) if only the eigenvalues are to be computed.
If \( liwork = -1 \), then a workspace query is assumed; the function only calculates the optimal size of the \( iwork \) array, returns this value as the first entry of the \( iwork \) array, and no error message related to \( liwork \) is issued.

\[ dol, dou \]

From the eigenvalues \( w[0] \) through \( w[m-1] \), only eigenvectors \( Z(:,dol) \) to \( Z(:,dou) \) are computed.

If \( dol > 1 \), then \( Z(:,dol-1-zoffset) \) is used and overwritten.

If \( dou < m \), then \( Z(:,dou+1-zoffset) \) is used and overwritten.

\[ needil, neediu \]

Describes which are the left and right outermost eigenvalues still to be computed. Initially computed by \(?larre2a\), modified in the course of the algorithm.

\[ pivmin \]

The minimum pivot in the sturm sequence for \( T \).

\[ scale \]

The scaling factor for \( T \). Used for unscaling the eigenvalues at the very end of the algorithm.

\[ wl, wu \]

The interval \( [wl, wu] \) contains all the wanted eigenvalues.

\[ vstart \]

Non-zero on initialization, set to zero afterwards.

\[ finish \]

Indicates whether all eigenpairs have been computed.

\[ maxcls \]

The largest cluster worked on by this processor in the representation tree.

\[ ndepth \]

The current depth of the representation tree. Set to zero on initial pass, changed when the deeper levels of the representation tree are generated.

\[ parity \]

An internal parameter needed for the storage of the clusters on the current level of the representation tree.

\[ zoffset \]

Offset for storing the eigenpairs when \( z \) is distributed in 1D-cyclic fashion.

**OUTPUT Parameters**

\[ z \]

Array of size \( ldz * \max(1,m) \)

If \( jobz = 'V' \), and if \( info = 0 \), then a subset of the first \( m \) columns of the matrix \( Z \), stored in \( z \), contain the orthonormal eigenvectors of the matrix \( T \) corresponding to the selected eigenvalues, with the \( i \)-th column of \( Z \) holding the eigenvector associated with \( w[i-1] \).

See \( dol, dou \) for more information.

\[ isuppz \]

array of size \( 2\max(1,m) \).

The support of the eigenvectors in \( z \), i.e., the indices indicating the nonzero elements in \( z \). The \( i \)-th computed eigenvector is nonzero only in elements \( isuppz[2*i-2] \) through \( isuppz[2*i-1] \). This is relevant in the case when the matrix is split. \( isuppz \) is only set if \( n>2 \).

\[ work \]

On exit, if \( info = 0 \), \( work[0] \) returns the optimal (and minimal) \( lwork \).

\[ iwork \]

On exit, if \( info = 0 \), \( iwork[0] \) returns the optimal \( liwork \).

\[ needil, neediu \]

Modified in the course of the algorithm.
**indwlc**

Pointer into the workspace location where the local eigenvalue representations are stored. ("Local eigenvalues" are those relative to the individual shifts of the RRRs.)

**vstart**

Non-zero on initialization, set to zero afterwards.

**finish**

Indicates whether all eigenpairs have been computed.

**maxcls**

The largest cluster worked on by this processor in the representation tree.

**ndepth**

The current depth of the representation tree. Set to zero on initial pass, changed when the deeper levels of the representation tree are generated.

**parity**

An internal parameter needed for the storage of the clusters on the current level of the representation tree.

**info**

On exit, info

= 0: successful exit

other: if info = -i, the i-th argument had an illegal value

if info = 20x, internal error in ?larrv2.

Here, the digit x = abs( iinfo ) < 10, where iinfo is the nonzero error code returned by ?larrv2.

**See Also**

*Overview* for details of ScaLAPACK array descriptor structures and related notations.

---

**?stein2**

*Computes the eigenvectors corresponding to specified eigenvalues of a real symmetric tridiagonal matrix, using inverse iteration.*

**Syntax**

```c
void sstein2 (MKL_INT *n, float *d, float *e, MKL_INT *m, float *w, MKL_INT *iblock, MKL_INT *isplit, float *orfac, float *z, MKL_INT *ldz, float *work, MKL_INT *iwork, MKL_INT *ifail, MKL_INT *info );
void dstein2 (MKL_INT *n, double *d, double *e, MKL_INT *m, double *w, MKL_INT *iblock, MKL_INT *isplit, double *orfac, double *z, MKL_INT *ldz, double *work, MKL_INT *iwork, MKL_INT *ifail, MKL_INT *info );
```

**Include Files**

- mkl_scalapack.h

**Description**

The ?stein2 function is a modified LAPACK function ?stein. It computes the eigenvectors of a real symmetric tridiagonal matrix $T$ corresponding to specified eigenvalues, using inverse iteration.

The maximum number of iterations allowed for each eigenvector is specified by an internal parameter maxits (currently set to 5).

**Input Parameters**

- $n$ The order of the matrix $T$ ($n \geq 0$).
The number of eigenvectors to be found \( (0 \leq m \leq n) \).

Arrays:

\( d \), of size \( n \). The \( n \) diagonal elements of the tridiagonal matrix \( T \).

\( e \), of size \( n \).

The \( (n-1) \) subdiagonal elements of the tridiagonal matrix \( T \), in elements 1 to \( n-1 \). \( e[n-1] \) need not be set.

\( w \), of size \( n \).

The first \( m \) elements of \( w \) contain the eigenvalues for which eigenvectors are to be computed. The eigenvalues should be grouped by split-off block and ordered from smallest to largest within the block. (The output array \( w \) from \texttt{?stebz} with ORDER = 'B' is expected here).

The size of \( w \) must be at least \( \max(1, n) \).

\( i\text{block} \)

Array of size \( n \).

The submatrix indices associated with the corresponding eigenvalues in \( w \); 

\( i\text{block}[i] = 1 \), if eigenvalue \( w[i] \) belongs to the first submatrix from the top,

\( i\text{block}[i] = 2 \), if eigenvalue \( w[i] \) belongs to the second submatrix, etc. (The output array \( i\text{block} \) from \texttt{?stebz} is expected here).

\( i\text{split} \)

Array of size \( n \).

The splitting points, at which \( T \) breaks up into submatrices. The first submatrix consists of rows/columns 1 to \( i\text{split}[0] \), the second submatrix consists of rows/columns \( i\text{split}[0]+1 \) through \( i\text{split}[1] \), etc. (The output array \( i\text{split} \) from \texttt{?stebz} is expected here).

\( \text{orfac} \)

\( \text{orfac} \) specifies which eigenvectors should be orthogonalized. Eigenvectors that correspond to eigenvalues which are within \( \text{orfac} \| T \| \) of each other are to be orthogonalized.

\( \text{ldz} \)

The leading dimension of the output array \( z \); \( \text{ldz} \geq \max(1, n) \).

\( \text{work} \)

Workspace array of size \( 5n \).

\( i\text{work} \)

Workspace array of size \( n \).

**Output Parameters**

\( z \)

Arrary of size \( \text{ldz} \times m \).

The computed eigenvectors. The eigenvector associated with the eigenvalue \( w[i] \) is stored in the \((i+1)\)-th column of the matrix \( Z \) represented by \( z \), \( i=0, ..., m-1 \). Any vector that fails to converge is set to its current iterate after \( \text{maxits} \) iterations.

\( i\text{fail} \)

Arrary of size \( m \).
On normal exit, all elements of `ifail` are zero. If one or more eigenvectors fail to converge after `maxits` iterations, then their indices are stored in the array `ifail`.

\[ info = 0, \text{the exit is successful.} \]
\[ info < 0: \text{if } info = -i, \text{the } i\text{-th had an illegal value.} \]
\[ info > 0: \text{if } info = i, \text{then } i \text{ eigenvectors failed to converge in } maxits \text{ iterations. Their indices are stored in the array } ifail. \]

**?dbtf2**

*Computes an LU factorization of a general band matrix with no pivoting (local unblocked algorithm).*

**Syntax**

```c
void sdbtf2 (MKL_INT *m, MKL_INT *n, MKL_INT *kl, MKL_INT *ku, float *ab, MKL_INT *ldab, MKL_INT *info);
void ddbtf2 (MKL_INT *m, MKL_INT *n, MKL_INT *kl, MKL_INT *ku, double *ab, MKL_INT *ldab, MKL_INT *info);
void cdbtf2 (MKL_INT *m, MKL_INT *n, MKL_INT *kl, MKL_INT *ku, MKL_Complex8 *ab, MKL_INT *ldab, MKL_INT *info);
void zdbtf2 (MKL_INT *m, MKL_INT *n, MKL_INT *kl, MKL_INT *ku, MKL_Complex16 *ab, MKL_INT *ldab, MKL_INT *info);
```

**Include Files**

- `mkl_scalapack.h`

**Description**

The `?dbtf2` function computes an LU factorization of a general real/complex \( m \)-by-\( n \) band matrix \( A \) without using partial pivoting with row interchanges.

This is the unblocked version of the algorithm, calling BLAS Routines and Functions.

**Input Parameters**

- `m`
  The number of rows of the matrix \( A (m \geq 0) \).

- `n`
  The number of columns in \( A (n \geq 0) \).

- `kl`
  The number of sub-diagonals within the band of \( A (kl \geq 0) \).

- `ku`
  The number of super-diagonals within the band of \( A (ku \geq 0) \).

- `ab`
  Array of size \( ldab \times n \).

  The matrix \( A \) in band storage, in rows \( kl+1 \) to \( 2kl+ku+1 \); rows 1 to \( kl \) of the matrix need not be set. The \( j \)-th column of \( A \) is stored in the array `ab` as follows: \( ab[kl+ku+i+j*(j-1)*ldab] = A(i,j) \) for \( \max(1,j-ku) \leq i \leq \min(m,j+kl) \).
ldab

The leading dimension of the array ab.

(ldab ≥ 2kl + ku + 1)

Output Parameters

ab

On exit, details of the factorization: U is stored as an upper triangular band matrix with kl+ku superdiagonals in rows 1 to kl+ku+1, and the multipliers used during the factorization are stored in rows kl+ku+2 to 2*kl+ku+1. See the Application Notes below for further details.

info

= 0: successful exit
< 0: if info = -i, the i-th argument had an illegal value,
> 0: if info = +i, the matrix element U(i,i) is 0. The factorization has been completed, but the factor U is exactly singular. Division by 0 will occur if you use the factor U for solving a system of linear equations.

Application Notes

The band storage scheme is illustrated by the following example, when m = n = 6, kl = 2, ku = 1:

<table>
<thead>
<tr>
<th></th>
<th>a11</th>
<th>a12</th>
<th>a13</th>
<th>a14</th>
<th>a15</th>
<th>a16</th>
</tr>
</thead>
<tbody>
<tr>
<td>a11</td>
<td>*</td>
<td>a22</td>
<td>a23</td>
<td>a24</td>
<td>a25</td>
<td>a26</td>
</tr>
</tbody>
</table>
| a21 | a32 | a33 | a34 | a35 | a36 |   *
| a31 | a42 | a43 | a44 | a45 | a46 |   *
| a41 |     | a53 | a54 | a55 | a56 |   *
| a51 |     |     | a64 | a65 | a66 |   *

The function does not use array elements marked *; elements marked + need not be set on entry, but the function requires them to store elements of U, because of fill-in resulting from the row interchanges.

?dbtrf

Computes an LU factorization of a general band matrix with no pivoting (local blocked algorithm).

Syntax

void sdbtrf (MKL_INT *m, MKL_INT *n, MKL_INT *kl, MKL_INT *ku, float *ab, MKL_INT *ldb, MKL_INT *info);

void ddbtrf (MKL_INT *m, MKL_INT *n, MKL_INT *kl, MKL_INT *ku, double *ab, MKL_INT *ldb, MKL_INT *info);

void cdbtrf (MKL_INT *m, MKL_INT *n, MKL_INT *kl, MKL_INT *ku, MKL_Complex8 *ab, MKL_INT *ldb, MKL_INT *info);

void zdbtrf (MKL_INT *m, MKL_INT *n, MKL_INT *kl, MKL_INT *ku, MKL_Complex16 *ab, MKL_INT *ldb, MKL_INT *info);

Include Files

• mkl_scalapack.h
Description
This function computes an LU factorization of a real \( m \)-by-\( n \) band matrix \( A \) without using partial pivoting or row interchanges.
This is the blocked version of the algorithm, calling BLAS Routines and Functions.

Input Parameters

\( m \)
The number of rows of the matrix \( A \) (\( m \geq 0 \)).

\( n \)
The number of columns in \( A \)(\( n \geq 0 \)).

\( kl \)
The number of sub-diagonals within the band of \( A \) (\( kl \geq 0 \)).

\( ku \)
The number of super-diagonals within the band of \( A \) (\( ku \geq 0 \)).

\( ab \)
Array of size \( ldab \) * \( n \).
The matrix \( A \) in band storage, in rows \( kl+1 \) to \( 2kl+ku+1 \); rows 1 to \( kl \) need not be set. The \( j \)-th column of \( A \) is stored in the array \( ab \) as follows:
\[
ab[(kl + ku + j + (j-1) \times ldab)] = A(i, j) \text{ for } \max(1, j - ku) \leq i \leq \min(m, j + kl).
\]

\( ldab \)
The leading dimension of the array \( ab \).
(\( ldab \geq 2kl + ku + 1 \))

Output Parameters

\( ab \)
On exit, details of the factorization: \( U \) is stored as an upper triangular band matrix with \( kl + ku \) superdiagonals in rows 1 to \( kl + ku + 1 \), and the multipliers used during the factorization are stored in rows \( kl + ku + 2 \) to \( 2 \times kl + ku + 1 \). See the Application Notes below for further details.

\( info \)
\[ = 0: \text{successful exit} \]
\[ < 0: \text{if } info = -i, \text{the } i\text{-th argument had an illegal value,} \]
\[ > 0: \text{if } info = +i, \text{the matrix element } U(i, i) \text{ is 0. The factorization has been completed, but the factor } U \text{ is exactly singular. Division by 0 will occur if you use the factor } U \text{ for solving a system of linear equations.} \]

Application Notes
The band storage scheme is illustrated by the following example, when \( m = n = 6, kl = 2, ku = 1 \):

\[
\begin{array}{cccccc}
\ast & a_{12} & a_{33} & a_{44} & a_{55} & a_{66} \\
a_{11} & a_{22} & a_{33} & a_{44} & a_{55} & a_{66} \\
a_{21} & a_{32} & a_{43} & a_{54} & a_{65} & \ast \\
a_{31} & a_{42} & a_{53} & a_{64} & \ast & \ast
\end{array}
\]

\[
\begin{array}{cccccc}
\ast & u_{12} & u_{23} & u_{34} & u_{45} & u_{56} \\
u_{11} & u_{22} & u_{33} & u_{44} & u_{55} & u_{66} \\
m_{21} & m_{32} & m_{43} & m_{54} & m_{65} & \ast \\
m_{31} & m_{42} & m_{53} & m_{64} & \ast & \ast
\end{array}
\]

The function does not use array elements marked \( \ast \).

Overview for details of ScaLAPACK array descriptor structures and related notations.
Computes an LU factorization of a general tridiagonal matrix with no pivoting (local blocked algorithm).

Syntax

void sdttrf (MKL_INT *n, float *dl, float *d, float *du, MKL_INT *info);
void ddttrf (MKL_INT *n, double *dl, double *d, double *du, MKL_INT *info);
void cdttrf (MKL_INT *n, MKL_Complex8 *dl, MKL_Complex8 *d, MKL_Complex8 *du, MKL_INT *info);
void zdttrf (MKL_INT *n, MKL_Complex16 *dl, MKL_Complex16 *d, MKL_Complex16 *du, MKL_INT *info);

Include Files

• mkl_scalapack.h

Description

The ?dttrf function computes an LU factorization of a real or complex tridiagonal matrix A using elimination without partial pivoting.

The factorization has the form $A = L*U$, where $L$ is a product of unit lower bidiagonal matrices and $U$ is upper triangular with nonzeros only in the main diagonal and first superdiagonal.

Input Parameters

$n$  
The order of the matrix $A$ ($n \geq 0$).

dl, d, du  
Arrays containing elements of $A$.

The array $dl$ of size $(n-1)$ contains the sub-diagonal elements of $A$.

The array $d$ of size $n$ contains the diagonal elements of $A$.

The array $du$ of size $(n-1)$ contains the super-diagonal elements of $A$.

Output Parameters

$dl$  
Overwritten by the $(n-1)$ multipliers that define the matrix $L$ from the LU factorization of $A$.

d  
Overwritten by the $n$ diagonal elements of the upper triangular matrix $U$ from the LU factorization of $A$.

$du$  
Overwritten by the $(n-1)$ elements of the first super-diagonal of $U$.

$info$  
= 0: successful exit

< 0: if $info = -i$, the $i$-th argument had an illegal value,

> 0: if $info = i$, the matrix element $U(i,i)$ is exactly 0. The factorization has been completed, but the factor $U$ is exactly singular. Division by 0 will occur if you use the factor $U$ for solving a system of linear equations.

See Also

Overview for details of ScaLAPACK array descriptor structures and related notations.
**?dttrsv**

Solves a general tridiagonal system of linear equations using the LU factorization computed by ?dttrf.

**Syntax**

```c
void sdttrsv(char *uplo, char *trans, MKL_INT *n, MKL_INT *nrhs, float *dl, float *d, float *du, float *b, MKL_INT *ldb, MKL_INT *info);
void ddttrsv(char *uplo, char *trans, MKL_INT *n, MKL_INT *nrhs, double *dl, double *d, double *du, double *b, MKL_INT *ldb, MKL_INT *info);
void cdttrsv(char *uplo, char *trans, MKL_INT *n, MKL_INT *nrhs, MKL_Complex8 *dl, MKL_Complex8 *d, MKL_Complex8 *du, MKL_Complex8 *b, MKL_INT *ldb, MKL_INT *info);
void zdttrsv(char *uplo, char *trans, MKL_INT *n, MKL_INT *nrhs, MKL_Complex16 *dl, MKL_Complex16 *d, MKL_Complex16 *du, MKL_Complex16 *b, MKL_INT *ldb, MKL_INT *info);
```

**Include Files**

- mkl_scalapack.h

**Description**

The ?dttrsv function solves one of the following systems of linear equations:

\[
LX = B, \quad L^T X = B, \quad \text{or} \quad L^H X = B, \\
UX = B, \quad U^T X = B, \quad \text{or} \quad U^H X = B
\]

with factors of the tridiagonal matrix \( A \) from the LU factorization computed by ?dttrf.

**Input Parameters**

- **uplo**
  Specifies whether to solve with \( L \) or \( U \).

- **trans**
  Must be 'N' or 'T' or 'C'.

  Indicates the form of the equations:

  - If \( \text{trans} = 'N' \), then \( A X = B \) is solved for \( X \) (no transpose).
  - If \( \text{trans} = 'T' \), then \( A^T X = B \) is solved for \( X \) (transpose).
  - If \( \text{trans} = 'C' \), then \( A^H X = B \) is solved for \( X \) (conjugate transpose).

- **n**
  The order of the matrix \( A (n \geq 0) \).

- **nrhs**
  The number of right-hand sides, that is, the number of columns in the matrix \( B (nrhs \geq 0) \).

- **dl, d, du, b**
  The array \( dl \) of size \((n - 1)\) contains the \((n - 1)\) multipliers that define the matrix \( L \) from the \( LU \) factorization of \( A \).
  The array \( d \) of size \( n \) contains \( n \) diagonal elements of the upper triangular matrix \( U \) from the \( LU \) factorization of \( A \).
  The array \( du \) of size \((n - 1)\) contains the \((n - 1)\) elements of the first super-diagonal of \( U \).
On entry, the array \( b \) of size \( ldb \times nrhs \) contains the right-hand side of matrix \( B \).

\[ ldb \]
The leading dimension of the array \( b \); \( ldb \geq \max(1, n) \).

**Output Parameters**

\( b \) Overwritten by the solution matrix \( X \).

\( info \)
- \( info = 0 \), the execution is successful.
- \( info = -i \), the \( i \)-th parameter had an illegal value.

**See Also**

Overview for details of ScaLAPACK array descriptor structures and related notations.

?pttrsv

Solves a symmetric (Hermitian) positive-definite tridiagonal system of linear equations, using the \( L*D*L^H \) factorization computed by ?pttrf.

**Syntax**

void spttrsv (char *trans , MKL_INT *n , MKL_INT *nrhs , float *d , float *e , float *b , MKL_INT *ldb , MKL_INT *info );

void dpttrsv (char *trans , MKL_INT *n , MKL_INT *nrhs , double *d , double *e , double *b , MKL_INT *ldb , MKL_INT *info );

void cpttrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *nrhs , float *d , MKL_Complex8 *e , MKL_Complex8 *b , MKL_INT *ldb , MKL_INT *info );

void zpttrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *nrhs , double *d , MKL_Complex16 *e , MKL_Complex16 *b , MKL_INT *ldb , MKL_INT *info );

**Include Files**

- mkl_scalapack.h

**Description**

The ?pttrsv function solves one of the triangular systems:

\[
L^T X = B, \text{ or } L X = B \] for real flavors,

or

\[
L^* X = B, \text{ or } L^{H*} X = B, \]

\[
U^* X = B, \text{ or } U^{H*} X = B \] for complex flavors,

where \( L \) (or \( U \) for complex flavors) is the Cholesky factor of a Hermitian positive-definite tridiagonal matrix \( A \) such that

\[
A = L^* D^* L^H \] (computed by spttrf/dpttrf)

or

\[
A = U^{H*} D^* U \text{ or } A = L^* D^* L^H \] (computed by cpttrf/zpttrf).

**Input Parameters**

*uplo*  
Must be 'U' or 'L'.

Specifies whether the superdiagonal or the subdiagonal of the tridiagonal matrix *A* is stored and the form of the factorization:

If *uplo* = 'U', *e* is the superdiagonal of *U*, and *A* = *U*H*D*U or *A* = *L*D*LU;

if *uplo* = 'L', *e* is the subdiagonal of *L*, and *A* = *L*D*LH.

The two forms are equivalent, if *A* is real.

*trans*  
Specifies the form of the system of equations:

for real flavors:

if *trans* = 'N': *L*X = *B* (no transpose)

if *trans* = 'T': *L*H*X = *B* (transpose)

for complex flavors:

if *trans* = 'N': *U*X = *B* or *L*X = *B* (no transpose)

if *trans* = 'C': *U*H*X = *B* or *L*H*X = *B* (conjugate transpose).

*n*  
The order of the tridiagonal matrix *A*. *n* ≥ 0.

*nrhs*  
The number of right hand sides, that is, the number of columns of the matrix *B*. *nrhs* ≥ 0.

*d*  
array of size *n*. The *n* diagonal elements of the diagonal matrix *D* from the factorization computed by ?pttrf.

*e*  
array of size (*n*-1). The (*n*-1) off-diagonal elements of the unit bidiagonal factor *U* or *L* from the factorization computed by ?pttrf. See *uplo*.

*b*  
array of size *ldb* *nrhs*.

On entry, the right hand side matrix *B*.

*ldb*  
The leading dimension of the array *b*.

*ldb* ≥ max(1, *n*).

**Output Parameters**

*b*  
On exit, the solution matrix *X*.

*info*  
= 0: successful exit

< 0: if *info* = −*i*, the *i*-th argument had an illegal value.

**See Also**

Overview for details of ScaLAPACK array descriptor structures and related notations.
?steqr2
Computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method.

Syntax

void ssteqr2 (char *compz, MKL_INT *n, float *d, float *e, float *z, MKL_INT *ldz, 
MKL_INT *nr, float *work, MKL_INT *info);
void dsteqr2 (char *compz, MKL_INT *n, double *d, double *e, double *z, MKL_INT 
*ldz, MKL_INT *nr, double *work, MKL_INT *info);

Include Files

• mkl_scalapack.h

Description

The ?steqr2 function is a modified version of LAPACK function ?steqr. The ?steqr2 function computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method. ?steqr2 is modified from ?steqr to allow each ScaLAPACK process running ?steqr2 to perform updates on a distributed matrix Q. Proper usage of ?steqr2 can be gleaned from examination of ScaLAPACK function p?syev.

Input Parameters

compz

Must be 'N' or 'I'.

If compz = 'N', the function computes eigenvalues only. If compz = 'I', the function computes the eigenvalues and eigenvectors of the tridiagonal matrix $T$.

$z$ must be initialized to the identity matrix by p?laset or ?laset prior to entering this function.

n

The order of the matrix $T (n \geq 0)$.

d, e, work

Arrays:

d contains the diagonal elements of $T$. The size of d must be at least max(1, n).

e contains the (n-1) subdiagonal elements of $T$. The size of e must be at least max(1, n-1).

work is a workspace array. The size of work is max(1, 2*n-2). If compz = 'N', then work is not referenced.

z

(local)

Array of global size n* n and of local size ldz* nr.

If compz = 'V', then z contains the orthogonal matrix used in the reduction to tridiagonal form.

ldz

The leading dimension of the array z. Constraints:

$ldz \geq 1,$
ldz ≥ max(1, n), if eigenvectors are desired.

nr = max(1, numroc(n, nb, myprow, 0, nprocs)).

If compz = 'N', then nr is not referenced.

Output Parameters

d
On exit, the eigenvalues in ascending order, if info = 0.
See also info.

e
On exit, e has been destroyed.

z
On exit, if info = 0, then,
if compz = 'V', z contains the orthonormal eigenvectors of the original symmetric matrix, and if compz = 'I', z contains the orthonormal eigenvectors of the symmetric tridiagonal matrix. If compz = 'N', then z is not referenced.

info
info = 0, the exit is successful.
info < 0: if info = -i, the i-th had an illegal value.
info > 0: the algorithm has failed to find all the eigenvalues in a total of 30n iterations;
if info = i, then i elements of e have not converged to zero; on exit, d and e contain the elements of a symmetric tridiagonal matrix, which is orthogonally similar to the original matrix.

See Also
Overview for details of ScaLAPACK array descriptor structures and related notations.

?trmvt
Performs matrix-vector operations.

Syntax
void strmvt (const char* uplo, const MKL_INT* n, const float* t, const MKL_INT* ldt, float* x, const MKL_INT* incx, const float* y, const MKL_INT* incy, float* w, const MKL_INT* incw, const float* z, const MKL_INT* incz);

void dtrmvt (const char* uplo, const MKL_INT* n, const double* t, const MKL_INT* ldt, double* x, const MKL_INT* incx, const double* y, const MKL_INT* incy, double* w, const MKL_INT* incw, const double* z, const MKL_INT* incz);

void ctrmvt (const char* uplo, const MKL_INT* n, const MKL_Complex8* t, const MKL_INT* ldt, MKL_Complex8* x, const MKL_INT* incx, const MKL_Complex8* y, const MKL_INT* incy, MKL_Complex8* w, const MKL_INT* incw, const MKL_Complex8* z, const MKL_INT* incz);

void ztrmvt (const char* uplo, const MKL_INT* n, const MKL_Complex16* t, const MKL_INT* ldt, MKL_Complex16* x, const MKL_INT* incx, const MKL_Complex16* y, const MKL_INT* incy, MKL_Complex16* w, const MKL_INT* incw, const MKL_Complex16* z, const MKL_INT* incz);
Include Files

- mkl_scalapack.h

Description

?trmv performs the matrix-vector operations as follows:

strmv and dtrmv: \( x := T' *y \), and \( w := T *z \)

ctrmv and ztrmv: \( x := \text{conjg}( T' ) *y \), and \( w := T *z \),

where \( x \) is an \( n \) element vector and \( T \) is an \( n \)-by-\( n \) upper or lower triangular matrix.

Input Parameters

\texttt{uplo}

On entry, \texttt{uplo} specifies whether the matrix is an upper or lower triangular matrix as follows:

\texttt{uplo} = 'U' or 'u'

\( A \) is an upper triangular matrix.

\texttt{uplo} = 'L' or 'l'

\( A \) is a lower triangular matrix.

Unchanged on exit.

\texttt{n}

On entry, \( n \) specifies the order of the matrix \( A \). \( n \) must be at least zero.

Unchanged on exit.

\texttt{t}

Array of size ( \texttt{ldt}, \texttt{n} ).

Before entry with \texttt{uplo} = 'U' or 'u', the leading \( n \)-by-\( n \) upper triangular part of the array \( t \) must contain the upper triangular matrix and the strictly lower triangular part of \( t \) is not referenced.

Before entry with \texttt{uplo} = 'L' or 'l', the leading \( n \)-by-\( n \) lower triangular part of the array \( t \) must contain the lower triangular matrix and the strictly upper triangular part of \( t \) is not referenced.

\texttt{ldt}

On entry, \texttt{lda} specifies the first dimension of \( A \) as declared in the calling (sub) program. \texttt{lda} must be at least max( 1, \texttt{n} ).

Unchanged on exit.

\texttt{incx}

On entry, \texttt{incx} specifies the increment for the elements of \( x \). \texttt{incx} must not be zero.

Unchanged on exit.

\texttt{y}

Array of size at least ( 1 + ( \texttt{n} - 1 )*abs( \texttt{incy} ) ).

Before entry, the incremented array \( y \) must contain the \( n \) element vector \( y \).

Unchanged on exit.

\texttt{incy}

On entry, \texttt{incy} specifies the increment for the elements of \( y \). \texttt{incy} must not be zero.

Unchanged on exit.
On entry, \( \text{incw} \) specifies the increment for the elements of \( w \). \( \text{incw} \) must not be zero.
Unchanged on exit.

- **z**
  - Array of size at least \( 1 + (n - 1) \times \text{abs}(\text{incz}) \).
  - Before entry, the incremented array \( z \) must contain the \( n \) element vector \( z \).
  - Unchanged on exit.

- **incz**
  - On entry, \( \text{incz} \) specifies the increment for the elements of \( z \). \( \text{incz} \) must not be zero.
  - Unchanged on exit.

**Output Parameters**

- **t**
  - Before entry with \( \text{uplo} = 'U' \) or \( 'u' \), the leading \( n \)-by-\( n \) upper triangular part of the array \( t \) must contain the upper triangular matrix and the strictly lower triangular part of \( t \) is not referenced.
  - Before entry with \( \text{uplo} = 'L' \) or \( 'l' \), the leading \( n \)-by-\( n \) lower triangular part of the array \( t \) must contain the lower triangular matrix and the strictly upper triangular part of \( t \) is not referenced.

- **x**
  - Array of size at least \( 1 + (n - 1) \times \text{abs}(\text{incx}) \).
  - On exit, \( x = T^* y \).

- **w**
  - Array of size at least \( 1 + (n - 1) \times \text{abs}(\text{incw}) \).
  - On exit, \( w = T^* z \).

**pilaenv**

*Returns the positive integer value of the logical blocking size.*

**Syntax**

```c
MKL_INT pilaenv (const MKL_INT *ictxt, const char *prec);
```

**Include Files**

- mkl_pblas.h

**Description**

\( \text{pilaenv} \) returns the positive integer value of the logical blocking size. This value is machine and precision specific. This version provides a logical blocking size which should give good though not optimal performance on many of the currently available distributed-memory concurrent computers. You are encouraged to modify this subroutine to set this tuning parameter for your particular machine.

**Input Parameters**

- **ictxt**
  - On entry, \( \text{ictxt} \) specifies the BLACS context handle, indicating the global context of the operation. The context itself is global, but the value of \( \text{ictxt} \) is local.
prec

On input, prec specifies the precision for which the logical block size should be returned as follows:

- prec = 'S' or 's' single precision real,
- prec = 'D' or 'd' double precision real,
- prec = 'C' or 'c' single precision complex,
- prec = 'Z' or 'z' double precision complex,
- prec = 'I' or 'i' integer.

Application Notes

Before modifying this routine to tune the library performance on your system, be aware of the following:

1. The value this function returns must be strictly larger than zero,
2. If you are planning to link your program with different instances of the library (for example, on a heterogeneous machine), you must compile each instance of the library with exactly the same version of this routine for obvious interoperability reasons.

pilaenvx

Called from the ScaLAPACK routines to choose problem-dependent parameters for the local environment.

Syntax

MKL_INT pilaenvx (const MKL_INT* ictxt, const MKL_INT* ispec, const char* name, const char* opts, const MKL_INT* n1, const MKL_INT* n2, const MKL_INT* n3, const MKL_INT*

Include Files

• mkl.h

Description

pilaenvx is called from the ScaLAPACK routines to choose problem-dependent parameters for the local environment. See ispec for a description of the parameters. This version provides a set of parameters which should give good, though not optimal, performance on many of the currently available computers. You are encouraged to modify this subroutine to set the tuning parameters for your particular machine using the option and problem size information in the arguments.

Input Parameters

ictxt

(local input) On entry, ictxt specifies the BLACS context handle, indicating the global context of the operation. The context itself is global, but the value of ictxt is local.

ispec

(global input)

Specifies the parameter to be returned as the value of pilaenvx.

- = 1: the optimal blocksize; if this value is 1, an unblocked algorithm will give the best performance (unlikely).
- = 2: the minimum block size for which the block routine should be used; if the usable block size is less than this value, an unblocked routine should be used.
= 3: the crossover point (in a block routine, for N less than this value, an unblocked routine should be used).

= 4: the number of shifts, used in the nonsymmetric eigenvalue routines (DEPRECATED).

= 5: the minimum column dimension for blocking to be used; rectangular blocks must have dimension at least \( k \) by \( m \), where \( k \) is given by \( \text{pilaenvx}(2,...) \) and \( m \) by \( \text{pilaenvx}(5,...) \).

= 6: the crossover point for the SVD (when reducing an \( m \) by \( n \) matrix to bidiagonal form, if \( \max(m,n)/\min(m,n) \) exceeds this value, a QR factorization is used first to reduce the matrix to a triangular form).

= 7: the number of processors.

= 8: the crossover point for the multishift QR method for nonsymmetric eigenvalue problems (DEPRECATED).

= 9: maximum size of the subproblems at the bottom of the computation tree in the divide-and-conquer algorithm (used by \?gelsd and \?geadd).

=10: IEEE NaN arithmetic can be trusted not to trap.

=11: infinity arithmetic can be trusted not to trap.

12 <= \textit{ispec} <= 16:

\textit{p?hseqr} or one of its subroutines, see piparmq for detailed explanation.

17 <= \textit{ispec} <= 22:

Parameters for \textit{pb?trord/p?hseqr} (not all), as follows:

=17: maximum number of concurrent computational windows;

=18: number of eigenvalues/bulges in each window;

=19: computational window size;

=20: minimal percentage of FLOPS required for performing matrix-matrix multiplications instead of pipelined orthogonal transformations;

=21: width of block column slabs for row-wise application of pipelined orthogonal transformations in their factorized form;

=22: the maximum number of eigenvalues moved together over a process border;

=23: the number of processors involved in Aggressive Early Deflation (AED);

=99: Maximum iteration chunksize in OpenMP parallelization.

\textbf{name}

\textit{name} (global input)

The name of the calling subroutine, in either upper case or lower case.

\textbf{opts}

\textit{opts} (global input) The character options to the subroutine name, concatenated into a single character string. For example, \textit{uplo} = 'U', \textit{trans} = 'T', and \textit{diag} = 'N' for a triangular routine would be specified as \textit{opts} = 'UTN'.

\textbf{n1, n2, n3, and n4}

\textit{n1, n2, n3, and n4} (global input) Problem dimensions for the subroutine name; these may not all be required.
Output Parameters

result (global output)

>= 0: the value of the parameter specified by ispec.

< 0: if pilaenvx = -k, the k-th argument had an illegal value.

Application Notes

The following conventions have been used when calling ilaenv from the LAPACK routines:

1. opts is a concatenation of all of the character options to subroutine name, in the same order that they appear in the argument list for name, even if they are not used in determining the value of the parameter specified by ispec.

2. The problem dimensions n1, n2, n3, and n4 are specified in the order that they appear in the argument list for name. n1 is used first, n2 second, and so on, and unused problem dimensions are passed a value of -1.

3. The parameter value returned by ilaenv is checked for validity in the calling subroutine. For example, ilaenv is used to retrieve the optimal block size for strtri as follows:

   NB = ilaenv( 1, 'STRTRI', UPLO // DIAG, N, -1, -1, -1 );
   if( NB<=1 ) {
       NB = MAX( 1, N );
   }

The same conventions hold for this ScaLAPACK-style variant.

pjlaenv

Called from the ScaLAPACK symmetric and Hermitian tailored eigen-routines to choose problem-dependent parameters for the local environment.

Syntax

MKL_INT pjlaenv (const MKL_INT*ictxt, const MKL_INT*ispec, const char*name, const char*opts, const MKL_INT*n1, const MKL_INT*n2, const MKL_INT*n3, const MKL_INT*n4);

Include Files

• mkl.h

Description

pjlaenv is called from the ScaLAPACK symmetric and Hermitian tailored eigen-routines to choose problem-dependent parameters for the local environment. See ispec for a description of the parameters. This version provides a set of parameters which should give good, though not optimal, performance on many of the currently available computers. You are encouraged to modify this subroutine to set the tuning parameters for your particular machine using the option and problem size information in the arguments.

Input Parameters

ispec (global input) Specifies the parameter to be returned as the value of pjlaenv.

= 1: the data layout blocksize;

= 2: the panel blocking factor;
= 3: the algorithmic blocking factor;
= 4: execution path control;
= 5: maximum size for direct call to the LAPACK routine.

name

(global input) The name of the calling subroutine, in either upper case or
lower case.

opts

(global input) The character options to the subroutine name, concatenated
into a single character string. For example, uplo = 'U', trans = 'T',
and diag = 'N' for a triangular routine would be specified as opts = 'UTN'.

n1, n2, n3, and n4

(global input) Problem dimensions for the subroutine name; these may not
all be required. At present, only n1 is used, and it (n1) is used only for
'TTRD'.

Output Parameters

result

(global or local output)

>= 0: the value of the parameter specified by ispec.

< 0: if pjlaenv = -k, the k-th argument had an illegal value. Most
parameters set via a call to pjlaenv must be identical on all
processors and hence pjlaenv will return the same value to all
processors (i.e. global output). However some, in particular, the panel
blocking factor can be different on each processor and hence pjlaenv
can return different values on different processors (i.e. local output).

Application Notes

The following conventions have been used when calling pjlaenv from the ScaLAPACK routines:

1. opts is a concatenation of all of the character options to subroutine name, in the same order that they
appear in the argument list for name, even if they are not used in determining the value of the
parameter specified by ispec.

2. The problem dimensions n1, n2, n3, and n4 are specified in the order that they appear in the argument
list for name. n1 is used first, n2 second, and so on, and unused problem dimensions are passed a
value of -1.

   a. The parameter value returned by pjlaenv is checked for validity in the calling subroutine. For
      example, pjlaenv is used to retrieve the optimal blocksize for STRTRI as follows:

      ```
      NB = pjlaenv( 1, 'STRTRI', UPL0 // DIAG, N, -1, -1, -1 );
      IF( NB>=1 ) {
          NB = MAX( 1, N );
      }
      ```

pjlaenv is patterned after ilaenv and keeps the same interface in anticipation of future needs, even though
pjlaenv is only sparsely used at present in ScaLAPACK. Most ScaLAPACK codes use the input data layout
blocking factor as the algorithmic blocking factor - hence there is no need or opportunity to set the
algorithmic or data decomposition blocking factor. pXYTevx.f and pXYTgvx.f and pXYTtrd.f are the
only codes which call pjlaenv. pXYTevx.f and pXYTgvx.f redistribute the data to the best data layout
for each transformation. pXYTtrd.f uses a data layout blocking factor of 1.

### p?labad

**Returns the square root of the underflow and overflow thresholds if the exponent-range is very large.**

**Syntax**

```c
void pslabad (MKL_INT *ictxt, float *small, float *large);
void pdlabad (MKL_INT *ictxt, double *small, double *large);
```

**Include Files**

- mkl_scalapack.h

**Description**

The `p?labad` function takes as input the values computed by `p?lamch` for underflow and overflow, and returns the square root of each of these values if the log of `large` is sufficiently large. This function is intended to identify machines with a large exponent range, such as the Crays, and redefine the underflow and overflow limits to be the square roots of the values computed by `p?lamch`. This function is needed because `p?lamch` does not compensate for poor arithmetic in the upper half of the exponent range, as is found on a Cray.

In addition, this function performs a global minimization and maximization on these values, to support heterogeneous computing networks.

**Input Parameters**

- `ictxt` (global)
  - The BLACS context handle in which the computation takes place.
- `small` (local)
  - On entry, the underflow threshold as computed by `p?lamch`.
- `large` (local)
  - On entry, the overflow threshold as computed by `p?lamch`. 

Excerpt from the document:

```

pxerbla  Error handling routine called by ScaLAPACK routines.

p?labad
Returns the square root of the underflow and overflow thresholds if the exponent-range is very large.

Syntax
void pslabad (MKL_INT *ictxt, float *small, float *large);
void pdlabad (MKL_INT *ictxt, double *small, double *large);

Include Files
- mkl_scalapack.h

Description
The p?labad function takes as input the values computed by p?lamch for underflow and overflow, and returns the square root of each of these values if the log of large is sufficiently large. This function is intended to identify machines with a large exponent range, such as the Crays, and redefine the underflow and overflow limits to be the square roots of the values computed by p?lamch. This function is needed because p?lamch does not compensate for poor arithmetic in the upper half of the exponent range, as is found on a Cray.

In addition, this function performs a global minimization and maximization on these values, to support heterogeneous computing networks.

Input Parameters

ictxt  (global)
   - The BLACS context handle in which the computation takes place.

small  (local).
   - On entry, the underflow threshold as computed by p?lamch.

large  (local).
   - On entry, the overflow threshold as computed by p?lamch.
```
Output Parameters

small (local).
On exit, if $\log_{10}(\text{large})$ is sufficiently large, the square root of small, otherwise unchanged.

large (local).
On exit, if $\log_{10}(\text{large})$ is sufficiently large, the square root of large, otherwise unchanged.

See Also
Overview for details of ScaLAPACK array descriptor structures and related notations.

p?lachkieee
Performs a simple check for the features of the IEEE standard.

Syntax

void pslachkieee (MKL_INT *isieee , float *rmax , float *rmin );
void pdlachkieee (MKL_INT *isieee , float *rmax , float *rmin );

Include Files

• mkl_scalapack.h

Description

The p?lachkieee function performs a simple check to make sure that the features of the IEEE standard are implemented. In some implementations, p?lachkieee may not return.

This is a ScaLAPACK internal function and arguments are not checked for unreasonable values.

Input Parameters

rmax (local).
The overflow threshold ($= ?\text{lamch} ('O')$).

rmin (local).
The underflow threshold ($= ?\text{lamch} ('U')$).

Output Parameters

isieee (local).
On exit, $\text{isieee} = 1$ implies that all the features of the IEEE standard that we rely on are implemented. On exit, $\text{isieee} = 0$ implies that some the features of the IEEE standard that we rely on are missing.

See Also
Overview for details of ScaLAPACK array descriptor structures and related notations.
**p?lamch**  
*Determines machine parameters for floating-point arithmetic.*

**Syntax**

```c
float pslamch (MKL_INT *ictxt, char *cmach);
double pdlamch (MKL_INT *ictxt, char *cmach);
```

**Include Files**

- mkl_scalapack.h

**Description**

The `p?lamch` function determines single precision machine parameters.

**Input Parameters**

- **ictxt** (global). The BLACS context handle in which the computation takes place.
- **cmach** (global). Specifies the value to be returned by `p?lamch`:
  - `'E'` or `'e'`, `p?lamch := eps`
  - `'S'` or `'s'`, `p?lamch := sfmin`
  - `'B'` or `'b'`, `p?lamch := base`
  - `'P'` or `'p'`, `p?lamch := eps*base`
  - `'N'` or `'n'`, `p?lamch := t`
  - `'R'` or `'r'`, `p?lamch := rnd`
  - `'M'` or `'m'`, `p?lamch := emin`
  - `'U'` or `'u'`, `p?lamch := rmin`
  - `'L'` or `'l'`, `p?lamch := emax`
  - `'O'` or `'o'`, `p?lamch := rmax`,

where
- `eps` = relative machine precision
- `sfmin` = safe minimum, such that `1/sfmin` does not overflow
- `base` = base of the machine
- `prec` = `eps*base`
- `t` = number of (base) digits in the mantissa
- `rnd` = 1.0 when rounding occurs in addition, 0.0 otherwise
- `emin` = minimum exponent before (gradual) underflow
- `rmin` = underflow threshold - `base`(emin-1)
- `emax` = largest exponent before overflow
\[ r_{\text{max}} = \text{overflow threshold} - (b_{\text{ase}^{\text{max}}})(1-\text{eps}) \]

**Output Parameters**

**val**
Value returned by the function.

**See Also**

*Overview* for details of ScaLAPACK array descriptor structures and related notations.

**p?lasnbt**

*Computes the position of the sign bit of a floating-point number.*

**Syntax**

```c
void pslasnbt (MKL_INT *ieflag);
void pdlasnbt (MKL_INT *ieflag);
```

**Include Files**

- `mkl_scalapack.h`

**Description**

The `p?lasnbt` function finds the position of the sign bit of a single/double precision floating point number. This function assumes IEEE arithmetic, and hence, tests only the 32-nd bit (for single precision) or 32-nd and 64-th bits (for double precision) as a possibility for the sign bit. `sizeof(int)` is assumed equal to 4 bytes.

If a compile time flag (`NO_IEEE`) indicates that the machine does not have IEEE arithmetic, `ieflag = 0` is returned.

**Output Parameters**

**ieflag**

This flag indicates the position of the sign bit of any single/double precision floating point number.

- `ieflag = 0`, if the compile time flag `NO_IEEE` indicates that the machine does not have IEEE arithmetic, or if `sizeof(int)` is different from 4 bytes.
- `ieflag = 1` indicates that the sign bit is the 32-nd bit for a single precision function.
- In the case of a double precision function:
  - `ieflag = 1` indicates that the sign bit is the 32-nd bit (Big Endian).
  - `ieflag = 2` indicates that the sign bit is the 64-th bit (Little Endian).

**See Also**

*Overview* for details of ScaLAPACK array descriptor structures and related notations.

**descinit**

*Initializes the array descriptor for distributed matrix.*
**Syntax**

```c
void descinit (MKL_INT *desc, const MKL_INT *m, const MKL_INT *n, const MKL_INT *mb,
               const MKL_INT *nb, const MKL_INT *lrsrc, const MKL_INT *lcsrc, const MKL_INT *ictxt,
               const MKL_INT *lld, MKL_INT *info);
```

**Description**

The `descinit` function initializes the array descriptor for distributed matrix.

**Input Parameters**

- `desc` (global) array of dimension DLEN_. The array descriptor of a distributed matrix to be set.
- `m` (global input) The number of rows in the distributed matrix. M >= 0.
- `n` (global input) The number of columns in the distributed matrix. N >= 0.
- `mb` (global input) The blocking factor used to distribute the rows of the matrix. MB >= 1.
- `nb` (global input) The blocking factor used to distribute the columns of the matrix. NB >= 1.
- `lrsrc` (global input) The process row over which the first row of the matrix is distributed. 0 <= IRSRC < NPROW.
- `lcsrc` (global input) The process column over which the first column of the matrix is distributed. 0 <= ICSRC < NPCOL.
- `ictxt` (global input) The BLACS context handle, indicating the global context of the operation on the matrix. The context itself is global.
- `lld` (local input) The leading dimension of the local array storing the local blocks of the distributed matrix. LLD >= MAX(1,LOCr(M)). LOCr() denotes the number of rows of a global dense matrix that the process in a grid receives after data distributing.

**Output Parameters**

- `info` (output)
  - = 0: successful exit
  - < 0: if INFO = -i, the i-th argument had an illegal value

**See Also**

Overview for details of ScaLAPACK array descriptor structures and related notations.

**numroc**

*Computes the number of rows or columns of a distributed matrix owned by the process.*

**Syntax**

```c
MKL_INT numroc (const MKL_INT *n, const MKL_INT *nb, const MKL_INT *iproc, const MKL_INT *srcproc, const MKL_INT *nprocs);
```
Description

The `numroc` function computes the number of rows or columns of a distributed matrix owned by the process.

Input Parameters

- `n` (global input) The number of rows/columns in distributed matrix.
- `nb` (global input) Block size, size of the blocks the distributed matrix is split into.
- `iproc` (local input) The coordinate of the process whose local array row or column is to be determined.
- `srcproc` (global input) The coordinate of the process that possesses the first row or column of the distributed matrix.
- `nprocs` (global input) The total number processes over which the matrix is distributed.

Output Parameters

- `info` (output) Value returned by the function.

</tr>
</tbody>
</table>

See Also

pxerbla Error handling routine called by ScaLAPACK routines.

p?gemr2d

Copies a submatrix from one general rectangular matrix to another.

Syntax

```c
void psgemr2d (MKL_INT *m, MKL_INT *n, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *b, MKL_INT *ib, MKL_INT *jb, MKL_INT *descb, MKL_INT *ictxt);
void pdgemr2d (MKL_INT *m, MKL_INT *n, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *b, MKL_INT *ib, MKL_INT *jb, MKL_INT *descb, MKL_INT *ictxt);
void pcgemr2d (MKL_INT *m, MKL_INT *n, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_Complex8 *b, MKL_INT *ib, MKL_INT *jb, MKL_INT *descb, MKL_INT *ictxt);
```
void pzgemr2d (MKL_INT *m, MKL_INT *n, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_Complex16 *b, MKL_INT *ib, MKL_INT *jb, MKL_INT *descb, MKL_INT *ictxt);
void pigemr2d (MKL_INT *m, MKL_INT *n, MKL_INT *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, MKL_INT *b, MKL_INT *ib, MKL_INT *jb, MKL_INT *descb, MKL_INT *ictxt);

Include Files
• mkl_scalapack.h

Description
The p?gemr2d function copies the indicated matrix or submatrix of A to the indicated matrix or submatrix of B. It provides a truly general copy from any block cyclicly-distributed matrix or submatrix to any other block cyclicly-distributed matrix or submatrix. With p?trmr2d, these functions are the only ones in the ScaLAPACK library which provide inter-context operations: they can take a matrix or submatrix A in context A (distributed over process grid A) and copy it to a matrix or submatrix B in context B (distributed over process grid B).

There does not need to be a relationship between the two operand matrices or submatrices other than their global size and the fact that they are both legal block cyclicly-distributed matrices or submatrices. This means that they can, for example, be distributed across different process grids, have varying block sizes and differing matrix starting points, or be contained in different sized distributed matrices.

Take care when context A is disjoint from context B. The general rules for which parameters need to be set are:
• All calling processes must have the correct m and n.
• Processes in context A must correctly define all parameters describing A.
• Processes in context B must correctly define all parameters describing B.
• Processes which are not members of context A must pass ctxt_a = -1 and need not set other parameters describing A.
• Processes which are not members of context B must pass ctxt_b = -1 and need not set other parameters describing B.

Because of its generality, p?gemr2d can be used for many operations not usually associated with copy functions. For instance, it can be used to take a matrix on one process and distribute it across a process grid, or the reverse. If a supercomputer is grouped into a virtual parallel machine with a workstation, for instance, this function can be used to move the matrix from the workstation to the supercomputer and back. In ScaLAPACK, it is called to copy matrices from a two-dimensional process grid to a one-dimensional process grid. It can be used to redistribute matrices so that distributions providing maximal performance can be used by various component libraries, as well.

Note that this function requires an array descriptor with dtype_ = 1.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804
Input Parameters

- **m** (global) The number of rows of matrix A to be copied ($m \geq 0$).
- **n** (global) The number of columns of matrix A to be copied ($n \geq 0$).
- **a** (local) Pointer into the local memory to array of size $lld_a \times LOCc(ja+n-1)$ containing the source matrix A.
- **ia, ja** (global) The row and column indices in the array A indicating the first row and the first column, respectively, of the submatrix of A) to copy. $1 \leq ia \leq total_rows_in_a - m + 1$, $1 \leq ja \leq total_columns_in_a - n + 1$.
- **desca** (global and local) array of size $dlen_\_$. The array descriptor for the distributed matrix A.
  
  Only $dtype_\_a = 1$ is supported, so $dlen_\_ = 9$.
  
  If the calling process is not part of the context of A, $ctxt_\_a$ must be equal to -1.
- **ib, jb** (global) The row and column indices in the array B indicating the first row and the first column, respectively, of the submatrix B to which to copy the matrix. $1 \leq ib \leq total_rows_in_b - m + 1$, $1 \leq jb \leq total_columns_in_b - n + 1$.
- **descb** (global and local) array of size $dlen_\_$. The array descriptor for the distributed matrix B.
  
  Only $dtype_\_b = 1$ is supported, so $dlen_\_ = 9$.
  
  If the calling process is not part of the context of B, $ctxt_\_b$ must be equal to -1.
- **ictxt** (global).
  
  The context encompassing at least the union of all processes in context A and context B. All processes in the context $ictxt$ must call this function, even if they do not own a piece of either matrix.

Output Parameters

- **b** Pointer into the local memory to array of size $lld_b \times LOCc(jb+n-1)$.
  
  Overwritten by the submatrix from A.

Description
The p?trmr2d function copies the indicated matrix or submatrix of A to the indicated matrix or submatrix of B. It provides a truly general copy from any block cyclicly-distributed matrix or submatrix to any other block cyclicly-distributed matrix or submatrix. With p?gemr2d, these functions are the only ones in the ScaLAPACK library which provide inter-context operations: they can take a matrix or submatrix A in context A (distributed over process grid A) and copy it to a matrix or submatrix B in context B (distributed over process grid B).

The p?trmr2d function assumes the matrix or submatrix to be trapezoidal. Only the upper or lower part is copied, and the other part is unchanged.

There does not need to be a relationship between the two operand matrices or submatrices other than their global size and the fact that they are both legal block cyclicly-distributed matrices or submatrices. This means that they can, for example, be distributed across different process grids, have varying block sizes and differing matrix starting points, or be contained in different sized distributed matrices.

Take care when context A is disjoint from context B. The general rules for which parameters need to be set are:
• All calling processes must have the correct m and n.
• Processes in context A must correctly define all parameters describing A.
• Processes in context B must correctly define all parameters describing B.
• Processes which are not members of context A must pass ctxt_a = -1 and need not set other parameters describing A.
• Processes which are not members of context B must pass ctxt_b = -1 and need not set other parameters describing B.

Because of its generality, p?trmr2d can be used for many operations not usually associated with copy functions. For instance, it can be used to take a matrix on one process and distribute it across a process grid, or the reverse. If a supercomputer is grouped into a virtual parallel machine with a workstation, for instance, this function can be used to move the matrix from the workstation to the supercomputer and back. In ScaLAPACK, it is called to copy matrices from a two-dimensional process grid to a one-dimensional process grid. It can be used to redistribute matrices so that distributions providing maximal performance can be used by various component libraries, as well.

Note that this function requires an array descriptor with dtype_ = 1.

Notice revision #20110804

Input Parameters

uplo  (global) Specifies whether to copy the upper or lower part of the matrix or submatrix.

- uplo = 'U'  Copy the upper triangular part.
- uplo = 'L'  Copy the lower triangular part.

diag  (global) Specifies whether to copy the diagonal of the matrix or submatrix.

- diag = 'U'  Do not copy the diagonal.
- diag = 'N'  Copy the diagonal.

m  (global) The number of rows of matrix A to be copied (m≥0).

n  (global) The number of columns of matrix A to be copied (n≥0).

a  (local)
Pointer into the local memory to array of size lld_a* LOCc(ja+n-1) containing the source matrix A.

ia, ja  (global) The row and column indices in the array A indicating the first row and the first column, respectively, of the submatrix of A) to copy. 1 ≤ ia ≤ total_rows_in_a - m + 1, 1 ≤ ja ≤ total_columns_in_a - n + 1.

desca  (global and local) array of size dlen_. The array descriptor for the distributed matrix A.

Only dtype_a = 1 is supported, so dlen_ = 9.

If the calling process is not part of the context of A, ctxt_a must be equal to -1.

ib, jb  (global) The row and column indices in the array B indicating the first row and the first column, respectively, of the submatrix B to which to copy the matrix. 1 ≤ ib ≤ total_rows_in_b - m + 1, 1 ≤ jb ≤ total_columns_in_b - n + 1.

descb  (global and local) array of size dlen_. The array descriptor for the distributed matrix B.

Only dtype_b = 1 is supported, so dlen_ = 9.

If the calling process is not part of the context of B, ctxt_b must be equal to -1.
ictxt

(global).

The context encompassing at least the union of all processes in context $A$
and context $B$. All processes in the context ictxt must call this function,
even if they do not own a piece of either matrix.

Output Parameters

$b$

Pointer into the local memory to array of size $ld_b \times \text{LOC}(jb+n-1)$.
Overwritten by the submatrix from $A$.

Sparse Solver Routines

Intel® Math Kernel Library (Intel® MKL) provides user-callable sparsesolver software to solve real or complex, symmetric, structurally symmetric or nonsymmetric, positive definite, indefinite or Hermitian square sparse linear system of algebraic equations.

The terms and concepts required to understand the use of the Intel® MKL sparse solver routines are discussed in the Appendix A “Linear Solvers Basics”. If you are familiar with linear sparse solvers and sparse matrix storage schemes, you can skip these sections and go directly to the interface descriptions.

This chapter describes
- the direct sparse solver based on PARDISO® which is referred to here as Intel MKL PARDISO;
- the alternative interface for the direct sparse solver which is referred to here as the DSS interface;
- iterative sparse solvers (ISS) based on the reverse communication interface (RCI);
- and two preconditioners based on the incomplete LU factorization technique.

Intel® MKL PARDISO - Parallel Direct Sparse Solver Interface

This section describes the interface to the shared-memory multiprocessing parallel direct sparse solver known as the Intel® MKL PARDISO solver.

The Intel® MKL PARDISO package is a high-performance, robust, memory efficient, and easy to use software package for solving large sparse linear systems of equations on shared memory multiprocessors. The solver uses a combination of left- and right-looking Level-3 BLAS supernode techniques [Schenk00-2]. To improve sequential and parallel sparse numerical factorization performance, the algorithms are based on a Level-3 BLAS update and pipelining parallelism is used with a combination of left- and right-looking supernode techniques [Schenk00, Schenk01, Schenk02, Schenk03]. The parallel pivoting methods allow complete supernode pivoting to compromise numerical stability and scalability during the factorization process. For sufficiently large problem sizes, numerical experiments demonstrate that the scalability of the parallel algorithm is nearly independent of the shared-memory multiprocessing architecture.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

The following table lists the names of the Intel® MKL PARDISO routines and describes their general use.

<table>
<thead>

</tbody>
</table>

**NOTE** pardiso_getenv and pardiso_setenv routines are deprecated and will be removed in Intel® MKL 2021. The routine pardiso_setenv should be replaced by either using the configuration file or by setting a corresponding environment variable MKL_PARDISO_OOC_FILE_NAME.

The Intel® MKL PARDISO solver supports a wide range of real and complex sparse matrix types (see the figure below).

---

**Sparse Matrices That Can Be Solved with the Intel MKL PARDISO Solver**

The Intel® MKL PARDISO solver performs four tasks:

- analysis and symbolic factorization
- numerical factorization
- forward and backward substitution including iterative refinement
termination to release all internal solver memory.

To find code examples that use Intel® MKL PARDISO routines to solve systems of linear equations, unzip the archive file in the examples folder of the Intel® MKL installation directory. Code examples will be in the examples/solverc/source folder.

**Supported Matrix Types**

The analysis steps performed by Intel® MKL PARDISO depend on the structure of the input matrix A.

**Symmetric Matrices**

The solver first computes a symmetric fill-in reducing permutation $P$ based on either the minimum degree algorithm [Liu85] or the nested dissection algorithm from the METIS package [Karypis98] (both included with Intel® MKL), followed by the parallel left-right looking numerical Cholesky factorization [Schenk00-2] of $PAP^T = LL^T$ for symmetric positive-definite matrices, or $PAP^T = LDL^T$ for symmetric indefinite matrices. The solver uses diagonal pivoting, or 1x1 and 2x2 Bunch-Kaufman pivoting for symmetric indefinite matrices. An approximation of $X$ is found by forward and backward substitution and optional iterative refinement.

Whenever numerically acceptable 1x1 and 2x2 pivots cannot be found within the diagonal supernode block, the coefficient matrix is perturbed. One or two passes of iterative refinement may be required to correct the effect of the perturbations. This restricting notion of pivoting with iterative refinement is effective for highly indefinite symmetric systems. Furthermore, for a large set of matrices from different applications areas, this method is as accurate as a direct factorization method that uses complete sparse pivoting techniques [Schenk04].

Another method of improving the pivoting accuracy is to use symmetric weighted matching algorithms. These algorithms identify large entries in the coefficient matrix $A$ that, if permuted close to the diagonal, permit the factorization process to identify more acceptable pivots and proceed with fewer pivot perturbations. These algorithms are based on maximum weighted matchings and improve the quality of the factor in a complementary way to the alternative of using more complete pivoting techniques.

The inertia is also computed for real symmetric indefinite matrices.

**Structurally Symmetric Matrices**

The solver first computes a symmetric fill-in reducing permutation $P$ followed by the parallel numerical factorization of $PAP^T = QLU^T$. The solver uses partial pivoting in the supernodes and an approximation of $X$ is found by forward and backward substitution and optional iterative refinement.

**Nonsymmetric Matrices**

The solver first computes a nonsymmetric permutation $P_{MPS}$ and scaling matrices $D_r$ and $D_c$ with the aim of placing large entries on the diagonal to enhance reliability of the numerical factorization process [Duff99]. In the next step the solver computes a fill-in reducing permutation $P$ based on the matrix $P_{MPS}A + (P_{MPS}A)^T$ followed by the parallel numerical factorization

$QLUR = PF_{MPS}D_rAD_cP$

with supernode pivoting matrices $Q$ and $R$. When the factorization algorithm reaches a point where it cannot factor the supernodes with this pivoting strategy, it uses a pivoting perturbation strategy similar to [Li99]. The magnitude of the potential pivot is tested against a constant threshold of

$alpha = eps*||A2||_inf$. 

where $\text{eps}$ is the machine precision, $A_2 = P*F_{\text{NP}}*D_r*A*D_c*P$, and $||A_2||_{\text{inf}}$ is the infinity norm of $A$. Any tiny pivots encountered during elimination are set to the sign $(1_{II})*\text{eps}||A_2||_{\text{inf}}$, which trades off some numerical stability for the ability to keep pivots from getting too small. Although many failures could render the factorization well-defined but essentially useless, in practice the diagonal elements are rarely modified for a large class of matrices. The result of this pivoting approach is that the factorization is, in general, not exact and iterative refinement may be needed.

**Sparse Data Storage**

Intel® MKL PARDISO stores sparse data in several formats:

- **CSR3:** The 3-array variation of the compressed sparse row format described in Three Array Variation of CSR Format.
- **BSR3:** The three-array variation of the block compressed sparse row format described in Three Array Variation of BSR Format. Use $\text{iparm}[36]$ to specify the block size.
- **VBSR:** Variable BSR format. Intel® MKL PARDISO analyzes the matrix provided in CSR3 format and converts it into an internal structure which can improve performance for matrices with a block structure. Use $\text{iparm}[36] = -t$ ($0 < t \leq 100$) to specify use of internal VBSR format and to set the degree of similarity required to combine elements of the matrix. For example, if you set $\text{iparm}[36] = -80$, two rows of the input matrix are combined when their non-zero patterns are 80% or more similar.

**NOTE**

Intel® MKL supports only the VBSR format for real and symmetric positive definite or indefinite matrices ($mtype = 2$ or $mtype = -2$).

Intel® MKL supports these features for all matrix types as long as $\text{iparm}[23] = 1$:

- $\text{iparm}[30] > 0$: Partial solution
- $\text{iparm}[35] > 0$: Schur complement
- $\text{iparm}[59] > 0$: OOC Intel® MKL PARDISO

For all storage formats, the Intel® MKL PARDISO parameter $ja$ is used for the columns array, $ia$ is used for rowIndex, and $a$ is used for values. The algorithms in Intel® MKL PARDISO require column indices $ja$ to be in increasing order per row and that the diagonal element in each row be present for any structurally symmetric matrix. For symmetric or nonsymmetric matrices the diagonal elements which are equal to zero are not necessary.

**Caution**

Intel® MKL PARDISO column indices $ja$ must be in increasing order per row. You can validate the sparse matrix structure with the matrix checker ($\text{iparm}[26]$)

**NOTE**

While the presence of zero diagonal elements for symmetric matrices is not required, you should explicitly set zero diagonal elements for symmetric matrices. Otherwise, Intel® MKL PARDISO creates internal copies of arrays $ia$, $ja$, and $a$ full of diagonal elements, which require additional memory and computational time. However, the memory and time required the diagonal elements in internal arrays is usually not significant compared to the memory and the time required to factor and solve the matrix.
Storage of Matrices

By default, Intel® MKL PARDISO stores data in RAM. This is referred to as In-Core (IC) mode. However, you can specify that Intel® MKL PARDISO store matrices on disk by setting iparm[59]. This mode is called the Out-of-Core (OOC) mode.

You can set the following parameters for the OOC mode.

<table>
<thead>
<tr>
<th>Parameter/Environment Variable Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MKL_PARDISO_OOC_PATH</td>
<td>Directory for storing data created in the OOC mode.</td>
</tr>
<tr>
<td>MKL_PARDISO_OOC_FILE_NAME</td>
<td>Full file name (incl. path) which will be used for the OOC files</td>
</tr>
<tr>
<td>MKL_PARDISO_OOC_MAX_CORE_SIZE</td>
<td>Maximum size of RAM (in megabytes) available for Intel® MKL PARDISO</td>
</tr>
<tr>
<td>MKL_PARDISO_OOC_MAX_SWAP_SIZE</td>
<td>Maximum swap size (in megabytes) available for Intel® MKL PARDISO</td>
</tr>
<tr>
<td>MKL_PARDISO_OOC_KEEP_FILE</td>
<td>A flag which determines whether temporary data files will be deleted or stored</td>
</tr>
</tbody>
</table>

By default, the current working directory is used in the OOC mode as a directory path for storing data. All work arrays will be stored in files named ooc_temp with different extensions. When MKL_PARDISO_OOC_FILE_NAME is not set and MKL_PARDISO_OOC_PATH is set, the names for the created files will contain <path>/mkl_pardiso or <path>/mkl_pardiso depending on the OS. Setting MKL_PARDISO_OOC_FILE_NAME=<filename> will override the path which could have been set in MKL_PARDISO_OOC_PATH. In this case <filename> will be used for naming the OOC files.

By default, MKL_PARDISO_OOC_MAX_CORE_SIZE is 2000 (MB) and MKL_PARDISO_OOC_MAX_SWAP_SIZE is 0.

**NOTE**
Do not set the sum of MKL_PARDISO_OOC_MAX_CORE_SIZE and MKL_PARDISO_OOC_MAX_SWAP_SIZE greater than the size of the RAM plus the size of the swap memory. Be sure to allow enough free memory for the operating system and any other processes which need to be running.

By default, all temporary data files will be deleted. For keeping them it is required to set MKL_PARDISO_OOC_KEEP_FILE to 0.

OOC parameters can be set in a configuration file. You can set the path to this file and its name using environmental variables MKL_PARDISO_OOC_CFG_PATH and MKL_PARDISO_OOC_CFG_FILE_NAME.
For setting parameters of OOC mode either environment variables or a configuration file can be used. When the last option is chosen, by default the name of the file is pardiso_ooc.cfg and it should be placed in the working directory. If needed, the user can set the path to the configuration file using environmental variables MKL_PARDISO_OOC_CFG_PATH and MKL_PARDISO_OOC_CFG_FILE_NAME. These variables specify the path and filename as follows:

- Linux* OS and OS X*: `<MKL_PARDISO_OOC_CFG_PATH>\<MKL_PARDISO_OOC_CFG_FILE_NAME>`
- Windows* OS: `<MKL_PARDISO_OOC_CFG_PATH>\<MKL_PARDISO_OOC_CFG_FILE_NAME>`

An example of the configuration file:

```
MKL_PARDISO_OOC_PATH = <path>
MKL_PARDISO_OOC_MAX_CORE_SIZE = N
MKL_PARDISO_OOC_MAX_SWAP_SIZE = K
MKL_PARDISO_OOC_KEEP_FILE = 0 (or 1)
```

**Caution**
The maximum length of the path lines in the configuration files is 1000 characters.

Alternatively, the OOC parameters can be set as environment variables via command line.

For Linux* OS and OS X*:

```
export MKL_PARDISO_OOC_PATH = <path>
export MKL_PARDISO_OOC_MAX_CORE_SIZE = N
export MKL_PARDISO_OOC_MAX_SWAP_SIZE = K
export MKL_PARDISO_OOC_KEEP_FILE = 0 (or 1)
```

For Windows* OS:

```
set MKL_PARDISO_OOC_PATH = <path>
set MKL_PARDISO_OOC_MAX_CORE_SIZE = N
set MKL_PARDISO_OOC_MAX_SWAP_SIZE = K
set MKL_PARDISO_OOC_KEEP_FILE = 0 (or 1)
```

where `<path>` should follow the OS naming convention.

**Direct-Iterative Preconditioning for Nonsymmetric Linear Systems**

The solver uses a combination of direct and iterative methods [Sonn89] to accelerate the linear solution process for transient simulation. Most applications of sparse solvers require solutions of systems with gradually changing values of the nonzero coefficient matrix, but with an identical sparsity pattern. In these applications, the analysis phase of the solvers has to be performed only once and the numerical factorizations are the important time-consuming steps during the simulation. Intel® MKL PARDISO uses a numerical factorization and applies the factors in a preconditioned Krylov Subspace iteration. If the iteration does not converge, the solver automatically switches back to the numerical factorization. This method can be applied to nonsymmetric matrices in Intel® MKL PARDISO. You can select the method using the `iparm[3]` input parameter. The `iparm[19]` parameter returns the error status after running Intel® MKL PARDISO.

**Single and Double Precision Computations**

Intel® MKL PARDISO solves tasks using single or double precision. Each precision has its benefits and drawbacks. Double precision variables have more digits to store value, so the solver uses more memory for keeping data. But this mode solves matrices with better accuracy, which is especially important for input matrices with large condition numbers.

Single precision variables have fewer digits to store values, so the solver uses less memory than in the double precision mode. Additionally this mode usually takes less time. But as computations are made less precisely, only some systems of equations can be solved accurately enough using single precision.
Separate Forward and Backward Substitution

The solver execution step (see parameter $phase = 33$ below) can be divided into two or three separate substitutions: forward, backward, and possible diagonal. This separation can be explained by the examples of solving systems with different matrix types.

A real symmetric positive definite matrix $A$ ($mtype = 2$) is factored by Intel® MKL PARDISO as $A = L^*L^T$. In this case the solution of the system $A^*x=b$ can be found as sequence of substitutions: $L^*y=b$ (forward substitution, $phase = 331$) and $L^T*x=y$ (backward substitution, $phase = 333$).

A real nonsymmetric matrix $A$ ($mtype = 11$) is factored by Intel® MKL PARDISO as $A = L^*U$. In this case the solution of the system $A^*x=b$ can be found by the following sequence: $L^*y=b$ (forward substitution, $phase = 331$) and $U^*x=y$ (backward substitution, $phase = 333$).

Solving a system with a real symmetric indefinite matrix $A$ ($mtype = -2$) is slightly different from the cases above. Intel® MKL PARDISO factors this matrix as $A = LDL^T$, and the solution of the system $A^*x=b$ can be calculated as the following sequence of substitutions: $L^*y=b$ (forward substitution, $phase = 331$), $D^*v=y$ (diagonal substitution, $phase = 332$), and finally $L^T*x=v$ (backward substitution, $phase = 333$). Diagonal substitution makes sense only for symmetric indefinite matrices ($mtype = -2, -4, 6$). For matrices of other types a solution can be found as described in the first two examples.

Caution

The number of refinement steps ($iparm[7]$) must be set to zero if a solution is calculated with separate substitutions ($phase = 331, 332, 333$), otherwise Intel® MKL PARDISO produces the wrong result.

NOTE

Different pivoting ($iparm[20]$) produces different $LDL^T$ factorization. Therefore results of forward, diagonal and backward substitutions with diagonal pivoting can differ from results of the same steps with Bunch-Kaufman pivoting. Of course, the final results of sequential execution of forward, diagonal and backward substitution are equal to the results of the full solving step ($phase = 33$) regardless of the pivoting used.

Callback Function for Pivoting Control

In-core Intel® MKL PARDISO allows you to control pivoting with a callback routine, mkl_pardiso_pivot. You can then use the pardiso_getdiag routine to access the diagonal elements. Set $iparm[55]$ to 1 in order to use the callback functionality.

Low Rank Update

Use low rank update to accelerate the factorization step in Intel® MKL PARDISO when you use multiple matrices with identical structure and similar values. After calling pardiso in the usual manner for factorization ($phase = 12, 13, 22, or 23$) for some matrix $A1$, low rank update can be applied to the factorization step ($phase = 22 or 23$) of some matrix $A2$ with identical structure.

To use the low rank update feature, set $iparm[38] = 1$ while also setting $iparm[23] = 10$. Additionally, supply an array that lists the values in $A2$ that are different from $A1$ using the $perm$ parameter as outlined in the pardiso $perm$ parameter description.
Important
Low rank update can only be called for matrices with the exact same pattern of nonzero values. As such, the value of the mtype, ia, ja, and iparm[23] parameters should also be identical. In general, the low rank factorization should be called with the same parameters as the preceding factorization step for the same internal data structure handle (except for array a, iparm[38], and perm).

Low rank update does not currently support Intel TBB threading. In this case, Intel® MKL PARDISO defaults to full factorization instead.

Low rank update cannot be used in combination with a user-supplied permutation vector - in other words, you must use the default values of iparm[4] = 0, iparm[30] = 0, and iparm[35] = 0. Additionally, iparm[3], iparm[5], iparm[27], iparm[36], iparm[55], and iparm[59] must all be set to the default value of 0.

pardiso
Calculates the solution of a set of sparse linear equations with single or multiple right-hand sides.

Syntax
void pardiso (_MKL_DSS_HANDLE_t pt, const MKL_INT *maxfct, const MKL_INT *mnum, const MKL_INT *mtype, const MKL_INT *phase, const MKL_INT *n, const void *a, const MKL_INT *ia, const MKL_INT *ja, MKL_INT *perm, const MKL_INT *nrhs, MKL_INT *iparm, const MKL_INT *msglvl, void *b, void *x, MKL_INT *error);

Include Files
• mkl.h

Description
The routine pardiso calculates the solution of a set of sparse linear equations

$$A \times X = B$$

with single or multiple right-hand sides, using a parallel LU, LDL, or LLᵀ factorization, where A is an n-by-n matrix, and X and B are n-by-nrhs vectors or matrices.

NOTE
This routine supports the Progress Routine feature. See Progress Function section for details. The case of iparm[23]=10 does not support this feature.

Optimization Notice

Intel’s compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804
Input Parameters

pt

Array with size of 64.
Handle to internal data structure. The entries must be set to zero prior to the first call to pardiso. Unique for factorization.

**Caution**
After the first call to pardiso do not directly modify pt, as that could cause a serious memory leak.

Use the pardiso_handle_store or pardiso_handle_store_64 routine to store the content of pt to a file. Restore the contents of pt from the file using pardiso_handle_restore or pardiso_handle_restore_64. Use pardiso_handle_store and pardiso_handle_restore with pardiso, and pardiso_handle_store_64 and pardiso_handle_restore_64 with pardiso_64.

maxfct

Maximum number of factors with identical sparsity structure that must be kept in memory at the same time. In most applications this value is equal to 1. It is possible to store several different factorizations with the same nonzero structure at the same time in the internal data structure management of the solver.

pardiso can process several matrices with an identical matrix sparsity pattern and it can store the factors of these matrices at the same time. Matrices with a different sparsity structure can be kept in memory with different memory address pointers pt.

mnum

Indicates the actual matrix for the solution phase. With this scalar you can define which matrix to factorize. The value must be: 1 \leq mnum \leq maxfct.
In most applications this value is 1.

mtype

Defines the matrix type, which influences the pivoting method. The Intel® MKL PARDISO solver supports the following matrices:

1    real and structurally symmetric
2    real and symmetric positive definite
-2   real and symmetric indefinite
3    complex and structurally symmetric
4    complex and Hermitian positive definite
-4   complex and Hermitian indefinite
6    complex and symmetric
11   real and nonsymmetric
13   complex and nonsymmetric
Controls the execution of the solver. Usually it is a two- or three-digit integer. The first digit indicates the starting phase of execution and the second digit indicates the ending phase. Intel® MKL PARDISO has the following phases of execution:

- Phase 1: Fill-reduction analysis and symbolic factorization
- Phase 2: Numerical factorization
- Phase 3: Forward and Backward solve including optional iterative refinement

This phase can be divided into two or three separate substitutions: forward, backward, and diagonal (see Separate Forward and Backward Substitution).

- Memory release phase (phase = 0 or phase = -1)

If a previous call to the routine has computed information from previous phases, execution may start at any phase. The phase parameter can have the following values:

<table>
<thead>
<tr>
<th>phase</th>
<th>Solver Execution Steps</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>Analysis</td>
</tr>
<tr>
<td>12</td>
<td>Analysis, numerical factorization</td>
</tr>
<tr>
<td>13</td>
<td>Analysis, numerical factorization, solve, iterative refinement</td>
</tr>
<tr>
<td>22</td>
<td>Numerical factorization</td>
</tr>
<tr>
<td>23</td>
<td>Numerical factorization, solve, iterative refinement</td>
</tr>
<tr>
<td>33</td>
<td>Solve, iterative refinement</td>
</tr>
<tr>
<td>331</td>
<td>like phase=33, but only forward substitution</td>
</tr>
<tr>
<td>332</td>
<td>like phase=33, but only diagonal substitution (if available)</td>
</tr>
<tr>
<td>333</td>
<td>like phase=33, but only backward substitution</td>
</tr>
<tr>
<td>0</td>
<td>Release internal memory for L and U matrix number mnum</td>
</tr>
<tr>
<td>-1</td>
<td>Release all internal memory for all matrices</td>
</tr>
</tbody>
</table>

If iparm[35] = 0, phases 331, 332, and 333 perform this decomposition:

\[
A = \begin{bmatrix}
L_{11} & 0 & D_{11} & 0 & U_{11} & U_{21} \\
L_{12} & L_{22} & 0 & D_{22} & 0 & U_{22}
\end{bmatrix}
\]

If iparm[35] = 2, phases 331, 332, and 333 perform a different decomposition:

\[
A = \begin{bmatrix}
L_{11} & 0 & I & 0 & U_{11} & U_{21} \\
L_{12} & I & 0 & S & 0 & I
\end{bmatrix}
\]
You can supply a custom implementation for phase 332 instead of calling 
pardiso. For example, it can be implemented with dense LAPACK 
functionality. Custom implementation also allows you to substitute the 
matrix $S$ with your own.

**NOTE**
For very large Schur complement matrices use LAPACK 
functionality to compute the Schur complement vector instead 
of the Intel® MKL PARDISO phase 332 implementation.

**n**
Number of equations in the sparse linear systems of equations $A*X = B$. 
Constraint: $n > 0$.

**a**
Array. Contains the non-zero elements of the coefficient matrix $A$ 
corresponding to the indices in $ja$. The coefficient matrix can be either real 
or complex. The matrix must be stored in the three-array variant of the 
compressed sparse row (CSR3) or in the three-array variant of the block 
compressed sparse row (BSR3) format, and the matrix must be stored with 
increasing values of $ja$ for each row.

For CSR3 format, the size of $a$ is the same as that of $ja$. Refer to the 
values array description in Three Array Variation of CSR Format for more 
details.

For BSR3 format the size of $a$ is the size of $ja$ multiplied by the square of 
the block size. Refer to the values array description in Three Array 
Variation of BSR Format for more details.

**NOTE**
If you set $iparm[36]$ to a negative value, Intel® MKL PARDISO 
converts the data from CSR3 format to an internal variable BSR 
(VBSR) format. See Sparse Data Storage.

**ia**
Array, size $(n+1)$.

For CSR3 format, $ia[i] \ (i<n)$ points to the first column index of row $i$ in 
the array $ja$. That is, $ia[i]$ gives the index of the element in array $a$ that 
contains the first non-zero element from row $i$ of $A$. The last element $ia[n]$ 
is taken to be equal to the number of non-zero elements in $A$, plus one. 
Refer to $rowIndex$ array description in Three Array Variation of CSR Format 
for more details.

For BSR3 format, $ia[i] \ (i<n)$ points to the first column index of row $i$ in 
the array $ja$. That is, $ia[i]$ gives the index of the element in array $a$ that 
contains the first non-zero block from row $i$ of $A$. The last element $ia[n]$ is 
taken to be equal to the number of non-zero blocks in $A$, plus one. Refer to 
$rowIndex$ array description in Three Array Variation of BSR Format for more 
details.

The array $ia$ is accessed in all phases of the solution process.

Indexing of $ia$ is one-based by default, but it can be changed to zero-based 
by setting the appropriate value to the parameter $iparm[34]$. 
For CSR3 format, array \( ja \) contains column indices of the sparse matrix \( A \).
It is important that the indices are in increasing order per row. For
structurally symmetric matrices it is assumed that all diagonal elements are
stored (even if they are zeros) in the list of non-zero elements in \( a \) and \( ja \).
For symmetric matrices, the solver needs only the upper triangular part of
the system as is shown for \( columns \) array in Three Array Variation of CSR
Format.

For BSR3 format, array \( ja \) contains column indices of the sparse matrix \( A \).
It is important that the indices are in increasing order per row. For
structurally symmetric matrices it is assumed that all diagonal blocks are
stored (even if they are zeros) in the list of non-zero blocks in \( a \) and \( ja \).
For symmetric matrices, the solver needs only the upper triangular part of
the system as is shown for \( columns \) array in Three Array Variation of BSR
Format.

The array \( ja \) is accessed in all phases of the solution process.

Indexing of \( ja \) is one-based by default, but it can be changed to zero-based
by setting the appropriate value to the parameter \( iparm[34] \).

Array, size \((n)\). Depending on the value of \( iparm[4] \) and \( iparm[30] \), holds
the permutation vector of size \( n \), specifies elements used for computing a
partial solution, or specifies differing values of the input matrices for low
rank update.

- If \( iparm[4] = 1, iparm[30] = 0, \) and \( iparm[35] = 0 \), \( perm \) specifies
  the fill-in reducing ordering to the solver. Let \( A \) be the original matrix
  and \( C = P^*A^*P^T \) be the permuted matrix. Row (column) \( i \) of \( C \) is the
  \( perm[i] \) row (column) of \( A \). The array \( perm \) is also used to return the
  permutation vector calculated during fill-in reducing ordering stage.

  **NOTE**
  Be aware that setting \( iparm[4] = 1 \) prevents use of a parallel
  algorithm for the solve step.

- If \( iparm[4] = 2, iparm[30] = 0, \) and \( iparm[35] = 0 \), the permutation
  vector computed in phase 11 is returned in the \( perm \) array.
- If \( iparm[4] = 0, iparm[30] > 0, \) and \( iparm[35] = 0 \), \( perm \) specifies
  elements of the right-hand side to use or of the solution to compute for
  a partial solution.
- If \( iparm[4] = 0, iparm[30] = 0, \) and \( iparm[35] > 0 \), \( perm \) specifies
  elements for a Schur complement.
- If \( iparm[38] = 1, \) \( perm \) specifies values that differ in \( A \) for low rank
  update (see Low Rank Update). The size of the array must be at least
  \( 2*ndiff + 1 \), where \( ndiff \) is the number of values of \( A \) that are different.
  The values of \( perm \) should be:
  \[
  perm = \{ ndiff, row_index1, column_index1, row_index2, column_index2, ..., row_index_ndiff, column_index_ndiff \}
  \]
  where \( row_index_m \) and \( column_index_m \) are the row and column
  indices of the \( m \)-th differing non-zero value in matrix \( A \). The row and
  column index pairs can be in any order, but must use zero-based
  indexing regardless of the value of \( iparm[34] \).
See iparm[4], iparm[30], and iparm[38] for more details.

Indexing of perm is one-based by default, but unless iparm[38] = 1 it can be changed to zero-based by setting the appropriate value to the parameter iparm[34].

**nrhs**
Number of right-hand sides that need to be solved for.

**iparm**
Array, size (64). This array is used to pass various parameters to Intel® MKL PARDISO and to return some useful information after execution of the solver.

See pardiso iparm Parameter for more details about the iparm parameters.

**msglvl**
Message level information. If msglvl = 0 then pardiso generates no output, if msglvl = 1 the solver prints statistical information to the screen.

**b**
Array, size (n*nrhs). On entry, contains the right-hand side vector/matrix B, which is placed in memory contiguously. The b[k*nrhs] element must hold the i-th component of k-th right-hand side vector. Note that b is only accessed in the solution phase.

### Output Parameters

(See also Intel MKL PARDISO Parameters in Tabular Form.)

**pt**
Handle to internal data structure.

See the Input Parameter description of the perm array.

**perm**
On output, some iparm values report information such as the numbers of non-zero elements in the factors.

See pardiso iparm Parameter for more details about the iparm parameters.

**iparm**
On output, the array is replaced with the solution if iparm[5] = 1.

**b**
Array, size (n*nrhs). If iparm[5]=0 it contains solution vector/matrix X, which is placed contiguously in memory. The x[i + k*n] element must hold the i-th component of the k-th solution vector. Note that x is only accessed in the solution phase.

**error**
The error indicator according to the below table:

<table>
<thead>
<tr>
<th>error</th>
<th>Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>no error</td>
</tr>
<tr>
<td>-1</td>
<td>input inconsistent</td>

<tr>
<td>-13</td>
<td>interrupted by the (user-defined) mkl_progress function</td>
</tr>
</tbody>
</table>

**pardisoinit**

Initialize Intel® MKL PARDISO with default parameters in accordance with the matrix type.

**Syntax**

```c
void pardisoinit (_MKL_DSS_HANDLE_t pt, const MKL_INT *mtype, MKL_INT *iparm );
```

**Include Files**

- mkl.h

**Description**

This function initializes Intel® MKL PARDISO internal address pointer `pt` with zero values (as needed for the very first call of pardiso) and sets default `iparm` values in accordance with the matrix type. Intel® MKL supplies the pardisoinit routine to be compatible with PARDISO 3.2 or lower.

**NOTE**

An alternative way to set default `iparm` values is to call pardiso in the analysis phase with `iparm(1)=0`. In this case you must initialize the internal address pointer `pt` with zero values manually.
NOTE
The pardisoinit routine initializes only the in-core version of Intel® MKL PARDISO. Switching on the out-of-core version of Intel® MKL PARDISO as well as changing default iparm values can be done after the call to pardisoinit but before the first call to pardiso.

Input Parameters

perm
Ignored.

mtype
This scalar value defines the matrix type. Based on this value pardisoinit sets default values for the iparm array. Refer to the section Intel MKL PARDISO Parameters in Tabular Form for more details about the default values of Intel® MKL PARDISO.

Output Parameters

pt
Array with a dimension of 64. Solver internal data address pointer. These addresses are passed to the solver, and all related internal memory management is organized through this array. The pardisoinit routine nullifies the array pt.

NOTE
It is very important that the pointer pt is initialized with zero before the first call of Intel® MKL PARDISO. After that first call you should never modify the pointer, because it could cause a serious memory leak or a crash.

iparm
Array with a dimension of 64. This array is used to pass various parameters to Intel® MKL PARDISO and to return some useful information after execution of the solver. The pardisoinit routine fills-in the iparm array with the default values. Refer to the section Intel MKL PARDISO Parameters in Tabular Form for more details about the default values of Intel® MKL PARDISO.

pardiso_64
Calculates the solution of a set of sparse linear equations with single or multiple right-hand sides, 64-bit integer version.

Syntax

void pardiso_64 (_MKL_DSS_HANDLE_t pt, const long long int *maxfct, const long long int *mnum, const long long int *mtype, const long long int *phase, const long long int *n, const void *a, const long long int *ia, const long long int *ja, long long int *perm, const long long int *nrhs, long long int *iparm, const long long int *msglvl, void *b, void *x, long long int *error);

Include Files

• mkl.h
Description

pardiso_64 is an alternative ILP64 (64-bit integer) version of the pardiso routine (see Description section for more details). The interface of pardiso_64 is the same as the interface of pardiso, but it accepts and returns all integer data as long long int.

Use pardiso_64 when pardiso for solving large matrices (with the number of non-zero elements on the order of 500 million or more). You can use it together with the usual LP64 interfaces for the rest of Intel® MKL functionality. In other words, if you use 64-bit integer version (pardiso_64), you do not need to re-link your applications with ILP64 libraries. Take into account that pardiso_64 may perform slower than regular pardiso on the reordering and symbolic factorization phase.

NOTE
pardiso_64 is supported only in the 64-bit libraries. If pardiso_64 is called from the 32-bit libraries, it returns error =-12.

NOTE
This routine supports the Progress Routine feature. See Progress Function section for details.

Input Parameters

The input parameters of pardiso_64 are the same as the input parameters of pardiso, but pardiso_64 accepts all integer data as long long int.

Output Parameters

The output parameters of pardiso_64 are the same as the output parameters of pardiso, but pardiso_64 returns all integer data as long long int.

pardiso_getenv, pardiso_setenv

Retrieves additional values from or sets additional values in the Intel® MKL PARDISO handle (deprecated).

Syntax

MKL_INT pardiso_getenv (const _MKL_DSS_HANDLE_t handle, const enum PARDISO_ENV_PARAM *param, char *value);
MKL_INT pardiso_setenv (_MKL_DSS_HANDLE_t handle, const enum PARDISO_ENV_PARAM *param, const char *value);

Include Files

• mkl.h

Description

These functions operate with the Intel® MKL PARDISO handle. The pardiso_getenv routine retrieves additional values from the Intel® MKL PARDISO handle, and pardiso_setenv sets specified values in the Intel® MKL PARDISO handle.

These functions enable retrieving and setting the name of the Intel® MKL PARDISO OOC file.
To retrieve the Intel® MKL PARDISO OOC file name, you can apply this function to any properly-created handle.

To set the Intel® MKL PARDISO OOC file name in the handle you must call the function before the reordering stage. This is because the OOC file name is stored in the handle after the reordering stage and it is not changed during further computations.

NOTE
A 1024-byte internal buffer is used inside Intel® MKL PARDISO for storing the OOC file name. Allocate a 1024-byte buffer for passing to the `pardiso_getenv` function as the value parameter.

**Input Parameters**

**handle**

Intel® MKL PARDISO handle for which to set and from which to retrieve information. (See DSS Interface Description for structure description)

**param**

Specifies the required parameter. The only value is `PARDISO_OOC_FILE_NAME`, defined in the corresponding include file.

**value**

Input parameter for `pardiso_setenv`. Contains the name of the OOC file that must be used in the handle.

**Output Parameters**

**handle**

Output parameter for `pardiso_setenv`. Data object of the MKL_DSS_HANDLE type (see DSS Interface Description).

**value**

Output parameter for `pardiso_getenv`. Contains the name of the OOC file which must be used in the handle.

**mkl_pardiso_pivot**

Replaces routine which handles Intel® MKL PARDISO pivots with user-defined routine.

**Syntax**

```c
void mkl_pardiso_pivot (const void *ai, void *bi, const void *eps);
```

**Include Files**

- mkl.h

**Description**

The `mkl_pardiso_pivot` routine allows you to handle diagonal elements which arise during numerical factorization that are zero or near zero. By default, Intel® MKL PARDISO determines that a diagonal element $bi$ is a pivot if $bi < eps$, and if so, replaces it with $eps$. But you can provide your own routine to modify the resulting factorized matrix in case there are small elements on the diagonal during the factorization step.

NOTE
To use this routine, you must set `iparm[55]` to 1 before the main `pardiso` loop.
Input Parameters

- $ai$: Diagonal element of initial matrix corresponding to pivot element.
- $bi$: Diagonal element of factorized matrix that could be chosen as a pivot element.
- $\epsilon$: Scalar to compare with diagonal of factorized matrix. On input equal to parameter described by $iparm[9]$.

Output Parameters

- $bi$: In case element is chosen as a pivot, value with which to replace the pivot.

**pardiso_getdiag**

_Returns diagonal elements of initial and factorized matrix._

**Syntax**

```c
void pardiso_getdiag (const _MKL_DSS_HANDLE_t pt, void *df, void *da, const MKL_INT *mnum, MKL_INT *error);
```

**Include Files**

- mkl.h

**Description**

This routine returns the diagonal elements of the initial and factorized matrix for a real or Hermitian matrix.

**NOTE**

In order to use this routine, you must set $iparm[55]$ to 1 before the main _pardiso_ loop.

**Input Parameters**

- $pt$: Array with a size of 64. Handle to internal data structure for the Intel® MKL PARDISO solver. The entries must be set to zero prior to the first call to _pardiso_. Unique for factorization.

- $mnum$: Indicates the actual matrix for the solution phase of the Intel® MKL PARDISO solver. With this scalar you can define the diagonal elements of the factorized matrix that you want to obtain. The value must be: $1 \leq mnum \leq maxfct$. In most applications this value is 1.

**Output Parameters**

- $df$: Array with a dimension of $n$. Contains diagonal elements of the factorized matrix after factorization.
**NOTE**
Elements of $df$ correspond to diagonal elements of matrix $L$ computed during phase 22. Because during phase 22 Intel® MKL PARDISO makes additional permutations to improve stability, it is possible that array $df$ is not in line with the $perm$ array computed during phase 11.

$da$
Array with a dimension of $n$. Contains diagonal elements of the initial matrix.

**NOTE**
Elements of $da$ correspond to diagonal elements of matrix $L$ computed during phase 22. Because during phase 22 Intel® MKL PARDISO makes additional permutations to improve stability, it is possible that array $da$ is not in line with the $perm$ array computed during phase 11.

$error$
The error indicator.

<table>
<thead>
<tr>
<th>error</th>
<th>Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>no error</td>
</tr>
<tr>
<td>-1</td>
<td>Diagonal information not turned on before pardiso main loop ($iparm[55]=0$).</td>
</tr>
</tbody>
</table>

**pardiso_export**
Places pointers dedicated for sparse representation of a requested matrix (values, rows, and columns) into MKL PARDISO

**Syntax**
```c
void pardiso_export (const _MKL_DSS_HANDLE_t pt, void* values, MKL_INT* rows, MKL_INT* columns, MKL_INT* step, MKL_INT* iparm, MKL_INT* error);
```

**Include Files**
- mkl.h

**Description**
This auxiliary routine places pointers dedicated for sparse representation of a requested matrix (values, rows, and columns) into MKL PARDISO. The matrix will be stored in the three-array variant of the compressed sparse row (CSR3 format) with 0-based indexing. For details, refer to Three Array Variation of CSR Format.

**NOTE**
Currently, this routine can be used only for a sparse Schur complement matrix. All parameters related to the Schur complement matrix ($perm$, $iparm$) must be set before the reordering stage of MKL PARDISO (phase = 11) is called.
**Input Parameters**

*pt*

Array with a size of 64. Handle to internal data structure for the Intel® MKL PARDISO solver. The entries must be set to zero prior to the first call to `pardiso`. Unique for factorization.

*iparm*

This array is used to pass various parameters to Intel® MKL PARDISO and to return some useful information after execution of the solver.

*step*

Stage indicator. These are the currently supported values:

<table>
<thead>
<tr>
<th>Step value</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Used to place pointers related to a Schur complement matrix in MKL PARDISO. The routine with <code>step</code> equal to 1 must be called between the reordering and factorization phases of MKL PARDISO.</td>
</tr>
<tr>
<td>-1</td>
<td>Used to clean the internal handle.</td>
</tr>
</tbody>
</table>

**Input/Output Parameters**

*values*

Parameter type: input/output parameter.

This array contains the non-zero elements of the requested matrix.

*rows*

Parameter type: input/output parameter.

Array of size (`size` + 1)

For CSR3 format, `rows[i]` (i < `size`) points to the first column index of row `i` in the array `columns`; that is, `rows[i]` gives the index of the element in the array `values` that contains the first non-zero element from row `i` of the sparse matrix. The last element, `rows[size]`, is equal to the number of non-zero elements in the sparse matrix.

*columns*

Parameter type: input/output parameter.

This array contains the column indices for the non-zero elements of the requested matrix.

*error*

Parameter type: output parameter.

The error status:

- 0 indicates no error.
- 1 indicates inconsistent input data.

**Usage Example**

The following C-style example demonstrates how to use the `pardiso_export` routine to get the sparse representation (that is, three-array CSR format) of a Schur complement matrix.

```c
#include "mkl.h"

/*
 * Call the reordering phase of MKL PARDISO with iparm[35] set to -1 in
 * order to compute the Schur complement matrix only, or -2 to compute all
```
* factorization arrays. perm array indices related to the Schur complement
  * matrix must be set to 1.
  */
phase = 11;

 */

**pardiso_handle_store**

*Store internal structures from `pardiso` to a file.*

**Syntax**

```c
void pardiso_handle_store (_MKL_DSS_HANDLE_t pt, const char *dirname, MKL_INT *error);
```

**Include Files**

- mkl.h

**Description**

This function stores Intel® MKL PARDISO structures to a file, allowing you to store Intel® MKL PARDISO internal structures between the stages of the `pardiso` routine. The `pardiso_handle_restorer` routine can restore the Intel® MKL PARDISO internal structures from the file.
Input Parameters

*pt*  
Array with a size of 64. Handle to internal data structure.

*dirname*  
String containing the name of the directory to which to write the files with the content of the internal structures. Use an empty string (""") to specify the current directory. The routine creates a file named handle.pds in the directory.

Output Parameters

*pt*  
Handle to internal data structure.

*error*  
The error indicator.

<table>
<thead>
<tr>
<th>error</th>
<th>Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No error.</td>
</tr>
<tr>
<td>-2</td>
<td>Not enough memory.</td>
</tr>
<tr>
<td>-10</td>
<td>Cannot open file for writing.</td>
</tr>
<tr>
<td>-11</td>
<td>Error while writing to file.</td>
</tr>
<tr>
<td>-13</td>
<td>Wrong file format.</td>
</tr>
</tbody>
</table>

**pardiso_handle_restore**

*Restore pardiso internal structures from a file.*

**Syntax**

```c
void pardiso_handle_restore (_MKL_DSS_HANDLE_t pt, const char *dirname, MKL_INT *error);
```

**Include Files**

- mkl.h

**Description**

This function restores Intel® MKL PARDISO structures from a file. This allows you to restore Intel® MKL PARDISO internal structures stored by `pardiso_handle_store` after a phase of the `pardiso` routine and continue execution of the next phase.

Input Parameters

*dirname*  
String containing the name of the directory in which the file with the content of the internal structures are located. Use an empty string (""") to specify the current directory.

Output Parameters

*pt*  
Array with a dimension of 64. Handle to internal data structure.

*error*  
The error indicator.
<table>

</tbody>
</table>

**pardiso_handle_delete**

Delete files with pardiso internal structure data.

**Syntax**

```c
void pardiso_handle_delete (const char *dirname, MKL_INT *error);
```

**Include Files**

- mkl.h

**Description**

This function deletes files generated with pardiso_handle_store that contain Intel® MKL PARDISO internal structures.

**Input Parameters**

- **dirname**
  
  String containing the name of the directory in which the file with the content of the internal structures are located. Use an empty string ("") to specify the current directory.

**Output Parameters**

- **error**
  
  The error indicator.

<table>
<thead>
<tr>
<th><strong>error</strong></th>

<tr>
<td>-10</td>
<td>Cannot delete files.</td>
</tr>
</tbody>
</table>

**pardiso_handle_store_64**

Store internal structures from pardiso_64 to a file.

**Syntax**

```c
void pardiso_handle_store_64 (_MKL_DSS_HANDLE_t pt, const char *dirname, MKL_INT *error);
```

**Include Files**

- mkl.h
**Description**

This function stores Intel® MKL PARDISO structures to a file, allowing you to store Intel® MKL PARDISO internal structures between the stages of the `pardiso_64` routine. The `pardiso_handle_restore_64` routine can restore the Intel® MKL PARDISO internal structures from the file.

**Input Parameters**

- `pt`: Array with a dimension of 64. Handle to internal data structure.
- `dirname`: String containing the name of the directory to which to write the files with the content of the internal structures. Use an empty string (""") to specify the current directory. The routine creates a file named `handle.pds` in the directory.

**Output Parameters**

- `pt`: Handle to internal data structure.
- `error`: The error indicator.

<table>

<td>in</td>
</tr>
<tr>
<td>ja</td>
<td>MKL_INT</td>
<td>columns array in CSR3 format</td>
<td>&gt;=0</td>
<td>in</td>
</tr>
</tbody>
</table>

**Values**

- **332** $\text{phase}=33$, but only diagonal substitution
- **333** $\text{phase}=33$, but only backward substitution
- **0** Release internal memory for L and U of the matrix number $mnum$
- **-1** Release all internal memory for all matrices

**Comments**

- The size of $a$ is the same as that of $ja$, and the coefficient matrix can be either real or complex. The matrix must be stored in the 3-array variation of compressed sparse row (CSR3) format with increasing values of $ja$ for each row.

- $ia[i]$ gives the index of the element in array $a$ that contains the first non-zero element from row $i$ of $A$. The last element $ia(n)$ is taken to be equal to the number of non-zero elements in $A$.

- **Note:** $iparm[34]$ indicates whether row/column indexing starts from 1 or 0.

- The column indices for each row of $A$ must be sorted in increasing order. For structurally symmetric matrices zero diagonal elements must be stored in $a$ and $ja$. Zero diagonal elements should be stored for symmetric matrices, although they are not required. For symmetric matrices, the solver needs only the upper triangular part of the system.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
<th>Values</th>
<th>Comments</th>
<th>In/Out</th>
</tr>
</thead>
<tbody>
<tr>
<td>perm[n]</td>
<td>MKL_INT*</td>
<td>Holds the permutation vector of size $n$, specifies elements used for computing a partial solution, or specifies differing values of the input matrices for low rank update.</td>
<td>$\geq 0$</td>
<td>Note: $iparm[34]$ indicates whether row/column indexing starts from 1 or 0. You can apply your own fill-in reducing ordering ($iparm[4]=1$) or return the permutation from the solver ($iparm[4]=2$). Let $C = P^t A^t P$ be the permuted matrix. Row (column) $i$ of $C$ is the $perm(i)$ row (column) of $A$. The numbering of the array must describe a permutation. To specify elements for a partial solution, set $iparm[4]=0$, $iparm[30]&gt;0$, and $iparm[35]=0$. To specify elements for a Schur complement, set $iparm[4]=0$, $iparm[30]=0$, and $iparm[35]&gt;0$. To specify values that differ in $A$ for low rank update (see Low Rank Update), set $iparm[38]=1$. The size of the array must be at least $2*ndiff + 1$, where $ndiff$ is the number of values of $A$ that are different. The values of $perm$ should be: $perm = {ndiff, row_index1, column_index1, row_index2, column_index2, ..., row_index_ndiff, column_index_ndiff}$ where $row_index_m$ and $column_index_m$ are the row and column indices of the $m$-th differing non-zero value in matrix $A$. The row and column index pairs can be in any order, but must use zero-based indexing regardless of the value of $iparm[34]$.</td>
<td>in/out</td>
</tr>
<tr>

**iparm[4]** input

User permutation.

This parameter controls whether user supplied fill-in reducing permutation is used instead of the integrated multiple-minimum degree or nested dissection algorithms. Another use of this parameter is to control obtaining the fill-in reducing permutation vector calculated during the reordering stage of Intel® MKL PARDISO.

This option is useful for testing reordering algorithms, adapting the code to special applications problems (for instance, to move zero diagonal elements to the end of $P^TAP$), or for using the permutation vector more than once for matrices with identical sparsity structures. For definition of the permutation, see the description of the perm parameter.

**Caution**

You can only set one of iparm[4], iparm[30], and iparm[35], so be sure that the iparm[30] (partial solution) and the iparm[35] (Schur complement) parameters are 0 if you set iparm[4].

<table>
<thead>
<tr>
<th>0*</th>
<th>User permutation in the perm array is ignored.</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Intel® MKL PARDISO uses the user supplied fill-in reducing permutation from the perm array. iparm[1] is ignored.</td>
</tr>
</tbody>
</table>

**NOTE**

| 2         | Intel® MKL PARDISO returns the permutation vector computed at phase 1 in the perm array. |

**iparm[5]** input

Write solution on x.

**NOTE**

The array x is always used.

<table>
<thead>
<tr>
<th>0*</th>
<th>The array x contains the solution; right-hand side vector b is kept unchanged.</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>The solver stores the solution on the right-hand side b.</td>
</tr>
</tbody>
</table>

**iparm[6]** output

Number of iterative refinement steps performed.

Reports the number of iterative refinement steps that were actually performed during the solve step.

**iparm[7]** input

Iterative refinement step.

On entry to the solve and iterative refinement step, iparm[7] must be set to the maximum number of iterative refinement steps that the solver performs.
<table>
<thead>
<tr>
<th>Component</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0*</td>
<td>The solver automatically performs two steps of iterative refinement when perturbed pivots are obtained during the numerical factorization.</td>
</tr>
</tbody>
</table>
| >0        | Maximum number of iterative refinement steps that the solver performs. The solver performs not more than the absolute value of $\text{iparm}[7]$ steps of iterative refinement. The solver might stop the process before the maximum number of steps if  
- a satisfactory level of accuracy of the solution in terms of backward error is achieved,  
- or if it determines that the required accuracy cannot be reached. In this case Intel® MKL PARDISO returns -4 in the error parameter.  
The number of executed iterations is reported in $\text{iparm}[6]$. |
| <0        | Same as above, but the accumulation of the residuum uses extended precision real and complex data types.  
Perturbed pivots result in iterative refinement (independent of $\text{iparm}[7]=0$) and the number of executed iterations is reported in $\text{iparm}[6]$. |
| $\text{iparm}[8]$ | Reserved. Set to zero. |
| $\text{iparm}[9]$ | Pivoting perturbation.  
This parameter instructs Intel® MKL PARDISO how to handle small pivots or zero pivots for nonsymmetric matrices ($\text{mtype}=11$ or $\text{mtype}=13$) and symmetric matrices ($\text{mtype}=-2$, $\text{mtype}=-4$, or $\text{mtype}=6$). For these matrices the solver uses a complete supernode pivoting approach. When the factorization algorithm reaches a point where it cannot factor the supernodes with this pivoting strategy, it uses a pivoting perturbation strategy similar to [Li99], [Schenk04].  
Small pivots are perturbed with $\text{eps} = 10^{-\text{iparm}[9]}$.  
The magnitude of the potential pivot is tested against a constant threshold of  
$\text{alpha} = \text{eps} ||A2||_{\text{inf}}$,  
where $\text{eps} = 10^{-\text{iparm}[9]}$, $A2 = P^*F_{\text{vol}}^*D_c^*A^*D_c^*P$, and $||A2||_{\text{inf}}$ is the infinity norm of the scaled and permuted matrix $A$. Any tiny pivots encountered during elimination are set to the sign $||A1||\cdot\text{eps}||A2||_{\text{inf}}$, which trades off some numerical stability for the ability to keep pivots from getting too small. Small pivots are therefore perturbed with $\text{eps} = 10^{-\text{iparm}[9]}$. |
| 13*       | The default value for nonsymmetric matrices ($\text{mtype}=11$, $\text{mtype}=13$), $\text{eps} = 10^{-13}$. |
| 8*        | The default value for symmetric indefinite matrices ($\text{mtype}=-2$, $\text{mtype}=-4$, $\text{mtype}=6$), $\text{eps} = 10^{-8}$. |
| $\text{iparm}[10]$ | Scaling vectors.  
Intel® MKL PARDISO uses a maximum weight matching algorithm to permute large elements on the diagonal and to scale so that the diagonal elements are equal to 1 and the absolute values of the off-diagonal entries are less than or equal to 1. This scaling method is applied only to nonsymmetric matrices ($\text{mtype}=11$ or $\text{mtype}=13$). The scaling can also be used for symmetric indefinite matrices ($\text{mtype}=-2$, $\text{mtype}=-4$, or $\text{mtype}=6$) when the symmetric weighted matchings are applied ($\text{iparm}[12]=1$). |

</tr>
</tbody>
</table>

**iparm[25]**  
Reserved. Set to zero.

**iparm[26]**  
Matrix checker.  
- **0** Intel® MKL PARDISO does not check the sparse matrix representation for errors.  
- **1** Intel® MKL PARDISO checks integer arrays ia and ja. In particular, Intel® MKL PARDISO checks whether column indices are sorted in increasing order within each row.

**iparm[27]**  
Single or double precision Intel® MKL PARDISO.  
See iparm[7] for information on controlling the precision of the refinement steps.  
**Important** The iparm[27] value is stored in the Intel® MKL PARDISO handle between Intel® MKL PARDISO calls, so the precision mode can be changed only during phase 1.

- **0** Input arrays (a, x and b) and all internal arrays must be presented in double precision.  
- **1** Input arrays (a, x and b) must be presented in single precision. In this case all internal computations are performed in single precision.

**iparm[28]**  
Reserved. Set to zero.

**iparm[29]**  
Number of zero or negative pivots.  
If Intel® MKL PARDISO detects zero or negative pivot for mtype=2 or mtype=4 matrix types, the factorization is stopped. Intel® MKL PARDISO returns immediately with an error = -4, and iparm[29] reports the number of the equation where the zero or negative pivot is detected.  
**Note:** The returned value can be different for the parallel and sequential version in case of several zero/negative pivots.

**iparm[30]**  
Partial solve and computing selected components of the solution vectors.  
This parameter controls the solve step of Intel® MKL PARDISO. It can be used if only a few components of the solution vectors are needed or if you want to reduce the computation cost at the solve step by utilizing the sparsity of the right-hand sides. To use this option the input permutation vector define perm so that when perm(i) = 1 it means that either the i-th component in the right-hand sides is nonzero, or the i-th component in the solution vectors is computed, or both, depending on the value of iparm[30].  
The permutation vector perm must be present in all phases of Intel® MKL PARDISO software. At the reordering step, the software overwrites the input vector perm by a permutation vector used by the software at the factorization and solver step. If m is the number of components such that perm(i) = 1, then the last m components of the output vector perm are a set of the indices i satisfying the condition perm(i) = 1 on input.
<table>
<thead>
<tr>
<th>Component</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NOTE</strong></td>
<td>Turning on this option often increases the time used by Intel® MKL PARDISO for factorization and reordering steps, but it can reduce the time required for the solver step.</td>
</tr>
<tr>
<td><strong>Important</strong></td>
<td>You can use this feature for both in-core and out-of-core Intel® MKL PARDISO as long as iparm[23]=1. Otherwise, you cannot use partial solve for out-of-core mode and you will need to set iparm[59]=0 for in-core mode. Set the parameters iparm[7] (iterative refinement steps), iparm[3] (preconditioned CGS), iparm[4] (user permutation), and iparm[35] (Schur complement) to 0 as well.</td>
</tr>
</tbody>
</table>

| 0* | Disables this option. |
| 1 | It is assumed that the right-hand sides have only a few non-zero components* and the input permutation vector perm is defined so that perm(i) = 1 means that the (i)-th component in the right-hand sides is nonzero. In this case Intel® MKL PARDISO only uses the non-zero components of the right-hand side vectors and computes only corresponding components in the solution vectors. That means the i-th component in the solution vectors is only computed if perm(i) = 1. |
| 2 | It is assumed that the right-hand sides have only a few non-zero components* and the input permutation vector perm is defined so that perm(i) = 1 means that the i-th component in the right-hand sides is nonzero. Unlike for iparm[30]=1, all components of the solution vector are computed for this setting and all components of the right-hand sides are used. Because all components are used, for iparm[30]=2 you must set the i-th component of the right-hand sides to zero explicitly if perm(i) is not equal to 1. |
| 3 | Selected components of the solution vectors are computed. The perm array is not related to the right-hand sides and it only indicates which components of the solution vectors should be computed. In this case perm(i) = 1 means that the i-th component in the solution vectors is computed. |

**iparm[31] - iparm[32]** | Reserved. Set to zero. |
| **iparm[33]** | Optimal number of OpenMP threads for conditional numerical reproducibility (CNR) mode. Intel® MKL PARDISO reads the value of iparm[33] during the analysis phase (phase 1), so you cannot change it later. |

Because Intel® MKL PARDISO uses C random number generator facilities during the analysis phase (phase 1) you must take these precautions to get numerically reproducible results:

- Do not alter the states of the random number generators.
- Do not run multiple instances of Intel® MKL PARDISO in parallel in the analysis phase (phase 1).
Component | Description
--- | ---

**NOTE**
CNR is only available for the in-core version of Intel® MKL PARDISO and the non-parallel version of the nested dissection algorithm. You must also:

- set `iparm[59]` to 0 in order to use the in-core version,
- not set `iparm[1]` to 3 in order to not use the parallel version of the nested dissection algorithm.

Otherwise Intel® MKL PARDISO does not produce numerically repeatable results even if CNR is enabled for Intel® MKL using the functionality described in Support Functions for CNR.

| 0* | CNR mode for Intel® MKL PARDISO is enabled only if it is enabled for Intel® MKL using the functionality described in Support Functions for CNR and the in-core version is used. Intel® MKL PARDISO determines the optimal number of OpenMP threads automatically, and produces numerically reproducible results regardless of the number of threads. |
| >0 | CNR mode is enabled for Intel® MKL PARDISO if in-core version is used and the optimal number of OpenMP threads for Intel® MKL PARDISO to rely on is defined by the value of `iparm[33]`. You can use `iparm[33]` to enable CNR mode independent from other Intel® MKL domains. To get the best performance, set `iparm[33]` to the actual number of hardware threads dedicated for Intel® MKL PARDISO. Setting `iparm[33]` to fewer OpenMP threads than the maximum number of them in use reduces the scalability of the problem being solved. Setting `iparm[33]` to more threads than are available can reduce the performance of Intel® MKL PARDISO. |

**iparm[34]**
input

One- or zero-based indexing of columns and rows.

**NOTE**
Schur complement may be inaccurate or incorrect if pivots are detected.
Please, check the output of `iparm[28]`.

| 0* | One-based indexing: columns and rows indexing in arrays `ia`, `ja`, and `perm` starts from 1 (Fortran-style indexing). |
| 1 | Zero-based indexing: columns and rows indexing in arrays `ia`, `ja`, and `perm` starts from 0 (C-style indexing). |

**iparm[35]**
input/output

Schur complement matrix computation control. To calculate this matrix, you must set the input permutation vector `perm` to a set of indexes such that when `perm(i) = 1`, the `i`-th element of the initial matrix is an element of the Schur matrix.

**Caution**

<p>| 0* | Do not compute Schur complement. |
| 1 | Compute Schur complement matrix as part of Intel® MKL PARDISO factorization step and return it in the solution vector. |</p>
