This document contains information on products, services and/or processes in development. All information provided here is subject to change without notice. Contact your Intel representative to obtain the latest forecast, schedule, specifications and roadmaps.

The products and services described may contain defects or errors which may cause deviations from published specifications. Current characterized errata are available on request.

Software and workloads used in performance tests may have been optimized for performance only on Intel microprocessors. Performance tests, such as SYSmark and MobileMark, are measured using specific computer systems, components, software, operations and functions. Any change to any of those factors may cause the results to vary. You should consult other information and performance tests to assist you in fully evaluating your contemplated purchases, including the performance of that product when combined with other products.

Introducing the Intel® Math Kernel Library

The Intel® Math Kernel Library (Intel® MKL) improves performance with math routines for software applications that solve large computational problems. Intel® MKL provides BLAS and LAPACK linear algebra routines, fast Fourier transforms, vectorized math functions, random number generation functions, and other functionality.

NOTE
Intel® MKL provides limited input validation to minimize the performance overheads. It is your responsibility when using Intel® MKL to ensure that input data has the required format and does not contain invalid characters. These can cause unexpected behavior of the library. Examples of the inputs that may result in unexpected behavior:

* Not-a-number (NaN) and other special floating point values
* Large inputs may lead to accumulator overflow

As the Intel® MKL API accepts raw pointers, it is your application's responsibility to validate the buffer sizes before passing them to the library. The library requires subroutine and function parameters to be valid before being passed. While some Intel® MKL routines do limited checking of parameter errors, your application should check for NULL pointers, for example.

Intel® MKL is optimized for the latest Intel processors, including processors with multiple cores (see the Intel® MKL Release Notes for the full list of supported processors). Intel® MKL also performs well on non-Intel processors.

For more details about functionality provided by Intel® MKL, see the Function Domains section.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804
Getting Help and Support

Intel provides a support web site that contains a rich repository of self help information, including getting started tips, known product issues, product errata, license information, user forums, and more. Visit the Intel® MKL support website at http://www.intel.com/software/products/support/.
What's New

This Developer Reference documents Intel® Math Kernel Library (Intel® MKL) 2020 release for the C interface

NOTE
This publication, the Intel® Math Kernel Library Developer Reference, was previously known as the Intel® Math Kernel Library Reference Manual.

The manual has been updated to reflect enhancements to the product, besides improvements and error corrections.

Optimization Notice

Intel’s compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804
Notational Conventions

This manual uses the following terms to refer to operating systems:

Windows* OS
This term refers to information that is valid on all supported Windows* operating systems.

Linux* OS
This term refers to information that is valid on all supported Linux* operating systems.

macOS*
This term refers to information that is valid on Intel®-based systems running the macOS* operating system.

This manual uses the following notational conventions:

- Routine name shorthand (for example, ?ungqr instead of cungqr/zungqr).
- Font conventions used for distinction between the text and the code.

Routine Name Shorthand

For shorthand, names that contain a question mark "?:" represent groups of routines with similar functionality. Each group typically consists of routines used with four basic data types: single-precision real, double-precision real, single-precision complex, and double-precision complex. The question mark is used to indicate any or all possible varieties of a function; for example:

\[ ?\text{swap} \]

Refers to all four data types of the vector-vector \( ?\text{swap} \) routine:
\[ \text{sswap}, \text{dswap}, \text{cswap}, \text{and zswap}. \]

Font Conventions

The following font conventions are used:

- **lowercase courier**
  - Code examples:
    - \[ a[k+i][j] = \text{matrix}[i][j]; \]
      - data types; for example, const float*

- **lowercase courier mixed with UpperCase courier**
  - Function names; for example, vmlSetMode

- **lowercase courier italic**
  - Variables in arguments and parameters description. For example, \( incx \).
  - Used as a multiplication symbol in code examples and equations and where required by the programming language syntax.
Function Domains

NOTE
Intel® MKL provides limited input validation to minimize the performance overheads. It is your responsibility when using Intel® MKL to ensure that input data has the required format and does not contain invalid characters. These can cause unexpected behavior of the library. Examples of the inputs that may result in unexpected behavior:

• Not-a-number (NaN) and other special floating point values
• Large inputs may lead to accumulator overflow

As the Intel® MKL API accepts raw pointers, it is your application's responsibility to validate the buffer sizes before passing them to the library. The library requires subroutine and function parameters to be valid before being passed. While some Intel® MKL routines do limited checking of parameter errors, your application should check for NULL pointers, for example.

The Intel® Math Kernel Library includes Fortran routines and functions optimized for Intel® processor-based computers running operating systems that support multiprocessing. In addition to the Fortran interface, Intel® MKL includes a C-language interface for the Discrete Fourier transform functions, as well as for the Vector Mathematics and Vector Statistics functions. For hardware and software requirements to use Intel® MKL, see Intel® MKL Release Notes.

NOTE
Functions calls at runtime for Intel® MKL libraries on the Microsoft Windows® operating system can utilize the function, LoadLibrary(), and related loading functions in static, dynamic, and single dynamic library linking models. These functions attempt to access the loader lock which when used within or at the same time as another DllMain function call, can lead to a deadlock. If possible, avoid making your calls to Intel® MKL in a DllMain function or at the same time as other calls to DllMain even on separate threads. Refer to Microsoft documentation about DllMain and Dynamic-Link Library Best Practices for more details.

BLAS Routines

The BLAS routines and functions are divided into the following groups according to the operations they perform:

• **BLAS Level 1 Routines** perform operations of both addition and reduction on vectors of data. Typical operations include scaling and dot products.
• **BLAS Level 2 Routines** perform matrix-vector operations, such as matrix-vector multiplication, rank-1 and rank-2 matrix updates, and solution of triangular systems.
• **BLAS Level 3 Routines** perform matrix-matrix operations, such as matrix-matrix multiplication, rank-k update, and solution of triangular systems.

Starting from release 8.0, Intel® MKL also supports the Fortran 95 interface to the BLAS routines.

Starting from release 10.1, a number of BLAS-like Extensions are added to enable the user to perform certain data manipulation, including matrix in-place and out-of-place transposition operations combined with simple matrix arithmetic operations.
Sparse BLAS Routines
The Sparse BLAS Level 1 Routines and Functions and Sparse BLAS Level 2 and Level 3 Routines routines and functions operate on sparse vectors and matrices. These routines perform vector operations similar to the BLAS Level 1, 2, and 3 routines. The Sparse BLAS routines take advantage of vector and matrix sparsity: they allow you to store only non-zero elements of vectors and matrices. Intel® MKL also supports Fortran 95 interface to Sparse BLAS routines.

Sparse QR
Sparse QR in Intel® MKL is a set of routines used to solve sparse matrices with real coefficients and general structure. All Sparse QR routines can be divided into three steps: reordering, factorization, and solving. Currently, only CSR format is supported for the input matrix, and Sparse QR operates on the matrix handle used in all SpBLAS IE routines. (For details on how to create a matrix handle, refer to mkl-sparse-create-csr.)

LAPACK Routines
The Intel® Math Kernel Library fully supports the LAPACK 3.7 set of computational, driver, auxiliary and utility routines.

The original versions of LAPACK from which that part of Intel® MKL was derived can be obtained from http://www.netlib.org/lapack/index.html. The authors of LAPACK are E. Anderson, Z. Bai, C. Bischof, S. Blackford, J. Demmel, J. Dongarra, J. Du Croz, A. Greenbaum, S. Hammarling, A. McKenney, and D. Sorensen.

The LAPACK routines can be divided into the following groups according to the operations they perform:
- Routines for solving systems of linear equations, factoring and inverting matrices, and estimating condition numbers (see LAPACK Routines: Linear Equations).
- Routines for solving least squares problems, eigenvalue and singular value problems, and Sylvester's equations (see LAPACK Routines: Least Squares and Eigenvalue Problems).

Starting from release 8.0, Intel® MKL also supports the Fortran 95 interface to LAPACK computational and driver routines. This interface provides an opportunity for simplified calls of LAPACK routines with fewer required arguments.

Sparse Solver Routines
Direct sparse solver routines in Intel® MKL (see Chapter 8) solve symmetric and symmetrically-structured sparse matrices with real or complex coefficients. For symmetric matrices, these Intel® MKL subroutines can solve both positive-definite and indefinite systems. Intel® MKL includes a solver based on the PARDISO* sparse solver, referred to as Intel® MKL PARDISO, as well as an alternative set of user callable direct sparse solver routines.

If you use the Intel® MKL PARDISO sparse solver, please cite:

Intel® MKL provides also an iterative sparse solver (see Chapter 8) that uses Sparse BLAS level 2 and 3 routines and works with different sparse data formats.

Extended Eigensolver Routines
The Extended Eigensolver RCI Routines is a set of high-performance numerical routines for solving standard \((Ax = \lambda x)\) and generalized \((Ax = \mu Bx)\) eigenvalue problems, where \(A\) and \(B\) are symmetric or Hermitian. It yields all the eigenvalues and eigenvectors within a given search interval. It is based on the Feast algorithm, an innovative fast and stable numerical algorithm presented in [Polizzi09], which deviates fundamentally from the traditional Krylov subspace iteration based techniques (Arnoldi and Lanczos algorithms [Bai00]) or other Davidson-Jacobi techniques [Sleijpen96]. The Feast algorithm is inspired by the density-matrix representation and contour integration technique in quantum mechanics.
It is free from orthogonalization procedures. Its main computational tasks consist of solving very few inner independent linear systems with multiple right-hand sides and one reduced eigenvalue problem orders of magnitude smaller than the original one. The Feast algorithm combines simplicity and efficiency and offers many important capabilities for achieving high performance, robustness, accuracy, and scalability on parallel architectures. This algorithm is expected to significantly augment numerical performance in large-scale modern applications.

Some of the characteristics of the Feast algorithm [Polizzi09] are:

- Converges quickly in 2-3 iterations with very high accuracy
- Naturally captures all eigenvalue multiplicities
- No explicit orthogonalization procedure
- Can reuse the basis of pre-computed subspace as suitable initial guess for performing outer-refinement iterations

This capability can also be used for solving a series of eigenvalue problems that are close one another.

- The number of internal iterations is independent of the size of the system and the number of eigenpairs in the search interval
- The inner linear systems can be solved either iteratively (even with modest relative residual error) or directly

**VM Functions**

The Vector Mathematics functions (see Chapter 9) include a set of highly optimized implementations of certain computationally expensive core mathematical functions (power, trigonometric, exponential, hyperbolic, etc.) that operate on vectors of real and complex numbers.

Application programs that might significantly improve performance with VM include nonlinear programming software, integrals computation, and many others. VM provides interfaces both for Fortran and C languages.

**Statistical Functions**

Vector Statistics (VS) contains three sets of functions (see Chapter 10) providing:

- Pseudorandom, quasi-random, and non-deterministic random number generator subroutines implementing basic continuous and discrete distributions. To provide best performance, the VS subroutines use calls to highly optimized Basic Random Number Generators (BRNGs) and a set of vector mathematical functions.
- A wide variety of convolution and correlation operations.
- Initial statistical analysis of raw single and double precision multi-dimensional datasets.

**Fourier Transform Functions**

The Intel® MKL multidimensional Fast Fourier Transform (FFT) functions with mixed radix support (see Chapter 11) provide uniformity of discrete Fourier transform computation and combine functionality with ease of use. Both Fortran and C interface specification are given. There is also a cluster version of FFT functions, which runs on distributed-memory architectures and is provided only for Intel® 64 and Intel® Many Integrated Core architectures.

The FFT functions provide fast computation via the FFT algorithms for arbitrary lengths. See the Intel® MKL Developer Guide for the specific radices supported.

**Partial Differential Equations Support**

Intel® MKL provides tools for solving Partial Differential Equations (PDE) (see Chapter 13). These tools are Trigonometric Transform interface routines and Poisson Solver.

The Trigonometric Transform routines may be helpful to users who implement their own solvers similar to the Intel® MKL Poisson Solver. The users can improve performance of their solvers by using fast sine, cosine, and staggered cosine transforms implemented in the Trigonometric Transform interface.
The Poisson Solver is designed for fast solving of simple Helmholtz, Poisson, and Laplace problems. The Trigonometric Transform interface, which underlies the solver, is based on the Intel® MKL FFT interface (refer to Chapter 11), optimized for Intel® processors.

**Support Functions**

The Intel® MKL support functions (see Chapter 15) are used to support the operation of the Intel® MKL software and provide basic information on the library and library operation, such as the current library version, timing, setting and measuring of CPU frequency, error handling, and memory allocation.

Starting from release 10.0, the Intel® MKL support functions provide additional threading control.

Starting from release 10.1, Intel® MKL selectively supports a Progress Routine feature to track progress of a lengthy computation and/or interrupt the computation using a callback function mechanism. The user application can define a function called `mkl_progress` that is regularly called from the Intel® MKL routine supporting the progress routine feature. See the Progress Routines section in Chapter 15 for reference. Refer to a specific LAPACK or DSS/PARDISO function description to see whether the function supports this feature or not.

---

**Optimization Notice**

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

---

**Performance Enhancements**

The Intel® Math Kernel Library has been optimized by exploiting both processor and system features and capabilities. Special care has been given to those routines that most profit from cache-management techniques. These especially include matrix-matrix operation routines such as `dgemm()`.

In addition, code optimization techniques have been applied to minimize dependencies of scheduling integer and floating-point units on the results within the processor.

The major optimization techniques used throughout the library include:

- Loop unrolling to minimize loop management costs
- Blocking of data to improve data reuse opportunities
- Copying to reduce chances of data eviction from cache
- Data prefetching to help hide memory latency
- Multiple simultaneous operations (for example, dot products in `dgemm`) to eliminate stalls due to arithmetic unit pipelines
- Use of hardware features such as the SIMD arithmetic units, where appropriate

These are techniques from which the arithmetic code benefits the most.

---

**Optimization Notice**

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain
Parallelism

In addition to the performance enhancements discussed above, Intel® MKL offers performance gains through parallelism provided by the symmetric multiprocessing performance (SMP) feature. You can obtain improvements from SMP in the following ways:

- One way is based on user-managed threads in the program and further distribution of the operations over the threads based on data decomposition, domain decomposition, control decomposition, or some other parallelizing technique. Each thread can use any of the Intel® MKL functions (except for the deprecated ?lacon LAPACK routine) because the library has been designed to be thread-safe.
- Another method is to use the FFT and BLAS level 3 routines. They have been parallelized and require no alterations of your application to gain the performance enhancements of multiprocessing. Performance using multiple processors on the level 3 BLAS shows excellent scaling. Since the threads are called and managed within the library, the application does not need to be recompiled thread-safe.
- Yet another method is to use tuned LAPACK routines. Currently these include the single- and double precision flavors of routines for QR factorization of general matrices, triangular factorization of general and symmetric positive-definite matrices, solving systems of equations with such matrices, as well as solving symmetric eigenvalue problems.

For instructions on setting the number of available processors for the BLAS level 3 and LAPACK routines, see Intel® MKL Developer Guide.

C Datatypes Specific to Intel MKL

The mkl_types.h file defines datatypes specific to Intel® MKL.

</table>

You can redefine datatypes specific to Intel® MKL. One reason to do this is if you have your own types which are binary-compatible with Intel® MKL datatypes, with the same representation or memory layout. To redefine a datatype, use one of these methods:

- Insert the `#define` statement redefining the datatype before the `mkl.h` header file `#include` statement. For example,
  ```
  #define MKL_INT size_t
  #include "mkl.h"
  ```
- Use the compiler `-D` option to redefine the datatype. For example,
  ```
  ...-DMKL_INT=size_t...
  ```

**NOTE**
As the user, if you redefine Intel® MKL datatypes you are responsible for making sure that your definition is compatible with that of Intel® MKL. If not, it might cause unpredictable results or crash the application.
This chapter describes the Intel® Math Kernel Library implementation of the BLAS and Sparse BLAS routines, and BLAS-like extensions. The routine descriptions are arranged in several sections:

- **BLAS Level 1 Routines** (vector-vector operations)
- **BLAS Level 2 Routines** (matrix-vector operations)
- **BLAS Level 3 Routines** (matrix-matrix operations)
- **Sparse BLAS Level 1 Routines** (vector-vector operations).
- **Sparse BLAS Level 2 and Level 3 Routines** (matrix-vector and matrix-matrix operations)
- **BLAS-like Extensions**

The question mark in the group name corresponds to different character codes indicating the data type (s, d, c, and z or their combination); see *Routine Naming Conventions*.

When BLAS or Sparse BLAS routines encounter an error, they call the error reporting routine `xerbla`.

### BLAS Routines

#### Naming Conventions for BLAS Routines

BLAS routine names have the following structure:

```
<character> <name> <mod> ( )
```

The `<character>` field indicates the data type:

- `s` real, single precision
- `c` complex, single precision
- `d` real, double precision
- `z` complex, double precision

Some routines and functions can have combined character codes, such as `sc` or `dz`.

For example, the function `scasum` uses a complex input array and returns a real value.

The `<name>` field, in BLAS level 1, indicates the operation type. For example, the BLAS level 1 routines `?dot`, `?rot`, `?swap` compute a vector dot product, vector rotation, and vector swap, respectively.

In BLAS level 2 and 3, `<name>` reflects the matrix argument type:

- `ge` general matrix
- `gb` general band matrix
- `sy` symmetric matrix
- `sp` symmetric matrix (packed storage)
- `sb` symmetric band matrix
- `he` Hermitian matrix
- `hp` Hermitian matrix (packed storage)
- `hb` Hermitian band matrix
tr triangular matrix
tp triangular matrix (packed storage)
tb triangular band matrix.

The <mod> field, if present, provides additional details of the operation. BLAS level 1 names can have the following characters in the <mod> field:

c conjugated vector
u unconjugated vector
g Givens rotation construction
m modified Givens rotation
mg modified Givens rotation construction

BLAS level 2 names can have the following characters in the <mod> field:

mv matrix-vector product
sv solving a system of linear equations with a single unknown vector
r rank-1 update of a matrix
r2 rank-2 update of a matrix.

BLAS level 3 names can have the following characters in the <mod> field:

mm matrix-matrix product
sm solving a system of linear equations with multiple unknown vectors
rk rank-k update of a matrix
r2k rank-2k update of a matrix.

The examples below illustrate how to interpret BLAS routine names:

ddot <d> <dot>: double-precision real vector-vector dot product
cdotc <c> <dot> <c>: complex vector-vector dot product, conjugated
scasum <sc> <asum>: sum of magnitudes of vector elements, single precision real output and single precision complex input
cdotu <c> <dot> <u>: vector-vector dot product, unconjugated, complex
sgemv <s> <ge> <mv>: matrix-vector product, general matrix, single precision
ztrmm <z> <tr> <mm>: matrix-matrix product, triangular matrix, double-precision complex.

Sparse BLAS level 1 naming conventions are similar to those of BLAS level 1. For more information, see Naming Conventions.

C Interface Conventions for BLAS Routines

CBLAS, the C interface to the Basic Linear Algebra Subprograms (BLAS), provides a C language interface to BLAS routines for Intel® MKL. While you can call the Fortran implementation of BLAS, for coding in C the CBLAS interface has some advantages such as allowing you to specify column-major or row-major ordering with the layout parameter.
For more information about calling Fortran routines from C in general, and specifically about calling BLAS and CBLAS routines, see "Mixed-language Programming with the Intel® Math Kernel Library" in the Intel® Math Kernel Library Developer Guide.

NOTE
This reference contains syntax in C for both the CBLAS interface and the Fortran BLAS routines.

In CBLAS, the Fortran routine names are prefixed with cblas_ (for example, dasum becomes cblas_dasum). Names of all CBLAS functions are in lowercase letters.

Complex functions ?dotc and ?dotu become CBLAS subroutines (void functions); they return the complex result via a void pointer, added as the last parameter. CBLAS names of these functions are suffixed with _sub. For example, the BLAS function cblas_cdotc corresponds to cblas_cdotc_sub.

WARNING
Users of the CBLAS interface should be aware that the CBLAS are just a C interface to the BLAS, which is based on the FORTRAN standard and subject to the FORTRAN standard restrictions. In particular, the output parameters should not be referenced through more than one argument.

NOTE
This interface is not implemented in the Sparse BLAS Level 2 and Level 3 routines.

The arguments of CBLAS functions comply with the following rules:

- Input arguments are declared with the const modifier.
- Non-complex scalar input arguments are passed by value.
- Complex scalar input arguments are passed as void pointers.
- Array arguments are passed by address.
- BLAS character arguments are replaced by the appropriate enumerated type.
- Level 2 and Level 3 routines acquire an additional parameter of type CBLAS_LAYOUT as their first argument. This parameter specifies whether two-dimensional arrays are row-major (CblasRowMajor) or column-major (CblasColMajor).

Enumerated Types
The CBLAS interface uses the following enumerated types:

```c
enum CBLAS_LAYOUT {
    CblasRowMajor=101, /* row-major arrays */
    CblasColMajor=102}; /* column-major arrays */
enum CBLAS_TRANSPOSE {
    CblasNoTrans=111,   /* trans='N' */
    CblasTrans=112,     /* trans='T' */
    CblasConjTrans=113}; /* trans='C' */
enum CBLAS_UPLO {
    CblasUpper=121,    /* uplo ='U' */
    CblasLower=122};   /* uplo ='L' */
enum CBLAS_DIAG {
    CblasNonUnit=131, /* diag ='N' */
    CblasUnit=132};   /* diag ='U' */
enum CBLAS_SIDE {
    CblasLeft=141,     /* side ='L' */
    CblasRight=142};   /* side ='R' */
```
Matrix Storage Schemes for BLAS Routines

Matrix arguments of BLAS and CBLAS routines can use the following storage schemes:

- **Full storage**: a matrix \( A \) is stored in a two-dimensional array \( a \), with the matrix element \( A_{ij} \) stored in the array element \( a[i + j*lda] \) for column-major layout and \( a[j + i*lda] \) for row-major layout, where \( lda \) is the leading dimension for the array.

- **Packed storage** scheme allows you to store symmetric, Hermitian, or triangular matrices more compactly. For column-major layout, the upper or lower triangle of the matrix is packed by columns in a one dimensional array. For row-major layout, the upper or lower triangle of the matrix is packed by rows in a one dimensional array.

- **Band storage**: a band matrix is stored compactly in a two-dimensional array. For column-major layout, columns of the matrix are stored in the corresponding columns of the array, and diagonals of the matrix are stored in a specific row of the array. For row-major layout, rows of the matrix are stored in the corresponding rows of the array, and diagonals of the matrix are stored in a specific column of the array.

For more information on matrix storage schemes, see Matrix Arguments in Appendix B.

Row-Major and Column-Major Layout

The BLAS routines follow the Fortran convention of storing two-dimensional arrays using column-major layout. When calling BLAS routines from C, remember that they require arrays to be in column-major format, not the row-major format that is the convention for C. Unless otherwise specified, the pseudo-code examples for the BLAS routines illustrate matrices stored using column-major layout.

The CBLAS interface allows you to specify either column-major or row-major layout for BLAS Level 2 and Level 3 routines, by setting the `layout` parameter to `CblasColMajor` or `CblasRowMajor`.

BLAS Level 1 Routines and Functions

BLAS Level 1 includes routines and functions, which perform vector-vector operations. The following table lists the BLAS Level 1 routine and function groups and the data types associated with them.

**BLAS Level 1 Routine and Function Groups and Their Data Types**

**cblas_?asum**

*Computes the sum of magnitudes of the vector elements.*

**Syntax**

```c
float cblas_sasum (const MKL_INT n, const float *x, const MKL_INT incx);
float cblas_scasum (const MKL_INT n, const void *x, const MKL_INT incx);
double cblas_dasum (const MKL_INT n, const double *x, const MKL_INT incx);
double cblas_dzasum (const MKL_INT n, const void *x, const MKL_INT incx);
```

**Include Files**

- mkl.h

**Description**

The ?asum routine computes the sum of the magnitudes of elements of a real vector, or the sum of magnitudes of the real and imaginary parts of elements of a complex vector:

\[
\text{res} = |\text{Re}x_1| + |\text{Im}x_1| + |\text{Re}x_2| + |\text{Im}x_2| + \ldots + |\text{Re}x_n| + |\text{Im}x_n|,
\]

\[
\text{result} = \sum_{i=1}^{n} \left( |\text{Re}(X_i)| + |\text{Im}(X_i)| \right)
\]

where \( x \) is a vector with \( n \) elements.

**Input Parameters**

- \( n \)
  - Specifies the number of elements in vector \( x \).
- \( x \)
  - Array, size at least \((1 + (n-1)\times\text{abs}(\text{incx}))\).
- \( \text{incx} \)
  - Specifies the increment for indexing vector \( x \).

**Output Parameters**

- \( \text{res} \)
  - Contains the sum of magnitudes of real and imaginary parts of all elements of the vector.
Return Values
Contains the sum of magnitudes of real and imaginary parts of all elements of the vector.

cblas_?axpy
Computes a vector-scalar product and adds the result to a vector.

Syntax
void cblas_saxpy (const MKL_INT n, const float a, const float *x, const MKL_INT incx, float *y, const MKL_INT incy);
void cblas_daxpy (const MKL_INT n, const double a, const double *x, const MKL_INT incx, double *y, const MKL_INT incy);
void cblas_caxpy (const MKL_INT n, const void *a, const void *x, const MKL_INT incx, void *y, const MKL_INT incy);
void cblas_zaxpy (const MKL_INT n, const void *a, const void *x, const MKL_INT incx, void *y, const MKL_INT incy);

Include Files
• mkl.h

Description
The ?axpy routines perform a vector-vector operation defined as

\[ y := a \cdot x + y \]

where:
- \( a \) is a scalar
- \( x \) and \( y \) are vectors each with a number of elements that equals \( n \).

Input Parameters
- \( n \) Specifies the number of elements in vectors \( x \) and \( y \).
- \( a \) Specifies the scalar \( a \).
- \( x \) Array, size at least \((1 + (n-1) \cdot \text{abs}(\text{incx}))\).
- \( \text{incx} \) Specifies the increment for the elements of \( x \).
- \( y \) Array, size at least \((1 + (n-1) \cdot \text{abs}(\text{incy}))\).
- \( \text{incy} \) Specifies the increment for the elements of \( y \).

Output Parameters
- \( y \) Contains the updated vector \( y \).

cblas_?copy
Copies a vector to another vector.
### Syntax

```c
void cblas_scopy (const MKL_INT n, const float *x, const MKL_INT incx, float *y, const MKL_INT incy);
void cblas_dcopy (const MKL_INT n, const double *x, const MKL_INT incx, double *y, const MKL_INT incy);
void cblas_ccopy (const MKL_INT n, const void *x, const MKL_INT incx, void *y, const MKL_INT incy);
void cblas_zcopy (const MKL_INT n, const void *x, const MKL_INT incx, void *y, const MKL_INT incy);
```

### Include Files
- mkl.h

### Description

The `copy` routines perform a vector-vector operation defined as

\[ y = x, \]

where \( x \) and \( y \) are vectors.

#### Input Parameters

- **n**
  - Specifies the number of elements in vectors \( x \) and \( y \).
- **x**
  - Array, size at least \((1 + (n-1)\times\text{abs}(\text{incx}))\).
- **incx**
  - Specifies the increment for the elements of \( x \).
- **y**
  - Array, size at least \((1 + (n-1)\times\text{abs}(\text{incy}))\).
- **incy**
  - Specifies the increment for the elements of \( y \).

#### Output Parameters

- **y**
  - Contains a copy of the vector \( x \) if \( n \) is positive. Otherwise, parameters are unaltered.

### cblas_?dot

**Computes a vector-vector dot product.**

### Syntax

```c
float cblas_sdot (const MKL_INT n, const float *x, const MKL_INT incx, const float *y, const MKL_INT incy);
double cblas_ddot (const MKL_INT n, const double *x, const MKL_INT incx, const double *y, const MKL_INT incy);
```

### Include Files
- mkl.h

### Description

The `dot` routines perform a vector-vector reduction operation defined as
\[ \text{res} = \sum_{i=1}^{n} x_i \cdot y_i \]

where \( x_i \) and \( y_i \) are elements of vectors \( x \) and \( y \).

**Input Parameters**

- \( n \)  
  Specifies the number of elements in vectors \( x \) and \( y \).
- \( x \)  
  Array, size at least \((1+(n-1)\cdot\text{abs}(\text{incx}))\).
- \( \text{incx} \)  
  Specifies the increment for the elements of \( x \).
- \( y \)  
  Array, size at least \((1+(n-1)\cdot\text{abs}(\text{incy}))\).
- \( \text{incy} \)  
  Specifies the increment for the elements of \( y \).

**Return Values**

The result of the dot product of \( x \) and \( y \), if \( n \) is positive. Otherwise, returns 0.

**cblas_?sdot**

Computes a vector-vector dot product with double precision.

**Syntax**

```c
float cblas_sdsdot (const MKL_INT n, const float sb, const float *sx, const MKL_INT incx, const float *sy, const MKL_INT incy);
double cblas_dsdot (const MKL_INT n, const float *sx, const MKL_INT incx, const float *sy, const MKL_INT incy);
```
Output Parameters

res

Contains the result of the dot product of sx and sy (with sb added for sdsdot), if n is positive. Otherwise, res contains sb for sdsdot and 0 for dsdot.

Return Values

The result of the dot product of sx and sy (with sb added for sdsdot), if n is positive. Otherwise, returns sb for sdsdot and 0 for dsdot.

cblas_?dotc

Computes a dot product of a conjugated vector with another vector.

Syntax

void cblas_cdotc_sub (const MKL_INT n, const void *x, const MKL_INT incx, const void *y, const MKL_INT incy, void *dotc);
void cblas_zdotc_sub (const MKL_INT n, const void *x, const MKL_INT incx, const void *y, const MKL_INT incy, void *dotc);

Include Files

• mkl.h

Description

The ?dotc routines perform a vector-vector operation defined as:

\[ res = \sum_{i=0}^{n} \text{conj}(x_i) \cdot y_i \]

where \( x_i \) and \( y_i \) are elements of vectors \( x \) and \( y \).

Input Parameters

n
Specifies the number of elements in vectors \( x \) and \( y \).

x
Array, size at least \((1 + (n -1) \cdot \text{abs}(\text{incx}))\).

incx
Specifies the increment for the elements of \( x \).

y
Array, size at least \((1 + (n -1) \cdot \text{abs}(\text{incy}))\).

incy
Specifies the increment for the elements of \( y \).

Output Parameters

dotc
Contains the result of the dot product of the conjugated \( x \) and unconjugated \( y \), if \( n \) is positive. Otherwise, it contains 0.

cblas_?dotu

Computes a vector-vector dot product.

Syntax

void cblas_cdotu_sub (const MKL_INT n, const void *x, const MKL_INT incx, const void *y, const MKL_INT incy, void *dotu);
void cblas_zdotu_sub (const MKL_INT n, const void *x, const MKL_INT incx, const void *y, const MKL_INT incy, void *dotu);

Include Files
• mkl.h

Description
The ?dotu routines perform a vector-vector reduction operation defined as

\[ \text{res} = \sum_{i=1}^{n} x_i \cdot y_i \]

where \( x_i \) and \( y_i \) are elements of complex vectors \( x \) and \( y \).

Input Parameters

\( n \) Specifies the number of elements in vectors \( x \) and \( y \).
\( x \) Array, size at least \( (1 + (n-1) \cdot \text{abs(incx)}) \).
\( \text{incx} \) Specifies the increment for the elements of \( x \).
\( y \) Array, size at least \( (1 + (n-1) \cdot \text{abs(incy)}) \).
\( \text{incy} \) Specifies the increment for the elements of \( y \).

Output Parameters

\( \text{dotu} \) Contains the result of the dot product of \( x \) and \( y \), if \( n \) is positive. Otherwise, it contains 0.

cblas_?nrm2

Computes the Euclidean norm of a vector.

Syntax

float cblas_snrm2 (const MKL_INT n, const float *x, const MKL_INT incx);
double cblas_dnrm2 (const MKL_INT n, const double *x, const MKL_INT incx);
float cblas_scnrm2 (const MKL_INT n, const void *x, const MKL_INT incx);
double cblas_dznrm2 (const MKL_INT n, const void *x, const MKL_INT incx);

Include Files
• mkl.h

Description
The ?nrm2 routines perform a vector reduction operation defined as

\[ \text{res} = ||x||, \]

where:
\( x \) is a vector;
\( \text{res} \) is a value containing the Euclidean norm of the elements of \( x \).
Input Parameters

\( n \)  
Specifies the number of elements in vector \( x \).

\( x \)  
Array, size at least \((1 + (n - 1) \cdot \text{abs (incx)})\).

\( \text{incx} \)  
Specifies the increment for the elements of \( x \).

Return Values

The Euclidean norm of the vector \( x \).

\texttt{cblas\_?rot}

\textit{Performs rotation of points in the plane.}

Syntax

\begin{verbatim}
void cblas_srot (const MKL_INT n, float *x, const MKL_INT incx, float *y, const MKL_INT incy, const float c, const float s);
void cblas_drot (const MKL_INT n, double *x, const MKL_INT incx, double *y, const MKL_INT incy, const double c, const double s);
void cblas csrot (const MKL_INT n, void *x, const MKL_INT incx, void *y, const MKL_INT incy, const float c, const float s);
void cblas zdrot (const MKL_INT n, void *x, const MKL_INT incx, void *y, const MKL_INT incy, const double c, const double s);
\end{verbatim}

Include Files

- mkl.h

Description

Given two complex vectors \( x \) and \( y \), each vector element of these vectors is replaced as follows:

\[
\begin{align*}
  x_i &= c \cdot x_i + s \cdot y_i \\
  y_i &= c \cdot y_i - s \cdot x_i
\end{align*}
\]

Input Parameters

\( n \)  
Specifies the number of elements in vectors \( x \) and \( y \).

\( x \)  
Array, size at least \((1 + (n-1) \cdot \text{abs (incx)})\).

\( \text{incx} \)  
Specifies the increment for the elements of \( x \).

\( y \)  
Array, size at least \((1 + (n-1) \cdot \text{abs (incy)})\).

\( \text{incy} \)  
Specifies the increment for the elements of \( y \).

\( c \)  
A scalar.

\( s \)  
A scalar.

Output Parameters

\( x \)  
Each element is replaced by \( c \cdot x + s \cdot y \).
Each element is replaced by \( c^*y - s^*x \).

**cblas_?rotg**  
*Computes the parameters for a Givens rotation.*

**Syntax**
void cblas_srotg (float *a, float *b, float *c, float *s);
void cblas_drotg (double *a, double *b, double *c, double *s);
void cblas_crotg (void *a, const void *b, float *c, void *s);
void cblas_zrotg (void *a, const void *b, double *c, void *s);

**Include Files**
- mkl.h

**Description**
Given the Cartesian coordinates \((a, b)\) of a point, these routines return the parameters \( c, s, r, \) and \( z \) associated with the Givens rotation. The parameters \( c \) and \( s \) define a unitary matrix such that:

\[
\begin{bmatrix}
  c & s \\
 r & -c \\
\end{bmatrix}
\begin{bmatrix}
  a \\
 b \\
\end{bmatrix}
= \begin{bmatrix}
  r \\
  0 \\
\end{bmatrix}
\]

The parameter \( z \) is defined such that if \(|a| > |b|\), \( z \) is \( s \); otherwise if \( c \) is not 0 \( z \) is \( 1/c \); otherwise \( z \) is 1.

**Input Parameters**
- \( a \)  
  Provides the \( x \)-coordinate of the point \( p \).
- \( b \)  
  Provides the \( y \)-coordinate of the point \( p \).

**Output Parameters**
- \( a \)  
  Contains the parameter \( r \) associated with the Givens rotation.
- \( b \)  
  Contains the parameter \( z \) associated with the Givens rotation.
- \( c \)  
  Contains the parameter \( c \) associated with the Givens rotation.
- \( s \)  
  Contains the parameter \( s \) associated with the Givens rotation.

**cblas_?rotm**  
*Performs modified Givens rotation of points in the plane.*

**Syntax**
void cblas_srotm (const MKL_INT n, float *x, const MKL_INT incx, float *y, const MKL_INT incy, const float *param);
void cblas_drotm (const MKL_INT n, double *x, const MKL_INT incx, double *y, const MKL_INT incy, const double *param);

**Include Files**
- mkl.h
Description

Given two vectors $x$ and $y$, each vector element of these vectors is replaced as follows:

$$
\begin{bmatrix}
  x_i \\
  y_i 
\end{bmatrix} = H
\begin{bmatrix}
  x_i \\
  y_i 
\end{bmatrix}
$$

for $i=1$ to $n$, where $H$ is a modified Givens transformation matrix whose values are stored in the $param[1]$ through $param[4]$ array. See discussion on the $param$ argument.

Input Parameters

$n$  
Specifies the number of elements in vectors $x$ and $y$.

$x$  
Array, size at least $(1 + (n-1) \times \text{abs}(\text{incx}))$.

$incx$  
Specifies the increment for the elements of $x$.

$y$  
Array, size at least $(1 + (n-1) \times \text{abs}(\text{incy}))$.

$incy$  
Specifies the increment for the elements of $y$.

$param$  
The elements of the $param$ array are:

- $param[0]$ contains a switch, $flag$. $param[1-4]$ contain $h_{11}$, $h_{21}$, $h_{12}$, and $h_{22}$, respectively, the components of the array $H$.

Depending on the values of $flag$, the components of $H$ are set as follows:

- $flag = -1.0$: $H = \begin{bmatrix} h_{11} & h_{12} \\ h_{21} & h_{22} \end{bmatrix}$
- $flag = 0.0$: $H = \begin{bmatrix} 1.0 & h_{12} \\ h_{21} & 1.0 \end{bmatrix}$
- $flag = 1.0$: $H = \begin{bmatrix} h_{11} & 1.0 \\ -1.0 & h_{22} \end{bmatrix}$
- $flag = -2.0$: $H = \begin{bmatrix} 1.0 & 0.0 \\ 0.0 & 1.0 \end{bmatrix}$

In the last three cases, the matrix entries of 1.0, -1.0, and 0.0 are assumed based on the value of $flag$ and are not required to be set in the $param$ vector.

Output Parameters

$x$  
Each element $x[i]$ is replaced by $h_{11} \times x[i] + h_{12} \times y[i]$.

$y$  
Each element $y[i]$ is replaced by $h_{21} \times x[i] + h_{22} \times y[i]$.

$cblas\_rotmg$

Computes the parameters for a modified Givens rotation.
Syntax

```c
void cblas_srotmg (float *d1, float *d2, float *x1, const float y1, float *param);
void cblas_drotmg (double *d1, double *d2, double *x1, const double y1, double *param);
```

Include Files

- mkl.h

Description

Given Cartesian coordinates \((x1, y1)\) of an input vector, these routines compute the components of a modified Givens transformation matrix \(H\) that zeros the \(y\)-component of the resulting vector:

\[
\begin{bmatrix}
x1 \\
0 \\
\end{bmatrix}
= H \begin{bmatrix}
x1 \sqrt{d1} \\
y1 \sqrt{d2} \\
\end{bmatrix}
\]

Input Parameters

- \(d1\): Provides the scaling factor for the \(x\)-coordinate of the input vector.
- \(d2\): Provides the scaling factor for the \(y\)-coordinate of the input vector.
- \(x1\): Provides the \(x\)-coordinate of the input vector.
- \(y1\): Provides the \(y\)-coordinate of the input vector.

Output Parameters

- \(d1\): Provides the first diagonal element of the updated matrix.
- \(d2\): Provides the second diagonal element of the updated matrix.
- \(x1\): Provides the \(x\)-coordinate of the rotated vector before scaling.
- \(param\): Array, size 5.

The elements of the \(param\) array are:

- \(param[0]\) contains a switch, \(flag\). the other array elements \(param[1-4]\) contain the components of the array \(H\): \(h_{11}, h_{21}, h_{12}, \) and \(h_{22}, \) respectively.

Depending on the values of \(flag\), the components of \(H\) are set as follows:

- \(flag = -1.0: H = \begin{bmatrix}
h_{11} & h_{12} \\
h_{21} & h_{22} \\
\end{bmatrix}\)
- \(flag = 0.0: H = \begin{bmatrix}
1.0 & h_{12} \\
h_{21} & 1.0 \\
\end{bmatrix}\)
- \(flag = 1.0: H = \begin{bmatrix}
h_{11} & 1.0 \\
-1.0 & h_{22} \\
\end{bmatrix}\)
- \(flag = -2.0: H = \begin{bmatrix}
1.0 & 0.0 \\
0.0 & 1.0 \\
\end{bmatrix}\)

In the last three cases, the matrix entries of 1.0, -1.0, and 0.0 are assumed based on the value of \(flag\) and are not required to be set in the \(param\) vector.
cblas_?scal

Computes the product of a vector by a scalar.

Syntax

```c
void cblas_sscal (const MKL_INT n, const float a, float *x, const MKL_INT incx);
void cblas_dscal (const MKL_INT n, const double a, double *x, const MKL_INT incx);
void cblas_cscal (const MKL_INT n, const void *a, void *x, const MKL_INT incx);
void cblas_zscal (const MKL_INT n, const void *a, void *x, const MKL_INT incx);
void cblas_csscal (const MKL_INT n, const float a, void *x, const MKL_INT incx);
void cblas_zdscal (const MKL_INT n, const double a, void *x, const MKL_INT incx);
```

Include Files

- mkl.h

Description

The ?scal routines perform a vector operation defined as

\[ x = a \times x \]

where:

- \( a \) is a scalar, \( x \) is an \( n \)-element vector.

Input Parameters

- \( n \)
  - Specifies the number of elements in vector \( x \).
- \( a \)
  - Specifies the scalar \( a \).
- \( x \)
  - Array, size at least \( 1 + (n - 1) \times \text{abs}(\text{incx}) \).
- \( \text{incx} \)
  - Specifies the increment for the elements of \( x \).

Output Parameters

- \( x \)
  - Updated vector \( x \).

cblas_?swap

Swaps a vector with another vector.

Syntax

```c
void cblas_sswap (const MKL_INT n, float *x, const MKL_INT incx, float *y, const MKL_INT incy);
void cblas_dswap (const MKL_INT n, double *x, const MKL_INT incx, double *y, const MKL_INT incy);
void cblas_cswap (const MKL_INT n, void *x, const MKL_INT incx, void *y, const MKL_INT incy);
void cblas_zswap (const MKL_INT n, void *x, const MKL_INT incx, void *y, const MKL_INT incy);
```
Include Files

- mkl.h

Description

Given two vectors \( x \) and \( y \), the \( \text{swap} \) routines return vectors \( y \) and \( x \) swapped, each replacing the other.

**Input Parameters**

- \( n \): Specifies the number of elements in vectors \( x \) and \( y \).
- \( x \): Array, size at least \( (1 + (n-1) \times \text{abs}(\text{incx})) \).
- \( \text{incx} \): Specifies the increment for the elements of \( x \).
- \( y \): Array, size at least \( (1 + (n-1) \times \text{abs}(\text{incy})) \).
- \( \text{incy} \): Specifies the increment for the elements of \( y \).

**Output Parameters**

- \( x \): Contains the resultant vector \( x \), that is, the input vector \( y \).
- \( y \): Contains the resultant vector \( y \), that is, the input vector \( x \).

**cblas_i?amax**

Find the index of the element with maximum absolute value.

**Syntax**

```c
CBLAS_INDEX cblas_isamax (const MKL_INT n, const float *x, const MKL_INT incx);
CBLAS_INDEX cblas_idamax (const MKL_INT n, const double *x, const MKL_INT incx);
CBLAS_INDEX cblas_icamax (const MKL_INT n, const void *x, const MKL_INT incx);
CBLAS_INDEX cblas_izamax (const MKL_INT n, const void *x, const MKL_INT incx);
```

Include Files

- mkl.h

Description

Given a vector \( x \), the \( i?amax \) functions return the position of the vector element \( x[i] \) that has the largest absolute value for real flavors, or the largest sum \( |\text{Re}(x[i])| + |\text{Im}(x[i])| \) for complex flavors.

If either \( n \) or \( \text{incx} \) are not positive, the routine returns 0.

If more than one vector element is found with the same largest absolute value, the index of the first one encountered is returned.

If the vector contains NaN values, then the routine returns the index of the first NaN.

**Input Parameters**

- \( n \): Specifies the number of elements in vector \( x \).
- \( x \): Array, size at least \( (1+(n-1) \times \text{abs}(\text{incx})) \).
incx

Specifies the increment for the elements of \( x \).

Return Values

Returns the position of vector element that has the largest absolute value such that \( x[\text{index}-1] \) has the largest absolute value. The index returned is zero-based.

\texttt{cblas_i?amin}

\textit{Finds the index of the element with the smallest absolute value.}

Syntax

\begin{verbatim}
CBLAS_INDEX cblas_isamin (const MKL_INT \( n \), const float *\( x \), const MKL_INT incx);
CBLAS_INDEX cblas_idamin (const MKL_INT \( n \), const double *\( x \), const MKL_INT incx);
CBLAS_INDEX cblas_icamin (const MKL_INT \( n \), const void *\( x \), const MKL_INT incx);
CBLAS_INDEX cblas_izamin (const MKL_INT \( n \), const void *\( x \), const MKL_INT incx);
\end{verbatim}

Include Files

• mkl.h

Description

Given a vector \( x \), the \texttt{i?amin} functions return the position of the vector element \( x[i] \) that has the smallest absolute value for real flavors, or the smallest sum \(|\text{Re}(x[i])|+|\text{Im}(x[i])|\) for complex flavors.

If either \( n \) or \( incx \) are not positive, the routine returns 0.

If more than one vector element is found with the same smallest absolute value, the index of the first one encountered is returned.

If the vector contains NaN values, then the routine returns the index of the first NaN.

Input Parameters

\begin{itemize}
\item \( n \) On entry, \( n \) specifies the number of elements in vector \( x \).
\item \( x \) Array, size at least \((1+(n-1)*\text{abs}(incx))\).
\item incx Specifies the increment for the elements of \( x \).
\end{itemize}

Return Values

Indicates the position of vector element with the smallest absolute value such that \( x[\text{index}-1] \) has the smallest absolute value. The index returned is zero-based.

\texttt{cblas_?cabs1}

\textit{Computes absolute value of complex number.}

Syntax

\begin{verbatim}
float cblas_scabs1 (const void *\( z \));
double cblas_dcabs1 (const void *\( z \));
\end{verbatim}

Include Files

• mkl.h
Description

The ?cabs1 is an auxiliary routine for a few BLAS Level 1 routines. This routine performs an operation defined as

\[ \text{res} = |\text{Re}(z)| + |\text{Im}(z)|, \]

where \( z \) is a scalar, and \( \text{res} \) is a value containing the absolute value of a complex number \( z \).

Input Parameters

\( z \)  
Scalar.

Return Values

The absolute value of a complex number \( z \).

BLAS Level 2 Routines

This section describes BLAS Level 2 routines, which perform matrix-vector operations. The following table lists the BLAS Level 2 routine groups and the data types associated with them.

**Routine Groups**  
**Data Types**  
**Description**  

cblas_?syr2  
s, d  
Rank-2 update of a symmetric matrix  

cblas_?tbmv  
s, d, c, z  
Matrix-vector product using a triangular band matrix  

cblas_?tbsv  
s, d, c, z  
Solution of a linear system of equations with a triangular band matrix  

cblas_?tpmv  
s, d, c, z  
Matrix-vector product using a triangular packed matrix  

cblas_?tpsv  
s, d, c, z  
Solution of a linear system of equations with a triangular packed matrix  

cblas_?trmv  
s, d, c, z  
Matrix-vector product using a triangular matrix  

cblas_?trsv  
s, d, c, z  
Solution of a linear system of equations with a triangular matrix  

cblas_?gbmv  
Computes a matrix-vector product with a general band matrix.  

**Syntax**  
void cblas_sgbmv (const CBLAS_LAYOUT Layout, const CBLAS_TRANSPOSE trans, const MKL_INT m, const MKL_INT n, const MKL_INT kl, const MKL_INT ku, const float alpha, const float *a, const MKL_INT lda, const float *x, const MKL_INT incx, const float beta, float *y, const MKL_INT incy);  

void cblas_dgbmv (const CBLAS_LAYOUT Layout, const CBLAS_TRANSPOSE trans, const MKL_INT m, const MKL_INT n, const MKL_INT kl, const MKL_INT ku, const double alpha, const double *a, const MKL_INT lda, const double *x, const MKL_INT incx, const double beta, double *y, const MKL_INT incy);  

void cblas_cgbmv (const CBLAS_LAYOUT Layout, const CBLAS_TRANSPOSE trans, const MKL_INT m, const MKL_INT n, const MKL_INT kl, const MKL_INT ku, const void *alpha, const void *a, const MKL_INT lda, const void *x, const MKL_INT incx, const void *beta, void *y, const MKL_INT incy);  

void cblas_zgbmv (const CBLAS_LAYOUT Layout, const CBLAS_TRANSPOSE trans, const MKL_INT m, const MKL_INT n, const MKL_INT kl, const MKL_INT ku, const void *alpha, const void *a, const MKL_INT lda, const void *x, const MKL_INT incx, const void *beta, void *y, const MKL_INT incy);  

**Include Files**  
- mkl.h  

**Description**  
The ?gbmv routines perform a matrix-vector operation defined as  
\[ y := \alpha A x + \beta y, \]  
or  
\[ y := \alpha A^{\prime} x + \beta y, \]  
or  
\[ y := \alpha \text{conjg}(A') x + \beta y, \]  

where:

*alpha* and *beta* are scalars,

*x* and *y* are vectors,

*A* is an *m*-by-*n* band matrix, with *kl* sub-diagonals and *ku* super-diagonals.

**Input Parameters**

*Layout* Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).

*trans* Specifies the operation:

- If *trans*=CblasNoTrans, then *y* := *alpha* *A* *x* + *beta* *y*
- If *trans*=CblasTrans, then *y* := *alpha* *A'* *x* + *beta* *y*
- If *trans*=CblasConjTrans, then *y* := *alpha* *conjg(A')* *x* + *beta* *y*

*m* Specifies the number of rows of the matrix *A*.
The value of *m* must be at least zero.

*n* Specifies the number of columns of the matrix *A*.
The value of *n* must be at least zero.

*kl* Specifies the number of sub-diagonals of the matrix *A*.
The value of *kl* must satisfy 0 ≤ *kl*.

*ku* Specifies the number of super-diagonals of the matrix *A*.
The value of *ku* must satisfy 0 ≤ *ku*.

*alpha* Specifies the scalar *alpha*.

*a* Array, size *lda* *n*.

*Layout* = CblasColMajor: Before entry, the leading (*kl* + *ku* + 1) by *n* part of the array *a* must contain the matrix of coefficients. This matrix must be supplied column-by-column, with the leading diagonal of the matrix in row (*ku*) of the array, the first super-diagonal starting at position 1 in row (*ku* − 1), the first sub-diagonal starting at position 0 in row (*ku* + 1), and so on. Elements in the array *a* that do not correspond to elements in the band matrix (such as the top left *ku* by *ku* triangle) are not referenced.

The following program segment transfers a band matrix from conventional full matrix storage (*matrix*, with leading dimension *ldm*) to band storage (*a*, with leading dimension *lda*):

```c
for (j = 0; j < n; j++) {
    k = ku - j;
    for (i = max(0, j-ku); i < min(m, j+kl+1); i++) {
        a[(k+i) + j*lda] = matrix[i + j*ldm];
    }
}
```

*Layout* = CblasRowMajor: Before entry, the leading (*kl* + *ku* + 1) by *m* part of the array *a* must contain the matrix of coefficients. This matrix must be supplied row-by-row, with the leading diagonal of the matrix in column (*kl*) of the array, the first super-diagonal starting at position 0 in column
The first sub-diagonal starting at position 1 in row \((kl - 1)\), and so on. Elements in the array \(a\) that do not correspond to elements in the band matrix (such as the top left \(kl\) by \(kl\) triangle) are not referenced.

The following program segment transfers a band matrix from row-major full matrix storage (\(matrix\), with leading dimension \(ldm\)) to band storage (\(a\), with leading dimension \(lda\)):

```c
for (i = 0; i < m; i++) {
    k = kl - i;
    for (j = max(0, i-kl); j < min(n, i+ku+1); j++) {
        a[(k+j) + i*lda] = matrix[j + i*ldm];
    }
}
```

- \(lda\) Specifies the leading dimension of \(a\) as declared in the calling (sub)program. The value of \(lda\) must be at least \((kl + ku + 1)\).

- \(x\) Array, size at least \((1 + (n - 1)*abs(incx))\) when \(trans=CblasNoTrans\), and at least \((1 + (m - 1)*abs(incx))\) otherwise. Before entry, the array \(x\) must contain the vector \(x\).

- \(incx\) Specifies the increment for the elements of \(x\). \(incx\) must not be zero.

- \(beta\) Specifies the scalar \(beta\). When \(beta\) is equal to zero, then \(y\) need not be set on input.

- \(y\) Array, size at least \((1 + (m - 1)*abs(incy))\) when \(trans=CblasNoTrans\) and at least \((1 + (n - 1)*abs(incy))\) otherwise. Before entry, the incremented array \(y\) must contain the vector \(y\).

- \(incy\) Specifies the increment for the elements of \(y\). The value of \(incy\) must not be zero.

### Output Parameters

- \(y\) Buffer holding the updated vector \(y\).

**cblas_?gemv**

*Computes a matrix-vector product using a general matrix.*

### Syntax

```c
void cblas_sgemv (const CBLAS_LAYOUT Layout, const CBLAS_TRANSPOSE trans, const MKL_INT m, const MKL_INT n, const float alpha, const float *a, const MKL_INT lda, const float *x, const MKL_INT incx, const float beta, float *y, const MKL_INT incy);
void cblas_dgemv (const CBLAS_LAYOUT Layout, const CBLAS_TRANSPOSE trans, const MKL_INT m, const MKL_INT n, const double alpha, const double *a, const MKL_INT lda, const double *x, const MKL_INT incx, const double beta, double *y, const MKL_INT incy);
void cblas_cgemv (const CBLAS_LAYOUT Layout, const CBLAS_TRANSPOSE trans, const MKL_INT m, const MKL_INT n, const void *alpha, const void *a, const MKL_INT lda, const void *x, const MKL_INT incx, const void *beta, void *y, const MKL_INT incy);
```
void cblas_zgemv (const CBLAS_LAYOUT Layout, const CBLAS_TRANSPOSE trans, const MKL_INT m, const MKL_INT n, const void *alpha, const void *a, const MKL_INT lda, const void *x, const MKL_INT incx, const void *beta, void *y, const MKL_INT incy);

Include Files
• mkl.h

Description
The ?gemv routines perform a matrix-vector operation defined as:

\[ y := \alpha A \star x + \beta y, \]

or

\[ y := \alpha A'^\ast \star x + \beta y, \]

or

\[ y := \alpha \text{conjg}(A'^\ast) \star x + \beta y, \]

where:
alpha and beta are scalars,
x and y are vectors,
A is an m-by-n matrix.

Input Parameters

Layout
Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).

trans
Specifies the operation:

if trans=CblasNoTrans, then \( y := \alpha A \star x + \beta y \);

if trans=CblasTrans, then \( y := \alpha A'^\ast \star x + \beta y \);

if trans=CblasConjTrans, then \( y := \alpha \text{conjg}(A'^\ast) \star x + \beta y \).

m
Specifies the number of rows of the matrix A. The value of \( m \) must be at least zero.

n
Specifies the number of columns of the matrix A. The value of \( n \) must be at least zero.

alpha
Specifies the scalar \( \alpha \).

a
Array, size lda*\( k \).

For Layout = CblasColMajor, \( k \) is \( n \). Before entry, the leading \( m \)-by-\( n \) part of the array \( a \) must contain the matrix \( A \).

For Layout = CblasRowMajor, \( k \) is \( m \). Before entry, the leading \( n \)-by-\( m \) part of the array \( a \) must contain the matrix \( A \).

lda
Specifies the leading dimension of \( a \) as declared in the calling (sub)program.

For Layout = CblasColMajor, the value of \( lda \) must be at least \( \max(1, m) \).
For \( Layout = \text{CblasRowMajor} \), the value of \( lda \) must be at least \( \max(1,n) \).

\[ x \]

Array, size at least \((1+(n-1)\cdot\text{abs}(\text{incx}))\) when \( \text{trans} = \text{CblasNoTrans} \) and at least \((1+(m-1)\cdot\text{abs}(\text{incx}))\) otherwise. Before entry, the incremented array \( x \) must contain the vector \( x \).

\[ \text{incx} \]

Specifies the increment for the elements of \( x \).

The value of \( \text{incx} \) must not be zero.

\[ \beta \]

Specifies the scalar \( \beta \). When \( \beta \) is set to zero, then \( y \) need not be set on input.

\[ y \]

Array, size at least \((1+(m-1)\cdot\text{abs}(\text{incy}))\) when \( \text{trans} = \text{CblasNoTrans} \) and at least \((1+(n-1)\cdot\text{abs}(\text{incy}))\) otherwise. Before entry with non-zero \( \beta \), the incremented array \( y \) must contain the vector \( y \).

\[ \text{incy} \]

Specifies the increment for the elements of \( y \).

The value of \( \text{incy} \) must not be zero.

**Output Parameters**

\[ y \]

Updated vector \( y \).

**cblas_?ger**

*Performs a rank-1 update of a general matrix.*

**Syntax**

\[
\text{void cblas_sger (const CBLAS_LAYOUT Layout, const MKL_INT m, const MKL_INT n, const float alpha, const float *x, const MKL_INT incx, const float *y, const MKL_INT incy, float *a, const MKL_INT lda);}\\
\text{void cblas_dger (const CBLAS_LAYOUT Layout, const MKL_INT m, const MKL_INT n, const double alpha, const double *x, const MKL_INT incx, const double *y, const MKL_INT incy, double *a, const MKL_INT lda);}\\
\]

**Include Files**

- mkl.h

**Description**

The \( ? \text{ger} \) routines perform a matrix-vector operation defined as

\[
A := \alpha x^t y + A,
\]

where:

- \( \alpha \) is a scalar,
- \( x \) is an \( m \)-element vector,
- \( y \) is an \( n \)-element vector,
- \( A \) is an \( m \text{-by-} n \) general matrix.
Input Parameters

Layout
Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).

\(m\)
Specifies the number of rows of the matrix \(A\).
The value of \(m\) must be at least zero.

\(n\)
Specifies the number of columns of the matrix \(A\).
The value of \(n\) must be at least zero.

\(alpha\)
Specifies the scalar \(alpha\).

\(x\)
Array, size at least \((1 + (m - 1) \times \text{abs}(\text{incx}))\). Before entry, the incremented array \(x\) must contain the \(m\)-element vector \(x\).

\(\text{incx}\)
Specifies the increment for the elements of \(x\).
The value of \(\text{incx}\) must not be zero.

\(y\)
Array, size at least \((1 + (n - 1) \times \text{abs}(\text{incy}))\). Before entry, the incremented array \(y\) must contain the \(n\)-element vector \(y\).

\(\text{incy}\)
Specifies the increment for the elements of \(y\).
The value of \(\text{incy}\) must not be zero.

\(a\)
Array, size \(\text{lda} \times k\).

For \(\text{Layout} = \text{CblasColMajor}\), \(k\) is \(n\). Before entry, the leading \(m\)-by-\(n\) part of the array \(a\) must contain the matrix \(A\).

For \(\text{Layout} = \text{CblasRowMajor}\), \(k\) is \(m\). Before entry, the leading \(n\)-by-\(m\) part of the array \(a\) must contain the matrix \(A\).

\(\text{lda}\)
Specifies the leading dimension of \(a\) as declared in the calling (sub)program.

For \(\text{Layout} = \text{CblasColMajor}\), the value of \(\text{lda}\) must be at least \(\max(1, m)\).

For \(\text{Layout} = \text{CblasRowMajor}\), the value of \(\text{lda}\) must be at least \(\max(1, n)\).

Output Parameters

\(a\)
Overwritten by the updated matrix.

\textbf{cblas\_?gerc}
Performs a rank-1 update (conjugated) of a general matrix.

Syntax

```c
void cblas_cgerc (const CBLAS_LAYOUT Layout, const MKL_INT m, const MKL_INT n, const void *alpha, const void *x, const MKL_INT incx, const void *y, const MKL_INT incy, void *a, const MKL_INT lda);
```
void cblas_zgerc (const CBLAS_LAYOUT Layout, const MKL_INT m, const MKL_INT n, const void *alpha, const void *x, const MKL_INT incx, const void *y, const MKL_INT incy, void *a, const MKL_INT lda);

Include Files

• mkl.h

Description

The ?gerc routines perform a matrix-vector operation defined as

\[ A := \alpha x^* \text{conj}(y^\prime) + A, \]

where:

\( \alpha \) is a scalar,
\( x \) is an \( m \)-element vector,
\( y \) is an \( n \)-element vector,
\( A \) is an \( m \times n \) matrix.

Input Parameters

- **Layout**: Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).
- **m**: Specifies the number of rows of the matrix \( A \).
The value of \( m \) must be at least zero.
- **n**: Specifies the number of columns of the matrix \( A \).
The value of \( n \) must be at least zero.
- **alpha**: Specifies the scalar \( \alpha \).
- **x**: Array, size at least \((1 + (m - 1)\cdot\text{abs(incx)})\). Before entry, the incremented array \( x \) must contain the \( m \)-element vector \( x \).
- **incx**: Specifies the increment for the elements of \( x \).
The value of \( incx \) must not be zero.
- **y**: Array, size at least \((1 + (n - 1)\cdot\text{abs(incy)})\). Before entry, the incremented array \( y \) must contain the \( n \)-element vector \( y \).
- **incy**: Specifies the increment for the elements of \( y \).
The value of \( incy \) must not be zero.
- **a**: Array, size \( lda \cdot k \).
  For \( \text{Layout} = \text{CblasColMajor} \), \( k \) is \( n \). Before entry, the leading \( m \times n \) part of the array \( a \) must contain the matrix \( A \).
  For \( \text{Layout} = \text{CblasRowMajor} \), \( k \) is \( m \). Before entry, the leading \( n \times m \) part of the array \( a \) must contain the matrix \( A \).
- **lda**: Specifies the leading dimension of \( a \) as declared in the calling (sub)program.
For Layout = CblasColMajor, the value of lda must be at least max(1, m).
For Layout = CblasRowMajor, the value of lda must be at least max(1, n).

**Output Parameters**

*a*

Overwritten by the updated matrix.

**cblas_geru**

Performs a rank-1 update (unconjugated) of a general matrix.

**Syntax**

```c
void cblas_cgeru (const CBLAS_LAYOUT Layout, const MKL_INT m, const MKL_INT n, const void *alpha, const void *x, const MKL_INT incx, const void *y, const MKL_INT incy, void *a, const MKL_INT lda);
void cblas_zgeru (const CBLAS_LAYOUT Layout, const MKL_INT m, const MKL_INT n, const void *alpha, const void *x, const MKL_INT incx, const void *y, const MKL_INT incy, void *a, const MKL_INT lda);
```

**Include Files**

- mkl.h

**Description**

The ?geru routines perform a matrix-vector operation defined as

\[ A := \alpha x y' + A, \]

where:

* \( \alpha \) is a scalar,
* \( x \) is an \( m \)-element vector,
* \( y \) is an \( n \)-element vector,
* \( A \) is an \( m \)-by-\( n \) matrix.

**Input Parameters**

- **Layout**
  Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).
- **m**
  Specifies the number of rows of the matrix \( A \).
  The value of \( m \) must be at least zero.
- **n**
  Specifies the number of columns of the matrix \( A \).
  The value of \( n \) must be at least zero.
- **alpha**
  Specifies the scalar \( \alpha \).
- **x**
  Array, size at least \((1 + (m - 1) \times \text{abs}(\text{incx}))\). Before entry, the incremented array \( x \) must contain the \( m \)-element vector \( x \).
Specifies the increment for the elements of x.
The value of incx must not be zero.

Array, size at least \((1 + (n - 1) \times \text{abs}(incy))\). Before entry, the incremented array y must contain the n-element vector y.

Specifies the increment for the elements of y.
The value of incy must not be zero.

Array, size lda*\(k\).

For Layout = CblasColMajor, \(k\) is \(n\). Before entry, the leading \(m\)-by-\(n\) part of the array a must contain the matrix A.

For Layout = CblasRowMajor, \(k\) is \(m\). Before entry, the leading \(n\)-by-\(m\) part of the array a must contain the matrix A.

Specifies the leading dimension of a as declared in the calling (sub)program.

For Layout = CblasColMajor, the value of lda must be at least \(\max(1, m)\).

For Layout = CblasRowMajor, the value of lda must be at least \(\max(1, n)\).

Output Parameters

Overwritten by the updated matrix.

cblas_?hbmv

Computes a matrix-vector product using a Hermitian band matrix.

Syntax

```c
void cblas_chbmv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n, const MKL_INT k, const void *alpha, const void *a, const MKL_INT lda, const void *x, const MKL_INT incx, const void *beta, void *y, const MKL_INT incy);
void cblas_zhbmv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n, const MKL_INT k, const void *alpha, const void *a, const MKL_INT lda, const void *x, const MKL_INT incx, const void *beta, void *y, const MKL_INT incy);
```

Include Files

- mkl.h

Description

The ?hbmv routines perform a matrix-vector operation defined as \(y := alpha*A*x + beta*y\),

where:

- \(alpha\) and \(beta\) are scalars,
- \(x\) and \(y\) are \(n\)-element vectors,
- \(A\) is an \(n\)-by-\(n\) Hermitian band matrix, with \(k\) super-diagonals.
Input Parameters

**Layout**

Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).

**uplo**

Specifies whether the upper or lower triangular part of the Hermitian band matrix $A$ is used:

If $\text{uplo} = \text{CblasUpper}$, then the upper triangular part of the matrix $A$ is used.

If $\text{uplo} = \text{CblasLower}$, then the lower triangular part of the matrix $A$ is used.

**n**

Specifies the order of the matrix $A$. The value of $n$ must be at least zero.

**k**

For $\text{uplo} = \text{CblasUpper}$: Specifies the number of super-diagonals of the matrix $A$.

For $\text{uplo} = \text{CblasLower}$: Specifies the number of sub-diagonals of the matrix $A$.

The value of $k$ must satisfy $0 \leq k$.

**alpha**

Specifies the scalar $\alpha$.

**a**

Array, size $\text{lda} \times n$.

$\text{Layout} = \text{CblasColMajor}$:

Before entry with $\text{uplo} = \text{CblasUpper}$, the leading $(k + 1)$ by $n$ part of the array $a$ must contain the upper triangular band part of the Hermitian matrix. The matrix must be supplied column-by-column, with the leading diagonal of the matrix in row $k$ of the array, the first super-diagonal starting at position $1$ in row $(k - 1)$, and so on. The top left $k$ by $k$ triangle of the array $a$ is not referenced.

The following program segment transfers the upper triangular part of a Hermitian band matrix from conventional full matrix storage ($\text{matrix}$, with leading dimension $\text{ldm}$) to band storage ($a$, with leading dimension $\text{lda}$):

```c
for (j = 0; j < n; j++) {
    m = k - j;
    for (i = max( 0, j - k); i <= j; i++) {
        a[(m+i) + j*lda] = matrix[i + j*ldm];
    }
}
```

Before entry with $\text{uplo} = \text{CblasLower}$, the leading $(k + 1)$ by $n$ part of the array $a$ must contain the lower triangular band part of the Hermitian matrix, supplied column-by-column, with the leading diagonal of the matrix in row $0$ of the array, the first sub-diagonal starting at position $0$ in row $1$, and so on. The bottom right $k$ by $k$ triangle of the array $a$ is not referenced.

The following program segment transfers the lower triangular part of a Hermitian band matrix from conventional full matrix storage ($\text{matrix}$, with leading dimension $\text{ldm}$) to band storage ($a$, with leading dimension $\text{lda}$):

```c
for (j = 0; j < n; j++) {
    m = -j;
    for (i = j; i < min(n, j + k + 1); i++) {
```
a[(m+i) + j*lda] = matrix[i + j*ldm];
}
}

Layout = CblasRowMajor:

Before entry with uplo = CblasUpper, the leading \((k + 1)\)-by-\(n\) part of array \(a\) must contain the upper triangular band part of the Hermitian matrix. The matrix must be supplied row-by-row, with the leading diagonal of the matrix in column 0 of the array, the first super-diagonal starting at position 0 in column 1, and so on. The bottom right \(k\)-by-\(k\) triangle of array \(a\) is not referenced.

The following program segment transfers the upper triangular part of a Hermitian band matrix from row-major full matrix storage (\(matrix\) with leading dimension \(ldm\)) to row-major band storage (\(a\), with leading dimension \(lda\)):

```c
for (i = 0; i < n; i++) {
    m = -i;
    for (j = i; j < MIN(n, i+k+1); j++) {
        a[(m+j) + i*lda] = matrix[j + i*ldm];
    }
}
```

Before entry with uplo = CblasLower, the leading \((k + 1)\)-by-\(n\) part of array \(a\) must contain the lower triangular band part of the Hermitian matrix, supplied row-by-row, with the leading diagonal of the matrix in column \(k\) of the array, the first sub-diagonal starting at position 1 in column \(k-1\), and so on. The top left \(k\)-by-\(k\) triangle of array \(a\) is not referenced.

The following program segment transfers the lower triangular part of a Hermitian row-major band matrix from row-major full matrix storage (\(matrix\), with leading dimension \(ldm\)) to row-major band storage (\(a\), with leading dimension \(lda\)):

```c
for (i = 0; i < n; i++) {
    m = k - i;
    for (j = max(0, i-k); j <= i; j++) {
        a[(m+j) + i*lda] = matrix[j + i*ldm];
    }
}
```

The imaginary parts of the diagonal elements need not be set and are assumed to be zero.

\(lda\)

Specifies the leading dimension of \(a\) as declared in the calling (sub)program. The value of \(lda\) must be at least \((k + 1)\).

\(x\)

Array, size at least \((1 + (n - 1)\cdot abs(incx))\). Before entry, the incremented array \(x\) must contain the vector \(x\).

\(incx\)

Specifies the increment for the elements of \(x\).

The value of \(incx\) must not be zero.

\(beta\)

Specifies the scalar \(beta\).

\(y\)

Array, size at least \((1 + (n - 1)\cdot abs(incy))\). Before entry, the incremented array \(y\) must contain the vector \(y\).
Specifies the increment for the elements of $y$.
The value of $incy$ must not be zero.

**Output Parameters**

$y$

Overwritten by the updated vector $y$.

**cblas_?hemv**

*Computes a matrix-vector product using a Hermitian matrix.*

**Syntax**

```c
void cblas_chemv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n, const void *alpha, const void *a, const MKL_INT lda, const void *x, const MKL_INT incx, const void *beta, void *y, const MKL_INT incy);
void cblas_zhemv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n, const void *alpha, const void *a, const MKL_INT lda, const void *x, const MKL_INT incx, const void *beta, void *y, const MKL_INT incy);
```

**Include Files**

- mkl.h

**Description**

The ?hemv routines perform a matrix-vector operation defined as

$$y := \alpha A x + \beta y,$$

where:

- $\alpha$ and $\beta$ are scalars,
- $x$ and $y$ are $n$-element vectors,
- $A$ is an $n$-by-$n$ Hermitian matrix.

**Input Parameters**

- **Layout**
  Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).

- **uplo**
  Specifies whether the upper or lower triangular part of the array $a$ is used.
  If $uplo = \text{CblasUpper}$, then the upper triangular of the array $a$ is used.
  If $uplo = \text{CblasLower}$, then the lower triangular of the array $a$ is used.

- **n**
  Specifies the order of the matrix $A$. The value of $n$ must be at least zero.

- **alpha**
  Specifies the scalar $\alpha$.

- **a**
  Array, size $lda\times n$.
  Before entry with $uplo = \text{CblasUpper}$, the leading $n$-by-$n$ upper triangular part of the array $a$ must contain the upper triangular part of the Hermitian matrix and the strictly lower triangular part of $a$ is not referenced.
entry with uplo = CblasLower, the leading $n$-by-$n$ lower triangular part of the array $a$ must contain the lower triangular part of the Hermitian matrix and the strictly upper triangular part of $a$ is not referenced.

The imaginary parts of the diagonal elements need not be set and are assumed to be zero.

$lda$ specifies the leading dimension of $a$ as declared in the calling (sub)program. The value of $lda$ must be at least $\max(1, n)$.

$x$ array, size at least $(1 + (n - 1) \times \text{abs}(\text{incx}))$. Before entry, the incremented array $x$ must contain the $n$-element vector $x$.

$\text{incx}$ specifies the increment for the elements of $x$.

The value of $\text{incx}$ must not be zero.

$\beta$ specifies the scalar $\beta$. When $\beta$ is supplied as zero then $y$ need not be set on input.

$y$ array, size at least $(1 + (n - 1) \times \text{abs}(\text{incy}))$. Before entry, the incremented array $y$ must contain the $n$-element vector $y$.

$\text{incy}$ specifies the increment for the elements of $y$.

The value of $\text{incy}$ must not be zero.

**Output Parameters**

$y$ Overwritten by the updated vector $y$.

**cblas_?her**

*Performs a rank-1 update of a Hermitian matrix.*

**Syntax**

```c
void cblas_cher (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n, const float alpha, const void *x, const MKL_INT incx, void *a, const MKL_INT lda);
void cblas_zher (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n, const double alpha, const void *x, const MKL_INT incx, void *a, const MKL_INT lda);
```

**Include Files**

- mkl.h

**Description**

The ?her routines perform a matrix-vector operation defined as

$$ A := \alpha x^* \text{conjg}(x') + A, $$

where:

$\alpha$ is a real scalar,

$x$ is an $n$-element vector,

$A$ is an $n$-by-$n$ Hermitian matrix.
Input Parameters

**Layout**

Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).

**uplo**

Specifies whether the upper or lower triangular part of the array $a$ is used.
- If $uplo = \text{CblasUpper}$, then the upper triangular of the array $a$ is used.
- If $uplo = \text{CblasLower}$, then the lower triangular of the array $a$ is used.

**n**

Specifies the order of the matrix $A$. The value of $n$ must be at least zero.

**alpha**

Specifies the scalar $\alpha$.

**x**

Array, dimension at least $(1 + (n - 1) \cdot \text{abs}(incx))$. Before entry, the incremented array $x$ must contain the $n$-element vector $x$.

**incx**

Specifies the increment for the elements of $x$.
- The value of $incx$ must not be zero.

**a**

Array, size $lda \cdot n$.
- Before entry with $uplo = \text{CblasUpper}$, the leading $n$-by-$n$ upper triangular part of the array $a$ must contain the upper triangular part of the Hermitian matrix and the strictly lower triangular part of $a$ is not referenced.
- Before entry with $uplo = \text{CblasLower}$, the leading $n$-by-$n$ lower triangular part of the array $a$ must contain the lower triangular part of the Hermitian matrix and the strictly upper triangular part of $a$ is not referenced.
- The imaginary parts of the diagonal elements need not be set and are assumed to be zero.

**lda**

Specifies the leading dimension of $a$ as declared in the calling (sub)program. The value of $lda$ must be at least $\text{max}(1, n)$.

Output Parameters

**a**

- With $uplo = \text{CblasUpper}$, the upper triangular part of the array $a$ is overwritten by the upper triangular part of the updated matrix.
- With $uplo = \text{CblasLower}$, the lower triangular part of the array $a$ is overwritten by the lower triangular part of the updated matrix.
- The imaginary parts of the diagonal elements are set to zero.

**cblas_?her2**

*Performs a rank-2 update of a Hermitian matrix.*

**Syntax**

```c
void cblas_cher2 (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n, const void *alpha, const void *x, const MKL_INT incx, const void *y, const MKL_INT incy, void *a, const MKL_INT lda);

void cblas_zher2 (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n, const void *alpha, const void *x, const MKL_INT incx, const void *y, const MKL_INT incy, void *a, const MKL_INT lda);
```
Include Files

- mkl.h

Description

The `her2` routines perform a matrix-vector operation defined as

\[ A := \alpha x^* \text{conjg}(y') + \text{conjg}(\alpha)y^* \text{conjg}(x') + A, \]

where:

- \( \alpha \) is scalar,
- \( x \) and \( y \) are \( n \)-element vectors,
- \( A \) is an \( n \times n \) Hermitian matrix.

Input Parameters

- **Layout**
  - Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).

- **uplo**
  - Specifies whether the upper or lower triangular part of the array \( a \) is used.
  - If \( \text{uplo} = \text{CblasUpper} \), then the upper triangular of the array \( a \) is used.
  - If \( \text{uplo} = \text{CblasLower} \), then the lower triangular of the array \( a \) is used.

- **n**
  - Specifies the order of the matrix \( A \). The value of \( n \) must be at least zero.

- **alpha**
  - Specifies the scalar \( \alpha \).

- **x**
  - Array, size at least \( (1 + (n - 1)\times\text{abs}(\text{incx})) \). Before entry, the incremented array \( x \) must contain the \( n \)-element vector \( x \).
  - Specifies the increment for the elements of \( x \).
  - The value of \( \text{incx} \) must not be zero.

- **y**
  - Array, size at least \( (1 + (n - 1)\times\text{abs}(\text{incy})) \). Before entry, the incremented array \( y \) must contain the \( n \)-element vector \( y \).
  - Specifies the increment for the elements of \( y \).
  - The value of \( \text{incy} \) must not be zero.

- **a**
  - Array, size \( \text{lda} \times n \).
  - Before entry with \( \text{uplo} = \text{CblasUpper} \), the leading \( n \times n \) upper triangular part of the array \( a \) must contain the upper triangular part of the Hermitian matrix and the strictly lower triangular part of \( a \) is not referenced.
  - Before entry with \( \text{uplo} = \text{CblasLower} \), the leading \( n \times n \) lower triangular part of the array \( a \) must contain the lower triangular part of the Hermitian matrix and the strictly upper triangular part of \( a \) is not referenced.
  - The imaginary parts of the diagonal elements need not be set and are assumed to be zero.

- **lda**
  - Specifies the leading dimension of \( a \) as declared in the calling (sub)program. The value of \( \text{lda} \) must be at least \( \max(1, n) \).
Output Parameters

\( a \)

With \( \text{uplo} = \text{CblasUpper} \), the upper triangular part of the array \( a \) is overwritten by the upper triangular part of the updated matrix.

With \( \text{uplo} = \text{CblasLower} \), the lower triangular part of the array \( a \) is overwritten by the lower triangular part of the updated matrix.

The imaginary parts of the diagonal elements are set to zero.

\texttt{cblas}\_\texttt{?hpmv}

\textit{Computes a matrix-vector product using a Hermitian packed matrix.}

\textbf{Syntax}

\begin{verbatim}
void cblas_chpmv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n, 
const void *alpha, const void *ap, const void *x, const MKL_INT incx, const void *beta, 
void *y, const MKL_INT incy);

void cblas_zhpmv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n, 
const void *alpha, const void *ap, const void *x, const MKL_INT incx, const void *beta, 
void *y, const MKL_INT incy);
\end{verbatim}

\textbf{Include Files}

- \texttt{mkl.h}

\textbf{Description}

The \texttt{?hpmv} routines perform a matrix-vector operation defined as

\[ y := \alpha A x + \beta y, \]

where:

- \( \alpha \) and \( \beta \) are scalars,
- \( x \) and \( y \) are \( n \)-element vectors,
- \( A \) is an \( n \)-by-\( n \) Hermitian matrix, supplied in packed form.

\textbf{Input Parameters}

- \textit{Layout}
  - Specifies whether two-dimensional array storage is row-major (\texttt{CblasRowMajor}) or column-major (\texttt{CblasColMajor}).

- \textit{uplo}
  - Specifies whether the upper or lower triangular part of the matrix \( A \) is supplied in the packed array \( ap \).

- \textit{n}
  - Specifies the order of the matrix \( A \). The value of \( n \) must be at least zero.

- \textit{alpha}
  - Specifies the scalar \( \alpha \).

- \textit{ap}
  - Array, size at least \( ((n^2(n + 1))/2) \).
For Layout = CblasColMajor:

Before entry with uplo = CblasUpper, the array ap must contain the upper triangular part of the Hermitian matrix packed sequentially, column-by-column, so that ap[0] contains $A_{1,1}$, ap[1] and ap[2] contain $A_{1,2}$ and $A_{2,2}$ respectively, and so on. Before entry with uplo = CblasLower, the array ap must contain the lower triangular part of the Hermitian matrix packed sequentially, column-by-column, so that ap[0] contains $A_{1,1}$, ap[1] and ap[2] contain $A_{2,1}$ and $A_{3,1}$ respectively, and so on.

For Layout = CblasRowMajor:

Before entry with uplo = CblasUpper, the array ap must contain the upper triangular part of the Hermitian matrix packed sequentially, row-by-row, ap[0] contains $A_{1,1}$, ap[1] and ap[2] contain $A_{1,2}$ and $A_{1,3}$ respectively, and so on. Before entry with uplo = CblasLower, the array ap must contain the lower triangular part of the Hermitian matrix packed sequentially, row-by-row, so that ap[0] contains $A_{1,1}$, ap[1] and ap[2] contain $A_{2,1}$ and $A_{2,2}$ respectively, and so on.

The imaginary parts of the diagonal elements need not be set and are assumed to be zero.

$x$

Array, size at least $(1 + (n - 1) \times \text{abs}(incx))$. Before entry, the incremented array $x$ must contain the $n$-element vector $x$.

$incx$

Specifies the increment for the elements of $x$.

The value of $incx$ must not be zero.

$beta$

Specifies the scalar $beta$.

When $beta$ is equal to zero then $y$ need not be set on input.

$y$

Array, size at least $(1 + (n - 1) \times \text{abs}(incy))$. Before entry, the incremented array $y$ must contain the $n$-element vector $y$.

$incy$

Specifies the increment for the elements of $y$.

The value of $incy$ must not be zero.

**Output Parameters**

$y$

Overwritten by the updated vector $y$.

**cblas_?hpr**

Performs a rank-1 update of a Hermitian packed matrix.

**Syntax**

```c
void cblas_chpr (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n, const float alpha, const void *x, const MKL_INT incx, void *ap);

void cblas_zhpr (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n, const double alpha, const void *x, const MKL_INT incx, void *ap);
```

**Include Files**

- mkl.h
The `?hpr` routines perform a matrix-vector operation defined as

\[ A := \alpha x^* \text{conjg}(x') + A, \]

where:
- \( \alpha \) is a real scalar,
- \( x \) is an \( n \)-element vector,
- \( A \) is an \( n \times n \) Hermitian matrix, supplied in packed form.

### Input Parameters

#### Layout

Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).

#### uplo

Specifies whether the upper or lower triangular part of the matrix \( A \) is supplied in the packed array \( ap \).

- If \( uplo = \text{CblasUpper} \), the upper triangular part of the matrix \( A \) is supplied in the packed array \( ap \).
- If \( uplo = \text{CblasLower} \), the lower triangular part of the matrix \( A \) is supplied in the packed array \( ap \).

#### n

Specifies the order of the matrix \( A \). The value of \( n \) must be at least zero.

#### alpha

Specifies the scalar \( \alpha \).

#### x

Array, size at least \((1 + (n - 1) \cdot \text{abs}(incx))\). Before entry, the incremented array \( x \) must contain the \( n \)-element vector \( x \).

#### incx

Specifies the increment for the elements of \( x \). \( incx \) must not be zero.

#### ap

Array, size at least \((n^2 + n)/2\).

For \( \text{Layout} = \text{CblasColMajor} \):

Before entry with \( uplo = \text{CblasUpper} \), the array \( ap \) must contain the upper triangular part of the Hermitian matrix packed sequentially, column-by-column, so that \( ap[0] \) contains \( A_{1,1} \), \( ap[1] \) and \( ap[2] \) contain \( A_{1,2} \) and \( A_{2,2} \) respectively, and so on.

Before entry with \( uplo = \text{CblasLower} \), the array \( ap \) must contain the lower triangular part of the Hermitian matrix packed sequentially, column-by-column, so that \( ap[0] \) contains \( A_{1,1} \), \( ap[1] \) and \( ap[2] \) contain \( A_{2,1} \) and \( A_{3,1} \) respectively, and so on.

For \( \text{Layout} = \text{CblasRowMajor} \):

Before entry with \( uplo = \text{CblasUpper} \), the array \( ap \) must contain the upper triangular part of the Hermitian matrix packed sequentially, row-by-row, so that \( ap[0] \) contains \( A_{1,1} \), \( ap[1] \) and \( ap[2] \) contain \( A_{1,2} \) and \( A_{1,3} \) respectively, and so on.

Before entry with \( uplo = \text{CblasLower} \), the array \( ap \) must contain the lower triangular part of the Hermitian matrix packed sequentially, row-by-row, so that \( ap[0] \) contains \( A_{1,1} \), \( ap[1] \) and \( ap[2] \) contain \( A_{2,1} \) and \( A_{2,2} \) respectively, and so on.
The imaginary parts of the diagonal elements need not be set and are assumed to be zero.

**Output Parameters**

*ap*

With `uplo = CblasUpper`, overwritten by the upper triangular part of the updated matrix.

With `uplo = CblasLower`, overwritten by the lower triangular part of the updated matrix.

The imaginary parts of the diagonal elements are set to zero.

**cblas_?hpr2**

*Performs a rank-2 update of a Hermitian packed matrix.*

**Syntax**

```c
void cblas_chpr2 (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n, const void *alpha, const void *x, const MKL_INT incx, const void *y, const MKL_INT incy, void *ap);
void cblas_zhpr2 (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n, const void *alpha, const void *x, const MKL_INT incx, const void *y, const MKL_INT incy, void *ap);
```

**Include Files**

- mkl.h

**Description**

The ?hpr2 routines perform a matrix-vector operation defined as

\[ \mathbf{A} := \alpha \mathbf{x} \mathbf{y}^H + \mathbf{y} \mathbf{x}^H \mathbf{A}^H + \mathbf{A}, \]

where:

- \( \alpha \) is a scalar,
- \( \mathbf{x} \) and \( \mathbf{y} \) are \( n \)-element vectors,
- \( \mathbf{A} \) is an \( n \times n \) Hermitian matrix, supplied in packed form.

**Input Parameters**

- **Layout**
  Specifies whether two-dimensional array storage is row-major (`CblasRowMajor`) or column-major (`CblasColMajor`).

- **uplo**
  Specifies whether the upper or lower triangular part of the matrix \( \mathbf{A} \) is supplied in the packed array \( \mathbf{ap} \).
  - If `uplo = CblasUpper`, then the upper triangular part of the matrix \( \mathbf{A} \) is supplied in the packed array \( \mathbf{ap} \).
  - If `uplo = CblasLower`, then the lower triangular part of the matrix \( \mathbf{A} \) is supplied in the packed array \( \mathbf{ap} \).

- **n**
  Specifies the order of the matrix \( \mathbf{A} \). The value of \( n \) must be at least zero.
\textbf{alpha}  
Specifies the scalar \textit{alpha}.

\textbf{x}  
Array, dimension at least \((1 + (n - 1) \times \text{abs}(\text{incx}))\). Before entry, the incremented array \(x\) must contain the \(n\)-element vector \(x\).

\textbf{incx}  
Specifies the increment for the elements of \(x\).  
The value of \(\text{incx}\) must not be zero.

\textbf{y}  
Array, size at least \((1 + (n - 1) \times \text{abs}(\text{incy}))\). Before entry, the incremented array \(y\) must contain the \(n\)-element vector \(y\).

\textbf{incy}  
Specifies the increment for the elements of \(y\).  
The value of \(\text{incy}\) must not be zero.

\textbf{ap}  
Array, size at least \(((n \times (n + 1))/2)\).  

For Layout = \texttt{CblasColMajor}:  
Before entry with \texttt{uplo} = \texttt{CblasUpper}, the array \(ap\) must contain the upper triangular part of the Hermitian matrix packed sequentially, column-by-column, so that \(ap[0]\) contains \(A_{1,1}\), \(ap[1]\) and \(ap[2]\) contain \(A_{1,2}\) and \(A_{2,2}\) respectively, and so on.

Before entry with \texttt{uplo} = \texttt{CblasLower}, the array \(ap\) must contain the lower triangular part of the Hermitian matrix packed sequentially, column-by-column, so that \(ap[0]\) contains \(A_{1,1}\), \(ap[1]\) and \(ap[2]\) contain \(A_{2,1}\) and \(A_{3,1}\) respectively, and so on.

For Layout = \texttt{CblasRowMajor}:  
Before entry with \texttt{uplo} = \texttt{CblasUpper}, the array \(ap\) must contain the upper triangular part of the Hermitian matrix packed sequentially, row-by-row, \(ap[0]\) contains \(A_{1,1}\), \(ap[1]\) and \(ap[2]\) contain \(A_{1,2}\) and \(A_{1,3}\) respectively, and so on.

Before entry with \texttt{uplo} = \texttt{CblasLower}, the array \(ap\) must contain the lower triangular part of the Hermitian matrix packed sequentially, row-by-row, so that \(ap[0]\) contains \(A_{1,1}\), \(ap[1]\) and \(ap[2]\) contain \(A_{2,1}\) and \(A_{2,2}\) respectively, and so on.

The imaginary parts of the diagonal elements need not be set and are assumed to be zero.

\textbf{Output Parameters}  
\textbf{ap}  
With \texttt{uplo} = \texttt{CblasUpper}, overwritten by the upper triangular part of the updated matrix.

With \texttt{uplo} = \texttt{CblasLower}, overwritten by the lower triangular part of the updated matrix.

The imaginary parts of the diagonal elements need are set to zero.

\textbf{cblas_?sbmv}  
 Computes a matrix-vector product with a symmetric band matrix.
**Syntax**

```c
void cblas_ssbmv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const MKL_INT k, const float alpha, const float *a, const MKL_INT lda, const float *x,
const MKL_INT incx, const float beta, float *y, const MKL_INT incy);
void cblas_dsbmv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const MKL_INT k, const double alpha, const double *a, const MKL_INT lda, const double
*x, const MKL_INT incx, const double beta, double *y, const MKL_INT incy);
```

**Include Files**
- mkl.h

**Description**

The `?sbmv` routines perform a matrix-vector operation defined as

\[ y := \alpha \cdot A \cdot x + \beta \cdot y, \]

where:
- \( \alpha \) and \( \beta \) are scalars,
- \( x \) and \( y \) are \( n \)-element vectors,
- \( A \) is an \( n \)-by-\( n \) symmetric band matrix, with \( k \) super-diagonals.

**Input Parameters**

- **Layout**
  Specifies whether two-dimensional array storage is row-major (`CblasRowMajor`) or column-major (`CblasColMajor`).

- **uplo**
  Specifies whether the upper or lower triangular part of the band matrix \( A \) is used:
  - if `uplo = CblasUpper` - upper triangular part;
  - if `uplo = CblasLower` - low triangular part.

- **n**
  Specifies the order of the matrix \( A \). The value of \( n \) must be at least zero.

- **k**
  Specifies the number of super-diagonals of the matrix \( A \).
  The value of \( k \) must satisfy \( 0 \leq k \).

- **alpha**
  Specifies the scalar \( \alpha \).

- **a**
  Array, size \( lda \cdot n \). Before entry with `uplo = CblasUpper`, the leading \((k + 1)\) by \( n \) part of the array \( a \) must contain the upper triangular band part of the symmetric matrix, supplied column-by-column, with the leading diagonal of the matrix in row \( k \) of the array, the first super-diagonal starting at position 1 in row \((k - 1)\), and so on. The top left \( k \) by \( k \) triangle of the array \( a \) is not referenced.

The following program segment transfers the upper triangular part of a symmetric band matrix from conventional full matrix storage (`matrix`, with leading dimension `ldm`) to band storage (`a`, with leading dimension `lda`):

```c
for (j = 0; j < n; j++) {
    m = k - j;
    for (i = max(0, j - k); i <= j; i++) {
```
Before entry with `uplo = CblasLower`, the leading \((k + 1)\) by \(n\) part of the array \(a\) must contain the lower triangular band part of the symmetric matrix, supplied column-by-column, with the leading diagonal of the matrix in row 0 of the array, the first sub-diagonal starting at position 0 in row 1, and so on. The bottom right \(k\) by \(k\) triangle of the array \(a\) is not referenced.

The following program segment transfers the lower triangular part of a symmetric band matrix from conventional full matrix storage (`matrix`, with leading dimension `ldm`) to band storage (`a`, with leading dimension `lda`):

```c
for (j = 0; j < n; j++) {
    m = -j;
    for (i = j; i < min(n, j + k + 1); i++) {
        a[(m+i) + j*lda] = matrix[i + j*ldm];
    }
}
```

**Layout = CblasRowMajor:**

Before entry with `uplo = CblasUpper`, the leading \((k + 1)\)-by-\(n\) part of array \(a\) must contain the upper triangular band part of the symmetric matrix. The matrix must be supplied row-by-row, with the leading diagonal of the matrix in column 0 of the array, the first super-diagonal starting at position 0 in column 1, and so on. The bottom right \(k\)-by-\(k\) triangle of array \(a\) is not referenced.

The following program segment transfers the upper triangular part of a symmetric band matrix from row-major full matrix storage (`matrix` with leading dimension `ldm`) to row-major band storage (`a`, with leading dimension `lda`):

```c
for (i = 0; i < n; i++) {
    m = -i;
    for (j = i; j < MIN(n, i+k+1); j++) {
        a[(m+j) + i*lda] = matrix[j + i*ldm];
    }
}
```

Before entry with `uplo = CblasLower`, the leading \((k + 1)\)-by-\(n\) part of array \(a\) must contain the lower triangular band part of the symmetric matrix, supplied row-by-row, with the leading diagonal of the matrix in column \(k\) of the array, the first sub-diagonal starting at position 1 in column \(k\)-1, and so on. The top left \(k\)-by-\(k\) triangle of array \(a\) is not referenced.

The following program segment transfers the lower triangular part of a symmetric row-major band matrix from row-major full matrix storage (`matrix`, with leading dimension `ldm`) to row-major band storage (`a`, with leading dimension `lda`):

```c
for (i = 0; i < n; i++) {
    m = k - i;
    for (j = max(0, i-k); j <= i; j++) {
        a[(m+j) + i*lda] = matrix[j + i*ldm];
    }
}
```
lda Specifies the leading dimension of $a$ as declared in the calling (sub)program. The value of $lda$ must be at least $(k + 1)$.

$x$ Array, size at least $(1 + (n - 1)\times abs(incx))$. Before entry, the incremented array $x$ must contain the vector $x$.

$incx$ Specifies the increment for the elements of $x$.
The value of $incx$ must not be zero.

$beta$ Specifies the scalar $beta$.

$y$ Array, size at least $(1 + (n - 1)\times abs(incy))$. Before entry, the incremented array $y$ must contain the vector $y$.

$incy$ Specifies the increment for the elements of $y$.
The value of $incy$ must not be zero.

Output Parameters

$y$ Overwritten by the updated vector $y$.

**cblas_sspmv**

*Computes a matrix-vector product with a symmetric packed matrix.*

**Syntax**

```c
void cblas_sspmv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n, const float alpha, const float *ap, const float *x, const MKL_INT incx, const float beta, float *y, const MKL_INT incy);
```

```c
void cblas_dspmv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n, const double alpha, const double *ap, const double *x, const MKL_INT incx, const double beta, double *y, const MKL_INT incy);
```

**Include Files**

- mkl.h

**Description**

The ?spmv routines perform a matrix-vector operation defined as

$$ y := alpha \times A \times x + beta \times y, $$

where:

- $alpha$ and $beta$ are scalars,
- $x$ and $y$ are $n$-element vectors,
- $A$ is an $n$-by-$n$ symmetric matrix, supplied in packed form.

**Input Parameters**

*Layout*

- Specifies whether two-dimensional array storage is row-major (**CblasRowMajor**) or column-major (**CblasColMajor**).

*uplo*

- Specifies whether the upper or lower triangular part of the matrix $A$ is supplied in the packed array $ap$. 
If $uplo = \text{CblasUpper}$, then the upper triangular part of the matrix $A$ is supplied in the packed array $ap$.

If $uplo = \text{CblasLower}$, then the lower triangular part of the matrix $A$ is supplied in the packed array $ap$.

$n$ Specifies the order of the matrix $A$. The value of $n$ must be at least zero.

$\alpha$ Specifies the scalar $\alpha$.

$ap$ Array, size at least $((n*(n + 1))/2)$.

For $Layout = \text{CblasColMajor}$:

Before entry with $uplo = \text{CblasUpper}$, the array $ap$ must contain the upper triangular part of the symmetric matrix packed sequentially, column-by-column, so that $ap[0]$ contains $A_{1,1}$, $ap[1]$ and $ap[2]$ contain $A_{1,2}$ and $A_{2,2}$ respectively, and so on. Before entry with $uplo = \text{CblasLower}$, the array $ap$ must contain the lower triangular part of the symmetric matrix packed sequentially, column-by-column, so that $ap[0]$ contains $A_{1,1}$, $ap[1]$ and $ap[2]$ contain $A_{2,1}$ and $A_{3,1}$ respectively, and so on.

For $Layout = \text{CblasRowMajor}$:

Before entry with $uplo = \text{CblasUpper}$, the array $ap$ must contain the upper triangular part of the symmetric matrix packed sequentially, row-by-row, $ap[0]$ contains $A_{1,1}$, $ap[1]$ and $ap[2]$ contain $A_{1,2}$ and $A_{1,3}$ respectively, and so on. Before entry with $uplo = \text{CblasLower}$, the array $ap$ must contain the lower triangular part of the symmetric matrix packed sequentially, row-by-row, so that $ap[0]$ contains $A_{1,1}$, $ap[1]$ and $ap[2]$ contain $A_{2,1}$ and $A_{2,2}$ respectively, and so on.

$x$ Array, size at least $(1 + (n - 1)\cdot\text{abs}(incx))$. Before entry, the incremented array $x$ must contain the $n$-element vector $x$.

$incx$ Specifies the increment for the elements of $x$.

The value of $incx$ must not be zero.

$\beta$ Specifies the scalar $\beta$.

When $\beta$ is supplied as zero, then $y$ need not be set on input.

$y$ Array, size at least $(1 + (n - 1)\cdot\text{abs}(incy))$. Before entry, the incremented array $y$ must contain the $n$-element vector $y$.

$incy$ Specifies the increment for the elements of $y$.

The value of $incy$ must not be zero.

Output Parameters

$y$ Overwritten by the updated vector $y$.

cblas_?spr Performs a rank-1 update of a symmetric packed matrix.
Syntax
void cblas_sspr (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n, const float alpha, const float *x, const MKL_INT incx, float *ap);
void cblas_dspr (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n, const double alpha, const double *x, const MKL_INT incx, double *ap);

Include Files
• mkl.h

Description
The ?spr routines perform a matrix-vector operation defined as

\[ a := \alpha x^\top x^\top + A, \]

where:
- \( \alpha \) is a real scalar,
- \( x \) is an \( n \)-element vector,
- \( A \) is an \( n \)-by-\( n \) symmetric matrix, supplied in packed form.

Input Parameters

- **Layout**
  Specifies whether two-dimensional array storage is row-major (\texttt{CblasRowMajor}) or column-major (\texttt{CblasColMajor}).
- **uplo**
  Specifies whether the upper or lower triangular part of the matrix \( A \) is supplied in the packed array \( ap \).
  - If \( uplo = \texttt{CblasUpper} \), then the upper triangular part of the matrix \( A \) is supplied in the packed array \( ap \).
  - If \( uplo = \texttt{CblasLower} \), then the lower triangular part of the matrix \( A \) is supplied in the packed array \( ap \).
- **n**
  Specifies the order of the matrix \( A \). The value of \( n \) must be at least zero.
- **alpha**
  Specifies the scalar \( \alpha \).
- **x**
  Array, size at least \( (1 + (n - 1) \times \text{abs(incx)}) \). Before entry, the incremented array \( x \) must contain the \( n \)-element vector \( x \).
  Specifies the increment for the elements of \( x \).
- **incx**
  The value of \( incx \) must not be zero.
- **ap**
  For \( \text{Layout} = \texttt{CblasColMajor} \):
  Before entry with \( uplo = \texttt{CblasUpper} \), the array \( ap \) must contain the upper triangular part of the symmetric matrix packed sequentially, column-by-column, so that \( ap[0] \) contains \( A_{1,1} \), \( ap[1] \) and \( ap[2] \) contain \( A_{1,2} \) and \( A_{2,2} \) respectively, and so on.
  Before entry with \( uplo = \texttt{CblasLower} \), the array \( ap \) must contain the lower triangular part of the symmetric matrix packed sequentially, column-by-column, so that \( ap[0] \) contains \( A_{1,1} \), \( ap[1] \) and \( ap[2] \) contain \( A_{2,1} \) and \( A_{3,1} \) respectively, and so on.
For \( \text{Layout} = \text{CblasRowMajor} \):

Before entry with \( \text{uplo} = \text{CblasUpper} \), the array \( \text{ap} \) must contain the upper triangular part of the symmetric matrix packed sequentially, row-by-row, \( \text{ap}[0] \) contains \( A_{1,1} \), \( \text{ap}[1] \) and \( \text{ap}[2] \) contain \( A_{1,2} \) and \( A_{1,3} \) respectively, and so on.

Before entry with \( \text{uplo} = \text{CblasLower} \), the array \( \text{ap} \) must contain the lower triangular part of the symmetric matrix packed sequentially, row-by-row, so that \( \text{ap}[0] \) contains \( A_{1,1} \), \( \text{ap}[1] \) and \( \text{ap}[2] \) contain \( A_{2,1} \) and \( A_{2,2} \) respectively, and so on.

**Output Parameters**

\( \text{ap} \)

With \( \text{uplo} = \text{CblasUpper} \), overwritten by the upper triangular part of the updated matrix.

With \( \text{uplo} = \text{CblasLower} \), overwritten by the lower triangular part of the updated matrix.

**cblas_?spr2**

*Computes a rank-2 update of a symmetric packed matrix.*

**Syntax**

```c
void cblas_sspr2 (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n, const float alpha, const float *x, const MKL_INT incx, const float *y, const MKL_INT incy, float *ap);
void cblas_dspr2 (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n, const double alpha, const double *x, const MKL_INT incx, const double *y, const MKL_INT incy, double *ap);
```

**Include Files**

- mkl.h

**Description**

The \(?spr2\) routines perform a matrix-vector operation defined as

\[
A := \alpha x^* y^* + \alpha y^* x^* + A,
\]

where:

- \( \alpha \) is a scalar,
- \( x \) and \( y \) are \( n \)-element vectors,
- \( A \) is an \( n \)-by-\( n \) symmetric matrix, supplied in packed form.

**Input Parameters**

- **Layout**
  - Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).

- **uplo**
  - Specifies whether the upper or lower triangular part of the matrix \( A \) is supplied in the packed array \( \text{ap} \).
If \( uplo = \text{CblasUpper} \), then the upper triangular part of the matrix \( A \) is supplied in the packed array \( ap \).

If \( uplo = \text{CblasLower} \), then the lower triangular part of the matrix \( A \) is supplied in the packed array \( ap \).

\( n \)

Specifies the order of the matrix \( A \). The value of \( n \) must be at least zero.

\( \alpha \)

Specifies the scalar \( \alpha \).

\( x \)

Array, size at least \((1 + (n - 1) \times \text{abs}(\text{incx}))\). Before entry, the incremented array \( x \) must contain the \( n \)-element vector \( x \).

\( \text{incx} \)

Specifies the increment for the elements of \( x \).

The value of \( \text{incx} \) must not be zero.

\( y \)

Array, size at least \((1 + (n - 1) \times \text{abs}(\text{incy}))\). Before entry, the incremented array \( y \) must contain the \( n \)-element vector \( y \).

\( \text{incy} \)

Specifies the increment for the elements of \( y \). The value of \( \text{incy} \) must not be zero.

\( \text{ap} \)

For \( \text{Layout} = \text{CblasColMajor} \):

Before entry with \( uplo = \text{CblasUpper} \), the array \( ap \) must contain the upper triangular part of the symmetric matrix packed sequentially, column-by-column, so that \( ap[0] \) contains \( A_{1,1} \), \( ap[1] \) and \( ap[2] \) contain \( A_{1,2} \) and \( A_{2,2} \) respectively, and so on.

Before entry with \( uplo = \text{CblasLower} \), the array \( ap \) must contain the lower triangular part of the symmetric matrix packed sequentially, column-by-column, so that \( ap[0] \) contains \( A_{1,1} \), \( ap[1] \) and \( ap[2] \) contain \( A_{2,1} \) and \( A_{3,1} \) respectively, and so on.

For \( \text{Layout} = \text{CblasRowMajor} \):

Before entry with \( uplo = \text{CblasUpper} \), the array \( ap \) must contain the upper triangular part of the symmetric matrix packed sequentially, row-by-row, \( ap[0] \) contains \( A_{1,1} \), \( ap[1] \) and \( ap[2] \) contain \( A_{1,2} \) and \( A_{1,3} \) respectively, and so on.

Before entry with \( uplo = \text{CblasLower} \), the array \( ap \) must contain the lower triangular part of the symmetric matrix packed sequentially, row-by-row, so that \( ap[0] \) contains \( A_{1,1} \), \( ap[1] \) and \( ap[2] \) contain \( A_{2,1} \) and \( A_{2,2} \) respectively, and so on.

Output Parameters

\( \text{ap} \)

With \( uplo = \text{CblasUpper} \), overwritten by the upper triangular part of the updated matrix.

With \( uplo = \text{CblasLower} \), overwritten by the lower triangular part of the updated matrix.

\texttt{cblas\_symv}

\textit{Computes a matrix-vector product for a symmetric matrix.}
Syntax

void cblas_ssymv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n, const float alpha, const float *a, const MKL_INT lda, const float *x, const MKL_INT incx, const float beta, float *y, const MKL_INT incy);

void cblas_dsymv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n, const double alpha, const double *a, const MKL_INT lda, const double *x, const MKL_INT incx, const double beta, double *y, const MKL_INT incy);

Include Files

• mkl.h

Description

The ?symv routines perform a matrix-vector operation defined as

\[ y := \alpha A x + \beta y, \]

where:

- \( \alpha \) and \( \beta \) are scalars,
- \( x \) and \( y \) are \( n \)-element vectors,
- \( A \) is an \( n \times n \) symmetric matrix.

Input Parameters

- **Layout**
  Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).

- **uplo**
  Specifies whether the upper or lower triangular part of the array \( a \) is used.
  
  If \( \text{uplo} = \text{CblasUpper} \), then the upper triangular part of the array \( a \) is used.
  
  If \( \text{uplo} = \text{CblasLower} \), then the lower triangular part of the array \( a \) is used.

- **n**
  Specifies the order of the matrix \( A \). The value of \( n \) must be at least zero.

- **alpha**
  Specifies the scalar \( \alpha \).

- **a**
  Array, size \( lda \times n \).
  
  Before entry with \( \text{uplo} = \text{CblasUpper} \), the leading \( n \times n \) upper triangular part of the array \( a \) must contain the upper triangular part of the symmetric matrix \( A \) and the strictly lower triangular part of \( a \) is not referenced. Before entry with \( \text{uplo} = \text{CblasLower} \), the leading \( n \times n \) lower triangular part of the array \( a \) must contain the lower triangular part of the symmetric matrix \( A \) and the strictly upper triangular part of \( a \) is not referenced.

- **lda**
  Specifies the leading dimension of \( a \) as declared in the calling (sub)program. The value of \( lda \) must be at least \( \max(1, n) \).

- **x**
  Array, size at least \( (1 + (n - 1) \times \text{abs}(\text{incx})) \). Before entry, the incremented array \( x \) must contain the \( n \)-element vector \( x \).

- **incx**
  Specifies the increment for the elements of \( x \).
  
  The value of \( \text{incx} \) must not be zero.
beta Specifies the scalar beta. When beta is supplied as zero, then y need not be set on input.

y Array, size at least (1 + (n - 1)*abs(incy)). Before entry, the incremented array y must contain the n-element vector y.

incy Specifies the increment for the elements of y. The value of incy must not be zero.

Output Parameters
y Overwritten by the updated vector y.

cblas_?syr
Performs a rank-1 update of a symmetric matrix.

Syntax
void cblas_ssyr (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n, const float alpha, const float *x, const MKL_INT incx, float *a, const MKL_INT lda);
void cblas_dsyr (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n, const double alpha, const double *x, const MKL_INT incx, double *a, const MKL_INT lda);

Include Files
• mkl.h

Description
The ?syr routines perform a matrix-vector operation defined as
A := alpha*x*x' + A,
where:
alpha is a real scalar,
x is an n-element vector,
A is an n-by-n symmetric matrix.

Input Parameters
Layout Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).

uplo Specifies whether the upper or lower triangular part of the array a is used.
If uplo = CblasUpper, then the upper triangular part of the array a is used.
If uplo = CblasLower, then the low triangular part of the array a is used.

n Specifies the order of the matrix A. The value of n must be at least zero.

alpha Specifies the scalar alpha.
Array, size at least \((1 + (n-1) \cdot \text{abs}(\text{incx}))\). Before entry, the incremented array \(x\) must contain the \(n\)-element vector \(x\).

**incx**

Specifies the increment for the elements of \(x\).

The value of \(\text{incx}\) must not be zero.

Array, size \(\text{lda} \cdot n\).

Before entry with \(\text{uplo} = \text{CblasUpper}\), the leading \(n\)-by-\(n\) upper triangular part of the array \(a\) must contain the upper triangular part of the symmetric matrix \(A\) and the strictly lower triangular part of \(a\) is not referenced.

Before entry with \(\text{uplo} = \text{CblasLower}\), the leading \(n\)-by-\(n\) lower triangular part of the array \(a\) must contain the lower triangular part of the symmetric matrix \(A\) and the strictly upper triangular part of \(a\) is not referenced.

Specifies the leading dimension of \(a\) as declared in the calling (sub)program. The value of \(\text{lda}\) must be at least \(\max(1, n)\).

**Output Parameters**

Array, size \(\text{lda} \cdot n\).

With \(\text{uplo} = \text{CblasUpper}\), the upper triangular part of the array \(a\) is overwritten by the upper triangular part of the updated matrix.

With \(\text{uplo} = \text{CblasLower}\), the lower triangular part of the array \(a\) is overwritten by the lower triangular part of the updated matrix.

**cblas_?syr2**

*Performs a rank-2 update of a symmetric matrix.*

**Syntax**

```c
void cblas_ssyr2 (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n, const float alpha, const float *x, const MKL_INT incx, const float *y, const MKL_INT incy, float *a, const MKL_INT lda);

void cblas_dsyr2 (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n, const double alpha, const double *x, const MKL_INT incx, const double *y, const MKL_INT incy, double *a, const MKL_INT lda);
```

**Include Files**

- mkl.h

**Description**

The ?syr2 routines perform a matrix-vector operation defined as

\[ A := \alpha x^* y' + \alpha y^* x' + A, \]

where:

- \(\alpha\) is scalar,
- \(x\) and \(y\) are \(n\)-element vectors,
- \(A\) is an \(n\)-by-\(n\) symmetric matrix.
Input Parameters

**Layout**
Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).

**uplo**
Specifies whether the upper or lower triangular part of the array \( a \) is used.
If \( \text{uplo} = \text{CblasUpper} \), then the upper triangular part of the array \( a \) is used.
If \( \text{uplo} = \text{CblasLower} \), then the low triangular part of the array \( a \) is used.

**n**
Specifies the order of the matrix \( A \). The value of \( n \) must be at least zero.

**alpha**
Specifies the scalar \( \alpha \).

**x**
Array, size at least \((1 + (n - 1) \times \text{abs}(\text{incx}))\). Before entry, the incremented array \( x \) must contain the \( n \)-element vector \( x \).

**incx**
Specifies the increment for the elements of \( x \).
The value of \( \text{incx} \) must not be zero.

**y**
Array, size at least \((1 + (n - 1) \times \text{abs}(\text{incy}))\). Before entry, the incremented array \( y \) must contain the \( n \)-element vector \( y \).

**incy**
Specifies the increment for the elements of \( y \). The value of \( \text{incy} \) must not be zero.

**a**
Array, size \( lda \times n \).
Before entry with \( \text{uplo} = \text{CblasUpper} \), the leading \( n \)-by-\( n \) upper triangular part of the array \( a \) must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of \( a \) is not referenced.
Before entry with \( \text{uplo} = \text{CblasLower} \), the leading \( n \)-by-\( n \) lower triangular part of the array \( a \) must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of \( a \) is not referenced.

**lda**
Specifies the leading dimension of \( a \) as declared in the calling (sub)program. The value of \( \text{lda} \) must be at least \( \max(1, n) \).

Output Parameters

**a**
With \( \text{uplo} = \text{CblasUpper} \), the upper triangular part of the array \( a \) is overwritten by the upper triangular part of the updated matrix.
With \( \text{uplo} = \text{CblasLower} \), the lower triangular part of the array \( a \) is overwritten by the lower triangular part of the updated matrix.

**cblas\_?tbmv**
*Computes a matrix-vector product using a triangular band matrix.*

**Syntax**
```c
void cblas_stbmv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const MKL_INT k, const float *a, const MKL_INT lda, float *x, const MKL_INT incx);
```
void cblas_dtbmv (const CBLAS_LAYOUT layout, const CBLAS_UPLO uplo, const CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const MKL_INT k, const double *a, const MKL_INT lda, double *x, const MKL_INT incx);
void cblas_ctbmv (const CBLAS_LAYOUT layout, const CBLAS_UPLO uplo, const CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const MKL_INT k, const void *a, const MKL_INT lda, void *x, const MKL_INT incx);
void cblas_ztbmv (const CBLAS_LAYOUT layout, const CBLAS_UPLO uplo, const CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const MKL_INT k, const void *a, const MKL_INT lda, void *x, const MKL_INT incx);

Include Files
• mkl.h

Description
The ?tbmv routines perform one of the matrix-vector operations defined as
\[ x := A \cdot x, \text{ or } x := A' \cdot x, \text{ or } x := \text{conjg}(A') \cdot x, \]
where:
- \( x \) is an \( n \)-element vector,
- \( A \) is an \( n \)-by-\( n \) unit, or non-unit, upper or lower triangular band matrix, with \((k + 1)\) diagonals.

Input Parameters

- **Layout**
  Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).

- **uplo**
  Specifies whether the matrix \( A \) is an upper or lower triangular matrix:
  \[
  \text{if } uplo = \text{CblasUpper}, \text{ then the matrix is upper triangular.} \\
  \text{if } uplo = \text{CblasLower}, \text{ then the matrix is lower triangular.} 
  \]

- **trans**
  Specifies the operation:
  \[
  \text{if } \text{trans=} \text{CblasNoTrans}, \text{ then } x := A \cdot x; \\
  \text{if } \text{trans=} \text{CblasTrans}, \text{ then } x := A' \cdot x; \\
  \text{if } \text{trans=} \text{CblasConjTrans}, \text{ then } x := \text{conjg}(A') \cdot x. 
  \]

- **diag**
  Specifies whether the matrix \( A \) is unit triangular:
  \[
  \text{if } diag = \text{CblasUnit} , \text{ then the matrix is unit triangular;} \\
  \text{if } diag = \text{CblasNonUnit} , \text{ then the matrix is not unit triangular.} 
  \]

- **n**
  Specifies the order of the matrix \( A \). The value of \( n \) must be at least zero.

- **k**
  On entry with \( uplo = \text{CblasUpper} \), specifies the number of super-diagonals of the matrix \( A \). On entry with \( uplo = \text{CblasLower} \), \( k \) specifies the number of sub-diagonals of the matrix \( a \).
  The value of \( k \) must satisfy \( 0 \leq k \).

- **a**
  Array, size \( lda \cdot n \).
  Layout = CblasColMajor:
Before entry with\texttt{uplo = CblasUpper}, the leading \((k + 1)\) by \(n\) part of the array \(a\) must contain the upper triangular band part of the matrix of coefficients, supplied column-by-column, with the leading diagonal of the matrix in row \(k\) of the array, the first super-diagonal starting at position 1 in row \((k - 1)\), and so on. The top left \(k\) by \(k\) triangle of the array \(a\) is not referenced. The following program segment transfers an upper triangular band matrix from conventional full matrix storage (\texttt{matrix}, with leading dimension \texttt{ldm}) to band storage (\texttt{a}, with leading dimension \texttt{lda}): 

```c
for (j = 0; j < n; j++) {
    m = k - j;
    for (i = max( 0, j - k); i <= j; i++) {
        a[(m+i) + j*lda] = matrix[i + j*ldm];
    }
}
```

Before entry with \texttt{uplo = CblasLower}, the leading \((k + 1)\) by \(n\) part of the array \(a\) must contain the lower triangular band part of the matrix of coefficients, supplied column-by-column, with the leading diagonal of the matrix in row 0 of the array, the first sub-diagonal starting at position 0 in row 1, and so on. The bottom right \(k\) by \(k\) triangle of the array \(a\) is not referenced. The following program segment transfers a lower triangular band matrix from conventional full matrix storage (\texttt{matrix}, with leading dimension \texttt{ldm}) to band storage (\texttt{a}, with leading dimension \texttt{lda}): 

```c
for (j = 0; j < n; j++) {
    m = -j;
    for (i = j; i < min(n, j + k + 1); i++) {
        a[(m+i) + j*lda] = matrix[i + j*ldm];
    }
}
```

Note that when \texttt{diag = CblasUnit}, the elements of the array \(a\) corresponding to the diagonal elements of the matrix are not referenced, but are assumed to be unity.

Layout = CblasRowMajor:

Before entry with \texttt{uplo = CblasUpper}, the leading \((k + 1)\)-by-\(n\) part of array \(a\) must contain the upper triangular band part of the matrix of coefficients. The matrix must be supplied row-by-row, with the leading diagonal of the matrix in column 0 of the array, the first super-diagonal starting at position 0 in column 1, and so on. The bottom right \(k\)-by-\(k\) triangle of array \(a\) is not referenced.

The following program segment transfers the upper triangular part of a Hermitian band matrix from row-major full matrix storage (\texttt{matrix} with leading dimension \texttt{ldm}) to row-major band storage (\texttt{a}, with leading dimension \texttt{lda}): 

```c
for (i = 0; i < n; i++) {
    m = -i;
    for (j = i; j < MIN(n, i+k+1); j++) {
        a[(m+j) + i*lda] = matrix[j + i*ldm];
    }
}
```
Before entry with \texttt{uplo = CblasLower}, the leading \((k + 1)\)-by-\(n\) part of array \(a\) must contain the lower triangular band part of the matrix of coefficients, supplied row-by-row, with the leading diagonal of the matrix in column \(k\) of the array, the first sub-diagonal starting at position 1 in column \(k-1\), and so on. The top left \(k\)-by-\(k\) triangle of array \(a\) is not referenced.

The following program segment transfers the lower triangular part of a Hermitian row-major band matrix from row-major full matrix storage (\texttt{matrix}, with leading dimension \(ldm\)) to row-major band storage (\(a\), with leading dimension \(lda\)):

```c
for (i = 0; i < n; i++) {
    m = k - i;
    for (j = max(0, i-k); j <= i; j++) {
        a[(m+j) + i*lda] = matrix[j + i*ldm];
    }
}
```

\(lda\)

Specifies the leading dimension of \(a\) as declared in the calling (sub)program. The value of \(lda\) must be at least \((k + 1)\).

\(x\)

Array, size at least \((1 + (n - 1)\cdot\text{abs}(\text{incx}))\). Before entry, the incremented array \(x\) must contain the \(n\)-element vector \(x\).

\(incx\)

Specifies the increment for the elements of \(x\).

The value of \(incx\) must not be zero.

**Output Parameters**

\(x\)

Overwritten with the transformed vector \(x\).

\texttt{cblas\_?tbsv}

Solves a system of linear equations whose coefficients are in a triangular band matrix.

**Syntax**

```c
void cblas_stbsv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const MKL_INT k, const float *a, const MKL_INT lda, float *x, const MKL_INT incx);
void cblas_dtbsv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const MKL_INT k, const double *a, const MKL_INT lda, double *x, const MKL_INT incx);
void cblas_ctbsv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const MKL_INT k, const void *a, const MKL_INT lda, void *x, const MKL_INT incx);
void cblas_ztbsv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const MKL_INT k, const void *a, const MKL_INT lda, void *x, const MKL_INT incx);
```

**Include Files**

- mkl.h
Description

The ?tbsv routines solve one of the following systems of equations:

\[ A^{}x = b, \text{ or } A'^{}x = b, \text{ or } \text{conjg}(A')^{}x = b, \]

where:

- \( b \) and \( x \) are \( n \)-element vectors,
- \( A \) is an \( n \)-by-\( n \) unit, or non-unit, upper or lower triangular band matrix, with \((k + 1)\) diagonals.

The routine does not test for singularity or near-singularity.

Such tests must be performed before calling this routine.

Input Parameters

- **Layout**
  Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).

- **uplo**
  Specifies whether the matrix \( A \) is an upper or lower triangular matrix:
  - if \( \text{uplo} = \text{CblasUpper} \) the matrix is upper triangular;
  - if \( \text{uplo} = \text{CblasLower} \), the matrix is low triangular.

- **trans**
  Specifies the system of equations:
  - if \( \text{trans} = \text{CblasNoTrans} \), then \( A^{}x = b \);
  - if \( \text{trans} = \text{CblasTrans} \), then \( A'^{}x = b \);
  - if \( \text{trans} = \text{CblasConjTrans} \), then \( \text{conjg}(A')^{}x = b \).

- **diag**
  Specifies whether the matrix \( A \) is unit triangular:
  - if \( \text{diag} = \text{CblasUnit} \) then the matrix is unit triangular;
  - if \( \text{diag} = \text{CblasNonUnit} \), then the matrix is not unit triangular.

- **n**
  Specifies the order of the matrix \( A \). The value of \( n \) must be at least zero.

- **k**
  On entry with \( \text{uplo} = \text{CblasUpper} \), \( k \) specifies the number of super-diagonals of the matrix \( A \). On entry with \( \text{uplo} = \text{CblasLower} \), \( k \) specifies the number of sub-diagonals of the matrix \( A \).
  The value of \( k \) must satisfy \( 0 \leq k \).

- **a**
  Array, size \( lda^{}n \).
  
  **Layout = CblasColMajor:**
  Before entry with \( \text{uplo} = \text{CblasUpper} \), the leading \((k + 1)\) by \( n \) part of the array \( a \) must contain the upper triangular band part of the matrix of coefficients, supplied column-by-column, with the leading diagonal of the matrix in row \( k \) of the array, the first super-diagonal starting at position 1 in row \((k - 1)\), and so on. The top left \( k \) by \( k \) triangle of the array \( a \) is not referenced.
The following program segment transfers an upper triangular band matrix from conventional full matrix storage (matrix, with leading dimension ldm) to band storage (a, with leading dimension lda):

```c
for (j = 0; j < n; j++) {
    m = k - j;
    for (i = max(0, j - k); i <= j; i++) {
        a[(m+i) + j*lda] = matrix[i + j*ldm];
    }
}
```

Before entry with uplo = CblasLower, the leading \((k + 1)\) by \(n\) part of the array \(a\) must contain the lower triangular band part of the matrix of coefficients, supplied column-by-column, with the leading diagonal of the matrix in row 0 of the array, the first sub-diagonal starting at position 0 in row 1, and so on. The bottom right \(k\) by \(k\) triangle of the array \(a\) is not referenced.

The following program segment transfers a lower triangular band matrix from conventional full matrix storage (matrix, with leading dimension ldm) to band storage (a, with leading dimension lda):

```c
for (j = 0; j < n; j++) {
    m = -j;
    for (i = j; i < min(n, j + k + 1); i++) {
        a[(m+i) + j*lda] = matrix[i + j*ldm];
    }
}
```

When diag = CblasUnit, the elements of the array \(a\) corresponding to the diagonal elements of the matrix are not referenced, but are assumed to be unity.

**Layout = CblasRowMajor:**

Before entry with uplo = CblasUpper, the leading \((k + 1)\)-by-\(n\) part of array \(a\) must contain the upper triangular band part of the matrix of coefficients. The matrix must be supplied row-by-row, with the leading diagonal of the matrix in column 0 of the array, the first super-diagonal starting at position 0 in column 1, and so on. The bottom right \(k\)-by-\(k\) triangle of array \(a\) is not referenced.

The following program segment transfers the upper triangular part of a Hermitian band matrix from row-major full matrix storage (matrix with leading dimension ldm) to row-major band storage (a, with leading dimension lda):

```c
for (i = 0; i < n; i++) {
    m = -i;
    for (j = i; j < MIN(n, i+k+1); j++) {
        a[(m+j) + i*lda] = matrix[j + i*ldm];
    }
}
```

Before entry with uplo = CblasLower, the leading \((k + 1)\)-by-\(n\) part of array \(a\) must contain the lower triangular band part of the matrix of coefficients, supplied row-by-row, with the leading diagonal of the matrix in column \(k\) of the array, the first sub-diagonal starting at position 1 in column \(k-1\), and so on. The top left \(k\)-by-\(k\) triangle of array \(a\) is not referenced.
The following program segment transfers the lower triangular part of a Hermitian row-major band matrix from row-major full matrix storage (\(matrix\), with leading dimension \(ldm\)) to row-major band storage (\(a\), with leading dimension \(lda\)):

```c
for (i = 0; i < n; i++) {
    m = k - i;
    for (j = max(0, i-k); j <= i; j++) {
        a[(m+j) + i*lda] = matrix[j + i*ldm];
    }
}
```

\(lda\) Specifies the leading dimension of \(a\) as declared in the calling (sub)program. The value of \(lda\) must be at least \((k + 1)\).

\(x\) Array, size at least \((1 + (n - 1)*abs(incx))\). Before entry, the incremented array \(x\) must contain the \(n\)-element right-hand side vector \(b\).

\(incx\) Specifies the increment for the elements of \(x\).

The value of \(incx\) must not be zero.

**Output Parameters**

\(x\) Overwritten with the solution vector \(x\).

**cblas_?tpmv**

*Computes a matrix-vector product using a triangular packed matrix.*

**Syntax**

```c
void cblas_stpmv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const float *ap, float *x, const MKL_INT incx);
void cblas_dtpmv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const double *ap, double *x, const MKL_INT incx);
void cblas_ctpmv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const void *ap, void *x, const MKL_INT incx);
void cblas_ztpmv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const void *ap, void *x, const MKL_INT incx);
```

**Include Files**

- mkl.h

**Description**

The ?tpmv routines perform one of the matrix-vector operations defined as

\[ x := A \cdot x, \text{ or } x := A^\top \cdot x, \text{ or } x := \text{conjg}(A^\top) \cdot x, \]

where:
x is an n-element vector,
A is an n-by-n unit, or non-unit, upper or lower triangular matrix, supplied in packed form.

**Input Parameters**

**Layout**

Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).

**uplo**

Specifies whether the matrix A is upper or lower triangular:

- if uplo = CblasUpper, then the matrix is upper triangular.
- if uplo = CblasLower, then the matrix is lower triangular.

**trans**

Specifies the operation:

- if trans=CblasNoTrans, then x := A*x;
- if trans=CblasTrans, then x := A'*x;
- if trans=CblasConjTrans, then x := conjg(A')*x.

**diag**

Specifies whether the matrix A is unit triangular:

- if diag = CblasUnit, then the matrix is unit triangular;
- if diag = CblasNonUnit, then the matrix is not unit triangular.

**n**

Specifies the order of the matrix A. The value of n must be at least zero.

**ap**

Array, size at least ((n*(n + 1))/2).

For Layout = CblasColMajor:

Before entry with uplo = CblasUpper, the array ap must contain the upper triangular matrix packed sequentially, column-by-column, so that respectively, and so on. Before entry with uplo = CblasLower, the array ap must contain the lower triangular matrix packed sequentially, column-by-column, so that respectively, and so on. When diag = CblasUnit, the diagonal elements of a are not referenced, but are assumed to be unity.

For Layout = CblasRowMajor:

Before entry with uplo = CblasUpper, the array ap must contain the upper triangular matrix packed sequentially, row-by-row, so that respectively, and so on. Before entry with uplo = CblasLower, the array ap must contain the lower triangular matrix packed sequentially, row-by-row, so that respectively, and so on.

**x**

Array, size at least (1 + (n - 1)*abs(incx)). Before entry, the incremented array x must contain the n-element vector x.

**incx**

Specifies the increment for the elements of x.

The value of incx must not be zero.
Output Parameters

\( x \)
Overwritten with the transformed vector \( x \).

cblas_?tpsv
Solves a system of linear equations whose coefficients
are in a triangular packed matrix.

Syntax

void cblas_stpsv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const float *ap, float

void cblas_ctpsv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const void *ap, void *x,
const MKL_INT incx);

void cblas_ztpsv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const void *ap, void *x,
const MKL_INT incx);

Include Files

- mkl.h

Description

The \( ?tpsv \) routines solve one of the following systems of equations
\[ A^t x = b, \text{ or } A'^* x = b, \text{ or } \text{conjg}(A')^* x = b, \]
where:
\( b \) and \( x \) are \( n \)-element vectors,
\( A \) is an \( n \)-by-\( n \) unit, or non-unit, upper or lower triangular matrix, supplied in packed form.
This routine does not test for singularity or near-singularity.
Such tests must be performed before calling this routine.

Input Parameters

- **Layout**
  Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).

- **uplo**
  Specifies whether the matrix \( A \) is upper or lower triangular:
  \[
  \text{if } uplo = \text{CblasUpper}, \text{ then the matrix is upper triangular.} \\
  \text{if } uplo = \text{CblasLower}, \text{ then the matrix is lower triangular.}
  \]

- **trans**
  Specifies the system of equations:
  \[
  \text{if } trans = \text{CblasNoTrans}, \text{ then } A^t x = b; \\
  \text{if } trans = \text{CblasTrans}, \text{ then } A'^* x = b;
  \]
if \( \text{trans} = \text{CblasConjTrans} \), then \( \text{conjg}(A') \times x = b \).

**diag**

Specifies whether the matrix \( A \) is unit triangular:

- if \( \text{diag} = \text{CblasUnit} \) then the matrix is unit triangular;
- if \( \text{diag} = \text{CblasNonUnit} \), then the matrix is not unit triangular.

**n**

Specifies the order of the matrix \( A \). The value of \( n \) must be at least zero.

**ap**

Array, size at least \( (\frac{n(n + 1)}{2}) \).

For **Layout** = **CblasColMajor**:

Before entry with \( \text{uplo} = \text{CblasUpper} \), the array \( ap \) must contain the upper triangular part of the triangular matrix packed sequentially, column-by-column, so that \( ap[0] \) contains \( A_{1,1} \), \( ap[1] \) and \( ap[2] \) contain \( A_{1,2} \) and \( A_{2,2} \) respectively, and so on.

Before entry with \( \text{uplo} = \text{CblasLower} \), the array \( ap \) must contain the lower triangular part of the triangular matrix packed sequentially, column-by-column, so that \( ap[0] \) contains \( A_{1,1} \), \( ap[1] \) and \( ap[2] \) contain \( A_{2,1} \) and \( A_{3,1} \) respectively, and so on.

For **Layout** = **CblasRowMajor**:

Before entry with \( \text{uplo} = \text{CblasUpper} \), the array \( ap \) must contain the upper triangular part of the triangular matrix packed sequentially, row-by-row, \( ap[0] \) contains \( A_{1,1} \), \( ap[1] \) and \( ap[2] \) contain \( A_{1,2} \) and \( A_{1,3} \) respectively, and so on. Before entry with \( \text{uplo} = \text{CblasLower} \), the array \( ap \) must contain the lower triangular part of the triangular matrix packed sequentially, row-by-row, so that \( ap[0] \) contains \( A_{1,1} \), \( ap[1] \) and \( ap[2] \) contain \( A_{2,1} \) and \( A_{2,2} \) respectively, and so on.

When \( \text{diag} = \text{CblasUnit} \), the diagonal elements of \( a \) are not referenced, but are assumed to be unity.

**x**

Array, size at least \( (1 + (n - 1) \times \text{abs}(\text{incx})) \). Before entry, the incremented array \( x \) must contain the \( n \)-element right-hand side vector \( b \).

**incx**

Specifies the increment for the elements of \( x \).

The value of \( \text{incx} \) must not be zero.

**Output Parameters**

**x**

Overwritten with the solution vector \( x \).

**cblas_?trmv**

*Computes a matrix-vector product using a triangular matrix.*

**Syntax**

```c
void cblas_strmv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const float *a, const MKL_INT lda, float *x, const MKL_INT incx);
```
void cblas_dtrmv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const double *a, const MKL_INT lda, double *x, const MKL_INT incx);

void cblas_ctrmv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const void *a, const MKL_INT lda, void *x, const MKL_INT incx);

void cblas_ztrmv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const void *a, const MKL_INT lda, void *x, const MKL_INT incx);

Include Files

- mkl.h

Description

The trmv routines perform one of the following matrix-vector operations defined as

\[ x := Ax \text{, or } x := A'x \text{, or } x := \text{conjg}(A')x, \]

where:

- \( x \) is an \( n \)-element vector,
- \( A \) is an \( n \)-by-\( n \) unit, or non-unit, upper or lower triangular matrix.

Input Parameters

- **Layout**: Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).

- **uplo**: Specifies whether the matrix \( A \) is upper or lower triangular:

  - \( uplo = \text{CblasUpper} \) if \( uplo = \text{CblasLower} \), then the matrix is low triangular.

- **trans**: Specifies the operation:

  - if \( trans = \text{CblasNoTrans} \), then \( x := Ax \);
  - if \( trans = \text{CblasTrans} \), then \( x := A'x \);
  - if \( trans = \text{CblasConjTrans} \), then \( x := \text{conjg}(A')x \).

- **diag**: Specifies whether the matrix \( A \) is unit triangular:

  - if \( diag = \text{CblasUnit} \) then the matrix is unit triangular;
  - if \( diag = \text{CblasNonUnit} \), then the matrix is not unit triangular.

- **n**: Specifies the order of the matrix \( A \). The value of \( n \) must be at least zero.

- **a**: Array, size \( lda \times n \). Before entry with \( uplo = \text{CblasUpper} \), the leading \( n \)-by-\( n \) upper triangular part of the array \( a \) must contain the upper triangular matrix and the strictly lower triangular part of \( a \) is not referenced. Before entry with \( uplo = \text{CblasLower} \), the leading \( n \)-by-\( n \) lower triangular part of the array \( a \) must contain the lower triangular matrix and the strictly upper triangular part of \( a \) is not referenced.

  - When \( diag = \text{CblasUnit} \), the diagonal elements of \( a \) are not referenced either, but are assumed to be unity.
Specifies the leading dimension of \( a \) as declared in the calling (sub)program. The value of \( lda \) must be at least \( \max(1, n) \).

Array, size at least \( (1 + (n - 1) \times \text{abs}(\text{incx})) \). Before entry, the incremented array \( x \) must contain the \( n \)-element vector \( x \).

Specifies the increment for the elements of \( x \).

The value of \( \text{incx} \) must not be zero.

**Output Parameters**

\( x \)

Overwritten with the transformed vector \( x \).

---

**cblas_?trsv**

Solves a system of linear equations whose coefficients are in a triangular matrix.

**Syntax**

```c
void cblas_strsv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const float *a, const MKL_INT lda, float *x, const MKL_INT incx);
void cblas_dtrsv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const double *a, const MKL_INT lda, double *x, const MKL_INT incx);
void cblas_ctrsv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const void *a, const MKL_INT lda, void *x, const MKL_INT incx);
void cblas_ztrsv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const void *a, const MKL_INT lda, void *x, const MKL_INT incx);
```

**Include Files**

- mkl.h

**Description**

The \( ? \text{trsv} \) routines solve one of the systems of equations:

\[
A \times x = b, \text{ or } A^\prime \times x = b, \text{ or } \text{conjg}(A^\prime) \times x = b,
\]

where:

\( b \) and \( x \) are \( n \)-element vectors,

\( A \) is an \( n \)-by-\( n \) unit, or non-unit, upper or lower triangular matrix.

The routine does not test for singularity or near-singularity.

Such tests must be performed before calling this routine.

**Input Parameters**

- **Layout**

  Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).
uplo

Specifies whether the matrix $A$ is upper or lower triangular:

- $\text{uplo} = \text{CblasUpper}$
  - if $\text{uplo} = \text{CblasLower}$, then the matrix is lower triangular.

$\text{trans}$

Specifies the systems of equations:

- if $\text{trans} = \text{CblasNoTrans}$, then $A*x = b$;
- if $\text{trans} = \text{CblasTrans}$, then $A'*x = b$;
- if $\text{trans} = \text{CblasConjTrans}$, then $\text{conj}(A')*x = b$.

$\text{diag}$

Specifies whether the matrix $A$ is unit triangular:

- if $\text{diag} = \text{CblasUnit}$ then the matrix is unit triangular;
- if $\text{diag} = \text{CblasNonUnit}$, then the matrix is not unit triangular.

$n$

Specifies the order of the matrix $A$. The value of $n$ must be at least zero.

$a$

Array, size $\text{lda}*n$. Before entry with $\text{uplo} = \text{CblasUpper}$, the leading $n$-by-$n$ upper triangular part of the array $a$ must contain the upper triangular matrix and the strictly lower triangular part of $a$ is not referenced. Before entry with $\text{uplo} = \text{CblasLower}$, the leading $n$-by-$n$ lower triangular part of the array $a$ must contain the lower triangular matrix and the strictly upper triangular part of $a$ is not referenced.

When $\text{diag} = \text{CblasUnit}$, the diagonal elements of $a$ are not referenced either, but are assumed to be unity.

$\text{lda}$

Specifies the leading dimension of $a$ as declared in the calling (sub)program. The value of $\text{lda}$ must be at least $\max(1, n)$.

$x$

Array, size at least $(1 + (n - 1)*\text{abs}(\text{incx}))$. Before entry, the incremented array $x$ must contain the $n$-element right-hand side vector $b$.

$\text{incx}$

Specifies the increment for the elements of $x$.

The value of $\text{incx}$ must not be zero.

Output Parameters

$x$

Overwritten with the solution vector $x$.

BLAS Level 3 Routines

BLAS Level 3 routines perform matrix-matrix operations. The following table lists the BLAS Level 3 routine groups and the data types associated with them.

<table>

### Symmetric Multiprocessing Version of Intel® MKL

Many applications spend considerable time executing BLAS routines. This time can be scaled by the number of processors available on the system through using the symmetric multiprocessing (SMP) feature built into the Intel® Math Kernel Library. The performance enhancements based on the parallel use of the processors are available without any programming effort on your part.

To enhance performance, the library uses the following methods:

- The BLAS functions are blocked where possible to restructure the code in a way that increases the localization of data reference, enhances cache memory use, and reduces the dependency on the memory bus.
- The code is distributed across the processors to maximize parallelism.

### cblas_?gemm

*Computes a matrix-matrix product with general matrices.*

#### Syntax

```c
void cblas_sgemm (const CBLAS_LAYOUT Layout, const CBLAS_TRANSPOSE transa, const CBLAS_TRANSPOSE transb, const MKL_INT m, const MKL_INT n, const MKL_INT k, const float alpha, const float *a, const MKL_INT lda, const float *b, const MKL_INT ldb, const float beta, float *c, const MKL_INT ldc);
void cblas_dgemm (const CBLAS_LAYOUT Layout, const CBLAS_TRANSPOSE transa, const CBLAS_TRANSPOSE transb, const MKL_INT m, const MKL_INT n, const MKL_INT k, const double alpha, const double *a, const MKL_INT lda, const double *b, const MKL_INT ldb, const double beta, double *c, const MKL_INT ldc);
void cblas_cgemm (const CBLAS_LAYOUT Layout, const CBLAS_TRANSPOSE transa, const CBLAS_TRANSPOSE transb, const MKL_INT m, const MKL_INT n, const MKL_INT k, const void *alpha, const void *a, const MKL_INT lda, const void *b, const MKL_INT ldb, const void *beta, void *c, const MKL_INT ldc);
void cblas_zgemm (const CBLAS_LAYOUT Layout, const CBLAS_TRANSPOSE transa, const CBLAS_TRANSPOSE transb, const MKL_INT m, const MKL_INT n, const MKL_INT k, const void *alpha, const void *a, const MKL_INT lda, const void *b, const MKL_INT ldb, const void *beta, void *c, const MKL_INT ldc);
```

### Include Files

- mkl.h

### Description
The ?gemm routines compute a scalar-matrix-matrix product and add the result to a scalar-matrix product, with general matrices. The operation is defined as

\[ C := \alpha \cdot \text{op}(A) \cdot \text{op}(B) + \beta \cdot C \]

where:

- \text{op}(X) is one of \text{op}(X) = X, or \text{op}(X) = X^T, or \text{op}(X) = X^H,
- \alpha and \beta are scalars,
- \( A, \ B \) and \( C \) are matrices:
  - \text{op}(A) is an \( m \)-by-\( k \) matrix,
  - \text{op}(B) is a \( k \)-by-\( n \) matrix,
  - \( C \) is an \( m \)-by-\( n \) matrix.

See also:
- ?gemm for the Fortran language interface to this routine
- ?gemm3m, BLAS-like extension routines, that use matrix multiplication for similar matrix-matrix operations

### Input Parameters

**Layout**

Specifies whether two-dimensional array storage is row-major (**CblasRowMajor** or column-major (**CblasColMajor**).

**transa**

Specifies the form of \text{op}(A) used in the matrix multiplication:

- if \( \text{transa} = \text{CblasNoTrans} \), then \text{op}(A) = A;
- if \( \text{transa} = \text{CblasTrans} \), then \text{op}(A) = A^T;
- if \( \text{transa} = \text{CblasConjTrans} \), then \text{op}(A) = A^H.

**transb**

Specifies the form of \text{op}(B) used in the matrix multiplication:

- if \( \text{transb} = \text{CblasNoTrans} \), then \text{op}(B) = B;
- if \( \text{transb} = \text{CblasTrans} \), then \text{op}(B) = B^T;
- if \( \text{transb} = \text{CblasConjTrans} \), then \text{op}(B) = B^H.

**m**

Specifies the number of rows of the matrix \text{op}(A) and of the matrix \( C \). The value of \( m \) must be at least zero.

**n**

Specifies the number of columns of the matrix \text{op}(B) and the number of columns of the matrix \( C \). The value of \( n \) must be at least zero.

**k**

Specifies the number of columns of the matrix \text{op}(A) and the number of rows of the matrix \text{op}(B). The value of \( k \) must be at least zero.

**alpha**

Specifies the scalar \( \alpha \).

<table>
<thead>
<tr>
<th>transa=CblasNoTrans</th>
<th>transa=CblasTrans or transa=CblasConjTrans</th>
</tr>
</thead>
<tbody>
<tr>
<td>Layout = CblasColMajor</td>
<td>Array, size lda*k. Before entry, the leading ( m )-by-( k ) part of the array ( a ) must contain the matrix ( A ).</td>
</tr>
<tr>
<td></td>
<td>Array, size lda*m. Before entry, the leading ( k )-by-( m ) part of the array ( a ) must contain the matrix ( A ).</td>
</tr>
</tbody>
</table>
CblasRowMajor

Array, size lda* m.
Before entry, the leading $k$-by-$m$ part of the array $a$
must contain the matrix $A$.

Array, size lda* k.
Before entry, the leading $m$-by-$k$ part of the array $a$
must contain the matrix $A$.

$lda$

Specifies the leading dimension of $a$ as declared in the calling
(sub)program.

transa=CblasNoTrans  transa=CblasTrans or
transa=CblasConjTrans

$transa$

$transa=CblasNoTrans$
tansa=CblasTrans or
transa=CblasConjTrans

$bdb$

Specifies the leading dimension of $b$ as declared in the calling
(sub)program.

When $transb$=CblasNoTrans, then $ldb$ must be at least $\max(1, k)$,
otherwise $ldb$ must be at least $\max(1, n)$.

beta

Specifies the scalar $beta$. When $beta$ is equal to zero, then $c$
need not be set on input.
c

<table>
<thead>
<tr>
<th>Layout</th>
<th>Array, size ldc by n. Before entry, the leading m-by-n part of the array c must contain the matrix C, except when beta is equal to zero, in which case c need not be set on entry.</th>
</tr>
</thead>
<tbody>
<tr>
<td>CblasColMajor</td>
<td>---------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Layout</th>
<th>Array, size ldc by m. Before entry, the leading n-by-m part of the array c must contain the matrix C, except when beta is equal to zero, in which case c need not be set on entry.</th>
</tr>
</thead>
<tbody>
<tr>
<td>CblasRowMajor</td>
<td>---------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>

ldc

Specifies the leading dimension of c as declared in the calling (sub)program.

<table>
<thead>
<tr>
<th>Layout</th>
<th>ldc must be at least max(1, m).</th>
</tr>
</thead>
<tbody>
<tr>
<td>CblasColMajor</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Layout</th>
<th>ldc must be at least max(1, n).</th>
</tr>
</thead>
<tbody>
<tr>
<td>CblasRowMajor</td>
<td></td>
</tr>
</tbody>
</table>

Output Parameters

- **c**
  Overwritten by the m-by-n matrix (alpha*op(A)*op(B) + beta*C).

Example

For examples of routine usage, see these code examples in the Intel® MKL installation directory:

- cblas_sgemm: examples\cblas\source\cblas_sgemmx.c
- cblas_dgemm: examples\cblas\source\cblas_dgemmx.c
- cblas_cgemm: examples\cblas\source\cblas_cgemmx.c
- cblas_zgemm: examples\cblas\source\cblas_zgemmx.c

**cblas_?hemm**

*Computes a matrix-matrix product where one input matrix is Hermitian.*

Syntax

```c
void cblas_chemm (const CBLAS_LAYOUT Layout, const CBLAS_SIDE side, const CBLAS_UPLO uplo, const MKL_INT m, const MKL_INT n, const void *alpha, const void *a, const MKL_INT lda, const void *b, const MKL_INT ldb, const void *beta, void *c, const MKL_INT ldc);
void cblas_zhemm (const CBLAS_LAYOUT Layout, const CBLAS_SIDE side, const CBLAS_UPLO uplo, const MKL_INT m, const MKL_INT n, const void *alpha, const void *a, const MKL_INT lda, const void *b, const MKL_INT ldb, const void *beta, void *c, const MKL_INT ldc);
```

Include Files

- mkl.h

Description

The ?hemm routines compute a scalar-matrix-matrix product using a Hermitian matrix A and a general matrix B and add the result to a scalar-matrix product using a general matrix C. The operation is defined as

\[ C := \alpha A^* B + \beta C \]
or
\[ C := \alpha A + \beta C \]

where:
\( \alpha \) and \( \beta \) are scalars,
\( A \) is a Hermitian matrix,
\( B \) and \( C \) are \( m \text{-by-} n \) matrices.

**Input Parameters**

**Layout**
Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).

**side**
Specifies whether the Hermitian matrix \( A \) appears on the left or right in the operation as follows:
- if \( \text{side} = \text{CblasLeft} \), then \( C := \alpha A B + \beta C \);
- if \( \text{side} = \text{CblasRight} \), then \( C := \alpha B A + \beta C \).

**uplo**
Specifies whether the upper or lower triangular part of the Hermitian matrix \( A \) is used:
- If \( \text{uplo} = \text{CblasUpper} \), then the upper triangular part of the Hermitian matrix \( A \) is used.
- If \( \text{uplo} = \text{CblasLower} \), then the lower triangular part of the Hermitian matrix \( A \) is used.

**m**
Specifies the number of rows of the matrix \( C \).
The value of \( m \) must be at least zero.

**n**
Specifies the number of columns of the matrix \( C \).
The value of \( n \) must be at least zero.

**alpha**
Specifies the scalar \( \alpha \).

**a**
Array, size \( lda \times ka \), where \( ka \) is \( m \) when \( \text{side} = \text{CblasLeft} \) and is \( n \) otherwise. Before entry with \( \text{side} = \text{CblasLeft} \), the \( m \text{-by-} m \) part of the array \( a \) must contain the Hermitian matrix, such that when \( \text{uplo} = \text{CblasUpper} \), the leading \( m \text{-by-} m \) upper triangular part of the array \( a \) must contain the upper triangular part of the Hermitian matrix and the strictly lower triangular part of \( a \) is not referenced, and when \( \text{uplo} = \text{CblasLower} \), the leading \( m \text{-by-} m \) lower triangular part of the array \( a \) must contain the lower triangular part of the Hermitian matrix, and the strictly upper triangular part of \( a \) is not referenced.

Before entry with \( \text{side} = \text{CblasRight} \), the \( n \text{-by-} n \) part of the array \( a \) must contain the Hermitian matrix, such that when \( \text{uplo} = \text{CblasUpper} \), the leading \( n \text{-by-} n \) upper triangular part of the array \( a \) must contain the upper triangular part of the Hermitian matrix and the strictly lower triangular part of \( a \) is not referenced, and when \( \text{uplo} = \text{CblasLower} \), the leading \( n \text{-by-} n \) lower triangular part of the array \( a \) must contain the lower triangular part of the Hermitian matrix, and the strictly upper triangular part of \( a \) is not referenced. The imaginary parts of the diagonal elements need not be set, they are assumed to be zero.
lda

Specifies the leading dimension of a as declared in the calling (sub) program. When side = CblasLeft then lda must be at least max(1, m), otherwise lda must be at least max(1, n).

b

For Layout = CblasColMajor: array, size ldb*n. The leading m-by-n part of the array b must contain the matrix B.

For Layout = CblasRowMajor: array, size ldb*m. The leading n-by-m part of the array b must contain the matrix B.

ldb

Specifies the leading dimension of b as declared in the calling (sub)program. When Layout = CblasColMajor, ldb must be at least max(1, m); otherwise, ldb must be at least max(1, n).

beta

Specifies the scalar beta.

When beta is supplied as zero, then c need not be set on input.

c

For Layout = CblasColMajor: array, size ldc*n. Before entry, the leading m-by-n part of the array c must contain the matrix C, except when beta is zero, in which case c need not be set on entry.

For Layout = CblasRowMajor: array, size ldc*m. Before entry, the leading n-by-m part of the array c must contain the matrix C, except when beta is zero, in which case c need not be set on entry.

ldc

Specifies the leading dimension of c as declared in the calling (sub)program. When Layout = CblasColMajor, ldc must be at least max(1, m); otherwise, ldc must be at least max(1, n).

Output Parameters

c

Overwritten by the m-by-n updated matrix.

cblas_?herk

Performs a Hermitian rank-k update.

Syntax

void cblas_cherk (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const CBLAS_TRANSPOSE trans, const MKL_INT n, const MKL_INT k, const float alpha, const void *a, const MKL_INT lda, const float beta, void *c, const MKL_INT ldc);

void cblas_zherk (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const CBLAS_TRANSPOSE trans, const MKL_INT n, const MKL_INT k, const double alpha, const void *a, const MKL_INT lda, const double beta, void *c, const MKL_INT ldc);

Include Files

• mkl.h

Description

The ?herk routines perform a rank-k matrix-matrix operation using a general matrix A and a Hermitian matrix C. The operation is defined as:

\[ C := \alpha A \bar{A}^T + \beta C, \]
\[ C := \alpha A^H A + \beta C, \]

where:
- \( \alpha \) and \( \beta \) are real scalars,
- \( C \) is an \( n \times n \) Hermitian matrix,
- \( A \) is an \( n \times k \) matrix in the first case and a \( k \times n \) matrix in the second case.

### Input Parameters

**Layout**

Specifies whether two-dimensional array storage is row-major (\texttt{CblasRowMajor}) or column-major (\texttt{CblasColMajor}).

**uplo**

Specifies whether the upper or lower triangular part of the array \( c \) is used.
- If \( \text{uplo} = \text{CblasUpper} \), then the upper triangular part of the array \( c \) is used.
- If \( \text{uplo} = \text{CblasLower} \), then the lower triangular part of the array \( c \) is used.

**trans**

Specifies the operation:
- If \( \text{trans} = \text{CblasNoTrans} \), then \( C := \alpha A^H A + \beta C \);
- If \( \text{trans} = \text{CblasConjTrans} \), then \( C := \alpha A^H A + \beta C \).

**n**

Specifies the order of the matrix \( C \). The value of \( n \) must be at least zero.

**k**

With \( \text{trans} = \text{CblasNoTrans} \), \( k \) specifies the number of columns of the matrix \( A \), and with \( \text{trans} = \text{CblasConjTrans} \), \( k \) specifies the number of rows of the matrix \( A \).

The value of \( k \) must be at least zero.

**alpha**

Specifies the scalar \( \alpha \).

**a**

<td>( \max(1, k) )</td>
<td>( \max(1, n) ).</td>
</tr>
</tbody>
</table>

\( beta \)

Specifies the scalar \( beta \).

\( c \)

Array, size \( ldc \) by \( n \).

Before entry with \( uplo = \) CblasUpper, the leading \( n \)-by-\( n \) upper triangular part of the array \( c \) must contain the upper triangular part of the Hermitian matrix and the strictly lower triangular part of \( c \) is not referenced.

Before entry with \( uplo = \) CblasLower, the leading \( n \)-by-\( n \) lower triangular part of the array \( c \) must contain the lower triangular part of the Hermitian matrix and the strictly upper triangular part of \( c \) is not referenced.

The imaginary parts of the diagonal elements need not be set, they are assumed to be zero.

\( ldc \)

Specifies the leading dimension of \( c \) as declared in the calling (sub)program. The value of \( ldc \) must be at least \( \max(1, n) \).

**Output Parameters**

\( c \)

With \( uplo = \) CblasUpper, the upper triangular part of the array \( c \) is overwritten by the upper triangular part of the updated matrix.

With \( uplo = \) CblasLower, the lower triangular part of the array \( c \) is overwritten by the lower triangular part of the updated matrix.

The imaginary parts of the diagonal elements are set to zero.

**cblas_\(_\!\!\_\!\!\_\!\!\_\)her2k**

Performs a Hermitian rank-2\( k \) update.

**Syntax**

```c
void cblas_cher2k (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const CBLAS_TRANSPOSE trans, const MKL_INT n, const MKL_INT k, const void *alpha, const void *a, const MKL_INT lda, const void *b, const MKL_INT ldb, const float beta, void *c, const MKL_INT ldc);
void cblas_zher2k (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const CBLAS_TRANSPOSE trans, const MKL_INT n, const MKL_INT k, const void *alpha, const void *a, const MKL_INT lda, const void *b, const MKL_INT ldb, const double beta, void *c, const MKL_INT ldc);
```

**Include Files**

- mkl.h

**Description**

The \(_\!\!\_\!\!\_\!\!\_\!\!\_\)her2k routines perform a rank-2\( k \) matrix-matrix operation using general matrices \( A \) and \( B \) and a Hermitian matrix \( C \). The operation is defined as

\[
C := alpha A B^H + \text{conjg}(alpha) B A^H + beta C
\]
or
\[
C := \alpha A^H B + \text{conjg}(\alpha) B^H A + \beta C
\]

where:
* \(\alpha\) is a scalar and \(\beta\) is a real scalar.
* \(C\) is an \(n\)-by-\(n\) Hermitian matrix.
* \(A\) and \(B\) are \(n\)-by-\(k\) matrices in the first case and \(k\)-by-\(n\) matrices in the second case.

**Input Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>

$c$ is an array, size $ldc$ by $n$. Before entry with $uplo = \text{CblasUpper}$, the leading $n$-by-$n$ upper triangular part of the array $c$ must contain the upper triangular part of the Hermitian matrix and the strictly lower triangular part of $c$ is not referenced.

Before entry with $uplo = \text{CblasLower}$, the leading $n$-by-$n$ lower triangular part of the array $c$ must contain the lower triangular part of the Hermitian matrix and the strictly upper triangular part of $c$ is not referenced.

The imaginary parts of the diagonal elements need not be set, they are assumed to be zero.

$ldc$ specifies the leading dimension of $c$ as declared in the calling (sub)program. The value of $ldc$ must be at least $\max(1, n)$.
Output Parameters

`c`

With `uplo = CblasUpper`, the upper triangular part of the array `c` is overwritten by the upper triangular part of the updated matrix.

With `uplo = CblasLower`, the lower triangular part of the array `c` is overwritten by the lower triangular part of the updated matrix.

The imaginary parts of the diagonal elements are set to zero.

### cblas_?symm

Computes a matrix-matrix product where one input matrix is symmetric.

#### Syntax

```c
void cblas_ssymm (const CBLAS_LAYOUT Layout, const CBLAS_SIDE side, const CBLAS_UPLO uplo, const MKL_INT m, const MKL_INT n, const float alpha, const float *a, const MKL_INT lda, const float *b, const MKL_INT ldb, const float beta, float *c, const MKL_INT ldc);
void cblas_dsymm (const CBLAS_LAYOUT Layout, const CBLAS_SIDE side, const CBLAS_UPLO uplo, const MKL_INT m, const MKL_INT n, const double alpha, const double *a, const MKL_INT lda, const double *b, const MKL_INT ldb, const double beta, double *c, const MKL_INT ldc);
void cblas_csymm (const CBLAS_LAYOUT Layout, const CBLAS_SIDE side, const CBLAS_UPLO uplo, const MKL_INT m, const MKL_INT n, const void *alpha, const void *a, const MKL_INT lda, const void *b, const MKL_INT ldb, const void *beta, void *c, const MKL_INT ldc);
void cblas_zsymm (const CBLAS_LAYOUT Layout, const CBLAS_SIDE side, const CBLAS_UPLO uplo, const MKL_INT m, const MKL_INT n, const void *alpha, const void *a, const MKL_INT lda, const void *b, const MKL_INT ldb, const void *beta, void *c, const MKL_INT ldc);
```

#### Include Files

- mkl.h

#### Description

The `?symm` routines compute a scalar-matrix-matrix product with one symmetric matrix and add the result to a scalar-matrix product. The operation is defined as

\[ C := \alpha A B + \beta C, \]

or

\[ C := \alpha B A + \beta C, \]

where:

- `alpha` and `beta` are scalars,
- `A` is a symmetric matrix,
- `B` and `C` are `m`-by-`n` matrices.

#### Input Parameters

`Layout`

Specifies whether two-dimensional array storage is row-major (`CblasRowMajor`) or column-major (`CblasColMajor`).
Specifies whether the symmetric matrix $A$ appears on the left or right in the operation:

- If $side = \text{CblasLeft}$, then $C := \alpha A^T B + \beta C$;
- If $side = \text{CblasRight}$, then $C := \alpha B^T A + \beta C$.

Specifies whether the upper or lower triangular part of the symmetric matrix $A$ is used:

- If $uplo = \text{CblasUpper}$, then the upper triangular part is used;
- If $uplo = \text{CblasLower}$, then the lower triangular part is used.

Specifies the number of rows of the matrix $C$.

The value of $m$ must be at least zero.

Specifies the number of columns of the matrix $C$.

The value of $n$ must be at least zero.

Specifies the scalar $\alpha$.

Array, size $lda \times ka$, where $ka$ is $m$ when $side = \text{CblasLeft}$ and is $n$ otherwise.

Before entry with $side = \text{CblasLeft}$, the $m$-by-$m$ part of the array $a$ must contain the symmetric matrix, such that when $uplo = \text{CblasUpper}$, the leading $m$-by-$m$ upper triangular part of the array $a$ must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of $a$ is not referenced, and when $side = \text{CblasLeft}$, the leading $m$-by-$m$ lower triangular part of the array $a$ must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of $a$ is not referenced.

Before entry with $side = \text{CblasRight}$, the $n$-by-$n$ part of the array $a$ must contain the symmetric matrix, such that when $uplo = \text{CblasUpper}$, the array $a$ must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of $a$ is not referenced, and when $side = \text{CblasLeft}$, the leading $n$-by-$n$ lower triangular part of the array $a$ must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of $a$ is not referenced.

Specifies the leading dimension of $a$ as declared in the calling (sub)program. When $side = \text{CblasLeft}$ then $lda$ must be at least $\max(1, m)$, otherwise $lda$ must be at least $\max(1, n)$.

For $Layout = \text{CblasColMajor}$: array, size $ldb \times n$. The leading $m$-by-$n$ part of the array $b$ must contain the matrix $B$.

For $Layout = \text{CblasRowMajor}$: array, size $ldb \times m$. The leading $n$-by-$m$ part of the array $b$ must contain the matrix $B$.

Specifies the leading dimension of $b$ as declared in the calling (sub)program. When $Layout = \text{CblasColMajor}$, $ldb$ must be at least $\max(1, m)$; otherwise, $ldb$ must be at least $\max(1, n)$.

Specifies the scalar $\beta$.

When $\beta$ is set to zero, then $C$ need not be set on input.
cblas_syrk
Performs a symmetric rank-k update.

Syntax

```c
void cblas_ssyrk (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo,
const CBLAS_TRANSPOSE trans, const MKL_INT n, const MKL_INT k, const float alpha, const float *a, const MKL_INT lda, const float beta, float *c, const MKL_INT ldc);
```

```c
void cblas_dsyrk (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const MKL_INT n, const MKL_INT k, const double alpha, const
double *a, const MKL_INT lda, const double beta, double *c, const MKL_INT ldc);
```

```c
void cblas_csyrk (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const MKL_INT n, const MKL_INT k, const void *alpha, const void
*a, const MKL_INT lda, const void *beta, void *c, const MKL_INT ldc);
```

```c
void cblas_zsyrk (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const MKL_INT n, const MKL_INT k, const void *alpha, const void
*a, const MKL_INT lda, const void *beta, void *c, const MKL_INT ldc);
```

Include Files

- mkl.h

Description

The ?syrk routines perform a rank-k matrix-matrix operation for a symmetric matrix \( C \) using a general
matrix \( A \). The operation is defined as:

\[
C := \alpha A A' + \beta C,
\]

or

\[
C := \alpha A' A + \beta C,
\]

where:

- \( \alpha \) and \( \beta \) are scalars,
- \( C \) is an \( n \)-by-\( n \) symmetric matrix,
- \( A \) is an \( n \)-by-\( k \) matrix in the first case and a \( k \)-by-\( n \) matrix in the second case.
Input Parameters

**Layout**
Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).

**uplo**
Specifies whether the upper or lower triangular part of the array \( c \) is used.
If \( \text{uplo} = \text{CblasUpper} \), then the upper triangular part of the array \( c \) is used.
If \( \text{uplo} = \text{CblasLower} \), then the lower triangular part of the array \( c \) is used.

**trans**
Specifies the operation:
if \( \text{trans} = \text{CblasNoTrans} \), then \( C := \alpha A A' + \beta C \);
if \( \text{trans} = \text{CblasTrans} \), then \( C := \alpha A'^* A + \beta C \);
if \( \text{trans} = \text{CblasConjTrans} \), then \( C := \alpha A'^* A + \beta C \).

**n**
Specifies the order of the matrix \( C \). The value of \( n \) must be at least zero.

**k**
On entry with \( \text{trans} = \text{CblasNoTrans} \), \( k \) specifies the number of columns of the matrix \( A \), and on entry with \( \text{trans} = \text{CblasTrans} \) or \( \text{trans} = \text{CblasConjTrans} \), \( k \) specifies the number of rows of the matrix \( A \).
The value of \( k \) must be at least zero.

**alpha**
Specifies the scalar \( \alpha \).

**a**
Array, size \( \text{lda}*k \), where \( k \) is \( k \) when \( \text{trans} = \text{CblasNoTrans} \), and is \( n \) otherwise. Before entry with \( \text{trans} = \text{CblasNoTrans} \), the leading \( n \)-by-\( k \) part of the array \( a \) must contain the matrix \( A \), otherwise the leading \( k \)-by-\( n \) part of the array \( a \) must contain the matrix \( A \).

<table>
<thead>
<tr>
<th>Layout = CblasColMajor</th>
<th>Layout = CblasRowMajor</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array, size ( \text{lda}*k ). Before entry, the leading ( n )-by-( k ) part of the array ( a ) must contain the matrix ( A ).</td>
<td>Array, size ( \text{lda}*n ). Before entry, the leading ( k )-by-( n ) part of the array ( a ) must contain the matrix ( A ).</td>
</tr>
</tbody>
</table>

**lda**

<table>
<thead>
<tr>
<th>Layout = CblasColMajor</th>
<th>Layout = CblasRowMajor</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \text{lda} ) must be at least ( \max(1, n) ).</td>
<td>( \text{lda} ) must be at least ( \max(1, k) ).</td>
</tr>
<tr>
<td>( \text{lda} ) must be at least ( \max(1, k) ).</td>
<td>( \text{lda} ) must be at least ( \max(1, n) ).</td>
</tr>
</tbody>
</table>
\( \beta \)

Specifies the scalar \( \beta \).

\( c \)

Array, size \( \text{ldc} \times n \). Before entry with \( \text{uplo} = \text{CblasUpper} \), the leading \( n \)-by-\( n \) upper triangular part of the array \( c \) must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of \( c \) is not referenced.

Before entry with \( \text{uplo} = \text{CblasLower} \), the leading \( n \)-by-\( n \) lower triangular part of the array \( c \) must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of \( c \) is not referenced.

\( \text{ldc} \)

Specifies the leading dimension of \( c \) as declared in the calling (sub)program. The value of \( \text{ldc} \) must be at least \( \max(1, n) \).

**Output Parameters**

\( c \)

With \( \text{uplo} = \text{CblasUpper} \), the upper triangular part of the array \( c \) is overwritten by the upper triangular part of the updated matrix.

With \( \text{uplo} = \text{CblasLower} \), the lower triangular part of the array \( c \) is overwritten by the lower triangular part of the updated matrix.

**cblas_\textcolor{red}{?}sy\textcolor{red}{r}2k**

**Performs a symmetric rank-2k update.**

**Syntax**

```c
void cblas_ssyr2k (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const CBLAS_TRANSPOSE trans, const MKL_INT n, const MKL_INT k, const float alpha, const float *a, const MKL_INT lda, const float *b, const MKL_INT ldb, const float beta, float *c, const MKL_INT ldc);
void cblas_dsyr2k (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const CBLAS_TRANSPOSE trans, const MKL_INT n, const MKL_INT k, const double alpha, const double *a, const MKL_INT lda, const double *b, const MKL_INT ldb, const double beta, double *c, const MKL_INT ldc);
void cblas_csyr2k (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const CBLAS_TRANSPOSE trans, const MKL_INT n, const MKL_INT k, const void *alpha, const void *a, const MKL_INT lda, const void *b, const MKL_INT ldb, const void *beta, void *c, const MKL_INT ldc);
void cblas_zsyr2k (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const CBLAS_TRANSPOSE trans, const MKL_INT n, const MKL_INT k, const void *alpha, const void *a, const MKL_INT lda, const void *b, const MKL_INT ldb, const void *beta, void *c, const MKL_INT ldc);
```

**Include Files**

- mkl.h

**Description**

The \( \textcolor{red}{?}\textcolor{red}{sy}2k \) routines perform a rank-2k matrix-matrix operation for a symmetric matrix \( C \) using general matrices \( A \) and \( B \). The operation is defined as:

\[
C := \alpha A B' + \alpha B' A' + \beta C,
\]
or
\[ C := \alpha A' B + \alpha B' A + \beta C, \]

where:

- \( \alpha \) and \( \beta \) are scalars,
- \( C \) is an \( n \times n \) symmetric matrix,
- \( A \) and \( B \) are \( n \times k \) matrices in the first case, and \( k \times n \) matrices in the second case.

**Input Parameters**

**Layout**

Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).

**uplo**

Specifies whether the upper or lower triangular part of the array \( c \) is used.

- If \( \text{uplo} = \text{CblasUpper} \), then the upper triangular part of the array \( c \) is used.
- If \( \text{uplo} = \text{CblasLower} \), then the lower triangular part of the array \( c \) is used.

**trans**

Specifies the operation:

- If \( \text{trans} = \text{CblasNoTrans} \), then \( C := \alpha A' B + \alpha B' A + \beta C \);
- If \( \text{trans} = \text{CblasTrans} \), then \( C := \alpha A' B + \alpha B' A + \beta C \);
- If \( \text{trans} = \text{CblasConjTrans} \), then \( C := \alpha A' B + \alpha B' A + \beta C \).

**n**

Specifies the order of the matrix \( C \). The value of \( n \) must be at least zero.

**k**

On entry with \( \text{trans} = \text{CblasNoTrans} \), \( k \) specifies the number of columns of the matrices \( A \) and \( B \), and on entry with \( \text{trans} = \text{CblasTrans} \) or \( \text{trans} = \text{CblasConjTrans} \), \( k \) specifies the number of rows of the matrices \( A \) and \( B \). The value of \( k \) must be at least zero.

**alpha**

Specifies the scalar \( \alpha \).

**a**

Specifies the two-dimensional array \( a \) as declared in the calling (sub)program.

<table>

### beta

Specifies the scalar \(beta\).

\(c\) Array, size \(ldc \times n\). Before entry with \(uplo = \text{CblasUpper}\), the leading \(n\)-by-\(n\) upper triangular part of the array \(c\) must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of \(c\) is not referenced.

Before entry with \(uplo = \text{CblasLower}\), the leading \(n\)-by-\(n\) lower triangular part of the array \(c\) must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of \(c\) is not referenced.

\(ldc\) Specifies the leading dimension of \(c\) as declared in the calling (sub)program. The value of \(ldc\) must be at least \(\max(1, n)\).

### Output Parameters

\(c\) With \(uplo = \text{CblasUpper}\), the upper triangular part of the array \(c\) is overwritten by the upper triangular part of the updated matrix.
With \( \text{uplo} = \text{CblasLower} \), the lower triangular part of the array \( c \) is overwritten by the lower triangular part of the updated matrix.

**cblas_?trmm**  
Computes a matrix-matrix product where one input matrix is triangular.

**Syntax**

void cblas_strmm (const CBLAS_LAYOUT Layout, const CBLAS_SIDE side, const CBLAS_UPLO uplo, const CBLAS_TRANSPOSE transa, const CBLAS_DIAG diag, const MKL_INT m, const MKL_INT n, const float alpha, const float *a, const MKL_INT lda, float *b, const MKL_INT ldb);

void cblas_dtrmm (const CBLAS_LAYOUT Layout, const CBLAS_SIDE side, const CBLAS_UPLO uplo, const CBLAS_TRANSPOSE transa, const CBLAS_DIAG diag, const MKL_INT m, const MKL_INT n, const double alpha, const double *a, const MKL_INT lda, double *b, const MKL_INT ldb);

void cblas_ctrmm (const CBLAS_LAYOUT Layout, const CBLAS_SIDE side, const CBLAS_UPLO uplo, const CBLAS_TRANSPOSE transa, const CBLAS_DIAG diag, const MKL_INT m, const MKL_INT n, const void *alpha, const void *a, const MKL_INT lda, void *b, const MKL_INT ldb);

void cblas_ztrmm (const CBLAS_LAYOUT Layout, const CBLAS_SIDE side, const CBLAS_UPLO uplo, const CBLAS_TRANSPOSE transa, const CBLAS_DIAG diag, const MKL_INT m, const MKL_INT n, const void *alpha, const void *a, const MKL_INT lda, void *b, const MKL_INT ldb);

**Include Files**

- mkl.h

**Description**

The \( ? \text{trmm} \) routines compute a scalar-matrix-matrix product with one triangular matrix. The operation is defined as

\[
B := \alpha \cdot \text{op}(A) \cdot B
\]

or

\[
B := \alpha \cdot B \cdot \text{op}(A)
\]

where:

- \( \alpha \) is a scalar,
- \( B \) is an \( m \)-by-\( n \) matrix,
- \( A \) is a unit, or non-unit, upper or lower triangular matrix

\( \text{op}(A) \) is one of \( \text{op}(A) = A \), \( \text{op}(A) = A' \), or \( \text{op}(A) = \text{conjg}(A') \).

**Input Parameters**

- **Layout** Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).
- **side** Specifies whether \( \text{op}(A) \) appears on the left or right of \( B \) in the operation:
if $side = \text{CblasLeft}$, then $B := \alpha \cdot \text{op}(A) \cdot B$;
if $side = \text{CblasRight}$, then $B := \alpha \cdot B \cdot \text{op}(A)$.

$\text{uplo}$
Specifies whether the matrix $A$ is upper or lower triangular.

$\text{uplo} = \text{CblasUpper}$
if $\text{uplo} = \text{CblasLower}$, then the matrix is lower triangular.

$\text{transa}$
Specifies the form of $\text{op}(A)$ used in the matrix multiplication:
if $\text{transa}=\text{CblasNoTrans}$, then $\text{op}(A) = A$;
if $\text{transa}=\text{CblasTrans}$, then $\text{op}(A) = A'$;
if $\text{transa}=\text{CblasConjTrans}$, then $\text{op}(A) = \text{conjg}(A')$.

$\text{diag}$
Specifies whether the matrix $A$ is unit triangular:
if $\text{diag} = \text{CblasUnit}$ then the matrix is unit triangular;
if $\text{diag} = \text{CblasNonUnit}$, then the matrix is not unit triangular.

$m$
Specifies the number of rows of $B$. The value of $m$ must be at least zero.

$n$
Specifies the number of columns of $B$. The value of $n$ must be at least zero.

$\alpha$
Specifies the scalar $\alpha$.
When $\alpha$ is zero, then $a$ is not referenced and $b$ need not be set before entry.

$a$
Array, size $lda$ by $k$, where $k$ is $m$ when $side = \text{CblasLeft}$ and is $n$ when $side = \text{CblasRight}$. Before entry with $\text{uplo} = \text{CblasUpper}$, the leading $k$ by $k$ upper triangular part of the array $a$ must contain the upper triangular matrix and the strictly lower triangular part of $a$ is not referenced.
Before entry with $\text{uplo} = \text{CblasLower}$, the leading $k$ by $k$ lower triangular part of the array $a$ must contain the lower triangular matrix and the strictly upper triangular part of $a$ is not referenced.
When $\text{diag} = \text{CblasUnit}$, the diagonal elements of $a$ are not referenced either, but are assumed to be unity.

$lda$
Specifies the leading dimension of $a$ as declared in the calling (sub)program. When $side = \text{CblasLeft}$, then $lda$ must be at least $\max(1, m)$, when $side = \text{CblasRight}$, then $lda$ must be at least $\max(1, n)$.

$b$
For Layout = CblasColMajor: array, size $ldb \cdot n$. Before entry, the leading $m$-by-$n$ part of the array $b$ must contain the matrix $B$.
For Layout = CblasRowMajor: array, size $ldb \cdot m$. Before entry, the leading $n$-by-$m$ part of the array $b$ must contain the matrix $B$.

$ldb$
Specifies the leading dimension of $b$ as declared in the calling (sub)program. When Layout = CblasColMajor, $ldb$ must be at least $\max(1, m)$; otherwise, $ldb$ must be at least $\max(1, n)$.

Output Parameters

$b$
Overwritten by the transformed matrix.
cblas_?trsm
Solves a triangular matrix equation.

Syntax
void cblas_strsm (const CBLAS_LAYOUT Layout, const CBLAS_SIDE side, const CBLAS_UPLO uplo, const CBLAS_TRANSPOSE transa, const CBLAS_DIAG diag, const MKL_INT m, const MKL_INT n, const float alpha, const float *a, const MKL_INT lda, float *b, const MKL_INT ldb);
void cblas_dtrsm (const CBLAS_LAYOUT Layout, const CBLAS_SIDE side, const CBLAS_UPLO uplo, const CBLAS_TRANSPOSE transa, const CBLAS_DIAG diag, const MKL_INT m, const MKL_INT n, const double alpha, const double *a, const MKL_INT lda, double *b, const MKL_INT ldb);
void cblas_ctrsm (const CBLAS_LAYOUT Layout, const CBLAS_SIDE side, const CBLAS_UPLO uplo, const CBLAS_TRANSPOSE transa, const CBLAS_DIAG diag, const MKL_INT m, const MKL_INT n, const void *alpha, const void *a, const MKL_INT lda, void *b, const MKL_INT ldb);
void cblas_ztrsm (const CBLAS_LAYOUT Layout, const CBLAS_SIDE side, const CBLAS_UPLO uplo, const CBLAS_TRANSPOSE transa, const CBLAS_DIAG diag, const MKL_INT m, const MKL_INT n, const void *alpha, const void *a, const MKL_INT lda, void *b, const MKL_INT ldb);

Include Files
• mkl.h

Description
The ?trsm routines solve one of the following matrix equations:

\[ \text{op}(A) \cdot X = \alpha \cdot B, \]

or

\[ X \cdot \text{op}(A) = \alpha \cdot B, \]

where:
\( \alpha \) is a scalar,
\( X \) and \( B \) are \( m \)-by-\( n \) matrices,
\( A \) is a unit, or non-unit, upper or lower triangular matrix, and
\( \text{op}(A) \) is one of \( \text{op}(A) = A, \text{op}(A) = A', \text{or} \text{op}(A) = \text{conjg}(A') \).

The matrix \( B \) is overwritten by the solution matrix \( X \).

Input Parameters

- **Layout**
  Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).

- **side**
  Specifies whether \( \text{op}(A) \) appears on the left or right of \( X \) in the equation:
  if \( \text{side} = \text{CblasLeft} \), then \( \text{op}(A) \cdot X = \alpha \cdot B; \)
  if \( \text{side} = \text{CblasRight} \), then \( X \cdot \text{op}(A) = \alpha \cdot B. \)
Specifies whether the matrix $A$ is upper or lower triangular.

$uplo = \text{CblasUpper}$

if $uplo = \text{CblasLower}$, then the matrix is lower triangular.

Specifies the form of $\text{op}(A)$ used in the matrix multiplication:

if $transa = \text{CblasNoTrans}$, then $\text{op}(A) = A$;

if $transa = \text{CblasTrans}$;

if $transa = \text{CblasConjTrans}$, then $\text{op}(A) = \text{conjg}(A')$.

Specifies whether the matrix $A$ is unit triangular:

if $diag = \text{CblasUnit}$ then the matrix is unit triangular;

if $diag = \text{CblasNonUnit}$, then the matrix is not unit triangular.

Specifies the number of rows of $B$. The value of $m$ must be at least zero.

Specifies the number of columns of $B$. The value of $n$ must be at least zero.

Specifies the scalar $\alpha$.

When $\alpha$ is zero, then $a$ is not referenced and $b$ need not be set before entry.

Array, size $lda \times k$, where $k$ is $m$ when $side = \text{CblasLeft}$ and is $n$ when $side = \text{CblasRight}$. Before entry with $uplo = \text{CblasUpper}$, the leading $k$ by $k$ upper triangular part of the array $a$ must contain the upper triangular matrix and the strictly lower triangular part of $a$ is not referenced.

Before entry with $uplo = \text{CblasLower}$ lower triangular part of the array $a$ must contain the lower triangular matrix and the strictly upper triangular part of $a$ is not referenced.

When $diag = \text{CblasUnit}$, the diagonal elements of $a$ are not referenced either, but are assumed to be unity.

Specifies the leading dimension of $a$ as declared in the calling (sub)program. When $side = \text{CblasLeft}$, then $lda$ must be at least $\max(1, m)$, when $side = \text{CblasRight}$, then $lda$ must be at least $\max(1, n)$.

For $Layout = \text{CblasColMajor}$: array, size $ldb \times n$. Before entry, the leading $m$-by-$n$ part of the array $b$ must contain the matrix $B$.

For $Layout = \text{CblasRowMajor}$: array, size $ldb \times m$. Before entry, the leading $n$-by-$m$ part of the array $b$ must contain the matrix $B$.

Specifies the leading dimension of $b$ as declared in the calling (sub)program. When $Layout = \text{CblasColMajor}$, $ldb$ must be at least $\max(1, m)$; otherwise, $ldb$ must be at least $\max(1, n)$.

**Output Parameters**

Overwritten by the solution matrix $X$. 

---

Intel® Math Kernel Library Developer Reference
Sparse BLAS Level 1 Routines

This section describes Sparse BLAS Level 1, an extension of BLAS Level 1 included in the Intel® Math Kernel Library beginning with the Intel® MKL release 2.1. Sparse BLAS Level 1 is a group of routines and functions that perform a number of common vector operations on sparse vectors stored in compressed form.

Sparse vectors are those in which the majority of elements are zeros. Sparse BLAS routines and functions are specially implemented to take advantage of vector sparsity. This allows you to achieve large savings in computer time and memory. If nz is the number of non-zero vector elements, the computer time taken by Sparse BLAS operations will be $O(nz)$.

Vector Arguments

Compressed sparse vectors. Let $a$ be a vector stored in an array, and assume that the only non-zero elements of $a$ are the following:

$$a[k_1], a[k_2], a[k_3] \ldots a[k_{nz}],$$

where $nz$ is the total number of non-zero elements in $a$.

In Sparse BLAS, this vector can be represented in compressed form by two arrays, $x$ (values) and $indx$ (indices). Each array has $nz$ elements:

$$x[0]=a[k_1], x[1]=a[k_2], \ldots x[nz-1]=a[k_{nz}],$$

$$indx[0]=k_1, indx[1]=k_2, \ldots indx[nz-1]=k_{nz}.$$ 

Thus, a sparse vector is fully determined by the triple ($nz$, $x$, $indx$). If you pass a negative or zero value of $nz$ to Sparse BLAS, the subroutines do not modify any arrays or variables.

Full-storage vectors. Sparse BLAS routines can also use a vector argument fully stored in a single array (a full-storage vector). If $y$ is a full-storage vector, its elements must be stored contiguously: the first element in $y[0]$, the second in $y[1]$, and so on. This corresponds to an increment $incy = 1$ in BLAS Level 1. No increment value for full-storage vectors is passed as an argument to Sparse BLAS routines or functions.

Naming Conventions for Sparse BLAS Routines

Similar to BLAS, the names of Sparse BLAS subprograms have prefixes that determine the data type involved: $s$ and $d$ for single- and double-precision real; $c$ and $z$ for single- and double-precision complex respectively.

If a Sparse BLAS routine is an extension of a "dense" one, the subprogram name is formed by appending the suffix $i$ (standing for indexed) to the name of the corresponding "dense" subprogram. For example, the Sparse BLAS routine $saxpyi$ corresponds to the BLAS routine $saxpy$, and the Sparse BLAS function $cdotci$ corresponds to the BLAS function $cdotc$.

Routines and Data Types

Routines and data types supported in the Intel® MKL implementation of Sparse BLAS are listed in Table “Sparse BLAS Routines and Their Data Types”.

<table>

BLAS Level 1 Routines That Can Work With Sparse Vectors

The following BLAS Level 1 routines will give correct results when you pass to them a compressed-form array \(x\) (with the increment \(\text{incx}=1\)):

<table>
<thead>
<tr>
<th>Routine</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cblas_?asum</td>
<td>sum of absolute values of vector elements</td>
</tr>
<tr>
<td>cblas_?copy</td>
<td>copying a vector</td>
</tr>
<tr>
<td>cblas_?nrm2</td>
<td>Euclidean norm of a vector</td>
</tr>
<tr>
<td>cblas_?scal</td>
<td>scaling a vector</td>
</tr>
<tr>
<td>cblas_i?amax</td>
<td>index of the element with the largest absolute value for real flavors, or the largest sum (</td>
</tr>
<tr>
<td>cblas_i?amin</td>
<td>index of the element with the smallest absolute value for real flavors, or the smallest sum (</td>
</tr>
</tbody>
</table>

The result \(i\) returned by \(i?amax\) and \(i?amin\) should be interpreted as index in the compressed-form array, so that the largest (smallest) value is \(x[i-1]\); the corresponding index in full-storage array is \(\text{indx}[i-1]\).

You can also call \(\text{cblas}_?\text{rotg}\) to compute the parameters of Givens rotation and then pass these parameters to the Sparse BLAS routines \(\text{cblas}_?\text{roti}\).

cblas_?axpyi

_Adds a scalar multiple of compressed sparse vector to a full-storage vector._

Syntax

```c
void cblas_saxpyi (const MKL_INT nz, const float a, const float *x, const MKL_INT *indx, float *y);
void cblas_daxpyi (const MKL_INT nz, const double a, const double *x, const MKL_INT *indx, double *y);
void cblas_caxpyi (const MKL_INT nz, const void *a, const void *x, const MKL_INT *indx, void *y);
void cblas_zaxpyi (const MKL_INT nz, const void *a, const void *x, const MKL_INT *indx, void *y);
```
Include Files

- mkl.h

Description

The `?axpyi` routines perform a vector-vector operation defined as

\[ y := a \cdot x + y \]

where:
- \( a \) is a scalar,
- \( x \) is a sparse vector stored in compressed form,
- \( y \) is a vector in full storage form.

The `?axpyi` routines reference or modify only the elements of \( y \) whose indices are listed in the array \( indx \).

The values in \( indx \) must be distinct.

Input Parameters

- \( nz \) The number of elements in \( x \) and \( indx \).
- \( a \) Specifies the scalar \( a \).
- \( x \) Array, size at least \( nz \).
- \( indx \) Specifies the indices for the elements of \( x \).
  Array, size at least \( nz \).
- \( y \) Array, size at least \( \max(indx[i]) \).

Output Parameters

- \( y \) Contains the updated vector \( y \).

**cblas_?doti**

*Computes the dot product of a compressed sparse real vector by a full-storage real vector.*

Syntax

```c
float cblas_sdoti (const MKL_INT nz, const float *x, const MKL_INT *indx, const float *y);
double cblas_ddoti (const MKL_INT nz, const double *x, const MKL_INT *indx, const double *y);
```

Include Files

- mkl.h

Description

The `?doti` routines return the dot product of \( x \) and \( y \) defined as

\[ \text{res} = x[0]y[indx[0]] + x[1]y[indx[1]] + \ldots + x[nz-1]y[indx[nz-1]] \]
where the triple \((nz, x, indx)\) defines a sparse real vector stored in compressed form, and \(y\) is a real vector in full storage form. The functions reference only the elements of \(y\) whose indices are listed in the array \(indx\). The values in \(indx\) must be distinct.

**Input Parameters**

- \(nz\) The number of elements in \(x\) and \(indx\).
- \(x\) Array, size at least \(nz\).
- \(indx\) Specifies the indices for the elements of \(x\). Array, size at least \(nz\).
- \(y\) Array, size at least \(\max(indx[i])\).

**Output Parameters**

- \(res\) Contains the dot product of \(x\) and \(y\), if \(nz\) is positive. Otherwise, \(res\) contains 0.

**cblas_?dotci**

*Computes the conjugated dot product of a compressed sparse complex vector with a full-storage complex vector.*

**Syntax**

```c
void cblas_cdotci_sub (const MKL_INT nz, const void *x, const MKL_INT *indx, const void *y, void *dotui);
void cblas_zdotci_sub (const MKL_INT nz, const void *x, const MKL_INT *indx, const void *y, void *dotui);
```

**Include Files**

- mkl.h

**Description**

The ?dotci routines return the dot product of \(x\) and \(y\) defined as

\[
\text{conjg}(x[0])y[indx[0]] + \ldots + \text{conjg}(x[nz-1])y[indx[nz-1]]
\]

where the triple \((nz, x, indx)\) defines a sparse complex vector stored in compressed form, and \(y\) is a real vector in full storage form. The functions reference only the elements of \(y\) whose indices are listed in the array \(indx\). The values in \(indx\) must be distinct.

**Input Parameters**

- \(nz\) The number of elements in \(x\) and \(indx\).
- \(x\) Array, size at least \(nz\).
- \(indx\) Specifies the indices for the elements of \(x\). Array, size at least \(nz\).
- \(y\) Array, size at least \(\max(indx[i])\).
Output Parameters

\textit{dotui} 

Contains the conjugated dot product of \textit{x} and \textit{y}, if \textit{nz} is positive. Otherwise, it contains 0.

\textbf{cblas\textunderscore ?dotui}

\textit{Computes the dot product of a compressed sparse complex vector by a full-storage complex vector.}

\textbf{Syntax}

\begin{verbatim}
void cblas_cdotui_sub (const MKL_INT nz, const void *x, const MKL_INT *indx, const void *y, void *dotui);
void cblas_zdotui_sub (const MKL_INT nz, const void *x, const MKL_INT *indx, const void *y, void *dotui);
\end{verbatim}

\textbf{Include Files}

- mkl.h

\textbf{Description}

The \textit{?dotui} routines return the dot product of \textit{x} and \textit{y} defined as

\[ \text{res} = x[0] \times y[\text{indx}[0]] + x[1] \times y(\text{indx}[1]) + \ldots + x[nz - 1] \times y(\text{indx}[nz - 1]) \]

where the triple (\textit{nz}, \textit{x}, \textit{indx}) defines a sparse complex vector stored in compressed form, and \textit{y} is a real vector in full storage form. The functions reference only the elements of \textit{y} whose indices are listed in the array \textit{indx}. The values in \textit{indx} must be distinct.

\textbf{Input Parameters}

\begin{itemize}
  \item \textit{nz} 
    The number of elements in \textit{x} and \textit{indx}.
  \item \textit{x} 
    Array, size at least \textit{nz}.
  \item \textit{indx} 
    Specifies the indices for the elements of \textit{x}.
    Array, size at least \textit{nz}.
  \item \textit{y} 
    Array, size at least max(\textit{indx}[j]).
\end{itemize}

\textbf{Output Parameters}

\begin{itemize}
  \item \textit{dotui} 
    Contains the dot product of \textit{x} and \textit{y}, if \textit{nz} is positive. Otherwise, \textit{res} contains 0.
\end{itemize}

\textbf{cblas\textunderscore ?gthr}

\textit{Gathers a full-storage sparse vector’s elements into compressed form.}

\textbf{Syntax}

\begin{verbatim}
void cblas_sgthr (const MKL_INT nz, const float *y, float *x, const MKL_INT *indx);
void cblas_dgthr (const MKL_INT nz, const double *y, double *x, const MKL_INT *indx);
\end{verbatim}
void cblas_cgthr (const MKL_INT nz, const void *y, void *x, const MKL_INT *indx);
void cblas_zgthr (const MKL_INT nz, const void *y, void *x, const MKL_INT *indx);

Include Files
• mkl.h

Description
The ?gthr routines gather the specified elements of a full-storage sparse vector y into compressed form (nz, x, indx). The routines reference only the elements of y whose indices are listed in the array indx:
\[ x[i] = y[indx[i]], \text{ for } i=0,1,\ldots,nz-1. \]

Input Parameters
\begin{itemize}
  \item \textit{nz} \hfill The number of elements of \textit{y} to be gathered.
  \item \textit{indx} \hfill Specifies indices of elements to be gathered.
    \begin{itemize}
      \item Array, size at least \textit{nz}.
    \end{itemize}
  \item \textit{y} \hfill Array, size at least \text{max(indx[i])}.
\end{itemize}

Output Parameters
\begin{itemize}
  \item \textit{x} \hfill Array, size at least \textit{nz}.
    \begin{itemize}
      \item Contains the vector converted to the compressed form.
    \end{itemize}
\end{itemize}

cblas_?gthrz
\textit{Gathers a sparse vector's elements into compressed form, replacing them by zeros.}

Syntax
void cblas_sgthrz (const MKL_INT nz, float *y, float *x, const MKL_INT *indx);
void cblas_dgthrz (const MKL_INT nz, double *y, double *x, const MKL_INT *indx);
void cblas_cgthrz (const MKL_INT nz, void *y, void *x, const MKL_INT *indx);
void cblas_zgthrz (const MKL_INT nz, void *y, void *x, const MKL_INT *indx);

Include Files
• mkl.h

Description
The ?gthrz routines gather the elements with indices specified by the array \textit{indx} from a full-storage vector \textit{y} into compressed form (\textit{nz}, \textit{x}, \textit{indx}) and overwrite the gathered elements of \textit{y} by zeros. Other elements of \textit{y} are not referenced or modified (see also ?gthr).

Input Parameters
\begin{itemize}
  \item \textit{nz} \hfill The number of elements of \textit{y} to be gathered.
  \item \textit{indx} \hfill Specifies indices of elements to be gathered.
\end{itemize}
Array, size at least \( nz \).

\( y \)

Array, size at least \( \max(\text{indx}[i]) \).

**Output Parameters**

\( x \)

Array, size at least \( nz \).

Contains the vector converted to the compressed form.

\( y \)

The updated vector \( y \).

**cblas_?roti**

Applies Givens rotation to sparse vectors one of which is in compressed form.

**Syntax**

```c
void cblas_sroti (const MKL_INT \( nz \), float *x, const MKL_INT *indx, float *y, const float c, const float s);
void cblas_droti (const MKL_INT \( nz \), double *x, const MKL_INT *indx, double *y, const double c, const double s);
```

**Include Files**

- mkl.h

**Description**

The \(?\text{roti}\) routines apply the Givens rotation to elements of two real vectors, \( x \) (in compressed form \( nz, x, \text{indx} \)) and \( y \) (in full storage form):

\[
\begin{align*}
    x[i] &= c*x[i] + s*y[\text{indx}[i]] \\
    y[\text{indx}[i]] &= c*y[\text{indx}[i]] - s*x[i]
\end{align*}
\]

The routines reference only the elements of \( y \) whose indices are listed in the array \( \text{indx} \). The values in \( \text{indx} \) must be distinct.

**Input Parameters**

- \( nz \)
  - The number of elements in \( x \) and \( \text{indx} \).
- \( x \)
  - Array, size at least \( nz \).
- \( \text{indx} \)
  - Specifies the indices for the elements of \( x \).
  - Array, size at least \( nz \).
- \( y \)
  - Array, size at least \( \max(\text{indx}[i]) \).
- \( c \)
  - A scalar.
- \( s \)
  - A scalar.

**Output Parameters**

- \( x \) and \( y \)
  - The updated arrays.
cblas_?sctr
Converts compressed sparse vectors into full storage form.

Syntax
void cblas_ssctr (const MKL_INT nz, const float *x, const MKL_INT *indx, float *y);
void cblas_dsctr (const MKL_INT nz, const double *x, const MKL_INT *indx, double *y);
void cblas_csctr (const MKL_INT nz, const void *x, const MKL_INT *indx, void *y);
void cblas_zsctr (const MKL_INT nz, const void *x, const MKL_INT *indx, void *y);

Include Files
• mkl.h

Description
The ?sctr routines scatter the elements of the compressed sparse vector \((nz, x, indx)\) to a full-storage vector \(y\). The routines modify only the elements of \(y\) whose indices are listed in the array \(indx\):
\[ y[indx[i]] = x[i], \text{for } i=0,1,...,nz-1. \]

Input Parameters
\(nz\) The number of elements of \(x\) to be scattered.
\(indx\) Specifies indices of elements to be scattered.
Array, size at least \(nz\).
\(x\) Array, size at least \(nz\).
Contains the vector to be converted to full-storage form.

Output Parameters
\(y\) Array, size at least \(\max(indx[i])\).
Contains the vector \(y\) with updated elements.

Sparse BLAS Level 2 and Level 3 Routines

NOTE The Intel® MKL Sparse BLAS Level 2 and Level 3 routines are deprecated. Use the corresponding routine from the Intel® MKL Inspector-executor Sparse BLAS interface as indicated in the description for each routine.

This section describes Sparse BLAS Level 2 and Level 3 routines included in the Intel® Math Kernel Library (Intel® MKL). Sparse BLAS Level 2 is a group of routines and functions that perform operations between a sparse matrix and dense vectors. Sparse BLAS Level 3 is a group of routines and functions that perform operations between a sparse matrix and dense matrices.

The terms and concepts required to understand the use of the Intel® MKL Sparse BLAS Level 2 and Level 3 routines are discussed in the Linear Solvers Basics appendix.
The Sparse BLAS routines can be useful to implement iterative methods for solving large sparse systems of equations or eigenvalue problems. For example, these routines can be considered as building blocks for Iterative Sparse Solvers based on Reverse Communication Interface (RCI ISS) described in the Chapter 8 of the manual.

Intel® MKL provides Sparse BLAS Level 2 and Level 3 routines with typical (or conventional) interface similar to the interface used in the NIST* Sparse BLAS library [Rem05].

Some software packages and libraries (the PARDISO* Solver used in Intel® MKL, Sparskit 2 [Saad94], the Compaq* Extended Math Library (CXML)[CXML01]) use different (early) variation of the compressed sparse row (CSR) format and support only Level 2 operations with simplified interfaces. Intel® MKL provides an additional set of Sparse BLAS Level 2 routines with similar simplified interfaces. Each of these routines operates only on a matrix of the fixed type.

The routines described in this section support both one-based indexing and zero-based indexing of the input data (see details in the section One-based and Zero-based Indexing).

### Naming Conventions in Sparse BLAS Level 2 and Level 3

Each Sparse BLAS Level 2 and Level 3 routine has a six- or eight-character base name preceded by the prefix mkl_ or mkl_cspblas_.

The routines with typical (conventional) interface have six-character base names in accordance with the template:

```
mkl_<character> <data> <operation>( )
```

The routines with simplified interfaces have eight-character base names in accordance with the templates:

```
mkl_<character> <data> <mtype> <operation>( )
```

for routines with one-based indexing; and

```
mkl_cspblas_<character> <data> <mtype> <operation>( )
```

for routines with zero-based indexing.

The <character> field indicates the data type:

- **s**: real, single precision
- **c**: complex, single precision
- **d**: real, double precision
- **z**: complex, double precision

The <data> field indicates the sparse matrix storage format (see section Sparse Matrix Storage Formats):

- **coo**: coordinate format
- **csr**: compressed sparse row format and its variations
- **csc**: compressed sparse column format and its variations
- **dia**: diagonal format
- **sky**: skyline storage format
- **bsr**: block sparse row format and its variations

The <operation> field indicates the type of operation:

- **mv**: matrix-vector product (Level 2)
- **mm**: matrix-matrix product (Level 3)
- **sv**: solving a single triangular system (Level 2)
The field `<mtype>` indicates the matrix type:
- `ge` sparse representation of a general matrix
- `sy` sparse representation of the upper or lower triangle of a symmetric matrix
- `tr` sparse representation of a triangular matrix

**Sparse Matrix Storage Formats for Sparse BLAS Routines**

The current version of Intel® MKL Sparse BLAS Level 2 and Level 3 routines support the following point entry [Duff86] storage formats for sparse matrices:
- *compressed sparse row* format (CSR) and its variations;
- *compressed sparse column* format (CSC);
- *coordinate* format;
- *diagonal* format;
- *skyline* storage format;

and one block entry storage format:
- *block sparse row* format (BSR) and its variations.

For more information see "Sparse Matrix Storage Formats" in Appendix A.

Intel® MKL provides auxiliary routines -matrix converters - that convert sparse matrix from one storage format to another.

**Routines and Supported Operations**

This section describes operations supported by the Intel® MKL Sparse BLAS Level 2 and Level 3 routines. The following notations are used here:
- \(A\) is a sparse matrix;
- \(B\) and \(C\) are dense matrices;
- \(D\) is a diagonal scaling matrix;
- \(x\) and \(y\) are dense vectors;
- \(\alpha\) and \(\beta\) are scalars;

\(\text{op}(A)\) is one of the possible operations:
- \(\text{op}(A) = A\);
- \(\text{op}(A) = A^T\) - transpose of \(A\);
- \(\text{op}(A) = A^H\) - conjugated transpose of \(A\).

\(\text{inv}(\text{op}(A))\) denotes the inverse of \(\text{op}(A)\).

The Intel® MKL Sparse BLAS Level 2 and Level 3 routines support the following operations:
- computing the vector product between a sparse matrix and a dense vector:
  \(y := \alpha \text{op}(A) x + \beta y\)
- solving a single triangular system:
  \(y := \alpha \text{inv}(\text{op}(A)) x\)
- computing a product between sparse matrix and dense matrix:
  \(C := \alpha \text{op}(A) B + \beta C\)
- solving a sparse triangular system with multiple right-hand sides:
  \(C := \alpha \text{inv}(\text{op}(A)) B\)
Intel® MKL provides an additional set of the Sparse BLAS Level 2 routines with simplified interfaces. Each of these routines operates on a matrix of the fixed type. The following operations are supported:

- computing the vector product between a sparse matrix and a dense vector (for general and symmetric matrices):
  \[ y := \text{op}(A) \cdot x \]
- solving a single triangular system (for triangular matrices):
  \[ y := \text{inv(op}(A) \cdot x \]

Matrix type is indicated by the field \(<mtype>\) in the routine name (see section Naming Conventions in Sparse BLAS Level 2 and Level 3).

**NOTE**
The routines with simplified interfaces support only four sparse matrix storage formats, specifically:
- CSR format in the 3-array variation accepted in the direct sparse solvers and in the CXML;
- diagonal format accepted in the CXML;
- coordinate format;
- BSR format in the 3-array variation.

Note that routines with both typical (conventional) and simplified interfaces use the same computational kernels that work with certain internal data structures.

The Intel® MKL Sparse BLAS Level 2 and Level 3 routines do not support in-place operations.

Complete list of all routines is given in the “Sparse BLAS Level 2 and Level 3 Routines”.

### Interface Consideration

#### One-Based and Zero-Based Indexing
The Intel® MKL Sparse BLAS Level 2 and Level 3 routines support one-based and zero-based indexing of data arrays.

Routines with typical interfaces support zero-based indexing for the following sparse data storage formats: CSR, CSC, BSR, and COO. Routines with simplified interfaces support zero based indexing for the following sparse data storage formats: CSR, BSR, and COO. See the complete list of Sparse BLAS Level 2 and Level 3 Routines.

The one-based indexing uses the convention of starting array indices at 1. The zero-based indexing uses the convention of starting array indices at 0. For example, indices of the 5-element array \(x\) can be presented in case of one-based indexing as follows:

Element index: 1 2 3 4 5
Element value: 1.0 5.0 7.0 8.0 9.0

and in case of zero-based indexing as follows:

Element index: 0 1 2 3 4
Element value: 1.0 5.0 7.0 8.0 9.0

The detailed descriptions of the one-based and zero-based variants of the sparse data storage formats are given in the "Sparse Matrix Storage Formats" in Appendix A.

Most parameters of the routines are identical for both one-based and zero-based indexing, but some of them have certain differences. The following table lists all these differences.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>One-based Indexing</th>
<th>Zero-based Indexing</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>val</strong></td>
<td>Array containing non-zero elements of the matrix ( A ), its length is ( \text{pntrb}[m] - \text{pntrb}[1] )</td>
<td>Array containing non-zero elements of the matrix ( A ), its length is ( \text{pntrb}[m-1] - \text{pntrb}[0] )</td>
</tr>
<tr>
<td><strong>pntrb</strong></td>
<td>Array of length ( m ). This array contains row indices, such that ( \text{pntrb}[i] - \text{pntrb}[i+1] ) is the first index of row ( i ) in the arrays ( \text{val} ) and ( \text{indx} )</td>
<td>Array of length ( m ). This array contains row indices, such that ( \text{pntrb}[i] - \text{pntrb}[0] ) is the first index of row ( i ) in the arrays ( \text{val} ) and ( \text{indx} )</td>
</tr>
<tr>
<td><strong>pntrc</strong></td>
<td>Array of length ( m ). This array contains row indices, such that ( \text{pntrc}[i] - \text{pntrc}[i+1] ) is the last index of row ( i ) in the arrays ( \text{val} ) and ( \text{indx} )</td>
<td>Array of length ( m ). This array contains row indices, such that ( \text{pntrc}[i] - \text{pntrc}[0] ) is the last index of row ( i ) in the arrays ( \text{val} ) and ( \text{indx} )</td>
</tr>
<tr>
<td><strong>ia</strong></td>
<td>Array of length ( m+1 ), containing indices of elements in the array ( A ), such that ( \text{ia}[i] ) is the index in the array ( A ) of the first non-zero element from the row ( i ). The value of the last element ( \text{ia}[m+1] ) is equal to the number of non-zeros plus one.</td>
<td>Array of length ( m+1 ), containing indices of elements in the array ( A ), such that ( \text{ia}[i] ) is the index in the array ( A ) of the first non-zero element from the row ( i ). The value of the last element ( \text{ia}[m] ) is equal to the number of non-zeros.</td>
</tr>
<tr>
<td><strong>ldb</strong></td>
<td>Specifies the leading dimension of ( B ) as declared in the calling (sub)program.</td>
<td>Specifies the second dimension of ( B ) as declared in the calling (sub)program.</td>
</tr>
<tr>
<td><strong>ldc</strong></td>
<td>Specifies the leading dimension of ( C ) as declared in the calling (sub)program.</td>
<td>Specifies the second dimension of ( C ) as declared in the calling (sub)program.</td>
</tr>
</tbody>
</table>

**Differences Between Intel MKL and NIST* Interfaces**

The Intel® MKL Sparse BLAS Level 3 routines have the following conventional interfaces:

\[
mkl_{\text{xyyym}}(\text{transa}, m, n, k, \alpha, \text{matdescra}, \text{arg}(A), b, \text{ldb}, \beta, c, \text{ldc}), \text{for matrix-matrix product};
\]

\[
mkl_{\text{xyyysm}}(\text{transa}, m, n, \alpha, \text{matdescra}, \text{arg}(A), b, \text{ldb}, c, \text{ldc}), \text{for triangular solvers with multiple right-hand sides}.
\]

Here \( x \) denotes data type, and \( yyy \) - sparse matrix data structure (storage format).

The analogous NIST* Sparse BLAS (NSB) library routines have the following interfaces:

\[
x_{\text{yysm}}(\text{transa}, m, n, k, \alpha, \text{descra}, \text{arg}(A), b, \text{ldb}, \beta, c, \text{ldc}, \text{work}, lwork), \text{for matrix-matrix product};
\]

\[
x_{\text{yyysm}}(\text{transa}, m, n, \text{unitd}, dv, \alpha, \text{descra}, \text{arg}(A), b, \text{ldb}, \beta, c, \text{ldc}, \text{work}, lwork), \text{for triangular solvers with multiple right-hand sides}.
\]

Some similar arguments are used in both libraries. The argument \( \text{transa} \) indicates what operation is performed and is slightly different in the NSB library (see Table "Parameter transa"). The arguments \( m \) and \( k \) are the number of rows and column in the matrix \( A \), respectively. \( n \) is the number of columns in the matrix \( C \). The arguments \( \alpha \) and \( \beta \) are scalar \( \alpha \) and \( \beta \) respectively (\( \beta \) not used in the Intel® MKL triangular solvers.) The arguments \( b \) and \( c \) are rectangular arrays with the leading dimension \( \text{ldb} \) and \( \text{ldc} \), respectively. \( \text{arg}(A) \) denotes the list of arguments that describe the sparse representation of \( A \).
**Parameter transa**

</tr>
</tbody>
</table>

**Parameter matdescra**

The parameter `matdescra` describes the relevant characteristic of the matrix \( A \). This manual describes `matdescra` as an array of six elements in line with the NIST* implementation. However, only the first four elements of the array are used in the current versions of the Intel® MKL Sparse BLAS routines. Elements `matdescra[4]` and `matdescra[5]` are reserved for future use. Note that whether `matdescra` is described in your application as an array of length 6 or 4 is of no importance because the array is declared as a pointer in the Intel® MKL routines. To learn more about declaration of the `matdescra` array, see the Sparse BLAS examples located in the Intel® MKL installation directory: examples/spblasc/ for C. The table below lists elements of the parameter `matdescra`, their Fortran values, and their meanings. The parameter `matdescra` corresponds to the argument `descra` from NSB library.

### Possible Values of the Parameter `matdescra [desca - 1]`

</tbody>
</table>

For a matrix in the skyline format with the main diagonal declared to be a unit, diagonal elements must be stored in the sparse representation even if they are zero. In all other formats, diagonal elements can be stored (if needed) in the sparse representation if they are not zero.

**Operations with Partial Matrices**

One of the distinctive feature of the Intel® MKL Sparse BLAS routines is a possibility to perform operations only on partial matrices composed of certain parts (triangles and the main diagonal) of the input sparse matrix. It can be done by setting properly first three elements of the parameter matdescra.

An arbitrary sparse matrix \( A \) can be decomposed as

\[
A = L + D + U
\]

where \( L \) is the strict lower triangle of \( A \), \( U \) is the strict upper triangle of \( A \), \( D \) is the main diagonal.

Table "Output Matrices for Multiplication Routines" shows correspondence between the output matrices and values of the parameter matdescra for the sparse matrix \( A \) for multiplication routines.

**Simplified interface, zero-based indexing**

- **mkl_cspblas_?csrgemv**
  Computes matrix - vector product of a sparse general matrix in the CSR format (3-array variation) with zero-based indexing.

- **mkl_cspblas_?bsrgemv**
  Computes matrix - vector product of a sparse general matrix in the BSR format (3-array variation) with zero-based indexing.

- **mkl_cspblas_?coogemv**
  Computes matrix - vector product of a sparse general matrix in the coordinate format with zero-based indexing.

- **mkl_cspblas_?csrsymv**
  Computes matrix - vector product of a sparse symmetrical matrix in the CSR format (3-array variation) with zero-based indexing.

- **mkl_cspblas_?bsrsymv**
  Computes matrix - vector product of a sparse symmetrical matrix in the BSR format (3-array variation) with zero-based indexing.

- **mkl_cspblas_?coosymv**
  Computes matrix - vector product of a sparse symmetrical matrix in the coordinate format with zero-based indexing.

- **mkl_cspblas_?csrtrsv**
  Triangular solvers with simplified interface for a sparse matrix in the CSR format (3-array variation) with zero-based indexing.

- **mkl_cspblas_?bsrtrsv**
  Triangular solver with simplified interface for a sparse matrix in the BSR format (3-array variation) with zero-based indexing.

- **mkl_cspblas_?cootrsv**
  Triangular solver with simplified interface for a sparse matrix in the coordinate format with zero-based indexing.

**Typical (conventional) interface, one-based and zero-based indexing**

- **mkl_?csrmv**
  Computes matrix - vector product of a sparse matrix in the CSR format.

- **mkl_?bsrmv**
  Computes matrix - vector product of a sparse matrix in the BSR format.

- **mkl_?cscmv**
  Computes matrix - vector product of a sparse matrix in the CSC format.

- **mkl_?coomv**
  Computes matrix - vector product of a sparse matrix in the coordinate format.

- **mkl_?csrsrv**
  Solves a system of linear equations for a sparse matrix in the CSR format.

- **mkl_?bsrsrv**
  Solves a system of linear equations for a sparse matrix in the BSR format.

**mkl_?csrgemv**

*Computes matrix - vector product of a sparse general matrix stored in the CSR format (3-array variation) with one-based indexing (deprecated).*

**Syntax**

```c
void mkl_scsrgemv (const char *transa, const MKL_INT *m, const float *a, const MKL_INT *ia, const MKL_INT *ja, const float *x, float *y);
void mkl_dcsrgemv (const char *transa, const MKL_INT *m, const double *a, const MKL_INT *ia, const MKL_INT *ja, const double *x, double *y);
void mkl_ccsrgemv (const char *transa, const MKL_INT *m, const MKL_Complex8 *a, const MKL_INT *ia, const MKL_INT *ja, const MKL_Complex8 *x, MKL_Complex8 *y);
void mkl_zcsrgemv (const char *transa, const MKL_INT *m, const MKL_Complex16 *a, const MKL_INT *ia, const MKL_INT *ja, const MKL_Complex16 *x, MKL_Complex16 *y);
```

**Include Files**

- `mkl.h`

**Description**

This routine is deprecated. Use `mkl_sparse_?_mv` from the Intel® MKL Inspector-executor Sparse BLAS interface instead.

The `mkl_?csrgemv` routine performs a matrix-vector operation defined as

\[ y := A \cdot x \]
or

\[ y := A^T x, \]

where:

- \( x \) and \( y \) are vectors,
- \( A \) is an \( m \)-by-\( m \) sparse square matrix in the CSR format (3-array variation), \( A^T \) is the transpose of \( A \).

**NOTE**
This routine supports only one-based indexing of the input arrays.

### Input Parameters

- **transa**
  Specifies the operation.
  - If \( transa = 'N' \) or \('n' \), then \( y := A x \)
  - If \( transa = 'T' \) or \('t' \) or \('C' \) or \('c' \), then \( y := A^T x \)

- **m**
  Number of rows of the matrix \( A \).

- **a**
  Array containing non-zero elements of the matrix \( A \). Its length is equal to the number of non-zero elements in the matrix \( A \). Refer to \( values \) array description in Sparse Matrix Storage Formats for more details.

- **ia**
  Array of length \( m + 1 \), containing indices of elements in the array \( a \), such that \( ia[i] - ia[0] \) is the index in the array \( a \) of the first non-zero element from the row \( i \). The value of the last element \( ia[m] - ia[0] \) is equal to the number of non-zeros. Refer to \( rowIndex \) array description in Sparse Matrix Storage Formats for more details.

- **ja**
  Array containing the column indices plus one for each non-zero element of the matrix \( A \).
  Its length is equal to the length of the array \( a \). Refer to \( columns \) array description in Sparse Matrix Storage Formats for more details.

- **x**
  Array, size is \( m \).
  On entry, the array \( x \) must contain the vector \( x \).

### Output Parameters

- **y**
  Array, size at least \( m \).
  On exit, the array \( y \) must contain the vector \( y \).

**mkl_?bsrgemv**

Computes matrix - vector product of a sparse general matrix stored in the BSR format (3-array variation) with one-based indexing (deprecated).

**Syntax**

```c
void mkl_sbsrgemv (const char *transa, const MKL_INT *m, const MKL_INT *lb, const float *a, const MKL_INT *ia, const MKL_INT *ja, const float *x, float *y);
```
void mkl_dbsrgemv (const char *transa, const MKL_INT *m, const MKL_INT *lb, const double *a, const MKL_INT *ia, const MKL_INT *ja, const double *x, double *y);

void mkl_cbsrgemv (const char *transa, const MKL_INT *m, const MKL_INT *lb, const MKL_Complex8 *a, const MKL_INT *ia, const MKL_INT *ja, const MKL_Complex8 *x, MKL_Complex8 *y);

void mkl_zbsrgemv (const char *transa, const MKL_INT *m, const MKL_INT *lb, const MKL_Complex16 *a, const MKL_INT *ia, const MKL_INT *ja, const MKL_Complex16 *x, MKL_Complex16 *y);

Include Files

• mkl.h

Description

This routine is deprecated. Use mkl_sparse_?_mv from the Intel® MKL Inspector-executor Sparse BLAS interface instead.

The mkl_?bsrgemv routine performs a matrix-vector operation defined as

\[ y := A x \]

or

\[ y := A^T x, \]

where:

- \( x \) and \( y \) are vectors,
- \( A \) is an \( m \)-by-\( m \) block sparse square matrix in the BSR format (3-array variation), \( A^T \) is the transpose of \( A \).

**NOTE**

This routine supports only one-based indexing of the input arrays.

Input Parameters

- **transa**
  - Specifies the operation.
  - If \( transa = 'N' \) or \( 'n' \), then the matrix-vector product is computed as \( y := A x \).
  - If \( transa = 'T' \) or \( 't' \) or \( 'C' \) or \( 'c' \), then the matrix-vector product is computed as \( y := A^T x, \)

- **m**
  - Number of block rows of the matrix \( A \).

- **lb**
  - Size of the block in the matrix \( A \).

- **a**
  - Array containing elements of non-zero blocks of the matrix \( A \). Its length is equal to the number of non-zero blocks in the matrix \( A \) multiplied by \( lb \times lb \).
  - Refer to \textit{values} array description in BSR Format for more details.
Array of length \((m + 1)\), containing indices of block in the array \(a\), such that \(ia[i] - ia[0]\) is the index in the array \(a\) of the first non-zero element from the row \(i\). The value of the last element \(ia[m] - ia[0]\) is equal to the number of non-zero blocks. Refer to \(rowIndex\) array description in BSR Format for more details.

Array containing the column indices plus one for each non-zero block in the matrix \(A\).

Its length is equal to the number of non-zero blocks of the matrix \(A\). Refer to \(columns\) array description in BSR Format for more details.

Array, size \((m \times lb)\).

On entry, the array \(x\) must contain the vector \(x\).

Output Parameters

Array, size at least \((m \times lb)\).

On exit, the array \(y\) must contain the vector \(y\).

**mkl_?coogemv**

*Computes matrix-vector product of a sparse general matrix stored in the coordinate format with one-based indexing (deprecated).*

**Syntax**

```c
void mkl_scoogemv (const char *transa, const MKL_INT *m, const float *val, const MKL_INT *rowind, const MKL_INT *colind, const MKL_INT *nnz, const float *x, float *y);
void mkl_dcoogemv (const char *transa, const MKL_INT *m, const double *val, const MKL_INT *rowind, const MKL_INT *colind, const MKL_INT *nnz, const double *x, double *y);
void mkl_ccoogemv (const char *transa, const MKL_INT *m, const MKL_Complex8 *val, const MKL_INT *rowind, const MKL_INT *colind, const MKL_INT *nnz, const MKL_Complex8 *x, MKL_Complex8 *y);
void mkl_zcoogemv (const char *transa, const MKL_INT *m, const MKL_Complex16 *val, const MKL_INT *rowind, const MKL_INT *colind, const MKL_INT *nnz, const MKL_Complex16 *x, MKL_Complex16 *y);
```

**Include Files**

- mkl.h

**Description**

This routine is deprecated. Use mkl_sparse_?_mv from the Intel® MKL Inspector-executor Sparse BLAS interface instead.

The mkl_?coogemv routine performs a matrix-vector operation defined as

\[
y := A \times x
\]
or

\[ y := A^T x, \]

where:

- \( x \) and \( y \) are vectors,
- \( A \) is an \( m \)-by-\( m \) sparse square matrix in the coordinate format, \( A^T \) is the transpose of \( A \).

**NOTE**
This routine supports only one-based indexing of the input arrays.

**Input Parameters**

- **transa**
  Specifies the operation.
  - If `transa` = 'N' or 'n', then the matrix-vector product is computed as \( y := A x \)
  - If `transa` = 'T' or 't' or 'C' or 'c', then the matrix-vector product is computed as \( y := A^T x \)

- **m**
  Number of rows of the matrix \( A \).

- **val**
  Array of length \( nnz \), contains non-zero elements of the matrix \( A \) in the arbitrary order.
  Refer to `values` array description in Coordinate Format for more details.

- **rowind**
  Array of length \( nnz \), contains the row indices plus one for each non-zero element of the matrix \( A \).
  Refer to `rows` array description in Coordinate Format for more details.

- **colind**
  Array of length \( nnz \), contains the column indices plus one for each non-zero element of the matrix \( A \). Refer to `columns` array description in Coordinate Format for more details.

- **nnz**
  Specifies the number of non-zero element of the matrix \( A \).
  Refer to `nnz` description in Coordinate Format for more details.

- **x**
  Array, size is \( m \).
  One entry, the array \( x \) must contain the vector \( x \).

**Output Parameters**

- **y**
  Array, size at least \( m \).
  On exit, the array \( y \) must contain the vector \( y \).

**mkl_?diagemv**

Computes matrix - vector product of a sparse general matrix stored in the diagonal format with one-based indexing (deprecated).
Syntax

void mkl_sdiagemv (const char *transa, const MKL_INT *m, const float *val, const MKL_INT *lval, const MKL_INT *idiag, const MKL_INT *ndiag, const float *x, float *y);
void mkl_ddiagemv (const char *transa, const MKL_INT *m, const double *val, const MKL_INT *lval, const MKL_INT *idiag, const MKL_INT *ndiag, const double *x, double *y);
void mkl_cdiagemv (const char *transa, const MKL_INT *m, const MKL_Complex8 *val, const MKL_INT *lval, const MKL_INT *idiag, const MKL_INT *ndiag, const MKL_Complex8 *x, MKL_Complex8 *y);
void mkl_zdiagemv (const char *transa, const MKL_INT *m, const MKL_Complex16 *val, const MKL_INT *lval, const MKL_INT *idiag, const MKL_INT *ndiag, const MKL_Complex16 *x, MKL_Complex16 *y);

Include Files

• mkl.h

Description

This routine is deprecated. Use mkl_sparse_?_mv from the Intel® MKL Inspector-executor Sparse BLAS interface instead.

The mkl_?diagemv routine performs a matrix-vector operation defined as

\[ y := Ax \]

or

\[ y := A^T x, \]

where:

- \( x \) and \( y \) are vectors,
- \( A \) is an \( m \)-by-\( m \) sparse square matrix in the diagonal storage format, \( A^T \) is the transpose of \( A \).

**NOTE**

This routine supports only one-based indexing of the input arrays.

Input Parameters

**transa**

Specifies the operation.

- If \( \text{transa} = 'N' \) or \( 'n' \), then \( y := Ax \)
- If \( \text{transa} = 'T' \) or \( 't' \) or \( 'C' \) or \( 'c' \), then \( y := A^T x, \)

**m**

Number of rows of the matrix \( A \).

**val**

Two-dimensional array of size \( \text{lval} \times \text{ndiag} \), contains non-zero diagonals of the matrix \( A \). Refer to \text{values} array description in Diagonal Storage Scheme for more details.

**lval**

Leading dimension of \( \text{val} \). Refer to \text{lval} description in Diagonal Storage Scheme for more details.
idiag

Array of length ndiag, contains the distances between main diagonal and each non-zero diagonals in the matrix A.
Refer to distance array description in Diagonal Storage Scheme for more details.

ndiag

Specifies the number of non-zero diagonals of the matrix A.

x

Array, size is m.
On entry, the array x must contain the vector x.

Output Parameters

y

Array, size at least m.
On exit, the array y must contain the vector y.

mkl_?csrsymv

Computes matrix - vector product of a sparse symmetrical matrix stored in the CSR format (3-array variation) with one-based indexing (deprecated).

Syntax

void mkl_scsrsymv (const char *uplo , const MKL_INT *m , const float *a , const MKL_INT *ia , const MKL_INT *ja , const float *x , float *y);
void mkl_dcsrsymv (const char *uplo , const MKL_INT *m , const double *a , const MKL_INT *ia , const MKL_INT *ja , const double *x , double *y);
void mkl_ccsrsymv (const char *uplo , const MKL_INT *m , const MKL_Complex8 *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_Complex8 *x , MKL_Complex8 *y);
void mkl_zcsrsymv (const char *uplo , const MKL_INT *m , const MKL_Complex16 *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_Complex16 *x , MKL_Complex16 *y);

Include Files

• mkl.h

Description

This routine is deprecated. Use mkl_sparse_?_mv from the Intel® MKL Inspector-executor Sparse BLAS interface instead.

The mkl_?csrsymv routine performs a matrix-vector operation defined as

\[ y := A^T \cdot x \]

where:

\( x \) and \( y \) are vectors,

\( A \) is an upper or lower triangle of the symmetrical sparse matrix in the CSR format (3-array variation).

**NOTE**

This routine supports only one-based indexing of the input arrays.
Input Parameters

**uplo**

Specifies whether the upper or lower triangle of the matrix $A$ is used.

If $uplo = 'U$' or 'u', then the upper triangle of the matrix $A$ is used.

If $uplo = 'L'$ or 'l', then the lower triangle of the matrix $A$ is used.

**m**

Number of rows of the matrix $A$.

**a**

Array containing non-zero elements of the matrix $A$. Its length is equal to the number of non-zero elements in the matrix $A$. Refer to values array description in Sparse Matrix Storage Formats for more details.

**ia**

Array of length $m + 1$, containing indices of elements in the array $a$, such that $ia[i] - ia[0]$ is the index in the array $a$ of the first non-zero element from the row $i$. The value of the last element $ia[m] - ia[0]$ is equal to the number of non-zero elements. Refer to rowIndex array description in Sparse Matrix Storage Formats for more details.

**ja**

Array containing the column indices plus one for each non-zero element of the matrix $A$.

Its length is equal to the length of the array $a$. Refer to columns array description in Sparse Matrix Storage Formats for more details.

**x**

Array, size is $m$.

On entry, the array $x$ must contain the vector $x$.

Output Parameters

**y**

Array, size at least $m$.

On exit, the array $y$ must contain the vector $y$.

**mkl_?bsrsymv**

Computes matrix-vector product of a sparse symmetrical matrix stored in the BSR format (3-array variation) with one-based indexing (deprecated).

**Syntax**

```c
void mkl_sbsrsymv (const char *uplo, const MKL_INT *m, const MKL_INT *lb, const float *a, const MKL_INT *ia, const MKL_INT *ja, const float *x, float *y);
void mkl_dbsrsymv (const char *uplo, const MKL_INT *m, const MKL_INT *lb, const double *a, const MKL_INT *ia, const MKL_INT *ja, const double *x, double *y);
void mkl_cbsrsymv (const char *uplo, const MKL_INT *m, const MKL_INT *lb, const MKL_Complex8 *a, const MKL_INT *ia, const MKL_INT *ja, const MKL_Complex8 *x, MKL_Complex8 *y);
void mkl_zbsrsymv (const char *uplo, const MKL_INT *m, const MKL_INT *lb, const MKL_Complex16 *a, const MKL_INT *ia, const MKL_INT *ja, const MKL_Complex16 *x, MKL_Complex16 *y);
```
Include Files
- mkl.h

Description
This routine is deprecated. Use mkl_sparse_?_mv from the Intel® MKL Inspector-executor Sparse BLAS interface instead.

The mkl_?bsrsymv routine performs a matrix-vector operation defined as

\[ y := A \cdot x \]

where:
- \( x \) and \( y \) are vectors,
- \( A \) is an upper or lower triangle of the symmetrical sparse matrix in the BSR format (3-array variation).

**NOTE**
This routine supports only one-based indexing of the input arrays.

Input Parameters

- **uplo**
  Specifies whether the upper or low triangle of the matrix \( A \) is considered.
  - If \( \text{uplo} = 'U' \) or 'u', then the upper triangle of the matrix \( A \) is used.
  - If \( \text{uplo} = 'L' \) or 'l', then the low triangle of the matrix \( A \) is used.

- **m**
  Number of block rows of the matrix \( A \).

- **lb**
  Size of the block in the matrix \( A \).

- **a**
  Array containing elements of non-zero blocks of the matrix \( A \). Its length is equal to the number of non-zero blocks in the matrix \( A \) multiplied by \( lb \cdot lb \). Refer to values array description in BSR Format for more details.

- **ia**
  Array of length \((m + 1)\), containing indices of block in the array \( a \), such that \( ia[i] - ia[0] \) is the index in the array \( a \) of the first non-zero element from the row \( i \). The value of the last element \( ia[m] - ia[0] \) is equal to the number of non-zero blocks. Refer to rowIndex array description in BSR Format for more details.

- **ja**
  Array containing the column indices plus one for each non-zero block in the matrix \( A \).
  Its length is equal to the number of non-zero blocks of the matrix \( A \). Refer to columns array description in BSR Format for more details.

- **x**
  Array, size \((m \cdot lb)\).
  On entry, the array \( x \) must contain the vector \( x \).

Output Parameters

- **y**
  Array, size at least \((m \cdot lb)\).
On exit, the array $y$ must contain the vector $y$.

**mkl_?coosymv**

*Computes matrix - vector product of a sparse symmetrical matrix stored in the coordinate format with one-based indexing (deprecated).*

**Syntax**

```c
void mkl_scoosymv (const char *uplo , const MKL_INT *m , const float *val , const MKL_INT *rowind , const MKL_INT *colind , const MKL_INT *nnz , const float *x , float *y );
void mkl_dcoosymv (const char *uplo , const MKL_INT *m , const double *val , const MKL_INT *rowind , const MKL_INT *colind , const MKL_INT *nnz , const double *x , double *y );
void mkl_ccosymv (const char *uplo , const MKL_INT *m , const MKL_Complex8 *val , const MKL_INT *rowind , const MKL_INT *colind , const MKL_INT *nnz , const MKL_Complex8 *x , MKL_Complex8 *y );
void mkl_zcoosymv (const char *uplo , const MKL_INT *m , const MKL_Complex16 *val , const MKL_INT *rowind , const MKL_INT *colind , const MKL_INT *nnz , const MKL_Complex16 *x , MKL_Complex16 *y );
```

**Include Files**

- mkl.h

**Description**

This routine is deprecated. Use mkl_sparse_?_mv from the Intel® MKL Inspector-executor Sparse BLAS interface instead.

The **mkl_?coosymv** routine performs a matrix-vector operation defined as

$$ y := A \times x $$

where:

- $x$ and $y$ are vectors,
- $A$ is an upper or lower triangle of the symmetrical sparse matrix in the coordinate format.

**NOTE**

This routine supports only one-based indexing of the input arrays.

**Input Parameters**

- **uplo**
  - Specifies whether the upper or low triangle of the matrix $A$ is used.
  - If $uplo = 'U' \ or \ 'u'$, then the upper triangle of the matrix $A$ is used.
  - If $uplo = 'L' \ or \ 'l'$, then the low triangle of the matrix $A$ is used.

- **m**
  - Number of rows of the matrix $A$. 
val

Array of length \(\text{nnz}\), contains non-zero elements of the matrix \(A\) in the arbitrary order.

Refer to values array description in Coordinate Format for more details.

rowind

Array of length \(\text{nnz}\), contains the row indices plus one for each non-zero element of the matrix \(A\).

Refer to rows array description in Coordinate Format for more details.

colin

Array of length \(\text{nnz}\), contains the column indices plus one for each non-zero element of the matrix \(A\). Refer to columns array description in Coordinate Format for more details.

\(\text{nnz}\)

Specifies the number of non-zero element of the matrix \(A\).

Refer to \(\text{nnz}\) description in Coordinate Format for more details.

\(x\)

Array, size is \(m\).

On entry, the array \(x\) must contain the vector \(x\).

\textbf{Output Parameters}

\(y\)

Array, size at least \(m\).

On exit, the array \(y\) must contain the vector \(y\).

\textbf{mkl\_?diasymv}

\textit{Computes matrix - vector product of a sparse symmetrical matrix stored in the diagonal format with one-based indexing (deprecated).}

\textbf{Syntax}

```c
void mkl_sdiasymv (const char *uplo , const MKL_INT *m , const float *val , const MKL_INT *lval , const MKL_INT *idiag , const MKL_INT *ndiag , const float *x , float *y );
void mkl_ddiasymv (const char *uplo , const MKL_INT *m , const double *val , const MKL_INT *lval , const MKL_INT *idiag , const MKL_INT *ndiag , const double *x , double *y );
void mkl_cdiasymv (const char *uplo , const MKL_INT *m , const MKL_Complex8 *val , const MKL_INT *lval , const MKL_INT *idiag , const MKL_INT *ndiag , const MKL_Complex8 *x , MKL_Complex8 *y );
void mkl_zdiasymv (const char *uplo , const MKL_INT *m , const MKL_Complex16 *val , const MKL_INT *lval , const MKL_INT *idiag , const MKL_INT *ndiag , const MKL_Complex16 *x , MKL_Complex16 *y );
```

\textbf{Include Files}

- mkl.h

\textbf{Description}

This routine is deprecated. Use mkl\_sparse\_?\_mv from the Intel\textsuperscript{®} MKL Inspector-executor Sparse BLAS interface instead.
The mkl_diasymv routine performs a matrix-vector operation defined as

\[ y := A^t x \]

where:

- \( x \) and \( y \) are vectors,
- \( A \) is an upper or lower triangle of the symmetrical sparse matrix.

**NOTE**
This routine supports only one-based indexing of the input arrays.

### Input Parameters

- **uplo**
  Specifies whether the upper or low triangle of the matrix \( A \) is used.
  - If \( \text{uplo} = 'U' \) or \( 'u' \), then the upper triangle of the matrix \( A \) is used.
  - If \( \text{uplo} = 'L' \) or \( 'l' \), then the low triangle of the matrix \( A \) is used.

- **m**
  Number of rows of the matrix \( A \).

- **val**
  Two-dimensional array of size \( lval \) by \( ndiag \), contains non-zero diagonals of the matrix \( A \). Refer to values array description in Diagonal Storage Scheme for more details.

- **lval**
  Leading dimension of \( val \), \( lval \geq m \). Refer to \( lval \) description in Diagonal Storage Scheme for more details.

- **idiag**
  Array of length \( ndiag \), contains the distances between main diagonal and each non-zero diagonals in the matrix \( A \).
  Refer to distance array description in Diagonal Storage Scheme for more details.

- **ndiag**
  Specifies the number of non-zero diagonals of the matrix \( A \).

- **x**
  Array, size is \( m \).
  On entry, the array \( x \) must contain the vector \( x \).

### Output Parameters

- **y**
  Array, size at least \( m \).
  On exit, the array \( y \) must contain the vector \( y \).

**mkl_csrtrsv**

Triangular solvers with simplified interface for a sparse matrix in the CSR format (3-array variation) with one-based indexing (deprecated).

**Syntax**

```c
void mkl_scsrtrsv(const char *uplo, const char *transa, const char *diag, const MKL_INT *m, const float *a, const MKL_INT *ia, const MKL_INT *ja, const float *x, float *y);
```
void mkl_dcsrtrsv (const char *uplo, const char *transa, const char *diag, const MKL_INT *m, const double *a, const MKL_INT *ia, const MKL_INT *ja, const double *x, double *y);

void mkl_ccsrtrsv (const char *uplo, const char *transa, const char *diag, const MKL_INT *m, const MKL_Complex8 *a, const MKL_INT *ia, const MKL_INT *ja, const MKL_Complex8 *x, MKL_Complex8 *y);

void mkl_zcsrtrsv (const char *uplo, const char *transa, const char *diag, const MKL_INT *m, const MKL_Complex16 *a, const MKL_INT *ia, const MKL_INT *ja, const MKL_Complex16 *x, MKL_Complex16 *y);

Include Files

- mkl.h

Description

This routine is deprecated. Use mkl_sparse_?_trsv from the Intel® MKL Inspector-executor Sparse BLAS interface instead.

The mkl ?csrtrsv routine solves a system of linear equations with matrix-vector operations for a sparse matrix stored in the CSR format (3 array variation):

\[ A \cdot y = x \]

or

\[ A^T \cdot y = x, \]

where:

- \( x \) and \( y \) are vectors,
- \( A \) is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, \( A^T \) is the transpose of \( A \).

**NOTE**

This routine supports only one-based indexing of the input arrays.

Input Parameters

**uplo**

Specifies whether the upper or lower triangle of the matrix \( A \) is used.

- If \( uplo = 'U' \) or \( 'u' \), then the upper triangle of the matrix \( A \) is used.
- If \( uplo = 'L' \) or \( 'l' \), then the lower triangle of the matrix \( A \) is used.

**transa**

Specifies the system of linear equations.

- If \( transa = 'N' \) or \( 'n' \), then \( A \cdot y = x \)
- If \( transa = 'T' \) or \( 't' \) or \( 'C' \) or \( 'c' \), then \( A^T \cdot y = x \)

**diag**

Specifies whether \( A \) is unit triangular.

- If \( diag = 'U' \) or \( 'u' \), then \( A \) is a unit triangular.
- If \( diag = 'N' \) or \( 'n' \), then \( A \) is not unit triangular.

**m**

Number of rows of the matrix \( A \).
Array containing non-zero elements of the matrix A. Its length is equal to the number of non-zero elements in the matrix A. Refer to \textit{values} array description in \textit{Sparse Matrix Storage Formats} for more details.

\textbf{NOTE}

The non-zero elements of the given row of the matrix must be stored in the same order as they appear in the row (from left to right).

No diagonal element can be omitted from a sparse storage if the solver is called with the non-unit indicator.

\begin{itemize}
\item \textit{ia} array of length \(m + 1\), containing indices of elements in the array \(a\), such that \(ia[i] - ia[0]\) is the index in the array \(a\) of the first non-zero element from the row \(i\). The value of the last element \(ia[m] - ia[0]\) is equal to the number of non-zeros. Refer to \textit{rowIndex} array description in \textit{Sparse Matrix Storage Formats} for more details.
\item \textit{ja} array containing the column indices plus one for each non-zero element of the matrix \(A\).
\end{itemize}

\begin{itemize}
\item Its length is equal to the length of the array \(a\). Refer to \textit{columns} array description in \textit{Sparse Matrix Storage Formats} for more details.
\end{itemize}

\textbf{NOTE}

Column indices must be sorted in increasing order for each row.

\begin{itemize}
\item \textit{x} array, size is \(m\).
\end{itemize}

On entry, the array \(x\) must contain the vector \(x\).

\textbf{Output Parameters}

\begin{itemize}
\item \textit{y} array, size at least \(m\).
\end{itemize}

Contains the vector \(y\).

\textbf{mkl?bsrtrsv}

\textit{Triangular solver with simplified interface for a sparse matrix stored in the BSR format (3-array variation) with one-based indexing (deprecated).}

\textbf{Syntax}

\begin{verbatim}
void mkl_sbsrtrsv (const char *uplo , const char *transa , const char *diag , const MKL_INT *m , const MKL_INT *lb , const float *a , const MKL_INT *ia , const MKL_INT *ja , const float *x , float *y );
void mkl_dbsrtrsv (const char *uplo , const char *transa , const char *diag , const MKL_INT *m , const MKL_INT *lb , const double *a , const MKL_INT *ia , const MKL_INT *ja , const double *x , double *y );
void mkl_cbsrtrsv (const char *uplo , const char *transa , const char *diag , const MKL_INT *m , const MKL_INT *lb , const MKL_Complex8 *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_Complex8 *x , MKL_Complex8 *y );
\end{verbatim}
void mkl_zbsrtrs (const char *uplo, const char *transa, const char *diag, const MKL_INT *m, const MKL_INT *lb, const MKL_Complex16 *a, const MKL_INT *ia, const MKL_INT *ja, const MKL_Complex16 *x, MKL_Complex16 *y);

Include Files
• mkl.h

Description
This routine is deprecated. Use mkl_sparse_?_trsv from the Intel® MKL Inspector-executor Sparse BLAS interface instead.

The mkl_zbsrtrs routine solves a system of linear equations with matrix-vector operations for a sparse matrix stored in the BSR format (3-array variation):

\[ y := A \times x \]
or
\[ y := A^T \times x, \]
where:

- \( x \) and \( y \) are vectors,
- \( A \) is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, \( A^T \) is the transpose of \( A \).

**NOTE**
This routine supports only one-based indexing of the input arrays.

Input Parameters

**uplo**
Specifies the upper or lower triangle of the matrix \( A \) is used.
- If \( uplo = 'U' \) or 'u', then the upper triangle of the matrix \( A \) is used.
- If \( uplo = 'L' \) or 'l', then the lower triangle of the matrix \( A \) is used.

**transa**
Specifies the operation.
- If \( transa = 'N' \) or 'n', then the matrix-vector product is computed as \( y := A \times x \)
- If \( transa = 'T' \) or 't' or 'C' or 'c', then the matrix-vector product is computed as \( y := A^T \times x \).

**diag**
Specifies whether \( A \) is a unit triangular matrix.
- If \( diag = 'U' \) or 'u', then \( A \) is a unit triangular.
- If \( diag = 'N' \) or 'n', then \( A \) is not a unit triangular.

**m**
Number of block rows of the matrix \( A \).

**lb**
Size of the block in the matrix \( A \).

**a**
Array containing elements of non-zero blocks of the matrix \( A \). Its length is equal to the number of non-zero blocks in the matrix \( A \) multiplied by \( lb \times lb \). Refer to values array description in BSR Format for more details.
NOTE
The non-zero elements of the given row of the matrix must be stored in the same order as they appear in the row (from left to right).
No diagonal element can be omitted from a sparse storage if the solver is called with the non-unit indicator.

\[ ia \]
Array of length \( (m + 1) \), containing indices of block in the array \( a \), such that \( ia[I] - ia[0] \) is the index in the array \( a \) of the first non-zero element from the row \( I \). The value of the last element \( ia[m] - ia[0] \) is equal to the number of non-zero blocks. Refer to \textit{rowIndex} array description in BSR Format for more details.

\[ ja \]
Array containing the column indices plus one for each non-zero block in the matrix \( A \).
Its length is equal to the number of non-zero blocks of the matrix \( A \). Refer to \textit{columns} array description in BSR Format for more details.

\[ x \]
Array, size \((m \times lb)\).
On entry, the array \( x \) must contain the vector \( x \).

\textbf{Output Parameters}

\[ y \]
Array, size at least \((m \times lb)\).
On exit, the array \( y \) must contain the vector \( y \).

\textbf{mkl\_cootrsv}
Triangular solvers with simplified interface for a sparse matrix in the coordinate format with one-based indexing (deprecated).

\textbf{Syntax}

```c
void mkl_scootrsv (const char *uplo , const char *transa , const char *diag , const MKL_INT *m , const float *val , const MKL_INT *rowind , const MKL_INT *colind , const MKL_INT *nnz , const float *x , float *y );

void mkl_dcootrsv (const char *uplo , const char *transa , const char *diag , const MKL_INT *m , const double *val , const MKL_INT *rowind , const MKL_INT *colind , const MKL_INT *nnz , const double *x , double *y );

void mkl_ccootrsv (const char *uplo , const char *transa , const char *diag , const MKL_INT *m , const MKL_Complex8 *val , const MKL_INT *rowind , const MKL_INT *colind , const MKL_INT *nnz , const MKL_Complex8 *x , MKL_Complex8 *y );

void mkl_zcootrsv (const char *uplo , const char *transa , const char *diag , const MKL_INT *m , const MKL_Complex16 *val , const MKL_INT *rowind , const MKL_INT *colind , const MKL_INT *nnz , const MKL_Complex16 *x , MKL_Complex16 *y );
```

\textbf{Include Files}

- mkl.h
Description

This routine is deprecated. Use \texttt{mkl_sparse_?_trsv} from the Intel® MKL Inspector-executor Sparse BLAS interface instead.

The \texttt{mkl_?cootrsv} routine solves a system of linear equations with matrix-vector operations for a sparse matrix stored in the coordinate format:

\[ A^T y = x \]

or

\[ A^T y = x, \]

where:

- \( x \) and \( y \) are vectors,
- \( A \) is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, \( A^T \) is the transpose of \( A \).

**NOTE**

This routine supports only one-based indexing of the input arrays.

Input Parameters

\texttt{uplo}

Specifies whether the upper or low triangle of the matrix \( A \) is considered.

- If \( \texttt{uplo} = 'U' \) or \'u', then the upper triangle of the matrix \( A \) is used.
- If \( \texttt{uplo} = 'L' \) or \'l', then the low triangle of the matrix \( A \) is used.

\texttt{transa}

Specifies the system of linear equations.

- If \( \texttt{transa} = 'N' \) or \'n', then \( A^T y = x \).
- If \( \texttt{transa} = 'T' \) or \'t' or \'C' or \'c', then \( A^T y = x \).

\texttt{diag}

Specifies whether \( A \) is unit triangular.

- If \( \texttt{diag} = 'U' \) or \'u', then \( A \) is unit triangular.
- If \( \texttt{diag} = 'N' \) or \'n', then \( A \) is not unit triangular.

\texttt{m}

Number of rows of the matrix \( A \).

\texttt{val}

Array of length \( \texttt{nnz} \), contains non-zero elements of the matrix \( A \) in the arbitrary order.

Refer to values array description in Coordinate Format for more details.

\texttt{rowind}

Array of length \( \texttt{nnz} \), contains the row indices plus one for each non-zero element of the matrix \( A \).

Refer to rows array description in Coordinate Format for more details.

\texttt{colind}

Array of length \( \texttt{nnz} \), contains the column indices plus one for each non-zero element of the matrix \( A \). Refer to columns array description in Coordinate Format for more details.

\texttt{nnz}

Specifies the number of non-zero element of the matrix \( A \).

Refer to \( \texttt{nnz} \) description in Coordinate Format for more details.
Array, size is \( m \).
On entry, the array \( x \) must contain the vector \( x \).

**Output Parameters**

\( y \)
Array, size at least \( m \).
Contains the vector \( y \).

**mkl_?diatrsv**

Triangular solvers with simplified interface for a sparse matrix in the diagonal format with one-based indexing (deprecated).

**Syntax**

```c
void mkl_sdiatrsv (const char *uplo , const char *transa , const char *diag , const MKL_INT *m , const float *val , const MKL_INT *lval , const MKL_INT *idiag , const MKL_INT *ndiag , const float *x , float *y );
void mkl_ddiatrsv (const char *uplo , const char *transa , const char *diag , const MKL_INT *m , const double *val , const MKL_INT *lval , const MKL_INT *idiag , const MKL_INT *ndiag , const double *x , double *y );
void mkl_cdiatrsv (const char *uplo , const char *transa , const char *diag , const MKL_INT *m , const MKL_Complex8 *val , const MKL_INT *lval , const MKL_INT *idiag , const MKL_INT *ndiag , const MKL_Complex8 *x , MKL_Complex8 *y );
void mkl_zdiatrsv (const char *uplo , const char *transa , const char *diag , const MKL_INT *m , const MKL_Complex16 *val , const MKL_INT *lval , const MKL_INT *idiag , const MKL_INT *ndiag , const MKL_Complex16 *x , MKL_Complex16 *y );
```

**Include Files**

- mkl.h

**Description**

This routine is deprecated. Use mkl_sparse_?_trsv from the Intel® MKL Inspector-executor Sparse BLAS interface instead.

The **mkl_?diatrsv** routine solves a system of linear equations with matrix-vector operations for a sparse matrix stored in the diagonal format:

\[
A \cdot y = x \\
\text{or} \\
A^T \cdot y = x,
\]

where:

\( x \) and \( y \) are vectors,

\( A \) is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, \( A^T \) is the transpose of \( A \).

**NOTE**

This routine supports only one-based indexing of the input arrays.
Input Parameters

\underline{uplo} Specifies whether the upper or low triangle of the matrix \( A \) is used.

- If \( \text{uplo} = 'U' \) or \'u'\), then the upper triangle of the matrix \( A \) is used.
- If \( \text{uplo} = 'L' \) or \'l'\), then the low triangle of the matrix \( A \) is used.

\underline{transa} Specifies the system of linear equations.

- If \( \text{transa} = 'N' \) or \'n'\), then \( A^T \cdot y = x \)
- If \( \text{transa} = 'T' \) or \'t'\), or \'C'\) or \'c'\), then \( A^T \cdot y = x \),

\underline{diag} Specifies whether \( A \) is unit triangular.

- If \( \text{diag} = 'U' \) or \'u'\), then \( A \) is unit triangular.
- If \( \text{diag} = 'N' \) or \'n'\), then \( A \) is not unit triangular.

\underline{m} Number of rows of the matrix \( A \).

\underline{val} Two-dimensional array of size \( \text{lval} \) by \( \text{ndiag} \), contains non-zero diagonals of the matrix \( A \). Refer to \text{values} array description in \text{Diagonal Storage Scheme} for more details.

\underline{lval} Leading dimension of \( \text{val} \), \( \text{lval} \geq m \). Refer to \text{lval} description in \text{Diagonal Storage Scheme} for more details.

\underline{idiat} Array of length \( \text{ndiag} \), contains the distances between main diagonal and each non-zero diagonals in the matrix \( A \).

\text{NOTE}
All elements of this array must be sorted in increasing order.

Refer to \text{distance} array description in \text{Diagonal Storage Scheme} for more details.

\underline{ndiag} Specifies the number of non-zero diagonals of the matrix \( A \).

\underline{x} Array, size is \( m \).

On entry, the array \( x \) must contain the vector \( x \).

Output Parameters

\underline{y} Array, size at least \( m \).

Contains the vector \( y \).

\text{mkl_cspblas_?csrgemv}
Computes matrix - vector product of a sparse general matrix stored in the CSR format (3-array variation) with zero-based indexing (deprecated).

\text{Syntax}

\begin{verbatim}
void mkl_cspblas_scsrgemv (const char *transa, const MKL_INT *m, const float *a, const MKL_INT *ia, const MKL_INT *ja, const float *x, float *y);
\end{verbatim}
void mkl_cspblas_dcsrgemv (const char *transa, const MKL_INT *m, const double *a, const MKL_INT *ia, const MKL_INT *ja, const double *x, double *y);
void mkl_cspblas_ccsrgemv (const char *transa, const MKL_INT *m, const MKL_Complex8 *a, const MKL_INT *ia, const MKL_INT *ja, const MKL_Complex8 *x, MKL_Complex8 *y);
void mkl_cspblas_zcsrgemv (const char *transa, const MKL_INT *m, const MKL_Complex16 *a, const MKL_INT *ia, const MKL_INT *ja, const MKL_Complex16 *x, MKL_Complex16 *y);

Include Files
• mkl.h

Description
This routine is deprecated. Use mkl_sparse_?_mv from the Intel® MKL Inspector-executor Sparse BLAS interface instead.

The mkl_cspblas_?csrgemv routine performs a matrix-vector operation defined as

\[ y := A \cdot x \]

or

\[ y := A^T \cdot x, \]

where:
- \( x \) and \( y \) are vectors,
- \( A \) is an \( m \)-by-\( m \) sparse square matrix in the CSR format (3-array variation) with zero-based indexing, \( A^T \) is the transpose of \( A \).

NOTE
This routine supports only zero-based indexing of the input arrays.

Input Parameters

transa

Specifies the operation.
- If \( \text{transa} = 'N' \) or \( 'n' \), then the matrix-vector product is computed as \( y := A \cdot x \).
- If \( \text{transa} = 'T' \) or \( 't' \) or \( 'C' \) or \( 'c' \), then the matrix-vector product is computed as \( y := A^T \cdot x \).

m

Number of rows of the matrix \( A \).

a

Array containing non-zero elements of the matrix \( A \). Its length is equal to the number of non-zero elements in the matrix \( A \). Refer to \( \text{values} \) array description in Sparse Matrix Storage Formats for more details.

ia

Array of length \( m + 1 \), containing indices of elements in the array \( a \), such that \( ia[I] \) is the index in the array \( a \) of the first non-zero element from the row \( I \). The value of the last element \( ia[m] \) is equal to the number of non-zeros. Refer to \( \text{rowIndex} \) array description in Sparse Matrix Storage Formats for more details.
Array containing the column indices for each non-zero element of the matrix A.
Its length is equal to the length of the array a. Refer to columns array description in Sparse Matrix Storage Formats for more details.

Array, size is m.
One entry, the array x must contain the vector x.

Output Parameters

Array, size at least m.
On exit, the array y must contain the vector y.

**mkl_cspblas_?bsrgemv**

*Computes matrix - vector product of a sparse general matrix stored in the BSR format (3-array variation) with zero-based indexing (deprecated).*

**Syntax**

```c
void mkl_cspblas_sbsrgemv (const char *transa , const MKL_INT *m , const MKL_INT *lb ,
const float *a , const MKL_INT *ia , const MKL_INT *ja , const float *x , float *y );
void mkl_cspblas_dbsrgemv (const char *transa , const MKL_INT *m , const MKL_INT *lb ,
const double *a , const MKL_INT *ia , const MKL_INT *ja , const double *x , double *y );
void mkl_cspblas_cbsrgemv (const char *transa , const MKL_INT *m , const MKL_INT *lb ,
const MKL_Complex8 *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_Complex8 *x ,
MKL_Complex8 *y );
void mkl_cspblas_zbsrgemv (const char *transa , const MKL_INT *m , const MKL_INT *lb ,
const MKL_Complex16 *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_Complex16 *
*x , MKL_Complex16 *y );
```

**Include Files**

**Description**

This routine is deprecated. Use mkl_sparse_?_mv from the Intel® MKL Inspector-executor Sparse BLAS interface instead.

The mkl_cspblas_?bsrgemv routine performs a matrix-vector operation defined as

\[ y := A \times x \]

or

\[ y := A^T \times x , \]

where:

x and y are vectors,

A is an m-by-m block sparse square matrix in the BSR format (3-array variation) with zero-based indexing, 
\( A^T \) is the transpose of A.
NOTE
This routine supports only zero-based indexing of the input arrays.

**Input Parameters**

*transa*  
Specifies the operation.
If *transa* = 'N' or 'n', then the matrix-vector product is computed as  
y := A*x
If *transa* = 'T' or 't' or 'C' or 'c', then the matrix-vector product is computed as  
y := A^T*x,

*m*  
Number of block rows of the matrix A.

*lb*  
Size of the block in the matrix A.

*a*  
Array containing elements of non-zero blocks of the matrix A. Its length is equal to the number of non-zero blocks in the matrix A multiplied by *lb*.*lb*. Refer to values array description in BSR Format for more details.

*ia*  
Array of length (*m* + 1), containing indices of block in the array a, such that *ia[i]* is the index in the array a of the first non-zero element from the row i. The value of the last element *ia[m]* is equal to the number of non-zero blocks. Refer to rowIndex array description in BSR Format for more details.

*ja*  
Array containing the column indices for each non-zero block in the matrix A. Its length is equal to the number of non-zero blocks of the matrix A. Refer to columns array description in BSR Format for more details.

*x*  
Array, size (*m*.*lb*).
On entry, the array *x* must contain the vector *x*.

**Output Parameters**

*y*  
Array, size at least (*m*.*lb*).
On exit, the array *y* must contain the vector *y*.

**mkl_cspblas_?coogemv**

Computes matrix - vector product of a sparse general matrix stored in the coordinate format with zero-based indexing (deprecated).

**Syntax**

```c
void mkl_cspblas_scoogemv (const char *transa , const MKL_INT *m , const float *val ,

Description

This routine is deprecated. Use mkl_sparse_?_mv from the Intel® MKL Inspector-executor Sparse BLAS interface instead.

The mkl_cspblas_dcoogemv routine performs a matrix-vector operation defined as

\[ y := Ax \]

or

\[ y := A^T x, \]

where:

- \( x \) and \( y \) are vectors,
- \( A \) is an \( m \)-by-\( m \) sparse square matrix in the coordinate format with zero-based indexing, \( A^T \) is the transpose of \( A \).

**NOTE**

This routine supports only zero-based indexing of the input arrays.

Input Parameters

**transa**

Specifies the operation.

- If \( \text{transa} = 'N' \) or \( 'n' \), then the matrix-vector product is computed as \( y := Ax \).
- If \( \text{transa} = 'T' \) or \( 't' \) or \( 'C' \) or \( 'c' \), then the matrix-vector product is computed as \( y := A^T x \).

**m**

Number of rows of the matrix \( A \).

**val**

Array of length \( \text{nnz} \), contains non-zero elements of the matrix \( A \) in the arbitrary order.

Refer to **values** array description in Coordinate Format for more details.

**rowind**

Array of length \( \text{nnz} \), contains the row indices for each non-zero element of the matrix \( A \).

Refer to **rows** array description in Coordinate Format for more details.

**colind**

Array of length \( \text{nnz} \), contains the column indices for each non-zero element of the matrix \( A \). Refer to **columns** array description in Coordinate Format for more details.
Specifies the number of non-zero element of the matrix $A$.
Refer to $nnz$ description in Coordinate Format for more details.

$x$
Array, size is $m$.
On entry, the array $x$ must contain the vector $x$.

Output Parameters

$y$
Array, size at least $m$.
On exit, the array $y$ must contain the vector $y$.

**mkl_cspblas_?csrsymv**

Computes matrix-vector product of a sparse
symmetrical matrix stored in the CSR format (3-array variation) with zero-based indexing (deprecated).

**Syntax**

void mkl_cspblas_scsrsymv (const char *uplo, const MKL_INT *m, const float *a, const MKL_INT *ia, const MKL_INT *ja, const float *x, float *y);
void mkl_cspblas_dcsrsymv (const char *uplo, const MKL_INT *m, const double *a, const MKL_INT *ia, const MKL_INT *ja, const double *x, double *y);
void mkl_cspblas_ccsrsymv (const char *uplo, const MKL_INT *m, const MKL_Complex8 *a, const MKL_INT *ia, const MKL_INT *ja, const MKL_Complex8 *x, MKL_Complex8 *y);
void mkl_cspblas_zcsrsymv (const char *uplo, const MKL_INT *m, const MKL_Complex16 *a, const MKL_INT *ia, const MKL_INT *ja, const MKL_Complex16 *x, MKL_Complex16 *y);

**Include Files**

**Description**

This routine is deprecated. Use mkl_sparse_?_mv from the Intel® MKL Inspector-executor Sparse BLAS interface instead.

The mkl_cspblas_?csrsymv routine performs a matrix-vector operation defined as

$$y := A \times x$$

where:

$x$ and $y$ are vectors,

$A$ is an upper or lower triangle of the symmetrical sparse matrix in the CSR format (3-array variation) with zero-based indexing.

**NOTE**

This routine supports only zero-based indexing of the input arrays.

**Input Parameters**
uplo

Specifies whether the upper or low triangle of the matrix A is used.
If uplo = 'U' or 'u', then the upper triangle of the matrix A is used.
If uplo = 'L' or 'l', then the low triangle of the matrix A is used.

m

Number of rows of the matrix A.

a

Array containing non-zero elements of the matrix A. Its length is equal to
the number of non-zero elements in the matrix A. Refer to values array
description in Sparse Matrix Storage Formats for more details.

ia

Array of length m + 1, containing indices of elements in the array a, such
that ia[i] is the index in the array a of the first non-zero element from the
row i. The value of the last element ia[m] is equal to the number of non-
zeros. Refer to rowIndex array description in Sparse Matrix Storage
Formats for more details.

ja

Array containing the column indices for each non-zero element of the
matrix A.
Its length is equal to the length of the array a. Refer to columns array
description in Sparse Matrix Storage Formats for more details.

x

Array, size is m.
On entry, the array x must contain the vector x.

Output Parameters

y

Array, size at least m.
On exit, the array y must contain the vector y.

mkl_cspblas_?bsrsymv

Computes matrix-vector product of a sparse
symmetrical matrix stored in the BSR format (3-arrays
variation) with zero-based indexing (deprecated).

Syntax

void mkl_cspblas_sbsrsymv (const char *uplo , const MKL_INT *m , const MKL_INT *lb ,
const float *a , const MKL_INT *ia , const MKL_INT *ja , const float *x , float *y );

  Array containing elements of non-zero blocks of the matrix \( A \). Its length is equal to the number of non-zero blocks in the matrix \( A \) multiplied by \( lb*lb \). Refer to values array description in BSR Format for more details.

- **ia**
  Array of length \((m + 1)\), containing indices of block in the array \( a \), such that \( ia[i] \) is the index in the array \( a \) of the first non-zero element from the row \( i \). The value of the last element \( ia[m] \) is equal to the number of non-zero blocks. Refer to rowIndex array description in BSR Format for more details.

- **ja**
  Array containing the column indices for each non-zero block in the matrix \( A \).
  Its length is equal to the number of non-zero blocks of the matrix \( A \). Refer to columns array description in BSR Format for more details.

- **x**
  Array, size \((m*lb)\).
  On entry, the array \( x \) must contain the vector \( x \).

Output Parameters

- **y**
  Array, size at least \((m*lb)\).
  On exit, the array \( y \) must contain the vector \( y \).
mkl_cspblas_?coosymv
Computes matrix - vector product of a sparse symmetrical matrix stored in the coordinate format with zero-based indexing (deprecated).

Syntax
void mkl_cspblas_scoosymv (const char *uplo, const MKL_INT *m, const float *val, const MKL_INT *rowind, const MKL_INT *colind, const MKL_INT *nnz, const float *x, float *y);

void mkl_cspblas_dcoosymv (const char *uplo, const MKL_INT *m, const double *val, const MKL_INT *rowind, const MKL_INT *colind, const MKL_INT *nnz, const double *x, double *y);

void mkl_cspblas_ccoosymv (const char *uplo, const MKL_INT *m, const MKL_Complex8 *val, const MKL_INT *rowind, const MKL_INT *colind, const MKL_INT *nnz, const MKL_Complex8 *x, MKL_Complex8 *y);

void mkl_cspblas_zcoosymv (const char *uplo, const MKL_INT *m, const MKL_Complex16 *val, const MKL_INT *rowind, const MKL_INT *colind, const MKL_INT *nnz, const MKL_Complex16 *x, MKL_Complex16 *y);

Include Files
• mkl.h

Description
This routine is deprecated. Use mkl_sparse_?_mvfrom the Intel® MKL Inspector-executor Sparse BLAS interface instead.

The mkl_cspblas_?coosymv routine performs a matrix-vector operation defined as

\[ y := A \times x \]

where:

\( x \) and \( y \) are vectors,

\( A \) is an upper or lower triangle of the symmetrical sparse matrix in the coordinate format with zero-based indexing.

**NOTE**
This routine supports only zero-based indexing of the input arrays.

Input Parameters

**uplo**
Specifies whether the upper or low triangle of the matrix \( A \) is used.
If \( uplo = 'U' \) or \( 'u' \), then the upper triangle of the matrix \( A \) is used.
If \( uplo = 'L' \) or \( 'l' \), then the low triangle of the matrix \( A \) is used.

**m**
Number of rows of the matrix \( A \).

**val**
Array of length \( nnz \), contains non-zero elements of the matrix \( A \) in the arbitrary order.
Refer to values array description in Coordinate Format for more details.

rowind
Array of length nnz, contains the row indices for each non-zero element of the matrix A.
Refer to rows array description in Coordinate Format for more details.

colind
Array of length nnz, contains the column indices for each non-zero element of the matrix A. Refer to columns array description in Coordinate Format for more details.

nnz
Specifies the number of non-zero element of the matrix A.
Refer to nnz description in Coordinate Format for more details.

x
Array, size is m.
On entry, the array x must contain the vector x.

Output Parameters

y
Array, size at least m.
On exit, the array y must contain the vector y.

mkl_cspblas_?csrtrsv
Triangular solvers with simplified interface for a sparse matrix in the CSR format (3-array variation) with zero-based indexing (deprecated).

Syntax

void mkl_cspblas_scsrtrsv (const char *uplo , const char *transa , const char *diag ,
const MKL_INT *m , const float *a , const MKL_INT *ia , const MKL_INT *ja ,
const float *x , float *y);
void mkl_cspblas_dcsrtrsv (const char *uplo , const char *transa , const char *diag ,
const MKL_INT *m , const double *a , const MKL_INT *ia , const MKL_INT *ja , const
double *x , double *y);
void mkl_cspblas_ccsrtrsv (const char *uplo , const char *transa , const char *diag ,
const MKL_INT *m , const MKL_Complex8 *a , const MKL_INT *ia , const MKL_INT *ja ,
const MKL_Complex8 *x , MKL_Complex8 *y );
void mkl_cspblas_zcsrtrsv (const char *uplo , const char *transa , const char *diag ,
const MKL_INT *m , const MKL_Complex16 *a , const MKL_INT *ia , const MKL_INT *ja ,
const MKL_Complex16 *x , MKL_Complex16 *y );

Include Files

• mkl.h

Description

This routine is deprecated. Use mkl_sparse_?_trsv from the Intel® MKL Inspector-executor Sparse BLAS interface instead.

The mkl_cspblas_?csrtrsv routine solves a system of linear equations with matrix-vector operations for a sparse matrix stored in the CSR format (3-array variation) with zero-based indexing:

\[ A^y = x \]
or

\[ A^T y = x, \]

where:

- \( x \) and \( y \) are vectors,
- \( A \) is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, \( A^T \) is the transpose of \( A \).

**NOTE**
This routine supports only zero-based indexing of the input arrays.

### Input Parameters

- **uplo**
  Specifies whether the upper or low triangle of the matrix \( A \) is used.
  - If \( uplo = 'U' \) or \( 'u' \), then the upper triangle of the matrix \( A \) is used.
  - If \( uplo = 'L' \) or \( 'l' \), then the low triangle of the matrix \( A \) is used.

- **transa**
  Specifies the system of linear equations.
  - If \( transa = 'N' \) or \( 'n' \), then \( A^T y = x \)
  - If \( transa = 'T' \) or \( 't' \) or \( 'C' \) or \( 'c' \), then \( A^T y = x \)

- **diag**
  Specifies whether matrix \( A \) is unit triangular.
  - If \( diag = 'U' \) or \( 'u' \), then \( A \) is unit triangular.
  - If \( diag = 'N' \) or \( 'n' \), then \( A \) is not unit triangular.

- **m**
  Number of rows of the matrix \( A \).

- **a**
  Array containing non-zero elements of the matrix \( A \). Its length is equal to the number of non-zero elements in the matrix \( A \). Refer to values array description in Sparse Matrix Storage Formats for more details.

**NOTE**
The non-zero elements of the given row of the matrix must be stored in the same order as they appear in the row (from left to right).

No diagonal element can be omitted from a sparse storage if the solver is called with the non-unit indicator.

- **ia**
  Array of length \( m+1 \), containing indices of elements in the array \( a \), such that \( ia[i] \) is the index in the array \( a \) of the first non-zero element from the row \( i \). The value of the last element \( ia[m] \) is equal to the number of non-zeros. Refer to rowIndex array description in Sparse Matrix Storage Formats for more details.

- **ja**
  Array containing the column indices for each non-zero element of the matrix \( A \).
  Its length is equal to the length of the array \( a \). Refer to columns array description in Sparse Matrix Storage Formats for more details.
Column indices must be sorted in increasing order for each row.

X

Array, size is \( m \).

On entry, the array \( x \) must contain the vector \( x \).

Output Parameters

Y

Array, size at least \( m \).

Contains the vector \( y \).

**mkl_cspblas_?bsrtrsv**

Triangular solver with simplified interface for a sparse matrix stored in the BSR format (3-array variation) with zero-based indexing (deprecated).

**Syntax**

```c
void mkl_cspblas_sbsrtrsv (const char *uplo , const char *transa , const char *diag ,
const MKL_INT *m , const MKL_INT *lb , const float *a , const MKL_INT *ia ,
const MKL_INT *ja , const float *x , float *y );
void mkl_cspblas_dbsrtrsv (const char *uplo , const char *transa , const char *diag ,
const MKL_INT *m , const MKL_INT *lb , const double *a , const MKL_INT *ia ,
const MKL_INT *ja , const double *x , double *y );
void mkl_cspblas_cbsrtrsv (const char *uplo , const char *transa , const char *diag ,
const MKL_INT *m , const MKL_INT *lb , const MKL_Complex8 *a , const MKL_INT *ia ,
const MKL_INT *ja , const MKL_Complex8 *x , MKL_Complex8 *y );
void mkl_cspblas_zbsrtrsv (const char *uplo , const char *transa , const char *diag ,
const MKL_INT *m , const MKL_INT *lb , const MKL_Complex16 *a , const MKL_INT *ia ,
const MKL_INT *ja , const MKL_Complex16 *x , MKL_Complex16 *y );
```

**Include Files**

- `mkl.h`

**Description**

This routine is deprecated. Use `mkl_sparse_?_trsv` from the Intel® MKL Inspector-executor Sparse BLAS interface instead.

The `mkl_cspblas_?bsrtrsv` routine solves a system of linear equations with matrix-vector operations for a sparse matrix stored in the BSR format (3-array variation) with zero-based indexing:

\[
y := A x
\]

or

\[
y := A^T x,
\]

where:

\( x \) and \( y \) are vectors,

\( A \) is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, \( A^T \) is the transpose of \( A \).
Input Parameters

**uplo**

Specifies the upper or low triangle of the matrix \( A \) is used.

If \( \text{uplo} = 'U' \) or \( 'u' \), then the upper triangle of the matrix \( A \) is used.

If \( \text{uplo} = 'L' \) or \( 'l' \), then the low triangle of the matrix \( A \) is used.

**transa**

Specifies the operation.

If \( \text{transa} = 'N' \) or \( 'n' \), then the matrix-vector product is computed as \( y := A \times x \)

If \( \text{transa} = 'T' \) or \( 't' \) or \( 'C' \) or \( 'c' \), then the matrix-vector product is computed as \( y := A^T \times x \).

**diag**

Specifies whether matrix \( A \) is unit triangular or not.

If \( \text{diag} = 'U' \) or \( 'u' \), \( A \) is unit triangular.

If \( \text{diag} = 'N' \) or \( 'n' \), \( A \) is not unit triangular.

**m**

Number of block rows of the matrix \( A \).

**lb**

Size of the block in the matrix \( A \).

**a**

Array containing elements of non-zero blocks of the matrix \( A \). Its length is equal to the number of non-zero blocks in the matrix \( A \) multiplied by \( lb \times lb \). Refer to \textit{values} array description in BSR Format for more details.

**ia**

Array of length \( (m + 1) \), containing indices of block in the array \( a \), such that \( ia[I] \) is the index in the array \( a \) of the first non-zero element from the row \( I \). The value of the last element \( ia[m] \) is equal to the number of non-zero blocks. Refer to \textit{rowIndex} array description in BSR Format for more details.

**ja**

Array containing the column indices for each non-zero block in the matrix \( A \).

Its length is equal to the number of non-zero blocks of the matrix \( A \). Refer to \textit{columns} array description in BSR Format for more details.

**x**

Array, size \( (m \times lb) \).

On entry, the array \( x \) must contain the vector \( x \).
Output Parameters

\( y \)

Array, size at least \((m \times lb)\).

On exit, the array \( y \) must contain the vector \( y \).

\textbf{mkl_cspblas_?cootrsv}

\textit{Triangular solvers with simplified interface for a sparse matrix in the coordinate format with zero-based indexing (deprecated).}

\textbf{Syntax}

\begin{verbatim}
void mkl_cspblas_scootrsv (const char *uplo, const char *transa, const char *diag,
const MKL_INT *m, const float *val, const MKL_INT *rowind, const MKL_INT *colind,
const MKL_INT *nnz, const float *x, float *y);
void mkl_cspblas_dcootrsv (const char *uplo, const char *transa, const char *diag,

void mkl_cspblas_zcootrsv (const char *uplo, const char *transa, const char *diag,
const MKL_INT *m, const MKL_Complex16 *val, const MKL_INT *rowind, const MKL_INT
*colind, const MKL_INT *nnz, const MKL_Complex16 *x, MKL_Complex16 *y);
\end{verbatim}

\textbf{Include Files}

- mkl.h

\textbf{Description}

This routine is deprecated. Use \texttt{mkl_sparse_?_trsv} from the Intel\textsuperscript{®} MKL Inspector-executor Sparse BLAS interface instead.

The \texttt{mkl_cspblas_?cootrsv} routine solves a system of linear equations with matrix-vector operations for a sparse matrix stored in the coordinate format with zero-based indexing:

\[ A \cdot y = x \]

or

\[ A^T \cdot y = x, \]

where:

- \( x \) and \( y \) are vectors,
- \( A \) is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, \( A^T \) is the transpose of \( A \).

\textbf{NOTE}

This routine supports only zero-based indexing of the input arrays.

\textbf{Input Parameters}
Specifies whether the upper or low triangle of the matrix A is considered.
If uplo = 'U' or 'u', then the upper triangle of the matrix A is used.
If uplo = 'L' or 'l', then the low triangle of the matrix A is used.

**transa**
Specifies the system of linear equations.
If transa = 'N' or 'n', then $A^T y = x$
If transa = 'T' or 't' or 'C' or 'c', then $A^T y = x$

**diag**
Specifies whether A is unit triangular.
If diag = 'U' or 'u', then A is unit triangular.
If diag = 'N' or 'n', then A is not unit triangular.

**m**
Number of rows of the matrix A.

**val**
Array of length nnz, contains non-zero elements of the matrix A in the arbitrary order.
Refer to values array description in Coordinate Format for more details.

**rowind**
Array of length nnz, contains the row indices for each non-zero element of the matrix A.
Refer to rows array description in Coordinate Format for more details.

**colind**
Array of length nnz, contains the column indices for each non-zero element of the matrix A. Refer to columns array description in Coordinate Format for more details.

**nnz**
Specifies the number of non-zero element of the matrix A.
Refer to nnz description in Coordinate Format for more details.

**x**
Array, size is m.
On entry, the array x must contain the vector x.

**Output Parameters**

**y**
Array, size at least m.
Contains the vector y.

**mkl_?csrmv**
Computes matrix - vector product of a sparse matrix stored in the CSR format (deprecated).

**Syntax**

```c
void mkl_scsrmv (const char *transa, const MKL_INT *m, const MKL_INT *k, const float *alpha, const char *matdescra, const float *val, const MKL_INT *index, const MKL_INT *pntrb, const MKL_INT *pntre, const float *x, const float *beta, float *y);
void mkl_dcsrmv (const char *transa, const MKL_INT *m, const MKL_INT *k, const double *alpha, const char *matdescra, const double *val, const MKL_INT *index, const MKL_INT *pntrb, const MKL_INT *pntre, const double *x, const double *beta, double *y);
```
void mkl_ccsr
  m (const char *transa, const MKL_INT *m, const MKL_INT *k, const MKL_Complex8 *alpha, const char *matdescra, const MKL_Complex8 *val, const MKL_INT *indx, const MKL_INT *pntrb, const MKL_INT *pnte, const MKL_Complex8 *x, const MKL_Complex8 *beta, MKL_Complex8 *y);

void mkl_zcsr
  m (const char *transa, const MKL_INT *m, const MKL_INT *k, const MKL_Complex16 *alpha, const char *matdescra, const MKL_Complex16 *val, const MKL_INT *indx, const MKL_INT *pntrb, const MKL_INT *pnte, const MKL_Complex16 *x, const MKL_Complex16 *beta, MKL_Complex16 *y);

Include Files
  • mkl.h

Description
This routine is deprecated. Use mkl_sparse_?_mv from the Intel® MKL Inspector-executor Sparse BLAS interface instead.

The mkl_?csrmv routine performs a matrix-vector operation defined as

\[ y := \alpha A x + \beta y \]

or

\[ y := \alpha A^T x + \beta y, \]

where:
- \( \alpha \) and \( \beta \) are scalars,
- \( x \) and \( y \) are vectors,
- \( A \) is an \( m \)-by-\( k \) sparse matrix in the CSR format, \( A^T \) is the transpose of \( A \).

**NOTE**
This routine supports a CSR format both with one-based indexing and zero-based indexing.

Input Parameters

- **transa**
  Specifies the operation.
  - If \( \text{transa} = 'N' \) or \( 'n' \), then \( y := \alpha A x + \beta y \)
  - If \( \text{transa} = 'T' \) or \( 't' \) or \( 'C' \) or \( 'c' \), then \( y := \alpha A^T x + \beta y \),

- **m**
  Number of rows of the matrix \( A \).

- **k**
  Number of columns of the matrix \( A \).

- **alpha**
  Specifies the scalar \( \alpha \).

- **matdescra**
  Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter matdescra (descra)". Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter matdescra".

- **val**
  Array containing non-zero elements of the matrix \( A \).
  - Its length is \( \text{pnte}[m-1] - \text{pntrb}[0] \).
Refer to *values* array description in **CSR Format** for more details.

**indx**
For one-based indexing, array containing the column indices plus one for each non-zero element of the matrix \( A \). For zero-based indexing, array containing the column indices for each non-zero element of the matrix \( A \).

Its length is equal to length of the *val* array.

Refer to *columns* array description in **CSR Format** for more details.

**pntrb**
Array of length \( m \).

This array contains row indices, such that \( pntrb[i] - pntrb[0] \) is the first index of row \( i \) in the arrays *val* and *indx*.

Refer to *pointerb* array description in **CSR Format** for more details.

**pntre**
Array of length \( m \).

This array contains row indices, such that \( pntre[i] - pntrb[0]-1 \) is the last index of row \( i \) in the arrays *val* and *indx*.

Refer to *pointerE* array description in **CSR Format** for more details.

**x**
Array, size at least \( k \) if \( transa = 'N' \) or \( 'n' \) and at least \( m \) otherwise. On entry, the array *x* must contain the vector *x*.

**beta**
Specifies the scalar *beta*.

**y**
Array, size at least \( m \) if \( transa = 'N' \) or \( 'n' \) and at least \( k \) otherwise. On entry, the array *y* must contain the vector *y*.

**Output Parameters**

*y*
Overwritten by the updated vector *y*.

**mkl_?bsrmv**
*Computes matrix - vector product of a sparse matrix stored in the BSR format (deprecated).*

**Syntax**

```c
void mkl_sbsrmv (const char *transa, const MKL_INT *m, const MKL_INT *k, const MKL_INT *lb, const float *alpha, const char *matdescra, const float *val, const MKL_INT *indx, const MKL_INT *pntrb, const MKL_INT *pntre, const float *x, const float *beta, float *y);

void mkl_dbsrmv (const char *transa, const MKL_INT *m, const MKL_INT *k, const MKL_INT *lb, const double *alpha, const char *matdescra, const double *val, const MKL_INT *indx, const MKL_INT *pntrb, const MKL_INT *pntre, const double *x, const double *beta, double *y);

void mkl_cbsrmv (const char *transa, const MKL_INT *m, const MKL_INT *k, const MKL_INT *lb, const MKL_Complex8 *alpha, const char *matdescra, const MKL_Complex8 *val, const MKL_INT *indx, const MKL_INT *pntrb, const MKL_INT *pntre, const MKL_Complex8 *x, const MKL_Complex8 *beta, MKL_Complex8 *y);
```
void mkl_zbsrmv (const char *transa, const MKL_INT *m, const MKL_INT *k, const MKL_INT *lb, const MKL_Complex16 *alpha, const char *matdescra, const MKL_Complex16 *val, const MKL_INT *indx, const MKL_INT *pntrb, const MKL_INT *pntre, const MKL_Complex16 *x, const MKL_Complex16 *beta, MKL_Complex16 *y);

Include Files
• mkl.h

Description
This routine is deprecated. Use mkl_sparse_?_mv from the Intel® MKL Inspector-executor Sparse BLAS interface instead.

The mkl_?bsrmv routine performs a matrix-vector operation defined as

\[ y := \alpha A x + \beta y \]

or

\[ y := \alpha A^T x + \beta y , \]

where:
- \( \alpha \) and \( \beta \) are scalars,
- \( x \) and \( y \) are vectors,
- \( A \) is an \( m \)-by-\( k \) block sparse matrix in the BSR format, \( A^T \) is the transpose of \( A \).

**NOTE**
This routine supports a BSR format both with one-based indexing and zero-based indexing.

Input Parameters

- **transa**
  Specifies the operation.
  If \( transa = 'N' \) or \'n' \), then the matrix-vector product is computed as \( y := \alpha A x + \beta y \)
  If \( transa = 'T' \) or \'t' \) or \'C' \) or \'c' \), then the matrix-vector product is computed as \( y := \alpha A^T x + \beta y , \)

- **m**
  Number of block rows of the matrix \( A \).

- **k**
  Number of block columns of the matrix \( A \).

- **lb**
  Size of the block in the matrix \( A \).

- **alpha**
  Specifies the scalar \( \alpha \).

- **matdescra**
  Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter matdescra (descra)". Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter matdescra".

  Array containing elements of non-zero blocks of the matrix \( A \). Its length is equal to the number of non-zero blocks in the matrix \( A \) multiplied by \( lb \times lb \).
Refer to *values* array description in BSR Format for more details.

**indx**
For one-based indexing, array containing the column indices plus one for each non-zero block of the matrix A. For zero-based indexing, array containing the column indices for each non-zero block of the matrix A.
Its length is equal to the number of non-zero blocks in the matrix A.
Refer to *columns* array description in BSR Format for more details.

**pntrb**
Array of length *m*.
This array contains row indices, such that \( pntrb[i] - pntrb[0] \) is the first index of block row \( i \) in the array *indx*
Refer to *pointerB* array description in BSR Format for more details.

**pntrc**
Array of length *m*.
For zero-based indexing this array contains row indices, such that \( pntre[i] - pntrb[0] - 1 \) is the last index of block row \( i \) in the array *indx*.
Refer to *pointerE* array description in BSR Format for more details.

**x**
Array, size at least \((k*lb)\) if transa = 'N' or 'n', and at least \((m*lb)\) otherwise. On entry, the array *x* must contain the vector *x*.

**beta**
Specifies the scalar *beta*.

**y**
Array, size at least \((m*lb)\) if transa = 'N' or 'n', and at least \((k*lb)\) otherwise. On entry, the array *y* must contain the vector *y*.

**Output Parameters**

*y*
Overwritten by the updated vector *y*.

**mkl_scscmv**
*Computes matrix-vector product for a sparse matrix in the CSC format (deprecated).*

**Syntax**

```c
void mkl_scscmv (const char *transa, const MKL_INT *m, const MKL_INT *k, const float *alpha, const char *matdescra, const float *val, const MKL_INT *indx, const MKL_INT *pntrb, const MKL_INT *pntre, const float *x, const float *beta, float *y);
void mkl_dcscmv (const char *transa, const MKL_INT *m, const MKL_INT *k, const double *alpha, const char *matdescra, const double *val, const MKL_INT *indx, const MKL_INT *pntrb, const MKL_INT *pntre, const double *x, const double *beta, double *y);

• mkl.h

Description

This routine is deprecated. Use mkl_sparse_?_mv from the Intel® MKL Inspector-executor Sparse BLAS interface instead.

The mkl_?cscmv routine performs a matrix-vector operation defined as

\[ y := \alpha A x + \beta y \]

or

\[ y := \alpha A^T x + \beta y, \]

where:

- \( \alpha \) and \( \beta \) are scalars,
- \( x \) and \( y \) are vectors,
- \( A \) is an \( m \)-by-\( k \) sparse matrix in compressed sparse column (CSC) format, \( A^T \) is the transpose of \( A \).

NOTE

This routine supports CSC format both with one-based indexing and zero-based indexing.

Input Parameters

transa

Specifies the operation.

- If \( \text{transa} = 'N' \) or \( 'n' \), then \( y := \alpha A x + \beta y \)
- If \( \text{transa} = 'T' \) or \( 't' \) or \( 'C' \) or \( 'c' \), then \( y := \alpha A^T x + \beta y \),

m

Number of rows of the matrix \( A \).

k

Number of columns of the matrix \( A \).

alpha

Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter matdescra (descra)". Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter matdescra".

val

Array containing non-zero elements of the matrix \( A \).

Its length is \( \text{pntr}[k-1] - \text{pntr}[0] \).

Refer to values array description in CSC Format for more details.
For one-based indexing, array containing the column indices plus one for each non-zero element of the matrix \(A\). For zero-based indexing, array containing the column indices for each non-zero element of the matrix \(A\).

Its length is equal to length of the \(val\) array.

Refer to \(rows\) array description in CSC Format for more details.

\(pntrb\)

*Array of length \(k\).*

This array contains column indices, such that \(pntrb[i] - pntrb[0] + 1\) is the first index of column \(i\) in the arrays \(val\) and \(indx\).

Refer to \(pointerb\) array description in CSC Format for more details.

\(pnre\)

*Array of length \(k\).*

For one-based indexing this array contains column indices, such that \(pnre[i] - pntrb[1]\) is the last index of column \(i\) in the arrays \(val\) and \(indx\).

For zero-based indexing this array contains column indices, such that \(pnre[i] - pntrb[1] - 1\) is the last index of column \(i\) in the arrays \(val\) and \(indx\).

Refer to \(pointerE\) array description in CSC Format for more details.

\(x\)

*Array, size at least \(k\) if \(transa = 'N'\) or \('n'\) and at least \(m\) otherwise. On entry, the array \(x\) must contain the vector \(x\).*

\(beta\)

*Specifies the scalar \(beta\).*

\(y\)

*Array, size at least \(m\) if \(transa = 'N'\) or \('n'\) and at least \(k\) otherwise. On entry, the array \(y\) must contain the vector \(y\).*

**Output Parameters**

\(y\)

*Overwritten by the updated vector \(y\).*

**mkl\_?coomv**

*Computes matrix - vector product for a sparse matrix in the coordinate format (deprecated).*

**Syntax**

```c
void mkl_scoomv (const char *transa , const MKL_INT *m , const MKL_INT *k , const float *alpha , const char *matdescra , const float *val , const MKL_INT *rowind , const MKL_INT *colind , const MKL_INT *nnz , const float *x , const float *beta , float *y ) ;
void mkl_dcoomv (const char *transa , const MKL_INT *m , const MKL_INT *k , const double *alpha , const char *matdescra , const double *val , const MKL_INT *rowind , const MKL_INT *colind , const MKL_INT *nnz , const double *x , const double *beta , double *y ) ;
void mkl_ccoomv (const char *transa , const MKL_INT *m , const MKL_INT *k , const MKL_Complex8 *alpha , const char *matdescra , const MKL_Complex8 *val , const MKL_INT *rowind , const MKL_INT *colind , const MKL_INT *nnz , const MKL_Complex8 *x , const MKL_Complex8 *beta , MKL_Complex8 *y ) ;
```
void mkl_zcoomv (const char *transa, const MKL_INT *m, const MKL_INT *k, const MKL_Complex16 *alpha, const char *matdescra, const MKL_Complex16 *val, const MKL_INT *rowind, const MKL_INT *colind, const MKL_INT *nnz, const MKL_Complex16 *x, const MKL_Complex16 *beta, MKL_Complex16 *y);

Include Files
- mkl.h

Description
This routine is deprecated. Use mkl_sparse_?_mv from the Intel® MKL Inspector-executor Sparse BLAS interface instead.

The mkl_?coomv routine performs a matrix-vector operation defined as

\[ y := \alpha A x + \beta y \]

or

\[ y := \alpha A^T x + \beta y, \]

where:
- \( \alpha \) and \( \beta \) are scalars,
- \( x \) and \( y \) are vectors,
- \( A \) is an \( m \)-by-\( k \) sparse matrix in compressed coordinate format, \( A^T \) is the transpose of \( A \).

NOTE
This routine supports a coordinate format both with one-based indexing and zero-based indexing.

Input Parameters

\textbf{transa} 
Specifies the operation.
If \textit{transa} = 'N' or 'n', then \( y := \alpha A x + \beta y \)
If \textit{transa} = 'T' or 't' or 'C' or 'c', then \( y := \alpha A^T x + \beta y, \)

\textbf{m} 
Number of rows of the matrix \( A \).

\textbf{k} 
Number of columns of the matrix \( A \).

\textbf{alpha} 
Specifies the scalar \( \alpha \).

\textbf{matdescra} 
Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter matdescra (descra)". Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter matdescra".

\textbf{val} 
Array of length \( \text{nnz} \), contains non-zero elements of the matrix \( A \) in the arbitrary order. Refer to values array description in \textit{Coordinate Format} for more details.

\textbf{rowind} 
Array of length \( \text{nnz} \).
For one-based indexing, contains the row indices plus one for each non-zero element of the matrix $A$.

For zero-based indexing, contains the row indices for each non-zero element of the matrix $A$.

Refer to rows array description in Coordinate Format for more details.

colind

Array of length $nnz$.

For one-based indexing, contains the column indices plus one for each non-zero element of the matrix $A$.

For zero-based indexing, contains the column indices for each non-zero element of the matrix $A$.

Refer to columns array description in Coordinate Format for more details.

$nnz$

Specifies the number of non-zero element of the matrix $A$.

Refer to $nnz$ description in Coordinate Format for more details.

$x$

Array, size at least $k$ if $transa = 'N'$ or 'n' and at least $m$ otherwise. On entry, the array $x$ must contain the vector $x$.

beta

Specifies the scalar $beta$.

$y$

Array, size at least $m$ if $transa = 'N'$ or 'n' and at least $k$ otherwise. On entry, the array $y$ must contain the vector $y$.

Output Parameters

$y$

Overwritten by the updated vector $y$.

**mkl?csrsv**

Solves a system of linear equations for a sparse matrix in the CSR format (deprecated).

**Syntax**

```c
void mkl_scsrsv (const char *transa, const MKL_INT *m, const float *alpha, const char *matdescra, const float *val, const MKL_INT *indx, const MKL_INT *pntrb, const MKL_INT *pntre, const float *x, float *y);
void mkl_dcsrsv (const char *transa, const MKL_INT *m, const double *alpha, const char *matdescra, const double *val, const MKL_INT *indx, const MKL_INT *pntrb, const MKL_INT *pntre, const double *x, double *y);
void mkl_ccsrsv (const char *transa, const MKL_INT *m, const MKL_Complex8 *alpha, const char *matdescra, const MKL_Complex8 *val, const MKL_INT *indx, const MKL_INT *pntrb, const MKL_INT *pntre, const MKL_Complex8 *x, MKL_Complex8 *y);
void mkl_zcsrsv (const char *transa, const MKL_INT *m, const MKL_Complex16 *alpha, const char *matdescra, const MKL_Complex16 *val, const MKL_INT *indx, const MKL_INT *pntrb, const MKL_INT *pntre, const MKL_Complex16 *x, MKL_Complex16 *y);
```

**Include Files**

- mkl.h
Description

This routine is deprecated. Use mkl_sparse_?_trsv from the Intel® MKL Inspector-executor Sparse BLAS interface instead.

The mkl_?csrsv routine solves a system of linear equations with matrix-vector operations for a sparse matrix in the CSR format:

\[ y := \alpha \cdot \text{inv}(A) \cdot x \]

or

\[ y := \alpha \cdot \text{inv}(A^T) \cdot x, \]

where:

\( \alpha \) is scalar, \( x \) and \( y \) are vectors, \( A \) is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, \( A^T \) is the transpose of \( A \).

NOTE

This routine supports a CSR format both with one-based indexing and zero-based indexing.

Input Parameters

**transa**

Specifies the system of linear equations.

If \( \text{transa} = 'N' \) or \( 'n' \), then \( y := \alpha \cdot \text{inv}(A) \cdot x \)

If \( \text{transa} = 'T' \) or \( 't' \) or \( 'C' \) or \( 'c' \), then \( y := \alpha \cdot \text{inv}(A^T) \cdot x \),

**m**

Number of columns of the matrix \( A \).

**alpha**

Specifies the scalar \( \alpha \).

**matdescra**

Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter matdescra (descra)". Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter matdescra".

**val**

Array containing non-zero elements of the matrix \( A \).

Its length is \( \text{pntr}[m - 1] - \text{pntr}[0] \).

Refer to \textit{values} array description in CSR Format for more details.

NOTE

The non-zero elements of the given row of the matrix must be stored in the same order as they appear in the row (from left to right).

No diagonal element can be omitted from a sparse storage if the solver is called with the non-unit indicator.

**indx**

For one-based indexing, array containing the column indices plus one for each non-zero element of the matrix \( A \). For zero-based indexing, array containing the column indices for each non-zero element of the matrix \( A \).

Its length is equal to length of the \textit{val} array.
Refer to *columns* array description in **CSR Format** for more details.

**NOTE**
Column indices must be sorted in increasing order for each row.

$pntrb$

Array of length $m$.
This array contains row indices, such that $pntrb[i] - pntrb[0]$ is the first index of row $i$ in the arrays $val$ and $indx$.
Refer to *pointerb* array description in **CSR Format** for more details.

$pnTre$

Array of length $m$.
This array contains row indices, such that $pnTre[i] - pntrb[0] - 1$ is the last index of row $i$ in the arrays $val$ and $indx$.
Refer to *pointerE* array description in **CSR Format** for more details.

$x$

Array, size at least $m$.
On entry, the array $x$ must contain the vector $x$. The elements are accessed with unit increment.

$y$

Array, size at least $m$.
On entry, the array $y$ must contain the vector $y$. The elements are accessed with unit increment.

**Output Parameters**

$y$

Contains solution vector $x$.

### mkl_?bsrsv

*Solves a system of linear equations for a sparse matrix in the BSR format (deprecated).*

**Syntax**

```c
void mkl_sbsrsv(const char *transa, const MKL_INT *m, const MKL_INT *lb, const float *alpha, const char *matdescra, const float *val, const MKL_INT *indx, const MKL_INT *pntrb, const MKL_INT *pnTre, const float *x, float *y);
void mkl_dbsrsv(const char *transa, const MKL_INT *m, const MKL_INT *lb, const double *alpha, const char *matdescra, const double *val, const MKL_INT *indx, const MKL_INT *pntrb, const MKL_INT *pnTre, const double *x, double *y);
void mkl_cbsrsv(const char *transa, const MKL_INT *m, const MKL_INT *lb, const MKL_Complex8 *alpha, const char *matdescra, const MKL_Complex8 *val, const MKL_INT *indx, const MKL_INT *pntrb, const MKL_INT *pnTre, const MKL_Complex8 *x, MKL_Complex8 *y);
void mkl_zbsrsv(const char *transa, const MKL_INT *m, const MKL_INT *lb, const MKL_Complex16 *alpha, const char *matdescra, const MKL_Complex16 *val, const MKL_INT *indx, const MKL_INT *pntrb, const MKL_INT *pnTre, const MKL_Complex16 *x, MKL_Complex16 *y);
```
Include Files

- mkl.h

Description

This routine is deprecated. Use mkl_sparse_?_trsv from the Intel® MKL Inspector-executor Sparse BLAS interface instead.

The mkl_?bsrsv routine solves a system of linear equations with matrix-vector operations for a sparse matrix in the BSR format:

\[ y := \alpha \cdot \text{inv}(A) \cdot x \]

or

\[ y := \alpha \cdot \text{inv}(A^T) \cdot x, \]

where:

- \( \alpha \) is scalar,
- \( x \) and \( y \) are vectors,
- \( A \) is a sparse upper or lower triangular matrix with unit or non-unit main diagonal,
- \( A^T \) is the transpose of \( A \).

**NOTE**

This routine supports a BSR format both with one-based indexing and zero-based indexing.

Input Parameters

- **transa**: Specifies the operation.
  - If \( \text{transa} = 'N' \) or \( 'n' \), then \( y := \alpha \cdot \text{inv}(A) \cdot x \)
  - If \( \text{transa} = 'T' \) or \( 't' \) or \( 'C' \) or \( 'c' \), then \( y := \alpha \cdot \text{inv}(A^T) \cdot x \)

- **m**: Number of block columns of the matrix \( A \).

- **lb**: Size of the block in the matrix \( A \).

- **alpha**: Specifies the scalar \( \alpha \).

- **matdescra**:
  - Array of six elements, specifies properties of the matrix used for operation.
  - Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter matdescra (descra)". Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter matdescra".

- **val**: Array containing elements of non-zero blocks of the matrix \( A \). Its length is equal to the number of non-zero blocks in the matrix \( A \) multiplied by \( lb \cdot lb \).

**NOTE**
The non-zero elements of the given row of the matrix must be stored in the same order as they appear in the row (from left to right).

No diagonal element can be omitted from a sparse storage if the solver is called with the non-unit indicator.
For one-based indexing, array containing the column indices plus one for each non-zero element of the matrix $A$. For zero-based indexing, array containing the column indices for each non-zero element of the matrix $A$. Its length is equal to the number of non-zero blocks in the matrix $A$. Refer to the columns array description in BSR Format for more details.

Array of length $m$.

This array contains row indices, such that $pntrb[i] - pntrb[0]$ is the first index of block row $i$ in the array $indx$.

Refer to pointerB array description in BSR Format for more details.

Array of length $m$.

For one-based indexing this array contains row indices, such that $pntre[i] - pntrb[1]$ is the last index of block row $i$ in the array $indx$.

For zero-based indexing this array contains row indices, such that $pntre[i] - pntrb[0] - 1$ is the last index of block row $i$ in the array $indx$.

Refer to pointerE array description in BSR Format for more details.

Array, size at least $(m*lb)$.

On entry, the array x must contain the vector $x$. The elements are accessed with unit increment.

Array, size at least $(m*lb)$.

On entry, the array $y$ must contain the vector $y$. The elements are accessed with unit increment.

Output Parameters

$y$

Contains solution vector $x$.

mkl_?cscsv

Solves a system of linear equations for a sparse matrix in the CSC format (deprecated).

Syntax

```c
void mkl_scscsv (const char *transa, const MKL_INT *m, const float *alpha, const char *matdescra, const float *val, const MKL_INT *indx, const MKL_INT *pntrb, const MKL_INT *pntre, const float *x, float *y);

void mkl_dcscsv (const char *transa, const MKL_INT *m, const double *alpha, const char *matdescra, const double *val, const MKL_INT *indx, const MKL_INT *pntrb, const MKL_INT *pntre, const double *x, double *y);

void mkl_ccscsv (const char *transa, const MKL_INT *m, const MKL_Complex8 *alpha, const char *matdescra, const MKL_Complex8 *val, const MKL_INT *indx, const MKL_INT *pntrb, const MKL_INT *pntre, const MKL_Complex8 *x, MKL_Complex8 *y);

void mkl_zcscsv (const char *transa, const MKL_INT *m, const MKL_Complex16 *alpha, const char *matdescra, const MKL_Complex16 *val, const MKL_INT *indx, const MKL_INT *pntrb, const MKL_INT *pntre, const MKL_Complex16 *x, MKL_Complex16 *y);

Include Files
• mkl.h

Description
This routine is deprecated. Use mkl_sparse_?_trsv from the Intel® MKL Inspector-executor Sparse BLAS 
interface instead.

The mkl _?coosv routine solves a system of linear equations with matrix-vector operations for a sparse 
matrix in the coordinate format:

\[ y := \alpha \cdot \text{inv}(A) \cdot x \]

or

\[ y := \alpha \cdot \text{inv}(A^T) \cdot x , \]

where:
\( \alpha \) is scalar, \( x \) and \( y \) are vectors, \( A \) is a sparse upper or lower triangular matrix with unit or non-unit main 
diagonal, \( A^T \) is the transpose of \( A \).

NOTE
This routine supports a coordinate format both with one-based indexing and zero-based indexing.

Input Parameters

**transa**

Specifies the system of linear equations.

If \( \text{transa} = 'N' \) or \( 'n' \), then \( y := \alpha \cdot \text{inv}(A) \cdot x \)

If \( \text{transa} = 'T' \) or \( 't' \) or \( 'C' \) or \( 'c' \), then \( y := \alpha \cdot \text{inv}(A^T) \) \cdot x , \)

\m

Number of rows of the matrix \( A \).

\alpha

Array of six elements, specifies properties of the matrix used for operation. 
Only first four array elements are used, their possible values are given in 
Table "Possible Values of the Parameter matdescra (descra)". Possible 
combinations of element values of this parameter are given in Table 
"Possible Combinations of Element Values of the Parameter matdescra".

\val

Array of length \( nnz \), contains non-zero elements of the matrix \( A \) in the 
arbitrary order.

Refer to values array description in Coordinate Format for more details.

\rowind

Array of length \( nnz \).

For one-based indexing, contains the row indices plus one for each non-zero 
element of the matrix \( A \).

For zero-based indexing, contains the row indices for each non-zero 
element of the matrix \( A \).

188
Refer to \textit{rows} array description in \textit{Coordinate Format} for more details.

\textit{colind}

Array of length \textit{nnz}.

For one-based indexing, contains the column indices plus one for each non-zero element of the matrix \(A\).

For zero-based indexing, contains the column indices for each non-zero element of the matrix \(A\).

Refer to \textit{columns} array description in \textit{Coordinate Format} for more details.

\textit{nnz}

Specifies the number of non-zero element of the matrix \(A\).

Refer to \textit{nnz} description in \textit{Coordinate Format} for more details.

\textit{x}

Array, size at least \(m\).

On entry, the array \(x\) must contain the vector \(x\). The elements are accessed with unit increment.

\textit{y}

Array, size at least \(m\).

On entry, the array \(y\) must contain the vector \(y\). The elements are accessed with unit increment.

\textbf{Output Parameters}

\textit{y}

Contains solution vector \(x\).

\textbf{mkl\_?csrmm}

\textit{Computes matrix - matrix product of a sparse matrix stored in the CSR format (deprecated).}

\textbf{Syntax}

\begin{verbatim}
void mkl_scsrmm (const char *transa, const MKL_INT *m, const MKL_INT *n, const MKL_INT *k, const float *alpha, const char *matdescra, const float *val, const MKL_INT *indx, const MKL_INT *pntrb, const MKL_INT *pntre, const float *b, const MKL_INT *ldb, const float *beta, float *c, const MKL_INT *ldc);

Include Files

• mkl.h

Description

This routine is deprecated. Use Use mkl_sparse_?_mm from the Intel® MKL Inspector-executor Sparse BLAS interface instead.

The mkl_?csrmm routine performs a matrix-matrix operation defined as

\[ C := \alpha A B + \beta C \]

or

\[ C := \alpha A^T B + \beta C \]

or

\[ C := \alpha A^H B + \beta C, \]

where:

\( \alpha \) and \( \beta \) are scalars,

\( B \) and \( C \) are dense matrices, \( A \) is an \( m \)-by-\( k \) sparse matrix in compressed sparse row (CSR) format, \( A^T \) is the transpose of \( A \), and \( A^H \) is the conjugate transpose of \( A \).

**NOTE**

This routine supports a CSR format both with one-based indexing and zero-based indexing.

Input Parameters

**transa**

Specifies the operation.

If \( \text{transa} = 'N' \) or \( 'n' \), then \( C := \alpha A B + \beta C \),

If \( \text{transa} = 'T' \) or \( 't' \), then \( C := \alpha A^T B + \beta C \),

If \( \text{transa} = 'C' \) or \( 'c' \), then \( C := \alpha A^H B + \beta C \).

**m**

Number of rows of the matrix \( A \).

**n**

Number of columns of the matrix \( C \).

**k**

Number of columns of the matrix \( A \).

**alpha**

Specifies the scalar \( \alpha \).

**matdescra**

Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table “Possible Values of the Parameter matdescra (descra)”. Possible combinations of element values of this parameter are given in Table “Possible Combinations of Element Values of the Parameter matdescra”.

**val**

Array containing non-zero elements of the matrix \( A \).

For zero-based indexing its length is \( \text{pntre}[m-1] - \text{pntrb}[0] \).

Refer to values array description in CSR Format for more details.
For one-based indexing, array containing the column indices plus one for each non-zero element of the matrix $A$.

For zero-based indexing, array containing the column indices for each non-zero element of the matrix $A$.

Its length is equal to length of the $val$ array.

Refer to $columns$ array description in CSR Format for more details.

Array of length $m$.

This array contains row indices, such that $pntrb[I] - pntrb[0]$ is the first index of row $I$ in the arrays $val$ and $indx$.

Refer to $pointerb$ array description in CSR Format for more details.

Array of length $m$.

This array contains row indices, such that $pntre[I] - pntrb[0] - 1$ is the last index of row $I$ in the arrays $val$ and $indx$.

Refer to $pointerE$ array description in CSR Format for more details.

Array, size $ldb$ by at least $n$ for non-transposed matrix $A$ and at least $m$ for transposed for one-based indexing, and (at least $k$ for non-transposed matrix $A$ and at least $m$ for transposed, $ldb$) for zero-based indexing.

On entry with $transa='N'$ or 'n', the leading $k$-by-$n$ part of the array $b$ must contain the matrix $B$, otherwise the leading $m$-by-$n$ part of the array $b$ must contain the matrix $B$.

Specifies the leading dimension of $b$ for one-based indexing, and the second dimension of $b$ for zero-based indexing, as declared in the calling (sub)program.

Specifies the scalar $beta$.

Array, size $ldc$ by $n$ for one-based indexing, and ($m$, $ldc$) for zero-based indexing.

On entry, the leading $m$-by-$n$ part of the array $c$ must contain the matrix $C$, otherwise the leading $k$-by-$n$ part of the array $c$ must contain the matrix $C$.

Specifies the leading dimension of $c$ for one-based indexing, and the second dimension of $c$ for zero-based indexing, as declared in the calling (sub)program.

Overwritten by the matrix $(alpha*\mathbf{A}*\mathbf{B} + beta* \mathbf{C})$, $(alpha*\mathbf{A}^T*\mathbf{B} + beta* \mathbf{C})$, or $(alpha*\mathbf{A}^H*\mathbf{B} + beta* \mathbf{C})$.

$\texttt{mkl}_\texttt{-}bsrmm$

Computes matrix - matrix product of a sparse matrix stored in the BSR format (deprecated).
Syntax

void mkl_sbsrmm (const char *transa , const MKL_INT *m , const MKL_INT *n , const MKL_INT *k , const MKL_INT *lb , const float *alpha , const char *matdescra , const float *val , const MKL_INT *indx , const MKL_INT *pntrb , const MKL_INT *pntre , const float *b , const MKL_INT *ldb , const float *beta , float *c , const MKL_INT *ldc );

void mkl_dbsrmm (const char *transa , const MKL_INT *m , const MKL_INT *n , const MKL_INT *k , const MKL_INT *lb , const double *alpha , const char *matdescra , const double *val , const MKL_INT *indx , const MKL_INT *pntrb , const MKL_INT *pntre , const double *b , const MKL_INT *ldb , const double *beta , double *c , const MKL_INT *ldc );

void mkl_cbsrmm (const char *transa , const MKL_INT *m , const MKL_INT *n , const MKL_INT *k , const MKL_INT *lb , const MKL_Complex8 *alpha , const char *matdescra , const MKL_Complex8 *val , const MKL_INT *indx , const MKL_INT *pntrb , const MKL_INT *pntre , const MKL_Complex8 *b , const MKL_INT *ldb , const MKL_Complex8 *beta , MKL_Complex8 *c , const MKL_INT *ldc );

void mkl_zbsrmm (const char *transa , const MKL_INT *m , const MKL_INT *n , const MKL_INT *k , const MKL_INT *lb , const MKL_Complex16 *alpha , const char *matdescra , const MKL_Complex16 *val , const MKL_INT *indx , const MKL_INT *pntrb , const MKL_INT *pntre , const MKL_Complex16 *b , const MKL_INT *ldb , const MKL_Complex16 *beta , MKL_Complex16 *c , const MKL_INT *ldc );

Include Files
- mkl.h

Description

This routine is deprecated. Use Use mkl_sparse_?_mm from the Intel® MKL Inspector-executor Sparse BLAS interface instead.

The mkl_?bsrmm routine performs a matrix-matrix operation defined as

\[ C := \alpha A \cdot B + \beta C \]

or

\[ C := \alpha A^\top \cdot B + \beta C \]

or

\[ C := \alpha A^\mathbb{H} \cdot B + \beta C , \]

where:

- \( \alpha \) and \( \beta \) are scalars,
- \( B \) and \( C \) are dense matrices, \( A \) is an \( m \)-by-\( k \) sparse matrix in block sparse row (BSR) format, \( A^\top \) is the transpose of \( A \), and \( A^\mathbb{H} \) is the conjugate transpose of \( A \).

**NOTE**

This routine supports a BSR format both with one-based indexing and zero-based indexing.

Input Parameters

- \( \text{transa} \): Specifies the operation.
If $\text{transa} = 'N'$ or '$n'$, then the matrix-matrix product is computed as 
\[
C := \alpha \cdot A \cdot B + \beta \cdot C
\]

If $\text{transa} = 'T'$ or '$t'$, then the matrix-vector product is computed as 
\[
C := \alpha \cdot A^T \cdot B + \beta \cdot C
\]

If $\text{transa} = 'C'$ or '$c'$, then the matrix-vector product is computed as 
\[
C := \alpha \cdot A^H \cdot B + \beta \cdot C,
\]

$m$
Number of block rows of the matrix $A$.

$n$
Number of columns of the matrix $C$.

$k$
Number of block columns of the matrix $A$.

$lb$
Size of the block in the matrix $A$.

$\alpha$
Specifies the scalar $\alpha$.

$\text{matdescra}$
Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter $\text{matdescra (descra)}$". Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter $\text{matdescra}$".

$val$
Array containing elements of non-zero blocks of the matrix $A$. Its length is equal to the number of non-zero blocks in the matrix $A$ multiplied by $lb \cdot lb$. Refer to the $values$ array description in $BSR$ Format for more details.

$indx$
For one-based indexing, array containing the column indices plus one for each non-zero block in the matrix $A$.

For zero-based indexing, array containing the column indices for each non-zero block in the matrix $A$.

Its length is equal to the number of non-zero blocks in the matrix $A$. Refer to the $columns$ array description in $BSR$ Format for more details.

$\text{pntrb}$
Array of length $m$.

This array contains row indices, such that $\text{pntrb}[I] - \text{pntrb}[0]$ is the first index of block row $I$ in the array $indx$.

Refer to $pointerB$ array description in $BSR$ Format for more details.

$\text{pntrc}$
Array of length $m$.

This array contains row indices, such that $\text{pntrc}[I] - \text{pntrc}[0] - 1$ is the last index of block row $I$ in the array $indx$.

Refer to $pointerE$ array description in $BSR$ Format for more details.

$b$
Array, size $ldb$ by at least $n$ for non-transposed matrix $A$ and at least $m$ for transposed for one-based indexing, and (at least $k$ for non-transposed matrix $A$ and at least $m$ for transposed, $ldb$) for zero-based indexing.

On entry with $\text{transa}='N'$ or '$n$', the leading $n$-by-$k$ block part of the array $b$ must contain the matrix $B$, otherwise the leading $m$-by-$n$ block part of the array $b$ must contain the matrix $B$. 
**ldb**

Specifies the leading dimension (in blocks) of \( b \) as declared in the calling (sub)program.

**beta**

Specifies the scalar \( \beta \).

**c**

Array, size \( ldc \times n \) for one-based indexing, size \( k \times ldc \) for zero-based indexing.

On entry, the leading \( m \)-by-\( n \) block part of the array \( c \) must contain the matrix \( C \), otherwise the leading \( n \)-by-\( k \) block part of the array \( c \) must contain the matrix \( C \).

**ldc**

Specifies the leading dimension (in blocks) of \( c \) as declared in the calling (sub)program.

**Output Parameters**

**c**

Overwritten by the matrix \((\alpha A^T B + \beta C)\) or \((\alpha A^H B + \beta C)\) or \((\alpha A^* B + \beta C)\).

---

**mkl_?cscmm**

Computes matrix-matrix product of a sparse matrix stored in the CSC format (deprecated).

**Syntax**

```c
void mkl_scscmm (const char *transa, const MKL_INT *m, const MKL_INT *n, const MKL_INT *k, const float *alpha, const char *matdescra, const float *val, const MKL_INT *indx, const MKL_INT *pntrb, const MKL_INT *pntre, const float *b, const MKL_INT *ldb, const float *beta, float *c, const MKL_INT *ldc);
void mkl_dcscmm (const char *transa, const MKL_INT *m, const MKL_INT *n, const MKL_INT *k, const double *alpha, const char *matdescra, const double *val, const MKL_INT *indx, const MKL_INT *pntrb, const MKL_INT *pntre, const double *b, const MKL_INT *ldb, const double *beta, double *c, const MKL_INT *ldc);
void mkl_ccscmm (const char *transa, const MKL_INT *m, const MKL_INT *n, const MKL_INT *k, const MKL_Complex8 *alpha, const char *matdescra, const MKL_Complex8 *val, const MKL_INT *indx, const MKL_INT *pntrb, const MKL_INT *pntre, const MKL_Complex8 *b, const MKL_INT *ldb, const MKL_Complex8 *beta, MKL_Complex8 *c, const MKL_INT *ldc);
void mkl_zcscmm (const char *transa, const MKL_INT *m, const MKL_INT *n, const MKL_INT *k, const MKL_Complex16 *alpha, const char *matdescra, const MKL_Complex16 *val, const MKL_INT *indx, const MKL_INT *pntrb, const MKL_INT *pntre, const MKL_Complex16 *b, const MKL_INT *ldb, const MKL_Complex16 *beta, MKL_Complex16 *c, const MKL_INT *ldc);
```

**Include Files**

**Description**

This routine is deprecated. Use Use mkl_sparse_?_mm from the Intel® MKL Inspector-executor Sparse BLAS interface instead.
The `mkl_?cscmm` routine performs a matrix-matrix operation defined as

\[ C := \alpha A B + \beta C \]

or

\[ C := \alpha A^T B + \beta C, \]

or

\[ C := \alpha A^H B + \beta C, \]

where:

\( \alpha \) and \( \beta \) are scalars,

\( B \) and \( C \) are dense matrices, \( A \) is an \( m \)-by-\( k \) sparse matrix in compressed sparse column (CSC) format, \( A^T \) is the transpose of \( A \), and \( A^H \) is the conjugate transpose of \( A \).

**NOTE**

This routine supports CSC format both with one-based indexing and zero-based indexing.

## Input Parameters

- **transa**: Specifies the operation.
  - If `transa = 'N'` or `'n'`, then \( C := \alpha A B + \beta C \)
  - If `transa = 'T'` or `'t'`, then \( C := \alpha A^T B + \beta C \)
  - If `transa = 'C'` or `'c'`, then \( C := \alpha A^H B + \beta C \)

- **m**: Number of rows of the matrix \( A \).

- **n**: Number of columns of the matrix \( C \).

- **k**: Number of columns of the matrix \( A \).

- **alpha**: Specifies the scalar \( \alpha \).

- **matdescra**: Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter matdescra (descra)". Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter matdescra".

- **val**: Array containing non-zero elements of the matrix \( A \).
  - Its length is \( \text{pntrb}[k-1] - \text{pntrb}[0] \).
  - Refer to `values` array description in CSC Format for more details.

- **indx**: For one-based indexing, array containing the row indices plus one for each non-zero element of the matrix \( A \).
  - For zero-based indexing, array containing the column indices for each non-zero element of the matrix \( A \).
  - Its length is equal to length of the `val` array.
  - Refer to `rows` array description in CSC Format for more details.

- **pntrb**: Array of length \( k \).
This array contains column indices, such that \( \text{pntrb}[i] - \text{pntrb}[0] \) is the first index of column \( i \) in the arrays \( \text{val} \) and \( \text{indx} \).

Refer to \( \text{pointerb} \) array description in \textit{CSC Format} for more details.

\textit{pntre} Array of length \( k \).

This array contains column indices, such that \( \text{pntre}[i] - \text{pntrb}[0] - 1 \) is the last index of column \( i \) in the arrays \( \text{val} \) and \( \text{indx} \).

Refer to \( \text{pointerE} \) array description in \textit{CSC Format} for more details.

\textit{b} Array, size \( \text{ldb} \) by at least \( n \) for non-transposed matrix \( A \) and at least \( m \) for transposed for one-based indexing, and (at least \( k \) for non-transposed matrix \( A \) and at least \( m \) for transposed, \( \text{ldb} \)) for zero-based indexing.

On entry with \( \text{transa} = 'N' \) or \( 'n' \), the leading \( k \)-by-\( n \) part of the array \( b \) must contain the matrix \( B \), otherwise the leading \( m \)-by-\( n \) part of the array \( b \) must contain the matrix \( B \).

\textit{ldb} Specifies the leading dimension of \( b \) for one-based indexing, and the second dimension of \( b \) for zero-based indexing, as declared in the calling (sub)program.

\textit{beta} Specifies the scalar \( \beta \).

\textit{c} Array, size \( \text{ldc} \) by \( n \) for one-based indexing, and \( (m, \text{ldc}) \) for zero-based indexing.

On entry, the leading \( m \)-by-\( n \) part of the array \( c \) must contain the matrix \( C \), otherwise the leading \( k \)-by-\( n \) part of the array \( c \) must contain the matrix \( C \).

\textit{ldc} Specifies the leading dimension of \( c \) for one-based indexing, and the second dimension of \( c \) for zero-based indexing, as declared in the calling (sub)program.

\textbf{Output Parameters}

\textit{c} Overwritten by the matrix \((\alpha A B + \beta C)\) or \((\alpha A^T B + \beta C)\) or \((\alpha A^H B + \beta C)\).

\textbf{mkl_?coomm}

\textit{Computes matrix-matrix product of a sparse matrix stored in the coordinate format (deprecated).}

\textbf{Syntax}

\begin{verbatim}
void mkl_scoomm (const char *transa, const MKL_INT *m, const MKL_INT *n, const MKL_INT *k, const float *alpha, const char *matdescra, const float *val, const MKL_INT *rowind, const MKL_INT *colind, const MKL_INT *nnz, const float *b, const MKL_INT *ldb, const float *beta, float *c, const MKL_INT *ldc);

void mkl_dcoomm (const char *transa, const MKL_INT *m, const MKL_INT *n, const MKL_INT *k, const double *alpha, const char *matdescra, const double *val, const MKL_INT *rowind, const MKL_INT *colind, const MKL_INT *nnz, const double *b, const MKL_INT *ldb, const double *beta, double *c, const MKL_INT *ldc);
\end{verbatim}
void mkl_ccoomm (const char *transa, const MKL_INT *m, const MKL_INT *n, const MKL_INT *k, const MKL_Complex8 *alpha, const char *matdescra, const MKL_Complex8 *val, const MKL_INT *rowind, const MKL_INT *colind, const MKL_INT *nnz, const MKL_Complex8 *b, const MKL_INT *ldb, const MKL_Complex8 *beta, MKL_Complex8 *c, const MKL_INT *ldc);

void mkl_zcoomm (const char *transa, const MKL_INT *m, const MKL_INT *n, const MKL_INT *k, const MKL_Complex16 *alpha, const char *matdescra, const MKL_Complex16 *val, const MKL_INT *rowind, const MKL_INT *colind, const MKL_INT *nnz, const MKL_Complex16 *b, const MKL_INT *ldb, const MKL_Complex16 *beta, MKL_Complex16 *c, const MKL_INT *ldc);

Description
This routine is deprecated. Use mkl_sparse_?_mm from the Intel® MKL Inspector-executor Sparse BLAS interface instead.

The mkl_?coomm routine performs a matrix-matrix operation defined as

\[ C := \alpha A B + \beta C \]

or

\[ C := \alpha A^T B + \beta C, \]

or

\[ C := \alpha A^H B + \beta C, \]

where:
\( \alpha \) and \( \beta \) are scalars,

\( B \) and \( C \) are dense matrices, \( A \) is an \( m \)-by-\( k \) sparse matrix in the coordinate format, \( A^T \) is the transpose of \( A \), and \( A^H \) is the conjugate transpose of \( A \).

NOTE
This routine supports a coordinate format both with one-based indexing and zero-based indexing.

Input Parameters

transa

Specifies the operation.

If \( \text{transa} = \text{'N'} \) or \( \text{'n'} \), then \( C := \alpha A B + \beta C \)

If \( \text{transa} = \text{'T'} \) or \( \text{'t'} \), then \( C := \alpha A^T B + \beta C, \)

If \( \text{transa} = \text{'C'} \) or \( \text{'c'} \), then \( C := \alpha A^H B + \beta C. \)

m

Number of rows of the matrix \( A \).

n

Number of columns of the matrix \( C \).

k

Number of columns of the matrix \( A \).

alpha

Specifies the scalar \( \alpha \).
matdescra

Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter matdescra (descra)". Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter matdescra".

val

Array of length \( nnz \), contains non-zero elements of the matrix \( A \) in the arbitrary order.

Refer to values array description in Coordinate Format for more details.

rowind

Array of length \( nnz \).

For one-based indexing, contains the row indices plus one for each non-zero element of the matrix \( A \).

For zero-based indexing, contains the row indices for each non-zero element of the matrix \( A \).

Refer to rows array description in Coordinate Format for more details.

colind

Array of length \( nnz \).

For one-based indexing, contains the column indices plus one for each non-zero element of the matrix \( A \).

For zero-based indexing, contains the column indices for each non-zero element of the matrix \( A \).

Refer to columns array description in Coordinate Format for more details.

nnz

Specifies the number of non-zero element of the matrix \( A \).

Refer to \( nnz \) description in Coordinate Format for more details.

b

Array, size \( ldb \) by at least \( n \) for non-transposed matrix \( A \) and at least \( m \) for transposed for one-based indexing, and (at least \( k \) for non-transposed matrix \( A \) and at least \( m \) for transposed, \( ldb \)) for zero-based indexing.

On entry with \( transa = 'N' \) or \( 'n' \), the leading \( k \)-by-\( n \) part of the array \( b \) must contain the matrix \( B \), otherwise the leading \( m \)-by-\( n \) part of the array \( b \) must contain the matrix \( B \).

ldb

Specifies the leading dimension of \( b \) for one-based indexing, and the second dimension of \( b \) for zero-based indexing, as declared in the calling (sub)program.

beta

Specifies the scalar \( beta \).

c

Array, size \( ldc \) by \( n \) for one-based indexing, and \( (m, \ ldc) \) for zero-based indexing.

On entry, the leading \( m \)-by-\( n \) part of the array \( c \) must contain the matrix \( C \), otherwise the leading \( k \)-by-\( n \) part of the array \( c \) must contain the matrix \( C \).

ldc

Specifies the leading dimension of \( c \) for one-based indexing, and the second dimension of \( c \) for zero-based indexing, as declared in the calling (sub)program.
Output Parameters

\[ c \quad \text{Overwritten by the matrix } (\alpha A B + \beta C), (\alpha A^T B + \beta C), \text{ or } (\alpha A^H B + \beta C). \]

mkl_?csrsm

Solves a system of linear matrix equations for a sparse matrix in the CSR format (deprecated).

Syntax

\[
\begin{align*}
\text{void mkl_scsrsm} & \quad (\text{const char}*\text{transa}, \text{const MKL_INT}*m, \text{const MKL_INT}*n, \text{const float}*\alpha, \text{const char}*\text{matdescra}, \text{const float}*\text{val}, \text{const MKL_INT}^{*}\text{indx}, \text{const MKL_INT}^{*}\text{pntrb}, \text{const MKL_INT}^{*}\text{pntre}, \text{const float}*b, \text{const MKL_INT}^{*}\text{ldb}, \text{float}*c, \text{const MKL_INT}^{*}\text{ldc}); \\
\text{void mkl_dcsrsm} & \quad (\text{const char}*\text{transa}, \text{const MKL_INT}*m, \text{const MKL_INT}*n, \text{const double}*\alpha, \text{const char}*\text{matdescra}, \text{const double}*\text{val}, \text{const MKL_INT}^{*}\text{indx}, \text{const MKL_INT}^{*}\text{pntrb}, \text{const MKL_INT}^{*}\text{pntre}, \text{const double}*b, \text{const MKL_INT}^{*}\text{ldb}, \text{double}*c, \text{const MKL_INT}^{*}\text{ldc}); \\
\text{void mkl_ccsrsm} & \quad (\text{const char}*\text{transa}, \text{const MKL_INT}*m, \text{const MKL_INT}*n, \text{const MKL_Complex8}*\alpha, \text{const char}*\text{matdescra}, \text{const MKL_Complex8}*\text{val}, \text{const MKL_INT}^{*}\text{indx}, \text{const MKL_INT}^{*}\text{pntrb}, \text{const MKL_INT}^{*}\text{pntre}, \text{const MKL_Complex8}*b, \text{const MKL_INT}^{*}\text{ldb}, \text{MKL_Complex8}*c, \text{const MKL_INT}^{*}\text{ldc}); \\
\text{void mkl_zcsrsm} & \quad (\text{const char}*\text{transa}, \text{const MKL_INT}*m, \text{const MKL_INT}*n, \text{const MKL_Complex16}*\alpha, \text{const char}*\text{matdescra}, \text{const MKL_Complex16}*\text{val}, \text{const MKL_INT}^{*}\text{indx}, \text{const MKL_INT}^{*}\text{pntrb}, \text{const MKL_INT}^{*}\text{pntre}, \text{const MKL_Complex16}*b, \text{const MKL_INT}^{*}\text{ldb}, \text{MKL_Complex16}*c, \text{const MKL_INT}^{*}\text{ldc});
\end{align*}
\]

Include Files

- mkl.h

Description

This routine is deprecated. Use mkl_sparse_?_trsm from the Intel® MKL Inspector-executor Sparse BLAS interface instead.

The mkl_?csrsm routine solves a system of linear equations with matrix-matrix operations for a sparse matrix in the CSR format:

\[
C := \alpha \text{inv}(A)B
\]

or

\[
C := \alpha \text{inv}(A^T)B,
\]

where:

\( \alpha \) is scalar, \( B \) and \( C \) are dense matrices, \( A \) is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, \( A^T \) is the transpose of \( A \).

NOTE

This routine supports a CSR format both with one-based indexing and zero-based indexing.
Input Parameters

transa

Specifies the system of linear equations.

If transa = 'N' or 'n', then \( C := \alpha \cdot \text{inv}(A) \cdot B \)

If transa = 'T' or 't' or 'C' or 'c', then \( C := \alpha \cdot \text{inv}(A^T) \cdot B \)

m

Number of columns of the matrix \( A \).

n

Number of columns of the matrix \( C \).

alpha

Specifies the scalar \( \alpha \).

matdescra

Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter matdescra (descra)". Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter matdescra".

val

Array containing non-zero elements of the matrix \( A \).

For zero-based indexing its length is \( pntre[m-1] - pntrb[0] \).

Refer to values array description in CSR Format for more details.

NOTE

The non-zero elements of the given row of the matrix must be stored in the same order as they appear in the row (from left to right).

No diagonal element can be omitted from a sparse storage if the solver is called with the non-unit indicator.

indx

For one-based indexing, array containing the column indices plus one for each non-zero element of the matrix \( A \).

For zero-based indexing, array containing the column indices for each non-zero element of the matrix \( A \).

Its length is equal to length of the val array.

Refer to columns array description in CSR Format for more details.

NOTE

Column indices must be sorted in increasing order for each row.

pntrb

Array of length \( m \).

This array contains row indices, such that \( \text{pntrb}[i] - \text{pntrb}[0] \) is the first index of row \( i \) in the arrays \( \text{val} \) and \( \text{indx} \).

Refer to pointerb array description in CSR Format for more details.

pntre

Array of length \( m \).

For zero-based indexing this array contains row indices, such that \( \text{pntre}[i] - \text{pntrb}[0] - 1 \) is the last index of row \( i \) in the arrays \( \text{val} \) and \( \text{indx} \).
Refer to pointerE array description in CSR Format for more details.

*b*

Array, size ldb* n for one-based indexing, and (m, ldb) for zero-based indexing.

On entry the leading m-by-n part of the array b must contain the matrix B.

*ldb*

Specifies the leading dimension of b for one-based indexing, and the second dimension of b for zero-based indexing, as declared in the calling (sub)program.

*ldc*

Specifies the leading dimension of c for one-based indexing, and the second dimension of c for zero-based indexing, as declared in the calling (sub)program.

**Output Parameters**

*c*

Array, size ldc by n for one-based indexing, and (m, ldc) for zero-based indexing.

The leading m-by-n part of the array c contains the output matrix C.

**mkl_?cscsm**

Solves a system of linear matrix equations for a sparse matrix in the CSC format (deprecated).

**Syntax**

```c
void mkl_scscsm (const char *transa, const MKL_INT *m, const MKL_INT *n, const float *alpha, const char *matdescra, const float *val, const MKL_INT *indx, const MKL_INT *pntrb, const MKL_INT *pntre, const float *b, const MKL_INT *ldb, float *c, const MKL_INT *ldc);
void mkl_dcscsm (const char *transa, const MKL_INT *m, const MKL_INT *n, const double *alpha, const char *matdescra, const double *val, const MKL_INT *indx, const MKL_INT *pntrb, const MKL_INT *pntre, const double *b, const MKL_INT *ldb, double *c, const MKL_INT *ldc);
void mkl_ccscsm (const char *transa, const MKL_INT *m, const MKL_INT *n, const MKL_Complex8 *alpha, const char *matdescra, const MKL_Complex8 *val, const MKL_INT *indx, const MKL_INT *pntrb, const MKL_INT *pntre, const MKL_Complex8 *b, const MKL_INT *ldb, MKL_Complex8 *c, const MKL_INT *ldc);

```

**Include Files**

- mkl.h

**Description**

This routine is deprecated. Use mkl_sparse_?_trsm from the Intel® MKL Inspector-executor Sparse BLAS interface instead.
The mkl_?cscsm routine solves a system of linear equations with matrix-matrix operations for a sparse matrix in the CSC format:

\[ C := \alpha \cdot \text{inv}(A) \cdot B \]

or

\[ C := \alpha \cdot \text{inv}(A^T) \cdot B, \]

where:

\( \alpha \) is scalar, \( B \) and \( C \) are dense matrices, \( A \) is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, \( A^T \) is the transpose of \( A \).

**NOTE**
This routine supports a CSC format both with one-based indexing and zero-based indexing.

**Input Parameters**

- **transa**
  Specifies the system of equations.
  - If \( \text{transa} = 'N' \) or \'n' \), then \( C := \alpha \cdot \text{inv}(A) \cdot B \)
  - If \( \text{transa} = 'T' \) or \'t' \) or \'C' \) or \'c' \), then \( C := \alpha \cdot \text{inv}(A^T) \cdot B, \)

- **m**
  Number of columns of the matrix \( A \).

- **n**
  Number of columns of the matrix \( C \).

- **alpha**
  Specifies the scalar \( \alpha \).

- **matdescra**
  Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter matdescra (descra)". Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter matdescra".

- **val**
  Array containing non-zero elements of the matrix \( A \).
  For zero-based indexing its length is \( \text{pnre}[m] - \text{pntrb}[0] \).
  Refer to values array description in CSC Format for more details.

**NOTE**
The non-zero elements of the given row of the matrix must be stored in the same order as they appear in the row (from left to right).

No diagonal element can be omitted from a sparse storage if the solver is called with the non-unit indicator.

- **indx**
  For one-based indexing, array containing the row indices plus one for each non-zero element of the matrix \( A \). For zero-based indexing, array containing the row indices for each non-zero element of the matrix \( A \).
  Refer to rows array description in CSC Format for more details.
Row indices must be sorted in increasing order for each column.

**pntrb**

Array of length \( m \).
This array contains column indices, such that \( pntrb[I] - pntrb[0] \) is the first index of column \( I \) in the arrays \( val \) and \( indx \).
Refer to \( pointerb \) array description in **CSC Format** for more details.

**pntrE**

Array of length \( m \).
This array contains column indices, such that \( pntrE[I] - pntrb[I]-1 \) is the last index of column \( I \) in the arrays \( val \) and \( indx \).
Refer to \( pointerE \) array description in **CSC Format** for more details.

**b**

Array, size \( ldb \) by \( n \) for one-based indexing, and \((m, ldb)\) for zero-based indexing.
On entry the leading \( m \)-by-\( n \) part of the array \( b \) must contain the matrix \( B \).

**ldb**

Specifies the leading dimension of \( b \) for one-based indexing, and the second dimension of \( b \) for zero-based indexing, as declared in the calling (sub)program.

**ldc**

Specifies the leading dimension of \( c \) for one-based indexing, and the second dimension of \( c \) for zero-based indexing, as declared in the calling (sub)program.

**Output Parameters**

**c**

Array, size \( ldc \) by \( n \) for one-based indexing, and \((m, ldc)\) for zero-based indexing.
The leading \( m \)-by-\( n \) part of the array \( c \) contains the output matrix \( C \).

**mkl_?coosm**

Solves a system of linear matrix equations for a sparse matrix in the coordinate format (deprecated).

**Syntax**

void mkl_scoosm (const char *transa, const MKL_INT *m, const MKL_INT *n, const float *alpha, const char *matdesca, const float *val, const MKL_INT *rowind, const MKL_INT *colind, const MKL_INT *nnz, const float *b, const MKL_INT *ldb, float *c, const MKL_INT *ldc);

void mkl_dcoosm (const char *transa, const MKL_INT *m, const MKL_INT *n, const double *alpha, const char *matdesca, const double *val, const MKL_INT *rowind, const MKL_INT *colind, const MKL_INT *nnz, const double *b, const MKL_INT *ldb, double *c, const MKL_INT *ldc);

void mkl_ccoosm (const char *transa, const MKL_INT *m, const MKL_INT *n, const MKL_Complex8 *alpha, const char *matdesca, const MKL_Complex8 *val, const MKL_INT *rowind, const MKL_INT *colind, const MKL_INT *nnz, const MKL_Complex8 *b, const MKL_INT *ldb, MKL_Complex8 *c, const MKL_INT *ldc);
void mkl_zcoosm (const char *transa, const MKL_INT *m, const MKL_INT *n, const MKL_Complex16 *alpha, const char *matdescra, const MKL_Complex16 *val, const MKL_INT *rowind, const MKL_INT *colind, const MKL_INT *nnz, const MKL_Complex16 *b, const MKL_INT *ldb, MKL_Complex16 *c, const MKL_INT *ldc);

Include Files

- mkl.h

Description

This routine is deprecated. Use mkl_sparse_?_trsm from the Intel® MKL Inspector-executor Sparse BLAS interface instead.

The mkl_zcoosm routine solves a system of linear equations with matrix-matrix operations for a sparse matrix in the coordinate format:

\[ C := alpha \cdot \text{inv}(A) \cdot B \]

or

\[ C := alpha \cdot \text{inv}(A^T) \cdot B, \]

where:

- \( alpha \) is scalar, \( B \) and \( C \) are dense matrices, \( A \) is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, \( A^T \) is the transpose of \( A \).

**NOTE**

This routine supports a coordinate format both with one-based indexing and zero-based indexing.

Input Parameters

- **transa**: Specifies the system of linear equations.
  - If \( transa = 'N' \) or \( 'n' \), then the matrix-matrix product is computed as \( C := alpha \cdot \text{inv}(A) \cdot B \).
  - If \( transa = 'T' \) or \( 't' \) or \( 'C' \) or \( 'c' \), then the matrix-vector product is computed as \( C := alpha \cdot \text{inv}(A^T) \cdot B \).

- **m**: Number of rows of the matrix \( A \).

- **n**: Number of columns of the matrix \( C \).

- **alpha**: Specifies the scalar \( alpha \).

- **matdescra**: Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter matdescra (descra)". Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter matdescra".

- **val**: Array of length \( nnz \), contains non-zero elements of the matrix \( A \) in the arbitrary order.
  - Refer to \( values \) array description in Coordinate Format for more details.

- **rowind**

- **colind**

- **nnz**

- **b**: Constant dense matrix \( B \).

- **ldb**

- **ldc**

- **c**: Constant dense matrix \( C \).

- **alpha**: Constant scalar \( alpha \).
For one-based indexing, contains the row indices plus one for each non-zero element of the matrix $A$.
For zero-based indexing, contains the row indices for each non-zero element of the matrix $A$.

Refer to rows array description in Coordinate Format for more details.

$\text{colind}$

Array of length $nnz$.
For one-based indexing, contains the column indices plus one for each non-zero element of the matrix $A$.
For zero-based indexing, contains the row indices for each non-zero element of the matrix $A$.

Refer to columns array description in Coordinate Format for more details.

$nnz$

Specifies the number of non-zero element of the matrix $A$.
Refer to nnz description in Coordinate Format for more details.

$b$

Array, size $ldb$ by $n$ for one-based indexing, and $(m, ldb)$ for zero-based indexing.
Before entry the leading $m$-by-$n$ part of the array $b$ must contain the matrix $B$.

$ldb$

Specifies the leading dimension of $b$ for one-based indexing, and the second dimension of $b$ for zero-based indexing, as declared in the calling (sub)program.

$ldc$

Specifies the leading dimension of $c$ for one-based indexing, and the second dimension of $c$ for zero-based indexing, as declared in the calling (sub)program.

**Output Parameters**

$c$

Array, size $ldc$ by $n$ for one-based indexing, and $(m, ldc)$ for zero-based indexing.
The leading $m$-by-$n$ part of the array $c$ contains the output matrix $C$.

**mkl\_?bsrsm**

Solves a system of linear matrix equations for a sparse matrix in the BSR format (deprecated).

**Syntax**

```c
void mkl_sbsrsm (const char *transa, const MKL_INT *m, const MKL_INT *n, const MKL_INT *lb, const float *alpha, const char *matdescra, const float *val, const MKL_INT *indx, const MKL_INT *pntrb, const MKL_INT *pntre, const float *b, const MKL_INT *ldb, float *c, const MKL_INT *ldc);
void mkl_dbsrsm (const char *transa, const MKL_INT *m, const MKL_INT *n, const MKL_INT *lb, const double *alpha, const char *matdescra, const double *val, const MKL_INT *indx, const MKL_INT *pntrb, const MKL_INT *pntre, const double *b, const MKL_INT *ldb, double *c, const MKL_INT *ldc);
```
void mkl_cbsrsm (const char *transa, const MKL_INT *m, const MKL_INT *n, const MKL_INT *lb, const MKL_Complex8 *alpha, const char *matdescra, const MKL_Complex8 *val, const MKL_INT *indx, const MKL_INT *pntrb, const MKL_INT *pntre, const MKL_Complex8 *b, const MKL_INT *ldb, MKL_Complex8 *c, const MKL_INT *ldc);

void mkl_zbsrsm (const char *transa, const MKL_INT *m, const MKL_INT *n, const MKL_INT *lb, const MKL_Complex16 *alpha, const char *matdescra, const MKL_Complex16 *val, const MKL_INT *indx, const MKL_INT *pntrb, const MKL_INT *pntre, const MKL_Complex16 *b, const MKL_INT *ldb, MKL_Complex16 *c, const MKL_INT *ldc);

Include Files

- mkl.h

Description

This routine is deprecated. Use mkl_sparse_?_trsm from the Intel® MKL Inspector-executor Sparse BLAS interface instead.

The mkl_?bsrsm routine solves a system of linear equations with matrix-matrix operations for a sparse matrix in the BSR format:

\[
C := \alpha * \text{inv}(A) * B
\]

or

\[
C := \alpha * \text{inv}(A^T) * B,
\]

where:

\(\alpha\) is scalar, \(B\) and \(C\) are dense matrices, \(A\) is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, \(A^T\) is the transpose of \(A\).

NOTE

This routine supports a BSR format both with one-based indexing and zero-based indexing.

Input Parameters

**transa**

Specifies the operation.

- If \(\text{transa} = 'N'\) or \(\text{'n'}\), then the matrix-matrix product is computed as \(C := \alpha * \text{inv}(A) * B\).
- If \(\text{transa} = 'T'\) or \(\text{'t'}\) or \(\text{'C'}\) or \(\text{'c'}\), then the matrix-vector product is computed as \(C := \alpha * \text{inv}(A^T) * B\).

**m**

Number of block columns of the matrix \(A\).

**n**

Number of columns of the matrix \(C\).

**lb**

Size of the block in the matrix \(A\).

**alpha**

Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter matdescra (descra)". Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter matdescra".

**matdescra**

Specifies the scalar \(\alpha\).
val

Array containing elements of non-zero blocks of the matrix $A$. Its length is equal to the number of non-zero blocks in the matrix $A$ multiplied by $lb*lb$. Refer to the values array description in BSR Format for more details.

NOTE
The non-zero elements of the given row of the matrix must be stored in the same order as they appear in the row (from left to right).

No diagonal element can be omitted from a sparse storage if the solver is called with the non-unit indicator.

indx

For one-based indexing, array containing the column indices plus one for each non-zero element of the matrix $A$. For zero-based indexing, array containing the column indices for each non-zero element of the matrix $A$. Its length is equal to the number of non-zero blocks in the matrix $A$. Refer to the columns array description in BSR Format for more details.

pntrb

Array of length $m$.

This array contains row indices, such that $\text{pntrb}[i] - \text{pntrb}[0]$ is the first index of block row $i$ in the array $\text{indx}$.

Refer to pointerB array description in BSR Format for more details.

pnre

Array of length $m$.

This array contains row indices, such that $\text{pnre}[i] - \text{pntrb}[0] - 1$ is the last index of block row $i$ in the arrays $\text{val}$ and $\text{indx}$.

Refer to pointerE array description in BSR Format for more details.

b

Array, size $ldb* n$ for one-based indexing, size $m* ldb$ for zero-based indexing.

On entry the leading $m$-by-$n$ part of the array $b$ must contain the matrix $B$.

$ldb$

Specifies the leading dimension (in blocks) of $b$ as declared in the calling (sub)program.

$ldc$

Specifies the leading dimension (in blocks) of $c$ as declared in the calling (sub)program.

Output Parameters

$c$

Array, size $ldc* n$ for one-based indexing, size $m* ldc$ for zero-based indexing.

The leading $m$-by-$n$ part of the array $c$ contains the output matrix $C$.

mkl_?diamv

Computes matrix - vector product for a sparse matrix in the diagonal format with one-based indexing (deprecated).
Syntax

```c
void mkl_sdiamv (const char *transa, const MKL_INT *m, const MKL_INT *k, const float *alpha, const char *matdescra, const float *val, const MKL_INT *lval, const MKL_INT *idiag, const MKL_INT *ndiag, const float *x, const float *beta, float *y);
void mkl_ddiamv (const char *transa, const MKL_INT *m, const MKL_INT *k, const double *alpha, const char *matdescra, const double *val, const MKL_INT *lval, const MKL_INT *idiag, const MKL_INT *ndiag, const double *x, const double *beta, double *y);
void mkl_cdiamv (const char *transa, const MKL_INT *m, const MKL_INT *k, const MKL_Complex8 *alpha, const char *matdescra, const MKL_Complex8 *val, const MKL_INT *lval, const MKL_INT *idiag, const MKL_INT *ndiag, const MKL_Complex8 *x, const MKL_Complex8 *beta, MKL_Complex8 *y);
void mkl_zdiamv (const char *transa, const MKL_INT *m, const MKL_INT *k, const MKL_Complex16 *alpha, const char *matdescra, const MKL_Complex16 *val, const MKL_INT *lval, const MKL_INT *idiag, const MKL_INT *ndiag, const MKL_Complex16 *x, const MKL_Complex16 *beta, MKL_Complex16 *y);
```

Include Files

- mkl.h

Description

This routine is deprecated. Use mkl_sparse_?_mv from the Intel® MKL Inspector-executor Sparse BLAS interface instead.

The `mkl_?diamv` routine performs a matrix-vector operation defined as

\[
y := \alpha A x + \beta y
\]

or

\[
y := \alpha A^T x + \beta y,
\]

where:

- \(\alpha\) and \(\beta\) are scalars,
- \(x\) and \(y\) are vectors,
- \(A\) is an \(m\)-by-\(k\) sparse matrix stored in the diagonal format, \(A^T\) is the transpose of \(A\).

**NOTE**

This routine supports only one-based indexing of the input arrays.

Input Parameters

- **transa**: Specifies the operation.
  
  If `transa` = 'N' or 'n', then \(y := \alpha A x + \beta y\),
  
  If `transa` = 'T' or 't' or 'C' or 'c', then \(y := \alpha A^T x + \beta y\).

- **m**: Number of rows of the matrix \(A\).
- **k**: Number of columns of the matrix \(A\).
alpha

Specifies the scalar $alpha$.

matdescra

Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter matdescra (descra)". Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter matdescra".

val

Two-dimensional array of size $lval$ by $ndiag$, contains non-zero diagonals of the matrix $A$. Refer to values array description in Diagonal Storage Scheme for more details.

lval

Leading dimension of $val$, $lval \geq m$. Refer to $lval$ description in Diagonal Storage Scheme for more details.

idiag

Array of length $ndiag$, contains the distances between main diagonal and each non-zero diagonals in the matrix $A$. Refer to distance array description in Diagonal Storage Scheme for more details.

ndiag

Specifies the number of non-zero diagonals of the matrix $A$.

x

Array, size at least $k$ if $transa = 'N'$ or 'n', and at least $m$ otherwise. On entry, the array $x$ must contain the vector $x$.

beta

Specifies the scalar $beta$.

y

Array, size at least $m$ if $transa = 'N'$ or 'n', and at least $k$ otherwise. On entry, the array $y$ must contain the vector $y$.

Output Parameters

y

Overwritten by the updated vector $y$.

mkl_?skymv

Computes matrix - vector product for a sparse matrix in the skyline storage format with one-based indexing (deprecated).

Syntax

```
void mkl_sskymv (const char *transa, const MKL_INT *m, const MKL_INT *k, const float *alpha, const char *matdescra, const float *val, const MKL_INT *pntr, const float *x, const float *beta, float *y);
void mkl_dskymv (const char *transa, const MKL_INT *m, const MKL_INT *k, const double *alpha, const char *matdescra, const double *val, const MKL_INT *pntr, const double *x, const double *beta, double *y);
void mkl_cskymv (const char *transa, const MKL_INT *m, const MKL_INT *k, const MKL_Complex8 *alpha, const char *matdescra, const MKL_Complex8 *val, const MKL_INT *pntr, const MKL_Complex8 *x, const MKL_Complex8 *beta, MKL_Complex8 *y);
void mkl_zskymv (const char *transa, const MKL_INT *m, const MKL_INT *k, const MKL_Complex16 *alpha, const char *matdescra, const MKL_Complex16 *val, const MKL_INT *pntr, const MKL_Complex16 *x, const MKL_Complex16 *beta, MKL_Complex16 *y);
```
Include Files
• mkl.h

Description
This routine is deprecated. Use mkl_sparse_?_mv from the Intel® MKL Inspector-executor Sparse BLAS interface instead.

The mkl_?skymv routine performs a matrix-vector operation defined as

\[ y := \alpha A x + \beta y \]

or

\[ y := \alpha A^T x + \beta y, \]

where:
\( \alpha \) and \( \beta \) are scalars,
\( x \) and \( y \) are vectors,
\( A \) is an \( m \)-by-\( k \) sparse matrix stored using the skyline storage scheme, \( A^T \) is the transpose of \( A \).

**NOTE**
This routine supports only one-based indexing of the input arrays.

Input Parameters

\( transa \)
Specifies the operation.
If \( transa = 'N' \) or \( 'n' \), then \( y := \alpha A x + \beta y \)
If \( transa = 'T' \) or \( 't' \) or \( 'C' \) or \( 'c' \), then \( y := \alpha A^T x + \beta y \),

\( m \)
Number of rows of the matrix \( A \).

\( k \)
Number of columns of the matrix \( A \).

\( alpha \)
Specifies the scalar \( \alpha \).

\( matdescra \)
Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter matdescra (descra)". Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter matdescra".

**NOTE**
General matrices (\( matdescra[0]='G' \)) is not supported.

\( val \)
Array containing the set of elements of the matrix \( A \) in the skyline profile form.
If \( matdescra[1]='L' \), then \( val \) contains elements from the low triangle of the matrix \( A \).
If \( matdescra[1]='U' \), then \( val \) contains elements from the upper triangle of the matrix \( A \).
Refer to values array description in Skyline Storage Scheme for more details.

pntr

Array of length \((m + 1)\) for lower triangle, and \((k + 1)\) for upper triangle.

It contains the indices specifying in the val the positions of the first element in each row (column) of the matrix \(A\). Refer to pointers array description in Skyline Storage Scheme for more details.

\(x\)

Array, size at least \(k\) if \(\text{transa} = 'N'\) or \('n'\) and at least \(m\) otherwise. On entry, the array \(x\) must contain the vector \(x\).

\(beta\)

Specifies the scalar \(beta\).

\(y\)

Array, size at least \(m\) if \(\text{transa} = 'N'\) or \('n'\) and at least \(k\) otherwise. On entry, the array \(y\) must contain the vector \(y\).

Output Parameters

\(y\)

Overwritten by the updated vector \(y\).

mkl_?diasv

Solves a system of linear equations for a sparse matrix in the diagonal format with one-based indexing (deprecated).

Syntax

void mkl_sdiasv (const char *transa , const MKL_INT *m , const float *alpha , const char *matdescra , const float *val , const MKL_INT *lval , const MKL_INT *idiag , const MKL_INT *ndiag , const float *x , float *y );
void mkl_ddiasv (const char *transa , const MKL_INT *m , const double *alpha , const char *matdescra , const double *val , const MKL_INT *lval , const MKL_INT *idiag , const MKL_INT *ndiag , const double *x , double *y );
void mkl_cdiasv (const char *transa , const MKL_INT *m , const MKL_Complex8 *alpha , const char *matdescra , const MKL_Complex8 *val , const MKL_INT *lval , const MKL_INT *idiag , const MKL_INT *ndiag , const MKL_INT *x , MKL_Complex8 *y );
void mkl_zdiasv (const char *transa , const MKL_INT *m , const MKL_Complex16 *alpha , const char *matdescra , const MKL_Complex16 *val , const MKL_INT *lval , const MKL_INT *idiag , const MKL_INT *ndiag , const MKL_Complex16 *x , MKL_Complex16 *y );

Include Files

• mkl.h

Description

This routine is deprecated. Use mkl_sparse_?_trsv from the Intel® MKL Inspector-executor Sparse BLAS interface instead.

The mkl_?diasv routine solves a system of linear equations with matrix-vector operations for a sparse matrix stored in the diagonal format:

\[ y := \alpha\text{inv}(A)\times \]
or

\[ y := \alpha \cdot \text{inv}(A^T) \cdot x, \]

where:

- \( \alpha \) is scalar,
- \( x \) and \( y \) are vectors,
- \( A \) is a sparse upper or lower triangular matrix with unit or non-unit main diagonal,
- \( A^T \) is the transpose of \( A \).

**NOTE**
This routine supports only one-based indexing of the input arrays.

### Input Parameters

- **transa**: Specifies the system of linear equations.
  - If \( \text{transa} = 'N' \) or \( 'n' \), then \( y := \alpha \cdot \text{inv}(A) \cdot x \)
  - If \( \text{transa} = 'T' \) or \( 't' \) or \( 'C' \) or \( 'c' \), then \( y := \alpha \cdot \text{inv}(A^T) \cdot x \)

- **m**: Number of rows of the matrix \( A \).

- **alpha**: Specifies the scalar \( \alpha \).

- **matdescra**: Array of six elements, specifies properties of the matrix used for operation.
  Only first four array elements are used, their possible values are given in Table “Possible Values of the Parameter \( \text{matdescra} \) (\( \text{descra} \))”. Possible combinations of element values of this parameter are given in Table “Possible Combinations of Element Values of the Parameter \( \text{matdescra} \)”.

- **val**: Two-dimensional array of size \( lval \) by \( ndiag \), contains non-zero diagonals of the matrix \( A \). Refer to \( \text{values} \) array description in Diagonal Storage Scheme for more details.

- **lval**: Leading dimension of \( \text{val} \), \( lval \geq m \). Refer to \( lval \) description in Diagonal Storage Scheme for more details.

- **idiag**: Array of length \( ndiag \), contains the distances between main diagonal and each non-zero diagonals in the matrix \( A \).
  - **NOTE**
    All elements of this array must be sorted in increasing order.

Refer to \( \text{distance} \) array description in Diagonal Storage Scheme for more details.

- **ndiag**: Specifies the number of non-zero diagonals of the matrix \( A \).

- **x**: Array, size at least \( m \).
  - On entry, the array \( x \) must contain the vector \( x \). The elements are accessed with unit increment.

- **y**: Array, size at least \( m \).
  - On entry, the array \( y \) must contain the vector \( y \). The elements are accessed with unit increment.
Output Parameters

\( y \)        Contains solution vector \( x \).

\textbf{mkl\_?skysv}  
\textit{Solves a system of linear equations for a sparse matrix in the skyline format with one-based indexing (deprecated).}

\textbf{Syntax}

\begin{verbatim}
void mkl_sskysv (const char *transa, const MKL_INT *m, const float *alpha, const char *matdescra, const float *val, const MKL_INT *pntr, const float *x, float *y);
void mkl_dskysv (const char *transa, const MKL_INT *m, const double *alpha, const char *matdescra, const double *val, const MKL_INT *pntr, const double *x, double *y);
void mkl_cskysv (const char *transa, const MKL_INT *m, const MKL_Complex8 *alpha, const char *matdescra, const MKL_Complex8 *val, const MKL_INT *pntr, const MKL_Complex8 *x, MKL_Complex8 *y);
void mkl_zskysv (const char *transa, const MKL_INT *m, const MKL_Complex16 *alpha, const char *matdescra, const MKL_Complex16 *val, const MKL_INT *pntr, const MKL_Complex16 *x, MKL_Complex16 *y);
\end{verbatim}

\textbf{Include Files}

- \texttt{mkl.h}

\textbf{Description}

This routine is deprecated. Use \texttt{mkl\_sparse\_?\_trsv} from the Intel\textsuperscript{®} MKL Inspector-executor Sparse BLAS interface instead.

The \texttt{mkl\_?skysv} routine solves a system of linear equations with matrix-vector operations for a sparse matrix in the skyline storage format:

\[
y := \alpha \cdot \text{inv}(A) \cdot x
\]

or

\[
y := \alpha \cdot \text{inv}(A^T) \cdot x,
\]

where:

\( \alpha \) is scalar, \( x \) and \( y \) are vectors, \( A \) is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, \( A^T \) is the transpose of \( A \).

\textbf{NOTE}

This routine supports only one-based indexing of the input arrays.

\textbf{Input Parameters}

\textit{transa}        Specifies the system of linear equations.

If \texttt{transa} = \texttt{'N'} or \texttt{'n'}, then \( y := \alpha \cdot \text{inv}(A) \cdot x \)
If $transa = 'T'$ or $'t'$ or $'C'$ or $'c'$, then $y := alpha*\text{inv}(A^T) \times x$.

**m**
Number of rows of the matrix $A$.

**alpha**
Specifies the scalar $alpha$.

**matdescra**
Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter matdescra (descra)". Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter matdescra".

**NOTE**
General matrices $(matdescra[0]='G')$ is not supported.

**val**
Array containing the set of elements of the matrix $A$ in the skyline profile form.

If $\text{matdescra}[2]='L'$, then $val$ contains elements from the low triangle of the matrix $A$.

If $\text{matdescsa}[2]='U'$, then $val$ contains elements from the upper triangle of the matrix $A$.

Refer to $values$ array description in Skyline Storage Scheme for more details.

**pntr**
Array of length $(m + 1)$ for lower triangle, and $(k + 1)$ for upper triangle.

It contains the indices specifying in the $val$ the positions of the first element in each row (column) of the matrix $A$. Refer to $pointers$ array description in Skyline Storage Scheme for more details.

**x**
Array, size at least $m$.

On entry, the array $x$ must contain the vector $x$. The elements are accessed with unit increment.

**y**
Array, size at least $m$.

On entry, the array $y$ must contain the vector $y$. The elements are accessed with unit increment.

**Output Parameters**

**y**
Contains solution vector $x$.

**mkl_?diamm**

Computes matrix-matrix product of a sparse matrix stored in the diagonal format with one-based indexing (deprecated).
**Syntax**

```c
void mkl_sdiamm (const char *transa , const MKL_INT *m , const MKL_INT *n , const MKL_INT *k , const float *alpha , const char *matdescra , const float *val , const MKL_INT *lval , const MKL_INT *idiag , const MKL_INT *ndiag , const float *b , const MKL_INT *ldb , const float *beta , float *c , const MKL_INT *ldc );

void mkl_ddiamm (const char *transa , const MKL_INT *m , const MKL_INT *n , const MKL_INT *k , const double *alpha , const char *matdescra , const double *val , const MKL_INT *lval , const MKL_INT *idiag , const MKL_INT *ndiag , const double *b , const MKL_INT *ldb , const double *beta , double *c , const MKL_INT *ldc );

void mkl_cdiamm (const char *transa , const MKL_INT *m , const MKL_INT *n , const MKL_INT *k , const MKL_Complex8 *alpha , const char *matdescra , const MKL_Complex8 *val , const MKL_INT *lval , const MKL_INT *idiag , const MKL_INT *ndiag , const MKL_Complex8 *b , const MKL_INT *ldb , const MKL_Complex8 *beta , MKL_Complex8 *c , const MKL_INT *ldc );

void mkl_zdiamm (const char *transa , const MKL_INT *m , const MKL_INT *n , const MKL_INT *k , const MKL_Complex16 *alpha , const char *matdescra , const MKL_Complex16 *val , const MKL_INT *lval , const MKL_INT *idiag , const MKL_INT *ndiag , const MKL_Complex16 *b , const MKL_INT *ldb , const MKL_Complex16 *beta , MKL_Complex16 *c , const MKL_INT *ldc );
```

**Description**

This routine is deprecated. Use `mkl_sparse_?_mm` from the Intel® MKL Inspector-executor Sparse BLAS interface instead.

The **mkl_?diamm** routine performs a matrix-matrix operation defined as

\[
C := \alpha A B + \beta C
\]

or

\[
C := \alpha A^T B + \beta C,
\]

or

\[
C := \alpha A^H B + \beta C,
\]

where:

- \( \alpha \) and \( \beta \) are scalars,
- \( B \) and \( C \) are dense matrices, \( A \) is an \( m \)-by-\( k \) sparse matrix in the diagonal format, \( A^T \) is the transpose of \( A \), and \( A^H \) is the conjugate transpose of \( A \).

**NOTE**

This routine supports only one-based indexing of the input arrays.

**Input Parameters**

- **transa**

  Specifies the operation.

  If `transa = 'N'` or `'n'`, then \( C := \alpha A B + \beta C \),
If transa = 'T' or 't', then \( C := \alpha A^T B + \beta C \),

If transa = 'C' or 'c', then \( C := \alpha A^H B + \beta C \).

\( m \)

Number of rows of the matrix \( A \).

\( n \)

Number of columns of the matrix \( C \).

\( k \)

Number of columns of the matrix \( A \).

\( \alpha \)

Specifies the scalar \( \alpha \).

\( \text{matdescra} \)

Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter \text{matdescra} (descra)". Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter \text{matdescra}".

\( \text{val} \)

Two-dimensional array of size \( lval \) by \( ndiag \), contains non-zero diagonals of the matrix \( A \). Refer to values array description in Diagonal Storage Scheme for more details.

\( lval \)

Leading dimension of \( \text{val} \), \( lval \geq m \). Refer to \( lval \) description in Diagonal Storage Scheme for more details.

\( \text{idiag} \)

Array of length \( ndiag \), contains the distances between main diagonal and each non-zero diagonals in the matrix \( A \). Refer to distance array description in Diagonal Storage Scheme for more details.

\( ndiag \)

Specifies the number of non-zero diagonals of the matrix \( A \).

\( \text{b} \)

Array, size \( ldb \times n \).

On entry with \( \text{transa} = 'N' \) or \( 'n' \), the leading \( k \)-by-\( n \) part of the array \( \text{b} \) must contain the matrix \( B \), otherwise the leading \( m \)-by-\( n \) part of the array \( \text{b} \) must contain the matrix \( B \).

\( ldb \)

Specifies the leading dimension of \( \text{b} \) as declared in the calling (sub)program.

\( \beta \)

Specifies the scalar \( \beta \).

\( \text{c} \)

Array, size \( ldc \) by \( n \).

On entry, the leading \( m \)-by-\( n \) part of the array \( \text{c} \) must contain the matrix \( C \), otherwise the leading \( k \)-by-\( n \) part of the array \( \text{c} \) must contain the matrix \( C \).

\( ldc \)

Specifies the leading dimension of \( \text{c} \) as declared in the calling (sub)program.

**Output Parameters**

\( \text{c} \)

Overwritten by the matrix \( (\alpha A B + \beta C), (\alpha A^T B + \beta C), \text{or} (\alpha A^H B + \beta C) \).
**mkl_?skymm**  
*Computes matrix-matrix product of a sparse matrix stored using the skyline storage scheme with one-based indexing (deprecated).*

**Syntax**

```c
void mkl_sskymm (const char *transa, const MKL_INT *m, const MKL_INT *n, const MKL_INT *k, const float *alpha, const char *matdescra, const float *val, const MKL_INT *pntr, const float *b, const MKL_INT *ldb, const float *beta, float *c, const MKL_INT *ldc);

void mkl_dskymm (const char *transa, const MKL_INT *m, const MKL_INT *n, const MKL_INT *k, const double *alpha, const char *matdescra, const double *val, const MKL_INT *pntr, const double *b, const MKL_INT *ldb, const double *beta, double *c, const MKL_INT *ldc);

void mkl_cskymm (const char *transa, const MKL_INT *m, const MKL_INT *n, const MKL_INT *k, const MKL_Complex8 *alpha, const char *matdescra, const MKL_Complex8 *val, const MKL_INT *pntr, const MKL_Complex8 *b, const MKL_INT *ldb, const MKL_Complex8 *beta, MKL_Complex8 *c, const MKL_INT *ldc);

void mkl_zskymm (const char *transa, const MKL_INT *m, const MKL_INT *n, const MKL_INT *k, const MKL_Complex16 *alpha, const char *matdescra, const MKL_Complex16 *val, const MKL_INT *pntr, const MKL_Complex16 *b, const MKL_INT *ldb, const MKL_Complex16 *beta, MKL_Complex16 *c, const MKL_INT *ldc);
```

**Include Files**

- mkl.h

**Description**

This routine is deprecated. Use `mkl_sparse_?_mm` from the Intel® MKL Inspector-executor Sparse BLAS interface instead.

The `mkl_?skymm` routine performs a matrix-matrix operation defined as

```
C := alpha*A*B + beta*C
```

or

```
C := alpha*Aᵀ*B + beta*C,
```

or

```
C := alpha*Aᴴ*B + beta*C,
```

where:

- *alpha* and *beta* are scalars,
- *B* and *C* are dense matrices, *A* is an *m*-by-*k* sparse matrix in the skyline storage format, *Aᵀ* is the transpose of *A*, and *Aᴴ* is the conjugate transpose of *A*.

**NOTE**

This routine supports only one-based indexing of the input arrays.

**Input Parameters**

BLAS and Sparse BLAS Routines
transa

Specifies the operation.
If transa = 'N' or 'n', then $C := \alpha A B + \beta C$,
If transa = 'T' or 't', then $C := \alpha A^\top B + \beta C$,
If transa = 'C' or 'c', then $C := \alpha A^H B + \beta C$.

m

Number of rows of the matrix A.

n

Number of columns of the matrix C.

k

Number of columns of the matrix A.

alpha

Specifies the scalar $\alpha$.

matdescra

Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter matdescra (descra)". Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter matdescra".

NOTE

General matrices (matdescra[0]='G') is not supported.

val

Array containing the set of elements of the matrix $A$ in the skyline profile form.
If matdescrsa[2]= 'L', then val contains elements from the low triangle of the matrix $A$.
If matdescrsa[2]= 'U', then val contains elements from the upper triangle of the matrix $A$.
Refer to values array description in Skyline Storage Scheme for more details.

pntr

Array of length $(m + 1)$ for lower triangle, and $(k + 1)$ for upper triangle. It contains the indices specifying the positions of the first element of the matrix $A$ in each row (for the lower triangle) or column (for upper triangle) in the val array such that val[pntr[i] - 1] is the first element in row or column $i + 1$. Refer to pointers array description in Skyline Storage Scheme for more details.

b

Array, size $ldb \times n$.
On entry with transa = 'N' or 'n', the leading $k$-by-$n$ part of the array $b$ must contain the matrix $B$, otherwise the leading $m$-by-$n$ part of the array $b$ must contain the matrix $B$.

ldb

Specifies the leading dimension of $b$ as declared in the calling (sub)program.

beta

Specifies the scalar $\beta$.

c

Array, size $ldc$ by $n$. 
On entry, the leading $m$-by-$n$ part of the array $c$ must contain the matrix $C$, otherwise the leading $k$-by-$n$ part of the array $c$ must contain the matrix $C$.

$\text{ldc}$

Specifies the leading dimension of $c$ as declared in the calling (sub)program.

**Output Parameters**

$c$

Overwritten by the matrix $(\alpha A B + \beta C)$, $(\alpha A^T B + \beta C)$, or $(\alpha A^H B + \beta C)$.

**mkl_?diasm**

Solves a system of linear matrix equations for a sparse matrix in the diagonal format with one-based indexing (deprecated).

**Syntax**

```c
void mkl_sdiasm (const char *transa, const MKL_INT *m, const MKL_INT *n, const float *alpha, const char *matdescra, const float *val, const MKL_INT *lval, const MKL_INT *idiag, const MKL_INT *ndiag, const float *b, const MKL_INT *ldb, float *c, const MKL_INT *ldc);
void mkl_ddiasm (const char *transa, const MKL_INT *m, const MKL_INT *n, const double *alpha, const char *matdescra, const double *val, const MKL_INT *lval, const MKL_INT *idiag, const MKL_INT *ndiag, const double *b, const MKL_INT *ldb, double *c, const MKL_INT *ldc);
void mkl_cdiasm (const char *transa, const MKL_INT *m, const MKL_INT *n, const MKL_Complex8 *alpha, const char *matdescra, const MKL_Complex8 *val, const MKL_INT *lval, const MKL_INT *idiag, const MKL_INT *ndiag, const MKL_Complex8 *b, const MKL_INT *ldb, MKL_Complex8 *c, const MKL_INT *ldc);
void mkl_zdiasm (const char *transa, const MKL_INT *m, const MKL_INT *n, const MKL_Complex16 *alpha, const char *matdescra, const MKL_Complex16 *val, const MKL_INT *lval, const MKL_INT *idiag, const MKL_INT *ndiag, const MKL_Complex16 *b, const MKL_INT *ldb, MKL_Complex16 *c, const MKL_INT *ldc);
```

**Include Files**

- mkl.h

**Description**

This routine is deprecated. Use `mkl_sparse_?_trsm` from the Intel® MKL Inspector-executor Sparse BLAS interface instead.

The `mkl_?diasm` routine solves a system of linear equations with matrix-matrix operations for a sparse matrix in the diagonal format:

$$C := \alpha \text{inv}(A) B$$

or

$$C := \alpha \text{inv}(A^T) B,$$

where:

$\alpha$ is scalar, $B$ and $C$ are dense matrices, $A$ is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, $A^T$ is the transpose of $A$. 
NOTE
This routine supports only one-based indexing of the input arrays.

Input Parameters

**transa**
Specifies the system of linear equations.
If \( transa = 'N' \) or \( \text{'}n\text{'} \), then \( C := \alpha \cdot \text{inv}(A) \cdot B \),
If \( transa = 'T' \) or \( \text{'}t\text{'} \) or \( 'C' \) or \( \text{'}c\text{'} \), then \( C := \alpha \cdot \text{inv}(A^T) \cdot B \).

**m**
Number of rows of the matrix \( A \).

**n**
Number of columns of the matrix \( C \).

**alpha**
Specifies the scalar \( \alpha \).

**matdescra**
Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter matdescra (descra)". Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter matdescra".

**val**
Two-dimensional array of size \( lval \) by \( ndiag \), contains non-zero diagonals of the matrix \( A \). Refer to values array description in Diagonal Storage Scheme for more details.

**lval**
Leading dimension of \( val \), \( lval \geq m \). Refer to \( lval \) description in Diagonal Storage Scheme for more details.

**idiag**
Array of length \( ndiag \), contains the distances between main diagonal and each non-zero diagonals in the matrix \( A \).

NOTE
All elements of this array must be sorted in increasing order.

Refer to distance array description in Diagonal Storage Scheme for more details.

**ndiag**
Specifies the number of non-zero diagonals of the matrix \( A \).

**b**
Array, size \( ldb \cdot n \).
On entry the leading \( m \)-by-\( n \) part of the array \( b \) must contain the matrix \( B \).

**ldb**
Specifies the leading dimension of \( b \) as declared in the calling (sub)program.

**ldc**
Specifies the leading dimension of \( c \) as declared in the calling (sub)program.

Output Parameters

**c**
Array, size \( ldc \) by \( n \).
The leading \( m \)-by-\( n \) part of the array \( c \) contains the matrix \( C \).
**mkl_?skysm**

Solves a system of linear matrix equations for a sparse matrix stored using the skyline storage scheme with one-based indexing (deprecated).

**Syntax**

void mkl_sskysm (const char *transa, const MKL_INT *m, const MKL_INT *n, const float *alpha, const char *matdescra, const float *val, const MKL_INT *pntr, const float *b, const MKL_INT *ldb, float *c, const MKL_INT *ldc);

void mkl_dskysm (const char *transa, const MKL_INT *m, const MKL_INT *n, const double *alpha, const char *matdescra, const double *val, const MKL_INT *pntr, const double *b, const MKL_INT *ldb, double *c, const MKL_INT *ldc);

void mkl_cskysm (const char *transa, const MKL_INT *m, const MKL_INT *n, const MKL_Complex8 *alpha, const char *matdescra, const MKL_Complex8 *val, const MKL_INT *pntr, const MKL_Complex8 *b, const MKL_INT *ldb, MKL_Complex8 *c, const MKL_INT *ldc);

void mkl_zskysm (const char *transa, const MKL_INT *m, const MKL_INT *n, const MKL_Complex16 *alpha, const char *matdescra, const MKL_Complex16 *val, const MKL_INT *pntr, const MKL_Complex16 *b, const MKL_INT *ldb, MKL_Complex16 *c, const MKL_INT *ldc);

```

Include Files

- mkl.h

Description

This routine is deprecated. Use the matrix manipulation routines from the Intel® MKL Inspector-executor Sparse BLAS interface instead.

This routine converts a sparse matrix $A$ between formats: stored as a rectangular array (dense representation) and stored using compressed sparse row (CSR) format (3-array variation).

Input Parameters

job

- **Array**, contains the following conversion parameters:
  - **job[0]**: Conversion type.
    - If job[0]=0, the rectangular matrix $A$ is converted to the CSR format;
    - if job[0]=1, the rectangular matrix $A$ is restored from the CSR format.
  - **job[1]**: Index base for the rectangular matrix $A$.
    - If job[1]=0, zero-based indexing for the rectangular matrix $A$ is used;
    - if job[1]=1, one-based indexing for the rectangular matrix $A$ is used.
  - **job[2]**: Index base for the matrix in CSR format.
    - If job[2]=0, zero-based indexing for the matrix in CSR format is used;
    - if job[2]=1, one-based indexing for the matrix in CSR format is used.
  - **job[3]**: Portion of matrix.
    - If job[3]=0, adns is a lower triangular part of matrix $A$;
    - If job[3]=1, adns is an upper triangular part of matrix $A$;
    - If job[3]=2, adns is a whole matrix $A$.
  - **job[4]**=nzmax: maximum number of the non-zero elements allowed if job[0]=0.
  - **job[5]**: Job indicator for conversion to CSR format.
    - If job[5]=0, only array ia is generated for the output storage.
If $\text{job}[5] > 0$, arrays $\text{acsr}, \text{ia}, \text{ja}$ are generated for the output storage.

$m$
Number of rows of the matrix $A$.

$n$
Number of columns of the matrix $A$.

$\text{adns}$
(input/output)
If the conversion type is from uncompressed to CSR, on input $\text{adns}$ contains an uncompressed (dense) representation of matrix $A$.

$\text{lda}$
Specifies the leading dimension of $\text{adns}$ as declared in the calling (sub)program.
For zero-based indexing of $A$, $\text{lda}$ must be at least $\max(1, n)$.
For one-based indexing of $A$, $\text{lda}$ must be at least $\max(1, m)$.

$\text{acsr}$
(input/output)
If conversion type is from CSR to uncompressed, on input $\text{acsr}$ contains the non-zero elements of the matrix $A$. Its length is equal to the number of non-zero elements in the matrix $A$. Refer to values array description in Sparse Matrix Storage Formats for more details.

$\text{ja}$
(input/output). If conversion type is from CSR to uncompressed, on input for zero-based indexing of $A$ $\text{ja}$ contains the column indices plus one for each non-zero element of the matrix $A$. For one-based indexing of $A$ $\text{ja}$ contains the column indices for each non-zero element of the matrix $A$.
Its length is equal to the length of the array $\text{acsr}$. Refer to columns array description in Sparse Matrix Storage Formats for more details.

$\text{ia}$
(input/output). Array of length $m + 1$.
If conversion type is from CSR to uncompressed, on input for zero-based indexing of $A$ $\text{ia}$ contains indices of elements in the array $\text{acsr}$, such that $\text{ia}[i] - 1$ is the index in the array $\text{acsr}$ of the first non-zero element from the row $i$. For one-based indexing of $A$ $\text{ia}$ contains indices of elements in the array $\text{acsr}$, such that $\text{ia}[i]$ is the index in the array $\text{acsr}$ of the first non-zero element from the row $i$.
The value of $\text{ia}[m] - \text{ia}[0]$ is equal to the number of non-zeros. Refer to rowIndex array description in Sparse Matrix Storage Formats for more details.

Output Parameters

$\text{adns}$
If conversion type is from CSR to uncompressed, on output $\text{adns}$ contains the uncompressed (dense) representation of matrix $A$.

$\text{acsr}, \text{ja}, \text{ia}$
If conversion type is from uncompressed to CSR, on output $\text{acsr}, \text{ja}, \text{ia}$ contain the compressed sparse row (CSR) format (3-array variation) of matrix $A$ (see Sparse Matrix Storage Formats for a description of the storage format).

$\text{info}$
Integer info indicator only for restoring the matrix $A$ from the CSR format.
If $\text{info}=0$, the execution is successful.
If \( \text{info}=i \), the routine is interrupted processing the \( i \)-th row because there is no space in the arrays \( acsr \) and \( ja \) according to the value \( nzmax \).

**mkl_?csrcoo**

Converting a sparse matrix in the CSR format to the coordinate format and vice versa (deprecated).

**Syntax**

```c
void mkl_scsrcoo (const MKL_INT *job, const MKL_INT *n, float *acsr, MKL_INT *ja, MKL_INT *ia, MKL_INT *nnz, float *acoo, MKL_INT *rowind, MKL_INT *colind, MKL_INT *info);
void mkl_dcsrcoo (const MKL_INT *job, const MKL_INT *n, double *acsr, MKL_INT *ja, MKL_INT *ia, MKL_INT *nnz, double *acoo, MKL_INT *rowind, MKL_INT *colind, MKL_INT *info);
void mkl_ccsrcoo (const MKL_INT *job, const MKL_INT *n, MKL_Complex8 *acsr, MKL_INT *ja, MKL_INT *ia, MKL_INT *nnz, MKL_Complex8 *acoo, MKL_INT *rowind, MKL_INT *colind, MKL_INT *info);
void mkl_zcsrcoo (const MKL_INT *job, const MKL_INT *n, MKL_Complex16 *acsr, MKL_INT *ja, MKL_INT *ia, MKL_INT *nnz, MKL_Complex16 *acoo, MKL_INT *rowind, MKL_INT *colind, MKL_INT *info);
```

**Include Files**

- mkl.h

**Description**

This routine is deprecated. Use the matrix manipulation routines from the Intel® MKL Inspector-executor Sparse BLAS interface instead.

This routine converts a sparse matrix \( A \) stored in the compressed sparse row (CSR) format (3-array variation) to coordinate format and vice versa.

**Input Parameters**

- **job**

  Array, contains the following conversion parameters:

  - **job[0]**
    - If \( \text{job[0]}=0 \), the matrix in the CSR format is converted to the coordinate format;
    - if \( \text{job[0]}=1 \), the matrix in the coordinate format is converted to the CSR format.
    - if \( \text{job[0]}=2 \), the matrix in the coordinate format is converted to the CSR format, and the column indices in CSR representation are sorted in the increasing order within each row.

  - **job[1]**
    - If \( \text{job[1]}=0 \), zero-based indexing for the matrix in CSR format is used;
    - if \( \text{job[1]}=1 \), one-based indexing for the matrix in CSR format is used.

  - **job[2]**
If \( \text{job}[2]=0 \), zero-based indexing for the matrix in coordinate format is used;
if \( \text{job}[2]=1 \), one-based indexing for the matrix in coordinate format is used.

\( \text{job}[4]=\text{nzmax} \) - maximum number of the non-zero elements allowed if \( \text{job}[0]=0 \).

\( \text{job}[5] \) - job indicator.

For conversion to the coordinate format:
If \( \text{job}[5]=1 \), only array \( \text{rowind} \) is filled in for the output storage.
If \( \text{job}[5]=2 \), arrays \( \text{rowind}, \text{colind} \) are filled in for the output storage.
If \( \text{job}[5]=3 \), all arrays \( \text{rowind}, \text{colind}, \text{acoo} \) are filled in for the output storage.

For conversion to the CSR format:
If \( \text{job}[5]=0 \), all arrays \( \text{acsr}, \text{ja}, \text{ia} \) are filled in for the output storage.
If \( \text{job}[5]=1 \), only array \( \text{ia} \) is filled in for the output storage.
If \( \text{job}[5]=2 \), then it is assumed that the routine already has been called with the \( \text{job}[5]=1 \), and the user allocated the required space for storing the output arrays \( \text{acsr} \) and \( \text{ja} \).

\( n \) - Dimension of the matrix \( A \).

\( \text{nnz} \) - Specifies the number of non-zero elements of the matrix \( A \) for \( \text{job}[0] \neq 0 \).
Refer to \( \text{nnz} \) description in Coordinate Format for more details.

\( \text{acsr} \) - (input/output) Array containing non-zero elements of the matrix \( A \). Its length is equal to the number of non-zero elements in the matrix \( A \). Refer to values array description in Sparse Matrix Storage Formats for more details.

\( \text{ja} \) - (input/output). For \( \text{job}[1] = 1 \) (one-based indexing for the matrix in CSR format), array containing the column indices plus one for each non-zero element of the matrix \( A \).

For \( \text{job}[1] = 0 \) (zero-based indexing for the matrix in CSR format), array containing the column indices for each non-zero element of the matrix \( A \). Its length is equal to the length of the array \( \text{acsr} \). Refer to columns array description in Sparse Matrix Storage Formats for more details.

\( \text{ia} \) - (input/output). Array of length \( n + 1 \), containing indices of elements in the array \( \text{acsr} \), such that \( \text{ia}[i] - \text{ia}[0] \) is the index in the array \( \text{acsr} \) of the first non-zero element from the row \( i \). The value of the last element \( \text{ia}[n] - \text{ia}[0] \) is equal to the number of non-zeros plus one. Refer to rowIndex array description in Sparse Matrix Storage Formats for more details.

\( \text{acoo} \) - (input/output)
Array containing non-zero elements of the matrix $A$. Its length is equal to the number of non-zero elements in the matrix $A$. Refer to values array description in Sparse Matrix Storage Formats for more details.

*rowind* (input/output). Array of length $nnz$, contains the row indices for each non-zero element of the matrix $A$. Refer to rows array description in Coordinate Format for more details.

*colind* (input/output). Array of length $nnz$, contains the column indices for each non-zero element of the matrix $A$. Refer to columns array description in Coordinate Format for more details.

**Output Parameters**

*nnz* Returns the number of converted elements of the matrix $A$ for $job[0]=0$.

*info* Integer info indicator only for converting the matrix $A$ from the CSR format.

If $info=0$, the execution is successful.

If $info=1$, the routine is interrupted because there is no space in the arrays $aco$, $rowind$, $colind$ according to the value $nzmax$.

**mkl_?csrbsr**

*Converts a square sparse matrix in the CSR format to the BSR format and vice versa (deprecated).*

**Syntax**

```c
void mkl_scsrbsr (const MKL_INT *job, const MKL_INT *m, const MKL_INT *mblk, const MKL_INT *ldabsr, float *acsr, MKL_INT *ja, MKL_INT *ia, float *absr, MKL_INT *jab, MKL_INT *iab, MKL_INT *info);
void mkl_dcsrbsr (const MKL_INT *job, const MKL_INT *m, const MKL_INT *mblk, const MKL_INT *ldabsr, double *acsr, MKL_INT *ja, MKL_INT *ia, double *absr, MKL_INT *jab, MKL_INT *iab, MKL_INT *info);
void mkl_ccsrbsr (const MKL_INT *job, const MKL_INT *m, const MKL_INT *mblk, const MKL_INT *ldabsr, MKL_Complex8 *acsr, MKL_INT *ja, MKL_INT *ia, MKL_Complex8 *absr, MKL_INT *jab, MKL_INT *iab, MKL_INT *info);
void mkl_zcsrbsr (const MKL_INT *job, const MKL_INT *m, const MKL_INT *mblk, const MKL_INT *ldabsr, MKL_Complex16 *acsr, MKL_INT *ja, MKL_INT *ia, MKL_Complex16 *absr, MKL_INT *jab, MKL_INT *iab, MKL_INT *info);
```

**Include Files**

- mkl.h

**Description**

This routine is deprecated. Use the matrix manipulation routines from the Intel® MKL Inspector-executor Sparse BLAS interface instead.

This routine converts a square sparse matrix $A$ stored in the compressed sparse row (CSR) format (3-array variation) to the block sparse row (BSR) format and vice versa.
Input Parameters

**job**

Array, contains the following conversion parameters:

- **job[0]**
  - If job[0]==0, the matrix in the CSR format is converted to the BSR format;
  - if job[0]==1, the matrix in the BSR format is converted to the CSR format.

- **job[1]**
  - If job[1]==0, zero-based indexing for the matrix in CSR format is used;
  - if job[1]==1, one-based indexing for the matrix in CSR format is used.

- **job[2]**
  - If job[2]==0, zero-based indexing for the matrix in the BSR format is used;
  - if job[2]==1, one-based indexing for the matrix in the BSR format is used.

- **job[3]** is only used for conversion to CSR format. By default, the converter saves the blocks without checking whether an element is zero or not. If job[3]==1, then the converter only saves non-zero elements in blocks.

- **job[5]** - job indicator.
  - For conversion to the BSR format:
    - If job[5]==0, only arrays jab, iab are generated for the output storage.
    - If job[5]>0, all output arrays absr, jab, and iab are filled in for the output storage.
    - If job[5]==-1, iab[m] - iab[0] returns the number of non-zero blocks.
  - For conversion to the CSR format:
    - If job[5]==0, only arrays ja, ia are generated for the output storage.

**m**

Actual row dimension of the matrix A for convert to the BSR format; block row dimension of the matrix A for convert to the CSR format.

**mblk**

Size of the block in the matrix A.

**ldabsr**

Leading dimension of the array absr as declared in the calling program. ldabsr must be greater than or equal to mblk*mblk.

**acsr**

Array containing non-zero elements of the matrix A. Its length is equal to the number of non-zero elements in the matrix A. Refer to values array description in Sparse Matrix Storage Formats for more details.

**ja**

Array containing the column indices for each non-zero element of the matrix A.

Its length is equal to the length of the array acsr. Refer to columns array description in Sparse Matrix Storage Formats for more details.
(input/output). Array of length \( m + 1 \), containing indices of elements in the array \( \text{acsr} \), such that \( \text{ia}[i] - \text{iab}[0] \) is the index in the array \( \text{acsr} \) of the first non-zero element from the row \( i \). The value of \( \text{ia}[m] - \text{iab}[0] \) is equal to the number of non-zeros. Refer to \( \text{rowIndex} \) array description in Sparse Matrix Storage Formats for more details.

\( \text{absr} \)

(input/output)
Array containing elements of non-zero blocks of the matrix \( A \). Its length is equal to the number of non-zero blocks in the matrix \( A \) multiplied by \( mblk \times mblk \). Refer to \( \text{values} \) array description in BSR Format for more details.

\( \text{jab} \)

(input/output). Array containing the column indices for each non-zero block of the matrix \( A \).
Its length is equal to the number of non-zero blocks of the matrix \( A \). Refer to \( \text{columns} \) array description in BSR Format for more details.

\( \text{iab} \)

(input/output). Array of length \( (m + 1) \), containing indices of blocks in the array \( \text{absr} \), such that \( \text{iab}[i] - \text{iab}[0] \) is the index in the array \( \text{absr} \) of the first non-zero element from the \( i \)-th row. The value of \( \text{iab}[m] \) is equal to the number of non-zero blocks. Refer to \( \text{rowIndex} \) array description in BSR Format for more details.

Output Parameters

\( \text{info} \)

Integer info indicator only for converting the matrix \( A \) from the CSR format.
If \( \text{info}=0 \), the execution is successful.
If \( \text{info}=1 \), it means that \( mblk \) is equal to 0.
If \( \text{info}=2 \), it means that \( \text{ldabsr} \) is less than \( mblk \times mblk \) and there is no space for all blocks.

\textbf{mkl\_?csrsc}

\textit{Converts a square sparse matrix in the CSR format to the CSC format and vice versa (deprecated).}

\textbf{Syntax}

void mkl_dcsrsc (const MKL_INT *job, const MKL_INT *n, double *acsr, MKL_INT *ja, MKL_INT *ia, double *acsc, MKL_INT *ja1, MKL_INT *ia1, MKL_INT *info);
void mkl_scsrsc (const MKL_INT *job, const MKL_INT *n, float *acsr, MKL_INT *ja, MKL_INT *ia, float *acsc, MKL_INT *ja1, MKL_INT *ia1, MKL_INT *info);
void mkl_ccsrsc (const MKL_INT *job, const MKL_INT *n, MKL_Complex8 *acsr, MKL_INT *ja, MKL_INT *ia, MKL_Complex8 *acsc, MKL_INT *ja1, MKL_INT *ia1, MKL_INT *info);
void mkl_zcsrsc (const MKL_INT *job, const MKL_INT *n, MKL_Complex16 *acsr, MKL_INT *ja, MKL_INT *ia, MKL_Complex16 *acsc, MKL_INT *ja1, MKL_INT *ia1, MKL_INT *info);

\textbf{Include Files}

- mkl.h
Description

This routine is deprecated. Use the matrix manipulation routines from the Intel® MKL Inspector-executor Sparse BLAS interface instead.

This routine converts a square sparse matrix $A$ stored in the compressed sparse row (CSR) format (3-array variation) to the compressed sparse column (CSC) format and vice versa.

**Input Parameters**

- **job**
  
  Array, contains the following conversion parameters:
  
  - *job[0]*
    
    If *job[0]=0*, the matrix in the CSR format is converted to the CSC format;
    
    if *job[0]=1*, the matrix in the CSC format is converted to the CSR format.
  
  - *job[1]*
    
    If *job[1]=0*, zero-based indexing for the matrix in CSR format is used;
    
    if *job[1]=1*, one-based indexing for the matrix in CSR format is used.
  
  - *job[2]*
    
    If *job[2]=0*, zero-based indexing for the matrix in the CSC format is used;
    
    if *job[2]=1*, one-based indexing for the matrix in the CSC format is used.
  
  - *job[5]* - job indicator.
    
    For conversion to the CSC format:
    
    - If *job[5]=0*, only arrays $ja1$, $ia1$ are filled in for the output storage.
    
    - If *job[5]≠0*, all output arrays $acsc$, $ja1$, and $ia1$ are filled in for the output storage.

    For conversion to the CSR format:
    
    - If *job[5]=0*, only arrays $ja$, $ia$ are filled in for the output storage.
    
    - If *job[5]≠0*, all output arrays $acsr$, $ja$, and $ia$ are filled in for the output storage.

- **m**
  
  Dimension of the square matrix $A$.

- **acsr**
  
  (input/output)
  
  Array containing non-zero elements of the square matrix $A$. Its length is equal to the number of non-zero elements in the matrix $A$. Refer to values array description in Sparse Matrix Storage Formats for more details.

- **ja**
  
  (input/output). Array containing the column indices for each non-zero element of the matrix $A$.
  
  Its length is equal to the length of the array $acsr$. Refer to columns array description in Sparse Matrix Storage Formats for more details.

- **ia**
  
  (input/output). Array of length $m + 1$, containing indices of elements in the array $acsr$, such that $ia[i] - ia[0]$ is the index in the array $acsr$ of the first non-zero element from the row $i$. The value of $ia[m] - ia[0]$ is equal to the number of non-zeros. Refer to rowIndex array description in Sparse Matrix Storage Formats for more details.
The input/output parameter `acsc` is an array containing non-zero elements of the square matrix \( A \). Its length is equal to the number of non-zero elements in the matrix \( A \). Refer to the values array description in Sparse Matrix Storage Formats for more details.

The input/output parameter `jal` is an array containing the row indices for each non-zero element of the matrix \( A \). Its length is equal to the length of the array `acsc`. Refer to the columns array description in Sparse Matrix Storage Formats for more details.

The input/output parameter `ial` is an array of length \( m + 1 \), containing indices of elements in the array `acsc`, such that \( ial[i] - ial[0] \) is the index in the array `acsc` of the first non-zero element from the column \( i \). The value of \( ial[m] - ial[0] \) is equal to the number of non-zeros. Refer to the rowIndex array description in Sparse Matrix Storage Formats for more details.

**Output Parameters**

The parameter `info` is not used now.

**mkl_?csrdia**

*Converts a sparse matrix in the CSR format to the diagonal format and vice versa (deprecated).*

**Syntax**

```c
void mkl_dcsrdia (const MKL_INT *job, const MKL_INT *n, double *acsr, MKL_INT *ja, MKL_INT *ia, double *adia, const MKL_INT *ndiag, MKL_INT *distance, MKL_INT *idimag, double *acsr_rem, MKL_INT *ja_rem, MKL_INT *ia_rem, MKL_INT *info);
void mkl_scsrdia (const MKL_INT *job, const MKL_INT *n, float *acsr, MKL_INT *ja, MKL_INT *ia, float *adia, const MKL_INT *ndiag, MKL_INT *distance, MKL_INT *idimag, float *acsr_rem, MKL_INT *ja_rem, MKL_INT *ia_rem, MKL_INT *info);
void mkl_ccsrdia (const MKL_INT *job, const MKL_INT *n, MKL_Complex8 *acsr, MKL_INT *ja, MKL_INT *ia, MKL_Complex8 *adia, const MKL_INT *ndiag, MKL_INT *distance, MKL_INT *idimag, MKL_Complex8 *acsr_rem, MKL_INT *ja_rem, MKL_INT *ia_rem, MKL_INT *info);
void mkl_zcsrdia (const MKL_INT *job, const MKL_INT *n, MKL_Complex16 *acsr, MKL_INT *ja, MKL_INT *ia, MKL_Complex16 *adia, const MKL_INT *ndiag, MKL_INT *distance, MKL_INT *idimag, MKL_Complex16 *acsr_rem, MKL_INT *ja_rem, MKL_INT *ia_rem, MKL_INT *info);
```

**Include Files**

- mkl.h

**Description**

This routine is deprecated. Use the matrix manipulation routines from the Intel® MKL Inspector-executor Sparse BLAS interface instead.

This routine converts a sparse matrix \( A \) stored in the compressed sparse row (CSR) format (3-array variation) to the diagonal format and vice versa.
Input Parameters

job

Array, contains the following conversion parameters:

job

job[0]
If \(job[0]=0\), the matrix in the CSR format is converted to the diagonal format;
if \(job[0]=1\), the matrix in the diagonal format is converted to the CSR format.

job[1]
If \(job[1]=0\), zero-based indexing for the matrix in CSR format is used;
if \(job[1]=1\), one-based indexing for the matrix in CSR format is used.

job[2]
If \(job[2]=0\), zero-based indexing for the matrix in the diagonal format is used;
if \(job[2]=1\), one-based indexing for the matrix in the diagonal format is used.

For conversion to the diagonal format:

If \(job[5]=0\), diagonals are not selected internally, and \(acsr\_rem, ja\_rem, ia\_rem\) are not filled in for the output storage.
If \(job[5]=1\), diagonals are not selected internally, and \(acsr\_rem, ja\_rem, ia\_rem\) are filled in for the output storage.
If \(job[5]=10\), diagonals are selected internally, and \(acsr\_rem, ja\_rem, ia\_rem\) are not filled in for the output storage.
If \(job[5]=11\), diagonals are selected internally, and \(csr\_rem, ja\_rem, ia\_rem\) are filled in for the output storage.

For conversion to the CSR format:

If \(job[5]=0\), each entry in the array \(adia\) is checked whether it is zero.
Zero entries are not included in the array \(acsr\).
If \(job[5] \neq 0\), each entry in the array \(adia\) is not checked whether it is zero.

m

Dimension of the matrix \(A\).

acsr

(input/output)
Array containing non-zero elements of the matrix \(A\). Its length is equal to the number of non-zero elements in the matrix \(A\). Refer to values array description in Sparse Matrix Storage Formats for more details.

ja

(input/output). Array containing the column indices for each non-zero element of the matrix \(A\).
Its length is equal to the length of the array \(acsr\). Refer to columns array description in Sparse Matrix Storage Formats for more details.
ia (input/output). Array of length \( m + 1 \), containing indices of elements in the array \( acsr \), such that \( ia[i] - ia[0] \) is the index in the array \( acsr \) of the first non-zero element from the row \( i \). The value of \( ia[m] - ia[0] \) is equal to the number of non-zeros. Refer to \( rowIndex \) array description in Sparse Matrix Storage Formats for more details.

adia (input/output)
Array of size \( (ndiag*idiag) \) containing diagonals of the matrix \( A \).

The key point of the storage is that each element in the array \( adia \) retains the row number of the original matrix. To achieve this diagonals in the lower triangular part of the matrix are padded from the top, and those in the upper triangular part are padded from the bottom.

ndiag
Specifies the leading dimension of the array \( adia \) as declared in the calling (sub)program, must be at least \( \max(1, m) \).

distance
Array of length \( idia \), containing the distances between the main diagonal and each non-zero diagonal to be extracted. The distance is positive if the diagonal is above the main diagonal, and negative if the diagonal is below the main diagonal. The main diagonal has a distance equal to zero.

idiag
Number of diagonals to be extracted. For conversion to diagonal format on return this parameter may be modified.

acsr\_rem, ja\_rem, ia\_rem
Remainder of the matrix in the CSR format if it is needed for conversion to the diagonal format.

Output Parameters

info
This parameter is not used now.

**mkl\_?csrsky**
Converts a sparse matrix in CSR format to the skyline format and vice versa (deprecated).

**Syntax**

```c
void mkl_dcsrsky (const MKL_INT *job, const MKL_INT *m, double *acsr, MKL_INT *ja, MKL_INT *ia, double *asky, MKL_INT *pointers, MKL_INT *info);
void mkl_scsrsky (const MKL_INT *job, const MKL_INT *m, float *acsr, MKL_INT *ja, MKL_INT *ia, float *asky, MKL_INT *pointers, MKL_INT *info);
void mkl_ccsrsky (const MKL_INT *job, const MKL_INT *m, MKL_Complex8 *acsr, MKL_INT *ja, MKL_INT *ia, MKL_Complex8 *asky, MKL_INT *pointers, MKL_INT *info);
void mkl_zcsrsky (const MKL_INT *job, const MKL_INT *m, MKL_Complex16 *acsr, MKL_INT *ja, MKL_INT *ia, MKL_Complex16 *asky, MKL_INT *pointers, MKL_INT *info);
```

**Include Files**

- mkl.h

**Description**

This routine is deprecated. Use the matrix manipulation routines from the Intel® MKL Inspector-executor Sparse BLAS interface instead.
This routine converts a sparse matrix \( A \) stored in the compressed sparse row (CSR) format (3-array variation) to the skyline format and vice versa.

**Input Parameters**

\( job \)

Array, contains the following conversion parameters:

\( job[0] \)

If \( job[0]=0 \), the matrix in the CSR format is converted to the skyline format;

if \( job[0]=1 \), the matrix in the skyline format is converted to the CSR format.

\( job[1] \)

If \( job[1]=0 \), zero-based indexing for the matrix in CSR format is used;

if \( job[1]=1 \), one-based indexing for the matrix in CSR format is used.

\( job[2] \)

If \( job[2]=0 \), zero-based indexing for the matrix in the skyline format is used;

if \( job[2]=1 \), one-based indexing for the matrix in the skyline format is used.

\( job[3] \)

For conversion to the skyline format:

If \( job[3]=0 \), the upper part of the matrix \( A \) in the CSR format is converted.

If \( job[3]=1 \), the lower part of the matrix \( A \) in the CSR format is converted.

For conversion to the CSR format:

If \( job[3]=0 \), the matrix is converted to the upper part of the matrix \( A \) in the CSR format.

If \( job[3]=1 \), the matrix is converted to the lower part of the matrix \( A \) in the CSR format.

\( job[4] \)

\( job[4]=nzmax \) - maximum number of the non-zero elements of the matrix \( A \) if \( job[0]=0 \).

Only for conversion to the skyline format:

If \( job[5]=0 \), only arrays \( pointers \) is filled in for the output storage.

If \( job[5]=1 \), all output arrays \( asky \) and \( pointers \) are filled in for the output storage.

\( m \)

Dimension of the matrix \( A \).

\( acsr \)

(input/output)

Array containing non-zero elements of the matrix \( A \). Its length is equal to the number of non-zero elements in the matrix \( A \). Refer to \( values \) array description in *Sparse Matrix Storage Formats* for more details.
ja

(input/output). Array containing the column indices for each non-zero element of the matrix $A$.

Its length is equal to the length of the array $acsr$. Refer to columns array description in Sparse Matrix Storage Formats for more details.

ia

(input/output). Array of length $m + 1$, containing indices of elements in the array $acsr$, such that $ia[i] - ia[0]$ is the index in the array $acsr$ of the first non-zero element from the row $i$. The value of $ia[m] - ia[0]$ is equal to the number of non-zeros. Refer to rowIndex array description in Sparse Matrix Storage Formats for more details.

asky

(input/output)

Array, for a lower triangular part of $A$ it contains the set of elements from each row starting from the first none-zero element to and including the diagonal element. For an upper triangular matrix it contains the set of elements from each column of the matrix starting with the first non-zero element down to and including the diagonal element. Encountered zero elements are included in the sets. Refer to values array description in Skyline Storage Format for more details.

pointers

(input/output).

Array with dimension $(m+1)$, where $m$ is number of rows for lower triangle (columns for upper triangle), $pointers[i-1] - pointers[0]$ gives the index of element in the array $asky$ that is first non-zero element in row (column) . The value of $pointers[m]$ is set to $nnz + pointers[0]$, where $nnz$ is the number of elements in the array $asky$. Refer to pointers array description in Skyline Storage Format for more details.

**Output Parameters**

**info**

Integer info indicator only for converting the matrix $A$ from the CSR format.

If $info=0$, the execution is successful.

If $info=1$, the routine is interrupted because there is no space in the array $asky$ according to the value $nzmax$.

**mkl_?csradd**

*Computes the sum of two matrices stored in the CSR format (3-array variation) with one-based indexing (deprecated).*

**Syntax**

```c
void mkl_dcsradd (const char *trans , const MKL_INT *request , const MKL_INT *sort ,
const MKL_INT *m , const MKL_INT *n , double *a , MKL_INT *ja , MKL_INT *ia , const
double *beta , double *b , MKL_INT *jb , MKL_INT *ib , double *c , MKL_INT *jc , MKL_INT
*ic , const MKL_INT *nzmax , MKL_INT *info );

void mkl_scsradd (const char *trans , const MKL_INT *request , const MKL_INT *sort ,
const MKL_INT *m , const MKL_INT *n , float *a , MKL_INT *ja , MKL_INT *ia , const
float *beta , float *b , MKL_INT *jb , MKL_INT *ib , float *c , MKL_INT *jc , MKL_INT
*ic , const MKL_INT *nzmax , MKL_INT *info );
```
void mkl_ccsradd (const char *trans , const MKL_INT *request , const MKL_INT *sort ,
const MKL_INT *m , const MKL_INT *n , MKL_Complex8 *a , MKL_INT *ja , MKL_INT *ia ,
const MKL_Complex8 *beta , MKL_Complex8 *b , MKL_INT *jb , MKL_INT *ib , MKL_Complex8

Include Files
• mkl.h

Description
This routine is deprecated. Use mkl_sparse_?_add from the Intel® MKL Inspector-executor Sparse BLAS
interface instead.

The mkl_?csradd routine performs a matrix-matrix operation defined as

\[ C := A + \beta \cdot \text{op}(B) \]

where:

- \( A, B, C \) are the sparse matrices in the CSR format (3-array variation).
- \( \text{op}(B) \) is one of \( \text{op}(B) = B, B^T, \) or \( B^H \)
- \( \beta \) is a scalar.

The routine works correctly if and only if the column indices in sparse matrix representations of matrices \( A \) and \( B \) are arranged in the increasing order for each row. If not, use the parameter sort (see below) to reorder column indices and the corresponding elements of the input matrices.

NOTE
This routine supports only one-based indexing of the input arrays.

Input Parameters

- trans
  - Specifies the operation.
  - If \( \text{trans} = 'N' \) or \( 'n' \), then \( C := A + \beta \cdot B \)
  - If \( \text{trans} = 'T' \) or \( 't' \), then \( C := A + \beta \cdot B^T \)
  - If \( \text{trans} = 'C' \) or \( 'c' \), then \( C := A + \beta \cdot B^H \).

- request
  - If request=0, the routine performs addition. The memory for the output arrays ic, jc, c must be allocated beforehand.
  - If request=1, the routine only computes the values of the array ic of length \( m + 1 \). The memory for the ic array must be allocated beforehand. On exit the value \( ic[m] - 1 \) is the actual number of the elements in the arrays c and jc.
  - If request=2, after the routine is called previously with the parameter request=1 and after the output arrays jc and c are allocated in the calling program with length at least \( ic[m] - 1 \), the routine performs addition.
sort

Specifies the type of reordering. If this parameter is not set (default), the routine does not perform reordering.

If sort=1, the routine arranges the column indices $ja$ for each row in the increasing order and reorders the corresponding values of the matrix $A$ in the array $a$.

If sort=2, the routine arranges the column indices $jb$ for each row in the increasing order and reorders the corresponding values of the matrix $B$ in the array $b$.

If sort=3, the routine performs reordering for both input matrices $A$ and $B$.

$m$

Number of rows of the matrix $A$.

$n$

Number of columns of the matrix $A$.

$a$

Array containing non-zero elements of the matrix $A$. Its length is equal to the number of non-zero elements in the matrix $A$. Refer to values array description in Sparse Matrix Storage Formats for more details.

$ja$

Array containing the column indices plus one for each non-zero element of the matrix $A$. For each row the column indices must be arranged in the increasing order.

The length of this array is equal to the length of the array $a$. Refer to columns array description in Sparse Matrix Storage Formats for more details.

$ia$

Array of length $m + 1$, containing indices of elements in the array $a$, such that $ia[i] - ia[0]$ is the index in the array $a$ of the first non-zero element from the row $i$. The value of the last element $ia[m]$ is equal to the number of non-zero elements of the matrix $A$ plus one. Refer to rowIndex array description in Sparse Matrix Storage Formats for more details.

$beta$

Specifies the scalar $beta$.

$b$

Array containing non-zero elements of the matrix $B$. Its length is equal to the number of non-zero elements in the matrix $B$. Refer to values array description in Sparse Matrix Storage Formats for more details.

$jb$

Array containing the column indices plus one for each non-zero element of the matrix $B$. For each row the column indices must be arranged in the increasing order.

The length of this array is equal to the length of the array $b$. Refer to columns array description in Sparse Matrix Storage Formats for more details.

$ib$

Array of length $m + 1$ when $trans = 'N'$ or $'n'$, or $n + 1$ otherwise.

This array contains indices of elements in the array $b$, such that $ib[i] - ib[0]$ is the index in the array $b$ of the first non-zero element from the row $i$. The value of the last element $ib[m]$ or $ib[n]$ is equal to the number of non-zero elements of the matrix $B$ plus one. Refer to rowIndex array description in Sparse Matrix Storage Formats for more details.

$nzmax$

The length of the arrays $c$ and $jc$. 
This parameter is used only if \texttt{request}=0. The routine stops calculation if the number of elements in the result matrix $C$ exceeds the specified value of $\texttt{nzmax}$.

**Output Parameters**

$c$

Array containing non-zero elements of the result matrix $C$. Its length is equal to the number of non-zero elements in the matrix $C$. Refer to \textit{values} array description in \textit{Sparse Matrix Storage Formats} for more details.

$jc$

Array containing the column indices plus one for each non-zero element of the matrix $C$.

The length of this array is equal to the length of the array $c$. Refer to \textit{columns} array description in \textit{Sparse Matrix Storage Formats} for more details.

$ic$

Array of length $m + 1$, containing indices of elements in the array $c$, such that $ic[i] - ic[0]$ is the index in the array $c$ of the first non-zero element from the row $i$. The value of the last element $ic[m]$ is equal to the number of non-zero elements of the matrix $C$ plus one. Refer to \textit{rowIndex} array description in \textit{Sparse Matrix Storage Formats} for more details.

$\texttt{info}$

If $\texttt{info}$=0, the execution is successful.

If $\texttt{info}$=I>0, the routine stops calculation in the I-th row of the matrix $C$ because number of elements in $C$ exceeds $\texttt{nzmax}$.

If $\texttt{info}$=-1, the routine calculates only the size of the arrays $c$ and $jc$ and returns this value plus 1 as the last element of the array $ic$.

\texttt{mkl_csrmultcsr}

\textit{Computes product of two sparse matrices stored in the CSR format (3-array variation) with one-based indexing (deprecated).}

**Syntax**

```c
void mkl_dcsrmultcsr (const char *trans, const MKL_INT *request, const MKL_INT *sort, const MKL_INT *m, const MKL_INT *n, const MKL_INT *k, double *a, MKL_INT *ja, MKL_INT *ia, double *b, MKL_INT *jb, MKL_INT *ib, double *c, MKL_INT *jc, MKL_INT *ic, const MKL_INT *nzmax, MKL_INT *info);

void mkl_scsrmultcsr (const char *trans, const MKL_INT *request, const MKL_INT *sort, const MKL_INT *m, const MKL_INT *n, const MKL_INT *k, float *a, MKL_INT *ja, MKL_INT *ia, float *b, MKL_INT *jb, MKL_INT *ib, float *c, MKL_INT *jc, MKL_INT *ic, const MKL_INT *nzmax, MKL_INT *info);

void mkl_ccsrmultcsr (const char *trans, const MKL_INT *request, const MKL_INT *sort, const MKL_INT *m, const MKL_INT *n, const MKL_INT *k, MKL_Complex8 *a, MKL_INT *ja, MKL_INT *ia, MKL_Complex8 *b, MKL_INT *jb, MKL_INT *ib, MKL_Complex8 *c, MKL_INT *jc, MKL_INT *ic, const MKL_INT *nzmax, MKL_INT *info);

void mkl_zcsrmultcsr (const char *trans, const MKL_INT *request, const MKL_INT *sort, const MKL_INT *m, const MKL_INT *n, const MKL_INT *k, MKL_Complex16 *a, MKL_INT *ja, MKL_INT *ia, MKL_Complex16 *b, MKL_INT *jb, MKL_INT *ib, MKL_Complex16 *c, MKL_INT *jc, MKL_INT *ic, const MKL_INT *nzmax, MKL_INT *info);
```
Include Files

• mkl.h

Description

This routine is deprecated. Use mkl_sparse_spmm from the Intel® MKL Inspector-executor Sparse BLAS interface instead.

The mkl_?csrmultcsr routine performs a matrix-matrix operation defined as

\[ C := \text{op}(A) \times B \]

where:

- \( A, B, C \) are the sparse matrices in the CSR format (3-array variation);
- \( \text{op}(A) \) is one of \( \text{op}(A) = A, \) or \( \text{op}(A) = A^T, \) or \( \text{op}(A) = A^H. \)

You can use the parameter sort to perform or not perform reordering of non-zero entries in input and output sparse matrices. The purpose of reordering is to rearrange non-zero entries in compressed sparse row matrix so that column indices in compressed sparse representation are sorted in the increasing order for each row.

The following table shows correspondence between the value of the parameter sort and the type of reordering performed by this routine for each sparse matrix involved:

<table>
<thead>
<tr>
<th>Value of the parameter sort</th>
<th>Reordering of ( A ) (arrays ( a, ja, ia ))</th>
<th>Reordering of ( B ) (arrays ( b, ja, ib ))</th>
<th>Reordering of ( C ) (arrays ( c, jc, ic ))</th>
</tr>
</thead>
<tbody>

</tr>
</tbody>
</table>

**NOTE**

This routine supports only one-based indexing of the input arrays.

Input Parameters

\[ \text{trans} \]

Specifies the operation.

- If \( \text{trans} = 'N' \) or \( 'n' \), then \( C := A \times B \)
- If \( \text{trans} = 'T' \) or \( 't' \) or \( 'C' \) or \( 'c' \), then \( C := A^T \times B. \)

\[ \text{request} \]

If \( \text{request}=0 \), the routine performs multiplication, the memory for the output arrays \( ic, jc, c \) must be allocated beforehand.

If \( \text{request}=1 \), the routine computes only values of the array \( ic \) of length \( m + 1 \), the memory for this array must be allocated beforehand. On exit the value \( ic[m] - 1 \) is the actual number of the elements in the arrays \( c \) and \( jc \).
If \( \text{request}=2 \), the routine has been called previously with the parameter \( \text{request}=1 \), the output arrays \( jc \) and \( c \) are allocated in the calling program and they are of the length \( ic[m] - 1 \) at least.

\textit{sort}

Specifies whether the routine performs reordering of non-zeros entries in input and/or output sparse matrices (see table above).

\( m \)

Number of rows of the matrix \( A \).

\( n \)

Number of columns of the matrix \( A \).

\( k \)

Number of columns of the matrix \( B \).

\( a \)

Array containing non-zero elements of the matrix \( A \). Its length is equal to the number of non-zero elements in the matrix \( A \). Refer to \textit{values} array description in \textit{Sparse Matrix Storage Formats} for more details.

\( ja \)

Array containing the column indices plus one for each non-zero element of the matrix \( A \). For each row the column indices must be arranged in the increasing order.

The length of this array is equal to the length of the array \( a \). Refer to \textit{columns} array description in \textit{Sparse Matrix Storage Formats} for more details.

\( ia \)

Array of length \( m + 1 \).

This array contains indices of elements in the array \( a \), such that \( ia[i] - ia[0] \) is the index in the array \( a \) of the first non-zero element from the row \( i \). The value of the last element \( ia[m] \) is equal to the number of non-zero elements of the matrix \( A \) plus one. Refer to \textit{rowIndex} array description in \textit{Sparse Matrix Storage Formats} for more details.

\( b \)

Array containing non-zero elements of the matrix \( B \). Its length is equal to the number of non-zero elements in the matrix \( B \). Refer to \textit{values} array description in \textit{Sparse Matrix Storage Formats} for more details.

\( jb \)

Array containing the column indices plus one for each non-zero element of the matrix \( B \). For each row the column indices must be arranged in the increasing order.

The length of this array is equal to the length of the array \( b \). Refer to \textit{columns} array description in \textit{Sparse Matrix Storage Formats} for more details.

\( ib \)

Array of length \( n + 1 \) when \( \text{trans} = 'N' \) or '\n', or \( m + 1 \) otherwise.

This array contains indices of elements in the array \( b \), such that \( ib[i] - ib[0] \) is the index in the array \( b \) of the first non-zero element from the row \( i \). The value of the last element \( ib[n] \) or \( ib[m] \) is equal to the number of non-zero elements of the matrix \( B \) plus one. Refer to \textit{rowIndex} array description in \textit{Sparse Matrix Storage Formats} for more details.

\( nzmax \)

The length of the arrays \( c \) and \( jc \).

This parameter is used only if \( \text{request}=0 \). The routine stops calculation if the number of elements in the result matrix \( C \) exceeds the specified value of \( nzmax \).
**Output Parameters**

- **c**: Array containing non-zero elements of the result matrix C. Its length is equal to the number of non-zero elements in the matrix C. Refer to values array description in Sparse Matrix Storage Formats for more details.

- **jc**: Array containing the column indices plus one for each non-zero element of the matrix C. The length of this array is equal to the length of the array c. Refer to columns array description in Sparse Matrix Storage Formats for more details.

- **ic**: Array of length \( m + 1 \) when \( \text{trans} = 'N' \) or \( 'n' \), or \( n + 1 \) otherwise. This array contains indices of elements in the array c, such that \( \text{ic}[i] - \text{ic}[0] \) is the index in the array c of the first non-zero element from the row \( i \). The value of the last element \( \text{ic}[m] \) or \( \text{ic}[n] \) is equal to the number of non-zero elements of the matrix C plus one. Refer to rowIndex array description in Sparse Matrix Storage Formats for more details.

- **info**: If \( \text{info}=0 \), the execution is successful. If \( \text{info}=I>0 \), the routine stops calculation in the \( I \)-th row of the matrix C because number of elements in C exceeds \( \text{nzmax} \). If \( \text{info}=-1 \), the routine calculates only the size of the arrays c and jc and returns this value plus 1 as the last element of the array ic.

**mkl_?csrmultd**

Computes product of two sparse matrices stored in the CSR format (3-array variation) with one-based indexing. The result is stored in the dense matrix (deprecated).

**Syntax**

```c
void mkl_dcsrmultd (const char *trans, const MKL_INT *m, const MKL_INT *n, const MKL_INT *k, double *a, MKL_INT *ja, MKL_INT *ia, double *b, MKL_INT *jb, MKL_INT *ib, double *c, MKL_INT *ldc);
void mkl_scsrmultd (const char *trans, const MKL_INT *m, const MKL_INT *n, const MKL_INT *k, float *a, MKL_INT *ja, MKL_INT *ia, float *b, MKL_INT *jb, MKL_INT *ib, float *c, MKL_INT *ldc);
void mkl_ccsrmultd (const char *trans, const MKL_INT *m, const MKL_INT *n, const MKL_INT *k, MKL_Complex8 *a, MKL_INT *ja, MKL_INT *ia, MKL_Complex8 *b, MKL_INT *jb, MKL_INT *ib, MKL_Complex8 *c, MKL_INT *ldc);
void mkl_zcsrmultd (const char *trans, const MKL_INT *m, const MKL_INT *n, const MKL_INT *k, MKL_Complex16 *a, MKL_INT *ja, MKL_INT *ia, MKL_Complex16 *b, MKL_INT *jb, MKL_INT *ib, MKL_Complex16 *c, MKL_INT *ldc);
```

**Include Files**

- mkl.h

**Description**
This routine is deprecated. Use `mkl_sparse_?_spmm` from the Intel® MKL Inspector-executor Sparse BLAS interface instead.

The `mkl_?csrmultd` routine performs a matrix-matrix operation defined as

$$ C := \text{op}(A) * B $$

where:

- $A$, $B$ are the sparse matrices in the CSR format (3-array variation), $C$ is dense matrix;
- $\text{op}(A)$ is one of $\text{op}(A) = A$, or $\text{op}(A) = A^T$, or $\text{op}(A) = A^H$.

The routine works correctly if and only if the column indices in sparse matrix representations of matrices $A$ and $B$ are arranged in the increasing order for each row.

**NOTE**
This routine supports only one-based indexing of the input arrays.

**Input Parameters**

- $trans$ Specifies the operation.
  - If $trans = \text{'N'}$ or $\text{'n'}$, then $C := A * B$
  - If $trans = \text{'T'}$ or $\text{'t'}$ or $\text{'C'}$ or $\text{'c'}$, then $C := A^T * B$.

- $m$ Number of rows of the matrix $A$.

- $n$ Number of columns of the matrix $A$.

- $k$ Number of columns of the matrix $B$.

- $a$ Array containing non-zero elements of the matrix $A$. Its length is equal to the number of non-zero elements in the matrix $A$. Refer to values array description in Sparse Matrix Storage Formats for more details.

- $ja$ Array containing the column indices plus one for each non-zero element of the matrix $A$. For each row the column indices must be arranged in the increasing order.
  - The length of this array is equal to the length of the array $a$. Refer to columns array description in Sparse Matrix Storage Formats for more details.

- $ia$ Array of length $m + 1$ when $trans = \text{'N'}$ or $\text{'n'}$, or $n + 1$ otherwise.
  - This array contains indices of elements in the array $a$, such that $ia[i] - ia[0]$ is the index in the array $a$ of the first non-zero element from the row $i$. The value of the last element $ia[m]$ or $ia[n]$ is equal to the number of non-zero elements of the matrix $A$ plus one. Refer to rowIndex array description in Sparse Matrix Storage Formats for more details.

- $b$ Array containing non-zero elements of the matrix $B$. Its length is equal to the number of non-zero elements in the matrix $B$. Refer to values array description in Sparse Matrix Storage Formats for more details.

- $jb$ Array containing the column indices plus one for each non-zero element of the matrix $B$. For each row the column indices must be arranged in the increasing order.
The length of this array is equal to the length of the array \( b \). Refer to columns array description in Sparse Matrix Storage Formats for more details.

\( \text{ib} \)

Array of length \( m + 1 \).

This array contains indices of elements in the array \( b \), such that \( \text{ib}[i] - \text{ib}[0] \) is the index in the array \( b \) of the first non-zero element from the row \( i \). The value of the last element \( \text{ib}[m] \) is equal to the number of non-zero elements of the matrix \( B \) plus one. Refer to \( \text{rowIndex} \) array description in Sparse Matrix Storage Formats for more details.

Output Parameters

\( \text{c} \)

Array containing non-zero elements of the result matrix \( C \).

\( \text{ldc} \)

Specifies the leading dimension of the dense matrix \( C \) as declared in the calling (sub)program. Must be at least \( \max(m, 1) \) when \( \text{trans} = 'N' \) or \( 'n' \), or \( \max(1, n) \) otherwise.

**Sparse QR Routines**

Sparse QR routines and their data types

<table>
<thead>
<tr>

</tbody>
</table>

**mkl_sparse_set_qr_hint**

Define the pivot strategy for further calls of \text{mkl_sparse_?_qr}.

**Syntax**

\[
\text{sparse_status_t mkl_sparse_set_qr_hint} (\text{sparse_matrix_t } A, \text{sparse_qr_hint_t } hint);
\]

**Include Files**

- \text{mkl_sparse_qr.h}

**Description**

You can use this routine to enable a pivot strategy in the case of an ill-conditioned matrix.

**Input Parameters**

\( A \)

Handle containing a sparse matrix in an internal data structure.
hint

Value specifying whether to use pivoting.

**NOTE** The only value currently supported is SPARSE_QR_WITH_PIVOTS, which enables the use of a pivot strategy for an ill-conditioned matrix.

**Return Values**

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>

**mkl_sparse_?_qr**

*Calculates the solution of sparse systems of linear equations using QR decomposition.*

**Syntax**

```c
sparse_status_t mkl_sparse_d_qr ( sparse_operation_t operation, sparse_matrix_t A, struct matrix_descr descr, sparse_layout_t layout, MKL_INT columns, double *x, MKL_INT ldx, const double *b, MKL_INT ldb );

sparse_status_t mkl_sparse_s_qr ( sparse_operation_t operation, sparse_matrix_t A, struct matrix_descr descr, sparse_layout_t layout, MKL_INT columns, float *x, MKL_INT ldx, const float *b, MKL_INT ldb );
```

**Include Files**

- mkl_sparse_qr.h

**Description**

The mkl_sparse_?_qr routine calculates the solution of sparse systems of linear equations \( A*x = b \) using QR decomposition (\( A = QR \)).

**NOTE** Currently, mkl_sparse_?_qr supports only CSR format for the input matrix, non-transpose operation, and single right-hand side.
Input Parameters

operation

Specifies the operation to perform.

ОUTЕ NOTE Currently, the only supported value is SPARSE_OPERATION_NON_TRANSPOSE (non-transpose case; that is, \( A^T x = b \) is solved).

\( A \)

Handle containing a sparse matrix in an internal data structure.

\( descr \)

Structure specifying sparse-matrix properties. Only the parameters listed here are currently supported.

\( type \)

Specifies the type of sparse matrix.

ОUTЕ NOTE Currently, the only supported value is SPARSE_MATRIX_TYPE_GENERAL (the matrix is processed as-is).

\( layout \)

Describes the storage scheme for the dense matrix:

<table>
<thead>
<tr>
<th>Layout Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPARSE_LAYOUT_COLUMN_MAJOR</td>
<td>Storage of elements uses column-major layout.</td>
</tr>
<tr>
<td>SPARSE_LAYOUT_ROW_MAJOR</td>
<td>Storage of elements uses row-major layout.</td>
</tr>
</tbody>
</table>

\( x \)

Array with a size of at least \( rows \times cols \):

<table>
<thead>
<tr>
<th>( rows ) (number of rows in ( x ))</th>
<th>( cols ) (number of columns in ( x ))</th>
<th>( layout = SPARSE_LAYOUT_COLUMN_MAJOR )</th>
<th>( layout = SPARSE_LAYOUT_ROW_MAJOR )</th>
</tr>
</thead>
<tbody>
<tr>
<td>( idx )</td>
<td>( columns )</td>
<td>( Number of columns in A )</td>
<td>( idx )</td>
</tr>
</tbody>
</table>

\( b \)

Array with a size of at least \( rows \times cols \):

<table>
<thead>
<tr>
<th>( rows ) (number of rows in ( b ))</th>
<th>( cols ) (number of columns in ( b ))</th>
<th>( layout = SPARSE_LAYOUT_COLUMN_MAJOR )</th>
<th>( layout = SPARSE_LAYOUT_ROW_MAJOR )</th>
</tr>
</thead>
<tbody>
<tr>
<td>( ldb )</td>
<td>( columns )</td>
<td>( Number of columns in A )</td>
<td>( ldb )</td>
</tr>
</tbody>
</table>
Specifies the leading dimension of matrix $b$.

**Output Parameters**

$x$ Overwritten by the updated matrix $y$.

**Return Values**

- **SPARSE_STATUS_SUCCESS** The operation was successful.
- **SPARSE_STATUS_NOT_INITIALIZED** The routine encountered an empty handle or matrix array.
- **SPARSE_STATUS_ALLOC_FAILED** Internal memory allocation failed.
- **SPARSE_STATUS_INVALID_VALUE** The input parameters contain an invalid value.
- **SPARSE_STATUS_EXECUTION_FAILED** Execution failed.
- **SPARSE_STATUS_INTERNAL_ERROR** An error in algorithm implementation occurred.
- **SPARSE_STATUS_NOT_SUPPORTED** The requested operation is not supported.

**mkl_sparse_qr_reorder**

Reordering step of SPARSE QR solver.

**Syntax**

```
sparse_status_t mkl_sparse_qr_reorder (sparse_matrix_t A, struct matrix_descr descr);
```

**Include Files**

- mkl_sparse_qr.h

**Description**

The `mkl_sparse_qr_reorder` routine performs ordering and symbolic analysis of matrix $A$.

**NOTE** Currently, `mkl_sparse_qr_reorder` supports only general structure and CSR format for the input matrix.

**Input Parameters**

- **$A$** Handle containing a sparse matrix in an internal data structure.
- **$descr$** Structure specifying sparse-matrix properties. Only the parameters listed here are currently supported.

**Return Values**

- **SPARSE_STATUS_SUCCESS** The operation was successful.
SPARSE_STATUS_NOT_INITIALIZED The routine encountered an empty handle or matrix array.

SPARSE_STATUS_ALLOC_FAILED Internal memory allocation failed.

SPARSE_STATUS_INVALID_VALUE The input parameters contain an invalid value.

SPARSE_STATUS_EXECUTION_FAILED Execution failed.

SPARSE_STATUS_INTERNAL_ERROR An error in algorithm implementation occurred.

SPARSE_STATUS_NOT_SUPPORTED The requested operation is not supported.

**mkl_sparse_?_qr_factorize**

*Factorization step of the SPARSE QR solver.*

**Syntax**

sparse_status_t mkl_sparse_d_qr_factorize (sparse_matrix_t A, double *alt_values);
sparse_status_t mkl_sparse_s_qr_factorize (sparse_matrix_t A, float *alt_values);

**Include Files**

- mkl_sparse_qr.h

**Description**

The `mkl_sparse_?_qr_factorize` routine perform numerical factorization of matrix $A$.

*NOTE* Currently, `mkl_sparse_?_qr_factorize` supports only CSR format for the input matrix.

**Input Parameters**

- $A$ Handle containing a sparse matrix in an internal data structure.
- $alt\_values$ Array with alternative values. Must be the size of the non-zeros in the initial input matrix. When passed to the routine, these values will be used during the factorization step instead of the values stored in handle $A$.

**Return Values**

- SPARSE_STATUS_SUCCESS The operation was successful.
- SPARSE_STATUS_NOT_INITIALIZED The routine encountered an empty handle or matrix array.
- SPARSE_STATUS_ALLOC_FAILED Internal memory allocation failed.
- SPARSE_STATUS_INVALID_VALUE The input parameters contain an invalid value.
mkl_sparse_?_qr_solve
Solving step of the SPARSE QR solver.

Syntax

```c
sparse_status_t mkl_sparse_d_qr_solve ( sparse_operation_t operation, sparse_matrix_t A, double *alt_values, sparse_layout_t layout, MKL_INT columns, double *x, MKL_INT ldx, const double *b, MKL_INT ldb );

sparse_status_t mkl_sparse_s_qr_solve ( sparse_operation_t operation, sparse_matrix_t A, float *alt_values, sparse_layout_t layout, MKL_INT columns, float *x, MKL_INT ldx, const float *b, MKL_INT ldb );
```

Include Files

- mkl_sparse_qr.h

Description

The `mkl_sparse_?_qr_solve` routine computes the solution of sparse systems of linear equations $A \times x = b$.

**NOTE**
Currently, `mkl_sparse_?_qr_solve` supports only CSR format for the input matrix, non-transpose operation, and single right-hand side.
Alternative values are not supported and must be set to NULL.

Input Parameters

- `operation` Specifies the operation to perform.

  **NOTE** Currently, the only supported value is `SPARSE_OPERATION_NON_TRANSPOSE` (non-transpose case; that is, $A \times x = b$ is solved).

- `A` Handle containing a sparse matrix in an internal data structure.

- `alt_values` Reserved for future use.

- `layout` Describes the storage scheme for the dense matrix:

<table>
<thead>
<tr>
<th>Storage of elements uses column-major layout.</th>
<th>Storage of elements uses row-major layout.</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>SPARSE_LAYOUT_COLUMN_MAJOR</code></td>
<td><code>SPARSE_LAYOUT_ROW_MAJOR</code></td>
</tr>
</tbody>
</table>

Execution failed.

An error in algorithm implementation occurred.

The requested operation is not supported.
Array with a size of at least \( rows \times cols \):

<table>
<thead>
<tr>
<th>layout</th>
<th>layout</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPARSE_LAYOUT_COLUMN_MAJOR</td>
<td>SPARSE_LAYOUT_ROW_MAJOR</td>
</tr>
<tr>
<td><strong>rows</strong> (number of rows in ( x ))</td>
<td>( ldx )</td>
</tr>
<tr>
<td></td>
<td>Number of columns in ( A )</td>
</tr>
<tr>
<td><strong>cols</strong> (number of columns in ( x ))</td>
<td>( columns )</td>
</tr>
<tr>
<td></td>
<td>( ldx )</td>
</tr>
</tbody>
</table>

\( columns \)

\( ldx \)

Number of columns in matrix \( b \).

Specifies the leading dimension of matrix \( x \).

Array with a size of at least \( rows \times cols \):

<table>
<thead>
<tr>
<th>layout</th>
<th>layout</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPARSE_LAYOUT_COLUMN_MAJOR</td>
<td>SPARSE_LAYOUT_ROW_MAJOR</td>
</tr>
<tr>
<td><strong>rows</strong> (number of rows in ( b ))</td>
<td>( ldb )</td>
</tr>
<tr>
<td></td>
<td>Number of columns in ( A )</td>
</tr>
<tr>
<td><strong>cols</strong> (number of columns in ( b ))</td>
<td>( columns )</td>
</tr>
<tr>
<td></td>
<td>( ldb )</td>
</tr>
</tbody>
</table>

\( ldb \)

Specifies the leading dimension of matrix \( b \).

**Output Parameters**

\( x \)

Contains the solution of system \( A \times x = b \).

**Return Values**

- **SPARSE_STATUS_SUCCESS**
  - The operation was successful.
- **SPARSE_STATUS_NOT_INITIALIZED**
  - The routine encountered an empty handle or matrix array.
- **SPARSE_STATUS_ALLOC_FAILED**
  - Internal memory allocation failed.
- **SPARSE_STATUS_INVALID_VALUE**
  - The input parameters contain an invalid value.
- **SPARSE_STATUS_EXECUTION_FAILED**
  - Execution failed.
- **SPARSE_STATUS_INTERNAL_ERROR**
  - An error in algorithm implementation occurred.
- **SPARSE_STATUS_NOT_SUPPORTED**
  - The requested operation is not supported.
mkl_sparse_?_qr_qmult
First stage of the solving step of the SPARSE QR solver.

Syntax

sparse_status_t mkl_sparse_d_qr_qmult ( sparse_operation_t operation, sparse_matrix_t A, sparse_layout_t layout, MKL_INT columns, double *x, MKL_INT ldx, const double *b, MKL_INT ldb );
sparse_status_t mkl_sparse_s_qr_qmult ( sparse_operation_t operation, sparse_matrix_t A, sparse_layout_t layout, MKL_INT columns, float *x, MKL_INT ldx, const float *b, MKL_INT ldb );

Include Files
• mkl_sparse_qr.h

Description
The mkl_sparse_?_qr_qmult routine computes multiplication of inversed matrix Q and right-hand side matrix b. This routine can be used to perform the solving step in two separate calls as an alternative to a single call of mkl_sparse_?_qr_solve.

NOTE Currently, mkl_sparse_?_qr_qmult supports only CSR format for the input matrix, non-transpose operation, and single right-hand side.

Input Parameters

operation
Specifies the operation to perform.

NOTE Currently, the only supported value is
SPARSE_OPERATION_NON_TRANSPOSE (non-transpose case; that is, A*x = b is solved).

A
Handle containing a sparse matrix in an internal data structure.

layout
Describes the storage scheme for the dense matrix:

<table>
<thead>
<tr>
<th>SPARSE_LAYOUT_COLUMN_MAJOR</th>
<th>Storage of elements uses column-major layout.</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPARSE_LAYOUT_ROW_MAJOR</td>
<td>Storage of elements uses row-major layout.</td>
</tr>
</tbody>
</table>

x
Array with a size of at least rows*cols:

<table>
<thead>
<tr>
<th>rows (number of rows in x)</th>
<th>layout = SPARSE_LAYOUT_COLUMN_MAJOR</th>
<th>layout = SPARSE_LAYOUT_ROW_MAJOR</th>
</tr>
</thead>
<tbody>
<tr>
<td>ldx</td>
<td>Number of columns in A</td>
<td></td>
</tr>
</tbody>
</table>
**Number of columns in matrix \( b \).**

Specifies the leading dimension of matrix \( x \).

**Array with a size of at least \( \text{rows} \times \text{cols} \):**

<table>
<thead>
<tr>
<th>( \text{layout} = \text{SPARSE_LAYOUT_COLUMN_MAJOR} )</th>
<th>( \text{layout} = \text{SPARSE_LAYOUT_ROW_MAJOR} )</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \text{rows} ) (number of rows in ( b ))</td>
<td>( \text{ldb} )</td>
</tr>
<tr>
<td>Number of columns in ( A )</td>
<td></td>
</tr>
<tr>
<td>( \text{cols} ) (number of columns in ( b ))</td>
<td>( \text{columns} )</td>
</tr>
<tr>
<td>( \text{ldb} )</td>
<td>( \text{ldb} )</td>
</tr>
</tbody>
</table>

**Output Parameters**

\( x \)

Overwritten by the updated matrix \( x = Q^{-1}b \).

**Return Values**

- \( \text{SPARSE\_STATUS\_SUCCESS} \) The operation was successful.
- \( \text{SPARSE\_STATUS\_NOT\_INITIALIZED} \) The routine encountered an empty handle or matrix array.
- \( \text{SPARSE\_STATUS\_ALLOC\_FAILED} \) Internal memory allocation failed.
- \( \text{SPARSE\_STATUS\_INVALID\_VALUE} \) The input parameters contain an invalid value.
- \( \text{SPARSE\_STATUS\_EXECUTION\_FAILED} \) Execution failed.
- \( \text{SPARSE\_STATUS\_INTERNAL\_ERROR} \) An error in algorithm implementation occurred.
- \( \text{SPARSE\_STATUS\_NOT\_SUPPORTED} \) The requested operation is not supported.

**mkl_sparse_?_qr_rsolve**

Second stage of the solving step of the \texttt{SPARSE QR solver}. 

---

**cols** 

(number of columns in \( x \))

\( \text{columns} \)

\( \text{ldx} \)

**Bla and Sparse BLAS Routines**
Syntax

```c
sparse_status_t mkl_sparse_d_qr_rsolve ( sparse_operation_t operation, sparse_matrix_t A, sparse_layout_t layout, MKL_INT columns, double *x, MKL_INT ldx, const double *b, MKL_INT ldb );
sparse_status_t mkl_sparse_s_qr_rsolve ( sparse_operation_t operation, sparse_matrix_t A, sparse_layout_t layout, MKL_INT columns, float *x, MKL_INT ldx, const float *b, MKL_INT ldb );
```

Include Files

- `mkl_sparse_qr.h`

Description

The `mkl_sparse_?_qr_rsolve` routine computes the solution of \( A x = b \).

**NOTE** Currently, `mkl_sparse_?_qr_rsolve` supports only CSR format for the input matrix, non-transpose operation, and single right-hand side.

Input Parameters

- **operation**
  Specifies the operation to perform.

  **NOTE** Currently, the only supported value is `SPARSE_OPERATION_NON_TRANSPOSE` (non-transpose case; that is, \( A x = b \) is solved).

- **A**
  Handle containing a sparse matrix in an internal data structure.

- **layout**
  Describes the storage scheme for the dense matrix:
  - `SPARSE_LAYOUT_COLUMN_MAJOR` Storage of elements uses column-major layout.
  - `SPARSE_LAYOUT_ROW_MAJOR` Storage of elements uses row-major layout.

- **x**
  Array with a size of at least \( rows \cdot cols \):

<table>
<thead>
<tr>
<th>layout =</th>
<th>layout =</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>SPARSE_LAYOUT_COLUMN_MAJOR</code></td>
<td><code>SPARSE_LAYOUT_ROW_MAJOR</code></td>
</tr>
<tr>
<td>( rows ) (number of rows in ( x ))</td>
<td>( ldx )</td>
</tr>
<tr>
<td>( cols ) (number of columns in ( x ))</td>
<td>( columns )</td>
</tr>
</tbody>
</table>

- **columns**
  Number of columns in matrix \( b \).

- **ldx**
  Specifies the leading dimension of matrix \( x \).
Array with a size of at least $rows \times cols$:

<table>
<thead>
<tr>
<th>layout = SPARSE_LAYOUT_COLUMN_MAJOR</th>
<th>layout = SPARSE_LAYOUT_ROW_MAJOR</th>
</tr>
</thead>
<tbody>
<tr>
<td>rows (number of rows in $b$)</td>
<td>$ldb$</td>
</tr>
<tr>
<td>cols (number of columns in $b$)</td>
<td>columns $\times ldb$</td>
</tr>
</tbody>
</table>

$ldb$

Specifies the leading dimension of matrix $b$.

**Output Parameters**

$x$

Contains the solution of the system $A \times x = b$.

**Return Values**

- **SPARSE_STATUS_SUCCESS**
  - The operation was successful.
- **SPARSE_STATUS_NOT_INITIALIZED**
  - The routine encountered an empty handle or matrix array.
- **SPARSE_STATUS_ALLOC_FAILED**
  - Internal memory allocation failed.
- **SPARSE_STATUS_INVALID_VALUE**
  - The input parameters contain an invalid value.
- **SPARSE_STATUS_EXECUTION_FAILED**
  - Execution failed.
- **SPARSE_STATUS_INTERNAL_ERROR**
  - An error in algorithm implementation occurred.
- **SPARSE_STATUS_NOT_SUPPORTED**
  - The requested operation is not supported.

**BLAS and LAPACK Compact Routines**

**Overview**

Many HPC applications rely on the application of BLAS and LAPACK operations on groups of very small matrices. While existing batch Intel® MKL BLAS routines already provide meaningful speedup over OpenMP* loops around BLAS operations for these sizes, another customization offers potential speedup by allocating matrices in a **SIMD-friendly format**, thus allowing for cross-matrix vectorization in the BLAS and LAPACK routines of the Intel® MKL called **Compact BLAS and LAPACK**.

The main idea behind these compact methods is to create true SIMD computations in which subgroups of matrices are operated on with kernels that abstractly appear as scalar kernels, while registers are filled by cross-matrix vectorization.

These are the BLAS/LAPACK compact functions:

- `mkl_?gemm_compact`
- `mkl_?trsm_compact`
• mkl_potrf_compact
• mkl_getrfnp_compact
• mkl_geqrf_compact
• mkl_getrinp_compact

The compact API provides additional service functions to refactor data. Because this capability is not specific to any particular BLAS or LAPACK operation, this data manipulation can be executed once for an application's data, allowing the entire program -- consisting of any number of BLAS and LAPACK operations for which compact kernels have been written -- to be performed on the compact data without any refactoring. For applications working on data in compact format, the packing function need not be used.

See "About the Compact Format" below for more details.

Along with this new data format, the API consists of two components:

• **BLAS and LAPACK Compact Kernels**: The first component of the API is a compact kernel that works on matrices stored in compact format.

• **Service Functions for the Compact Format**: The second component of the API is a compact service function allowing for data to be factored into and out of compact format. These are:
  
  • mkl_gepack_compact
  • mkl_igeunpack_compact
  • mkl_get_format_compact
  • mkl_get_size_compact

Note that there are some **Numerical Limitations** for the routines mentioned above.

**About the Compact Format**

In compact format, for calculations involving **real** precision, matrices are organized in packs of size \( V \), where \( V \) is the SIMD vector length of the underlying architecture. Each pack is a 3D-tensor with the matrix index incrementing the fastest. These packs are then loaded into registers and operated on using SIMD instructions.
The figure below demonstrates the packing of a set of four $3 \times 3$ real-precision matrices into compact format. The pack length for this example is $V = 2$, resulting in 2 compact packs.

For calculations involving complex precision, the real and imaginary parts of each matrix are packed separately. In the figure below, the group of four 3 x 3 complex matrices is packed into compact format with pack length $V = 2$. The first pack consists of the real parts of the first two matrices, and the second pack consists of the imaginary parts of the first two matrices. Real and imaginary packs alternate in memory. This storage format means that all compact arrays can be handled as a real type.

**Compact Format for Complex Precision**

The particular specifications (size and number) of the compact packs for the architecture and problem-precision definition are specified by an *MKL_COMPACT_PACK* enum type. For example: given a double-precision problem involving a group of 128 matrices working on an architecture with a 256-bit SIMD vector length, the optimal pack length is $V = 4$, and the number of packs is 32.

The initially-permitted values for the enum are:

- *MKL_COMPACT_SSE* - pack length 2 for double precision, pack length 4 for single precision.
- *MKL_COMPACT_AVX* - pack length 4 for double precision, pack length 8 for single precision.
- *MKL_COMPACT_AVX512* - pack length 8 for double precision, pack length 16 for single precision.

For calculations involving complex precision, the pack length is the same; however, half of the packs store the real parts of matrices, and half store the imaginary parts. The means that it takes double the number of packs to store the same number of matrices.
The above examples illustrate the case when the number of matrices is evenly-divisible by the pack length. When this is not the case, there will be partially-unfilled packs at the end of the memory segment, and the compact-packing routine will pad these partially unfilled packs with *identity matrices*, so that compact routines use only the completely-filled registers in their calculations. The next figure illustrates this padding for a group of three 3 x 3 real-precision matrices with a pack length of 2.

**Compact Format with Padding**

![Diagram showing compact format with padding](image)

Before calling a BLAS or LAPACK compact function, the input data must be packed in compact format. After execution, the output data should be unpacked from this compact format, unless another compact routine will be called immediately following the first. Two service functions, *mkl_?gepack_compact*, and *mkl_?geunpack_compact*, facilitate the process of storing matrices in compact format. It is recommended that the user call the function *mkl_get_format_compact* before calling the *mkl_?gepack_compact* routine to obtain the optimal format for performance. Advanced users can pack and unpack the matrices themselves and still use Intel® MKL compact functions on the packed set.

Compact routines can only be called for groups of matrices that have the same dimensions, leading dimension, and storage format. For example, the routine *mkl_?getrfnp_compact*, which calculates the LU factorization of a group of m x n matrices without pivoting, can only be called for a group of matrices with the same number of rows (m) and the same number of columns (n). All of the matrices must also be stored in arrays with the same leading dimension, and all must be stored in the same storage format (column-major or row-major).

### mkl_?gemm_compact

*Computes a matrix-matrix product of a set of compact format general matrices.*

**Syntax**

```c
void mkl_sgemm_compact (MKL_LAYOUT layout, MKL_TRANSPOSE transa, MKL_TRANSPOSE transb,
MKL_INT m, MKL_INT n, MKL_INT k, float alpha, const float *ap, MKL_INT ldap, const float
*bp, MKL_INT ldbp, float beta, float *cp, MKL_INT ldcp, MKL_COMPACT_PACK format, MKL_INT
nm);
```
void mkl_dgemm_compact (MKL_LAYOUT layout, MKL_TRANSPOSE transa, MKL_TRANSPOSE transb, MKL_INT m, MKL_INT n, MKL_INT k, double alpha, const double *ap, MKL_INT ldap, const double *bp, MKL_INT ldbp, double beta, double *cp, MKL_INT ldcp, MKL_COMPACT_PACK format, MKL_INT nm);

void mkl_cgemm_compact (MKL_LAYOUT layout, MKL_TRANSPOSE transa, MKL_TRANSPOSE transb, MKL_INT m, MKL_INT n, MKL_INT k, mkl_compact_complex_float *alpha, const float *ap, MKL_INT ldap, const float *bp, MKL_INT ldbp, mkl_compact_complex_float *beta, float *cp, MKL_INT ldcp, MKL_COMPACT_PACK format, MKL_INT nm);

void mkl_zgemm_compact (MKL_LAYOUT layout, MKL_TRANSPOSE transa, MKL_TRANSPOSE transb, MKL_INT m, MKL_INT n, MKL_INT k, mkl_compact_complex_double *alpha, const double *ap, MKL_INT ldap, const double *bp, MKL_INT ldbp, mkl_compact_complex_double *beta, double *cp, MKL_INT ldcp, MKL_COMPACT_PACK format, MKL_INT nm);

Description

The mkl_?gemm_compact routine computes a scalar-matrix-matrix product and adds the result to a scalar-matrix product for a group of nm general matrices $A_c$ that have been stored in compact format. The operation is defined for each matrix as:

$$C_c := \alpha \cdot \text{op}(A_c) \cdot \text{op}(B_c) + \beta \cdot C_c$$

Where

- $\text{op}(X_c)$ is one of $\text{op}(X_c) = X_c$, or $\text{op}(X_c) = X_c^T$, or $\text{op}(X_c) = X_c^H$,
- $\alpha$ and $\beta$ are scalars,
- $A_c$, $B_c$, and $C_c$ are matrices that have been stored in compact format,
- $\text{op}(A_c)$ is an $m$-by-$k$ matrix for each matrix in the group,
- $\text{op}(B_c)$ is a $k$-by-$n$ matrix for each matrix in the group,
- and $C_c$ is an $m$-by-$n$ matrix.

Input Parameters

layout

Specifies whether two-dimensional array storage is row-major (MKL_ROW_MAJOR) or column-major (MKL_COL_MAJOR).

transa

Specifies the operation:

If $\text{transa}=\text{MKL_NOTRANS}$, then $\text{op}(A_c) := A_c$.
If $\text{transa}=\text{MKL_TRANS}$, then $\text{op}(A_c) := A_c^T$.
If $\text{transa}=\text{MKL_CONJTRANS}$, then $\text{op}(A_c) := A_c^H$.

transb

Specifies the operation:

If $\text{transb}=\text{MKL_NOTRANS}$, then $\text{op}(B_c) := B_c$.
If $\text{transb}=\text{MKL_TRANS}$, then $\text{op}(B_c) := B_c^T$.
If $\text{transb}=\text{MKL_CONJTRANS}$, then $\text{op}(B_c) := B_c^H$.

m

The number of rows of the matrices $\text{op}(A_c)$, $m \geq 0$.

n

The number of columns of matrices $\text{op}(B_c)$ and $C_c$, $n \geq 0$.

k

The number of columns of matrices $\text{op}(A_c)$ and the number of rows of matrices $\text{op}(B_c)$, $k \geq 0$.

alpha

Specifies the scalar $\alpha$. 
Points to the beginning of the array that stores the \( nmA_c \) matrices. See Compact Format for more details.

<table>
<thead>
<tr>
<th>( transa=\text{MKL_NOTRANS} ) &amp;</th>
<th>( transa=\text{MKL_TRANS or transa=MKL_CONJTRANS} )</th>
</tr>
</thead>
<tbody>
<tr>
<td>( layout = \text{MKL_COL_MAJOR} ) &amp; ( ap ) has size ( ldap\times k\times nm ).</td>
<td></td>
</tr>
<tr>
<td>( layout = \text{MKL_ROW_MAJOR} ) &amp; ( ap ) has size ( ldap\times m\times nm ).</td>
<td></td>
</tr>
</tbody>
</table>

Specifies the leading dimension of \( A_c \).

Points to the beginning of the array that stores the \( nmB_c \) matrices. See Compact Format for more details.

<table>
<thead>
<tr>
<th>( transb=\text{MKL_NOTRANS} ) &amp;</th>
<th>( transb=\text{MKL_TRANS or transb=MKL_CONJTRANS} )</th>
</tr>
</thead>
<tbody>
<tr>
<td>( layout = \text{MKL_COL_MAJOR} ) &amp; ( bp ) has size ( ldbp\times n\times nm ).</td>
<td></td>
</tr>
<tr>
<td>( layout = \text{MKL_ROW_MAJOR} ) &amp; ( bp ) has size ( ldbp\times k\times nm ).</td>
<td></td>
</tr>
</tbody>
</table>

Specifies the leading dimension of \( B_c \).

Specifies the scalar \( \beta \).

Before entry, \( cp \) points to the beginning of the array that stores the \( nmC_c \) matrices, except when \( \beta \) is equal to zero, in which case \( cp \) need not be set on entry.

|\( layout = \text{MKL\_COL\_MAJOR} \) & \( cp \) has size \( ldap\times n\times nm \). |
|\( layout = \text{MKL\_ROW\_MAJOR} \) & \( cp \) has size \( ldap\times m\times nm \). |

Specifies the leading dimension of \( C_c \).

|\( layout = \text{MKL\_COL\_MAJOR} \) & \( ldcp \) must be at least \( (1,m) \). |
|\( layout = \text{MKL\_ROW\_MAJOR} \) & \( ldcp \) must be at least \( (1,n) \). |

Specifies the format of the compact matrices. See Compact Format or mkl_get_format_compact for details.

Total number of matrices stored in compact format in the group of matrices.
NOTE
The values of ldap, ldbp, and ldcp used in mkl_?gemm_compact must be consistent with the values used in mkl_?get_size_compact, mkl_?gepack_compact, and mkl_?geunpack_compact.

Output Parameters

cp
Each matrix \( C_c \) is overwritten by the \( m \)-by-\( n \) matrix \((alpha*op(A_c)*op(B_c) + beta*C_c)\).

**mkl_?trsm_compact**
Solves a triangular matrix equation for a set of general, \( m \times n \) matrices that have been stored in Compact format.

**Syntax**

```c
mkl_strsm_compact (MKL_LAYOUT layout, MKL_SIDE side, MKL_UPLO uplo, MKL_TRANSPOSE transa, MKL_DIAG diag, MKL_INT m, MKL_INT n, float alpha, const float *ap, MKL_INT a_stride, float *bp, MKL_INT b_stride, MKL_COMPACT_PACK format, MKL_INT nm);
```

```c
mkl_dtrsm_compact (MKL_LAYOUT layout, MKL_SIDE side, MKL_UPLO uplo, MKL_TRANSPOSE transa, MKL_DIAG diag, MKL_INT m, MKL_INT n, double alpha, const double*ap, MKL_INT a_stride, double *bp, MKL_INT b_stride, MKL_COMPACT_PACK format, MKL_INT nm);
```

```c
mkl_ctrsm_compact (MKL_LAYOUT layout, MKL_SIDE side, MKL_UPLO uplo, MKL_TRANSPOSE transa, MKL_DIAG diag, MKL_INT m, MKL_INT n, mkl_compact_complex_float *alpha, const float*ap, MKL_INT a_stride, float*bp, MKL_INT b_stride, MKL_COMPACT_PACK format, MKL_INT nm);
```

```c
mkl_ztrsm_compact (MKL_LAYOUT layout, MKL_SIDE side, MKL_UPLO uplo, MKL_TRANSPOSE transa, MKL_DIAG diag, MKL_INT m, MKL_INT n, mkl_compact_complex_double *alpha, const double*ap, MKL_INT a_stride, double*bp, MKL_INT b_stride, MKL_COMPACT_PACK format, MKL_INT nm);
```

**Description**
The routine solves one of the following matrix equations for a group of \( nm \) matrices:

\[
op(A_c) \ast X_c = \alpha \ast B_c\]

or

\[
X_c \ast \text{op}(A_c) = \alpha \ast B_c
\]

where:

- \( \alpha \) is a scalar, \( X_c \) and \( B_c \) are \( m \)-by-\( n \) matrices that have been stored in compact format, and \( A_c \) is a \( m \)-by-\( m \) unit, or non-unit, upper or lower triangular matrix that has been stored in compact format.
- \( \text{op}(A_c) \) is one of \( \text{op}(A_c) = A_c \), or \( \text{op}(A_c) = A_c^T \), or \( \text{op}(A_c) = A_c^H \),
- \( B_c \) is overwritten by the solution matrix \( X_c \).

**Input Parameters**

**layout**
Specifies whether two-dimensional array storage is row-major (MKL_ROW_MAJOR) or column-major (MKL_COL_MAJOR).
Specifies whether op(A_c) appears on the left or right of X_c in the equation:

if side = MKL_LEFT, then op(A_c)*X_c = alpha*B_c, if side = MKL_RIGHT, then X_c*op(A_c) = alpha*B_c

**uplo**

Specifies whether matrix A_c is upper or lower triangular.

If uplo = MKL_UPPER, A_c is upper triangular.

If uplo = MKL_LOWER, A_c is lower triangular.

**transa**

Specifies the operation:

If transa=MKL_NOTRANS, then op(A_c) = A_c;

If transa=MKL_TRANS, then op(A_c) = A_c^T;

If transa=MKL_CONJTRANS, then op(A_c) = A_c^H;

**diag**

Specifies whether the matrix A_c is unit triangular:

If diag=MKL_UNIT, then the matrix is unit triangular;

if diag=MKL_NONUNIT, then the matrix is not unit triangular.

**m**

The number of rows of B_c and the number of rows and columns of A_c when side=MKL_LEFT; m >= 0.

**n**

The number of columns of B_c and the number of rows and columns of A_c when side=MKL_RIGHT; n >= 0.

**alpha**

Specifies the scalar alpha. When alpha is zero, then ap is not referenced and bp need not be set before entry.

**ap**

Array, size ldap*k*nm, where k is m when side = MKL_LEFT and n when side = MKL_RIGHT. ap points to the beginning of nm A_c matrices stored in compact format. When uplo = MKL_UPPER, A_c is assumed to be an upper triangular matrix and the lower triangular part of A_c is not referenced. With uplo = MKL_LOWER, A_c is assumed to be a lower triangular matrix and the upper triangular part of A_c is not referenced. With diag = MKL_UNIT, the diagonal elements of A_c are not referenced either, but are assumed to be unity.

**ldap**

Column stride (column-major layout) or row stride (row-major layout) of A_c.

When side=MKL_LEFT, ldap must be at least max (1,m).

When side=MKL_RIGHT, ldap must be at least max (1,n).

**bp**

Array, size ldbp*n*nm when layout = MKL_COL_MAJOR; size ldbp*m*nm when layout = MKL_ROW_MAJOR. Before entry, bp points to the beginning of nm B_c matrices stored in compact format.

**ldbp**

Column stride (column-major layout) or row stride (row-major layout) of B_c.

<table>
<thead>
<tr>
<th>layout</th>
<th>Constraint</th>
</tr>
</thead>
<tbody>
<tr>
<td>MKL_COL_MAJOR</td>
<td>ldbp must be at least max (1,m).</td>
</tr>
<tr>
<td>MKL_ROW_MAJOR</td>
<td>*ldbp must be at least max (1,n).</td>
</tr>
</tbody>
</table>

**format**

Specifies the format of the compact matrices. See <Compact Format> or mkl_get_format_compact for details.
Total number of matrices stored in Compact format; \( nm \geq 0 \).

**NOTE**
The values of `ldap` and `ldbp` used in `mkl_\text{?}trsm\text{?}compact` must be consistent with the values used in `mkl_\text{?}get\text{?}size\text{?}compact`, `mkl_\text{?}gepack\text{?}compact`, and `mkl_\text{?}geunpack\text{?}compact`.

### Output Parameters

\( bp \)

On exit, \( B_c \) is overwritten by the solution matrix \( X_c \). \( bp \) points to the beginning of \( nm \) such \( X_c \) matrices.

### mkl_\text{?}potrf\text{?}compact

**Computes the Cholesky factorization of a set of symmetric (Hermitian), positive-definite matrices, stored in Compact format (see Compact Format for details).**

**Syntax**

```c
void mkl_spotrf\text{?}compact (MKL_LAYOUT layout, MKL_UPLO uplo, MKL_INT n, float * ap, MKL_INT \( \text{ldap} \), MKL_INT * info, MKL_COMPACT\text{?}PACK format, MKL_INT nm);

void mkl_cpotrf\text{?}compact (MKL_LAYOUT layout, MKL_UPLO uplo, MKL_INT n, float * ap, MKL_INT \( \text{ldap} \), MKL_INT * info, MKL_COMPACT\text{?}PACK format, MKL_INT nm);

void mkl_dpotrf\text{?}compact (MKL_LAYOUT layout, MKL_UPLO uplo, MKL_INT n, double * ap, MKL_INT \( \text{ldap} \), MKL_INT * info, MKL_COMPACT\text{?}PACK format, MKL_INT nm);

void mkl_zpotrf\text{?}compact (MKL_LAYOUT layout, MKL_UPLO uplo, MKL_INT n, double * ap, MKL_INT \( \text{ldap} \), MKL_INT * info, MKL_COMPACT\text{?}PACK format, MKL_INT nm);
```

**Description**

The routine forms the Cholesky factorization of a set of symmetric, positive definite (or, for complex data, Hermitian, positive-definite), \( n \times n \) matrices \( A_c \), stored in Compact format, as:

- \( A_c = U_c^T U_c \) (for real data), \( A_c = U_c^H U_c \) (for complex data), if `uplo = MKL\_UPPER`
- \( A_c = L_c^T L_c \) (for real data), \( A_c = L_c^H L_c \) (for complex data), if `uplo = MKL\_LOWER`

where \( L_c \) is a lower triangular matrix, and \( U_c \) is upper triangular. The factorization (output) data will also be stored in Compact format.

Before calling this routine, call `mkl_\text{?}gepack\text{?}compact` to store the matrices in the Compact format.

**NOTE**

Compact routines have some limitations; see Numerical Limitations.

### Input Parameters

\( layout \)

Specifies whether two-dimensional array storage is row-major (`MKL\_ROW\_MAJOR`) or column-major (`MKL\_COL\_MAJOR`).

\( uplo \)

Must be `MKL\_UPPER` or `MKL\_LOWER`.
Indicates whether the upper or lower triangular part of $A_c$ has been stored and will be factored.

If $\text{uplo} = \text{MKL\_UPPER}$, the upper triangular part of $A_c$ is stored, and the strictly lower triangular part of $A_c$ is not referenced.

If $\text{uplo} = \text{MKL\_LOWER}$, the lower triangular part of $A_c$ is stored, and the strictly upper triangular part of $A_c$ is not referenced.

$n$ The order of $A_c$; $n \geq 0$.

$ldap$ Column stride (column-major layout) or row stride (row-major layout) of $A_c$.

$ap$ Points to the beginning of the $nm$ $A_c$ matrices. On entry, $ap$ contains either the upper or the lower triangular part of $A_c$ (see uplo).

$format$ Specifies the format of the compact matrices. See Compact Format or mkl_get_format_compact for details.

$nm$ Total number of matrices stored in Compact format; $nm \geq 0$.

Application Notes:

Before calling this routine, mkl_?gepack_compact must be called. After calling this routine, mkl_?geunpack_compact should be called, unless another compact routine will be called for the Compact format matrices.

The total number of floating-point operations is approximately $nm \times \frac{1}{3} n^3$ for real flavors and $nm \times \frac{4}{3} n^3$ for complex flavors.

Output Parameters

$ap$ The upper or lower triangular part of $A_c$, stored in Compact format in $ap$, is overwritten by its Cholesky factor $U_c$ or $L_c$ (as specified by $uplo$). $ap$ now points to the beginning of this set of factors, stored in Compact format.

$info$ The parameter is not currently used in this routine. It is reserved for the future use.

mkl_?getrfnp_compact

The routine computes the LU factorization, without pivoting, of a set of general, $m \times n$ matrices that have been stored in Compact format (see Compact Format).

Syntax

```c
void mkl_sgetrfnp_compact (MKL_LAYOUT layout, MKL_INT m, MKL_INT n, float * ap, MKL_INT ldap, MKL_INT * info, MKL_COMPACT_PACK format, MKL_INT nm);
void mkl_dgetrfnp_compact (MKL_LAYOUT layout, MKL_INT m, MKL_INT n, double * ap, MKL_INT ldap, MKL_INT * info, MKL_COMPACT_PACK format, MKL_INT nm);
void mkl_cgetrfnp_compact (MKL_LAYOUT layout, MKL_INT m, MKL_INT n, float * ap, MKL_INT ldap, MKL_INT * info, MKL_COMPACT_PACK format, MKL_INT nm);
void mkl_zgetrfnp_compact (MKL_LAYOUT layout, MKL_INT m, MKL_INT n, double * ap, MKL_INT ldap, MKL_INT * info, MKL_COMPACT_PACK format, MKL_INT nm);
```
Description

The `mkl_?getrfnp_compact` routine calculates the LU factorizations of a set of \( nm \) general \((m \times n)\) matrices \( A \), stored in Compact format, as \( A_c = L_c \cdot U_c \). The factorization (output) data will also be stored in Compact format.

**NOTE**
Compact routines have some limitations; see Numerical Limitations.

## Input Parameters

- **layout**
  Specifies whether two-dimensional array storage is row-major (`MKL_ROW_MAJOR`) or column-major (`MKL_COL_MAJOR`).
- **m**
  The number of rows of \( A \); \( m \geq 0 \).
- **n**
  The number of columns of \( A \); \( n \geq 0 \).
- **ap**
  Points to the beginning of the array which stores \( nm \) \( A_c \) matrices.
  See Compact Format for more details.
- **ldap**
  Leading dimension of \( A_c \).
- **format**
  Specifies the format of the compact matrices. See Compact Format or `mkl_get_format_compact` for details.
- **nm**
  Total number of matrices stored in Compact format.

**Application Notes:**

Before calling this routine, `mkl_?gepack_compact` must be called. After calling this routine, `mkl_?geunpack_compact` should be called, unless another compact routine will be subsequently called for the Compact format matrices.

The approximate number of floating-point operations for real flavors is:

- \( nm \cdot (2/3)n^3 \), if \( m = n \),
- \( nm \cdot (1/3)n^2(3m-n) \), if \( m > n \),
- \( nm \cdot (1/3)m^2(3n-m) \), if \( m < n \).

The number of operations for complex flavors is four times greater. Directly after calling this routine, you can call the following:

- `mkl_?getrinp_compact`, for computing the inverse of the \( nm \) input matrices in Compact format

## Output Parameters

- **ap**
  On exit, \( A_c \) is overwritten by its factorization data. \( ap \) points to the beginning of \( nm \) \( L_c \) and \( U_c \) factors of \( A_c \). The unit diagonal elements of \( L_c \) are not stored.
- **info**
  The parameter is not currently used in this routine. It is reserved for the future use.
**mkl_?geqrf_compact**

Computes the QR factorization of a set of general m x n, matrices, stored in Compact format (see Compact Format for details).

**Syntax**

```c
void mkl_sgeqrf_compact (MKL_LAYOUT layout, MKL_INT m, MKL_INT n, float * ap, MKL_INT ldap, float * taup, float * work, MKL_INT lwork, MKL_INT * info, MKL_COMPACT_PACK format, MKL_INT nm);

void mkl_cgeqrf_compact (MKL_LAYOUT layout, MKL_INT m, MKL_INT n, float * ap, MKL_INT ldap, float * taup, float * work, MKL_INT lwork, MKL_INT * info, MKL_COMPACT_PACK format, MKL_INT nm);

void mkl_dgeqrf_compact (MKL_LAYOUT layout, MKL_INT m, MKL_INT n, double * ap, MKL_INT ldap, double * taup, double * work, MKL_INT lwork, MKL_INT * info, MKL_COMPACT_PACK format, MKL_INT nm);

void mkl_zgeqrf_compact (MKL_LAYOUT layout, MKL_INT m, MKL_INT n, double * ap, MKL_INT ldap, double * taup, double * work, MKL_INT lwork, MKL_INT * info, MKL_COMPACT_PACK format, MKL_INT nm);
```

**Description**

The routine forms the QR factorization of a set of general, m x n matrices A, stored in Compact format. The routine does not form the Q factors explicitly. Instead, Q is represented as a product of min(m,n) elementary reflectors. The factorization (output) data will also be stored in Compact format.

---

**NOTE**

Compact routines have some limitations; see Numerical Limitations.

**Input Parameters**

- **layout**
  
  Specifies whether two-dimensional array storage is row-major (MKL_Row_MAJOR) or column-major (MKL_Col_MAJOR).

- **m**
  
  The number of rows of A; m ≥ 0.

- **n**
  
  The number of columns of A; n ≥ 0.

- **ap**
  
  Points to the beginning of the nm A matrices. On entry, ap contains either the upper or the lower triangular part of A (see uplo).

- **ldap**
  
  Column stride (column-major layout) or row stride (row-major layout) of A.

- **work**
  
  Points to the beginning of the workspace array.

- **lwork**
  
  The size of the work array. If lwork = -1, a workspace query is assumed; the routine only calculates the optimal size of the work array and returns this value as the first entry of the work array.

- **format**
  
  Specifies the format of the compact matrices. See Compact Format or mkl_get_format_compact for details.

- **nm**
  
  Total number of matrices stored in Compact format.

**Application Notes:**
The compact array that will store the elementary reflectors needs to be allocated before the routine is called and unpacked after. First, the routine mkl_?get_size_compact should be called, to determine the size of taup, and memory for taup should be allocated. After calling mkl_?geqrf_compact, taup stores the elementary reflectors in compact form, so should be unpacked using mkl_?geunpack_compact. See Compact Format for more details, or reference the example below. (Note: the following example is meant to demonstrate the calling sequence to allocate memory and unpack taup. All other parameters are assumed to be already set up before the sequence below is executed.)

```c
MKL_R_TYPE *tau_array[nm];
// ...
tau_buffer_size = mkl_?get_size_compact(min(m, n), 1, format, nm);
MKL_R_TYPE *tau_compact = (MKL_R_TYPE *)mkl_malloc(tau_buffer_size, 128);
mkl_?geqrf_compact(layout, m, n, a_compact, ldap, tau_compact, work, lwork, &info, format, nm);
// Note that here MKL_COL_MAJOR is used because tau is a 1-d array
mkl_?geunpack_compact(MKL_COL_MAJOR, min(m, n), 1, tau_array, min(m, n), tau_compact, min(m, n),
format, nm);
```

### Output Parameters

- **ap**
  
  On exit, A_c is overwritten by its factorization data. ap points to the beginning of nm factorizations of A_c, stored in Compact format. The factorization data is stored as follows: The elements on and above the diagonal contain the min( m, n )-by- n upper trapezoidal matrix R_c ( R_c is upper triangular if m ≥ n ); the elements below the diagonal, with tau_c, present the orthogonal matrix Q_c as a product of min( m, n ) elementary reflectors (see Orthogonal Factorizations: LAPACK Computational Routines). See Compact Format for more details.

- **taup**
  
  Points to the beginning of a set of the tau_c arrays, each of which has size min(m,n), stored in Compact format. tau_c contains scalars that define elementary reflectors for Q_c in its decomposition in a product of elementary reflectors. taup needs to be allocated by the user before calling this routine. See the application notes (below the description) for more details.

- **work[0]**
  
  On exit contains the minimum value of lwork required for optimum performance. Use this lwork for subsequent runs.

- **info**
  
  The parameter is not currently used in this routine. It is reserved for the future use.

### mkl_?getrinp_compact

**Computes the inverse of a set of LU-factorized general matrices, without pivoting, stored in the compact format** (see Compact Format for details).

### Syntax

```c
void mkl_sgetrinp_compact (MKL_LAYOUT layout, MKL_INT n, float * ap, MKL_INT lda, float * work, MKL_INT lwork, MKL_INT * info, MKL_COMPACT_PACK format, MKL_INT nm);
void mkl_dgetrinp_compact (MKL_LAYOUT layout, MKL_INT n, double * ap, MKL_INT lda, double * work, MKL_INT lwork, MKL_INT * info, MKL_COMPACT_PACK format, MKL_INT nm);
void mkl_cgetrinp_compact (MKL_LAYOUT layout, MKL_INT n, float * ap, MKL_INT lda, float * work, MKL_INT lwork, MKL_INT * info, MKL_COMPACT_PACK format, MKL_INT nm);
void mkl_zgetrinp_compact (MKL_LAYOUT layout, MKL_INT n, double * ap, MKL_INT lda, double * work, MKL_INT lwork, MKL_INT * info, MKL_COMPACT_PACK format, MKL_INT nm);
```
Description

This routine computes the inverse \( \text{inv}(A_c) \) of a set of general, \( n \times n \) matrices \( A_c \), that have been stored in Compact format. The factorization (output) data will also be stored in Compact format.

**NOTE**
Compact routines have some limitations; see Numerical Limitations.

**Input Parameters**

- **layout**: Specifies whether two-dimensional array storage is row-major (MKL_ROW_MAJOR) or column-major (MKL_COL_MAJOR).
- **n**: The order of \( A_c \); \( n \geq 0 \).
- **ap**: Points to the beginning of the \( nm \) \( A_c \) matrices. On entry, \( ap \) contains the LU factorizations of \( A_c \), stored in Compact format, as returned by mkl_\text{getrfnp}_\text{compact} : \( A_c = L_c U_c \).
  See Compact Format for more details.
- **ldap**: Column stride (column-major layout) or row stride (row-major layout) of \( A_c \).
- **work**: Points to the beginning of the work array.
- **lwork**: The size of the work array. If lwork = -1, a workspace query is assumed; the routine calculates only the optimal size of the work array and returns this value as the first entry of the work array.
- **format**: Specifies the format of the compact matrices. See Compact Format or mkl_\text{get_format}_\text{compact} for details.
- **nm**: Total number of matrices stored in Compact format.

**Application Notes:**
Before calling this routine, mkl_\text{?gepack}_\text{compact} must be called. After calling this routine, mkl_\text{?geunpack}_\text{compact} should be called, unless another compact routine will be subsequently called on the Compact format matrices.

The total number of floating-point operations is approximately \( nm \times (4/3) n^3 \) for real flavors and \( nm \times (16/3) n^3 \) for complex flavors.

**Output Parameters**

- **ap**: On exit, \( A_c \) is overwritten by \( \text{inv}(A_c) \). \( ap \) points to the beginning of \( nm \) \( \text{inv}(A_c) \) matrices stored in Compact format.
- **work[0]**: On exit, work[0] contains the minimum value of lwork required for optimum performance. Use this lwork for subsequent runs.
- **info**: The parameter is not currently used in this routine. It is reserved for the future use.

**Numerical Limitations for Compact BLAS and Compact LAPACK Routines**
Compact routines are subject to a set of numerical limitations. They also skip most of the checks presented in regular BLAS and LAPACK routines in order to provide effective vectorization. The following limitations apply to at least one compact routine.
Complex division: BLAS and LAPACK compact routines rely on a naïve method for complex division that does not protect the solution against overflow, underflow, or loss of precision.

Error checking : the LAPACK compact routines skip error checking for performance reasons; therefore, the user is responsible for passing correct parameters. There are no checks for incorrect matrices (such as singular for LU, non-positive-definite for Cholesky) - it is always assumed that the algorithm for the input matrix can be completed without error.

No pivoting: the generic LU factorization routine, ?getrf, calculates the factorization using partial pivoting. However, because pivoting includes comparisons which cannot be effectively vectorized, only non-pivoting versions of LU mkl_?getrfnp_compact and Inverse from LU (mkl_?getrinp_compact) are provided as compact routines.

Matrices scaled near underflow/overflow: the LAPACK compact routines do not provide safe handling for values near underflow/overflow. This means that Compact routines may return incorrect results for such matrices. This limitation is related to compact routine for QR: mkl_?geqrf_compact.

It is the responsibility of the user to ensure that the input matrices can be factorized, inverted, and/or solved given these numerical limitations.

mkl_?get_size_compact

Returns the buffer size, in bytes, needed to pack data in Compact format.

Syntax

MKL_INT mkl_sget_size_compact (MKL_INT ld, MKL_INT sd, MKL_COMPACT_PACK format, MKL_INT nm);
MKL_INT mkl_dget_size_compact (MKL_INT ld, MKL_INT sd, MKL_COMPACT_PACK format, MKL_INT nm);
MKL_INT mkl_cget_size_compact (MKL_INT ld, MKL_INT sd, MKL_COMPACT_PACK format, MKL_INT nm);
MKL_INT mkl_zget_size_compact (MKL_INT ld, MKL_INT sd, MKL_COMPACT_PACK format, MKL_INT nm);

Description

The routine returns the buffer size, in bytes, required for mkl_?gepack_compact.

Input Parameters

ld
Leading dimension of the matrices in Compact format.

sd
Second dimension of the matrices in Compact format.

format
 Describes the compact packing format according to the MKL_COMPACT_PACK enum type.

nm
Total number of matrices to be packed in Compact format.

Application Notes:

Before calling this routine, mkl_?get_format_compact can be called to determine the optimal format.

After calling this routine and allocating the amount of memory indicated by size, the user can call mkl_?gepack_compact to pack the nm input matrices in Compact format.

Return Values

This function returns a value size.
The buffer size, in bytes, required by the packing function mkl_?gepack_compact.

**mkl_get_format_compact**

*Returns the optimal compact packing format for the architecture, needed for all compact routines.*

**Syntax**

MKL_COMPACT_PACK mkl_get_format_compact ();

**Description**

The routine returns the optimal compact packing format, which is an MKL_COMPACT_PACK type, for the current architecture. The optimal value of format is determined by the architecture’s vector-register length. format is a required parameter for any packing, unpacking, or BLAS/LAPACK compact routine. See Compact Format for details.

**Return Values**

The function returns a value format.

<table>
<thead>
<tr>
<th>format</th>
<th>format can be returned as any of the following three values. MKL_COMPACT_AVX512 is the optimal format value for:</th>
</tr>
</thead>
<tbody>
<tr>
<td>MKL_COMPACT_AVX512</td>
<td>• Intel® Advanced Vector Extensions 512 (Intel® AVX-512)-enabled processors.</td>
</tr>
<tr>
<td>MKL_COMPACT_AVX</td>
<td>• Intel® Advanced Vector Extensions 512 (Intel® AVX-512) for Intel® Many Integrated Core Architecture (Intel® MIC Architecture)-enabled processors.</td>
</tr>
<tr>
<td>MKL_COMPACT_SSE</td>
<td>• Intel® Advanced Vector Extensions 512 (Intel® AVX-512) for Intel® Many Integrated Core Architecture (Intel® MIC Architecture) with support of AVX512_4FMAPS and AVX512_4VNNIW instruction groups processors.</td>
</tr>
</tbody>
</table>

**Application Notes:**

After calling this routine, mkl_?get_size_compact can be called to calculate the buffer size needed for mkl_?gepack_compact.

**mkl_?gepack_compact**

*Packs matrices from standard (row or column-major) format to Compact format.*
Syntax

mkl_sgepack_compact (MKL_LAYOUT layout, MKL_INT rows, MKL_INT columns, const float * const *a, MKL_INT lda, float *ap, MKL_INT ldap, MKL_COMPACT_PACK format, MKL_INT nm);
mkl_dgepack_compact (MKL_LAYOUT layout, MKL_INT rows, MKL_INT columns, const double * const *a, MKL_INT lda, double *ap, MKL_INT ldap, MKL_COMPACT_PACK format, MKL_INT nm);
mkl_cgepack_compact (MKL_LAYOUT layout, MKL_INT rows, MKL_INT columns, const mkl_compact_complex_float * const *a, MKL_INT lda, float *ap, MKL_INT ldap, MKL_COMPACT_PACK format, const MKL_INT nm);
mkl_zgepack_compact (MKL_LAYOUT layout, MKL_INT rows, MKL_INT columns, const mkl_compact_complex_double * const *a, MKL_INT lda, double *ap, MKL_INT ldap, MKL_COMPACT_PACK format, MKL_INT nm);

Description

The routine packs nm matrices A from standard format (row or column-major, pointer to pointer) in a into Compact format, storing the new compact format matrices Ac in array ap.

Input Parameters

- **layout**
  Specifies whether two-dimensional array storage is row-major (MKL_ROW_MAJOR) or column-major (MKL_COL_MAJOR).

- **rows**
  The number of rows of A; rows >= 0.

- **columns**
  The number of columns of A; columns >= 0.

- **a**
  A standard format (row or column-major, pointer-to-pointer) array, storing nm input A matrices.

- **lda**
  Leading dimension of A.

<table>
<thead>
<tr>
<th>layout</th>
<th>lda must be at least max (1,rows).</th>
</tr>
</thead>
<tbody>
<tr>
<td>MKL_COL_MAJOR</td>
<td></td>
</tr>
<tr>
<td>MKL_ROW_MAJOR</td>
<td></td>
</tr>
</tbody>
</table>

- **ldap**
  Leading dimension of Ac.

<table>
<thead>
<tr>
<th>layout</th>
<th>ldap must be at least max (1,columns).</th>
</tr>
</thead>
<tbody>
<tr>
<td>MKL_COL_MAJOR</td>
<td></td>
</tr>
<tr>
<td>MKL_ROW_MAJOR</td>
<td></td>
</tr>
</tbody>
</table>

- **format**
  Specifies the format of the compact matrices. See Compact Format or mkl_get_format_compact for details.

- **nm**
  Total number of matrices that will be stored in Compact format.

Application Notes:

**NOTE**
The values of ldap used in mkl ?gepack_compact must be consistent with the values used in mkl ?get_size_compact and mkl ?geunpack_compact.
Directly after calling this routine, any BLAS or LAPACK compact routine can be called. Unpacking matrices from Compact format can be done by calling `mkl_?geunpack_compact`.

**Output Parameters**

`ap`  
Array storing the compact format input matrices $A_c$. $ap$ must have size at least $size = mkl_?get_size_compact$.

---

**mkl_?geunpack_compact**

*Unpacks matrices from Compact format to standard (row- or column-major, pointer-to-pointer) format.*

**Syntax**

```c
mkl_sgeunpack_compact (MKL_LAYOUT layout, MKL_INT rows, MKL_INT columns, float * const *a, MKL_INT lda, const float *ap, MKL_INT ldap, MKL_COMPACT_PACK format, MKL_INT nm);
mkl_dgeunpack_compact (MKL_LAYOUT layout, MKL_INT rows, MKL_INT columns, double * const *a, MKL_INT lda, const double *ap, MKL_INT ldap, MKL_COMPACT_PACK format, MKL_INT nm);
mkl_cgeunpack_compact (MKL_LAYOUT layout, MKL_INT rows, MKL_INT columns, mkl_compact_complex_float * const *a, MKL_INT lda, const float *ap, MKL_INT ldap, MKL_COMPACT_PACK format, MKL_INT nm);
mkl_zgeunpack_compact (MKL_LAYOUT layout, MKL_INT rows, MKL_INT columns, mkl_compact_complex_double * const *a, MKL_INT lda, const double *ap, MKL_INT ldap, MKL_COMPACT_PACK format, MKL_INT nm);
```

**Description**

The routine unpacks $nm$ Compact format matrices $A_c$ from array $ap$ into standard (row- or column-major, pointer-to-pointer) format in array $A$.

**Input Parameters**

- `layout`  
  Specifies whether two-dimensional array storage is *row-major* (MKL_ROW_MAJOR) or *column-major* (MKL_COL_MAJOR).

- `rows`  
  The number of rows of $A$; $rows \geq 0$.

- `columns`  
  The number of columns of $A$; $columns \geq 0$.

- `lda`  
  Leading dimension of $A$.

<table>
<thead>
<tr>
<th><code>layout</code></th>
<th>±</th>
</tr>
</thead>
<tbody>
<tr>
<td>MKL_COL_MAJOR</td>
<td>lda must be at least max (1,rows).</td>
</tr>
<tr>
<td>MKL_ROW_MAJOR</td>
<td>lda must be at least max (1,columns).</td>
</tr>
</tbody>
</table>

- `ap`  
  Array storing the compact format of input matrices $A_c$. See [Compact Formator](#) `mkl_get_format_compact` for details.

<table>
<thead>
<tr>
<th><code>layout</code></th>
<th>±</th>
</tr>
</thead>
<tbody>
<tr>
<td>MKL_COL_MAJOR</td>
<td>$ap$ has size $ldap<em>columns</em>nm$.</td>
</tr>
<tr>
<td>MKL_ROW_MAJOR</td>
<td>$ap$ has size $ldap<em>rows</em>nm$.</td>
</tr>
</tbody>
</table>
ldap

Leading dimension of of \( A_c \).

<table>
<thead>
<tr>
<th>layout = MKL_COL_MAJOR</th>
<th>ldap must be at least max (1, rows).</th>
</tr>
</thead>
<tbody>
<tr>
<td>layout = MKL_ROW_MAJOR</td>
<td>ldap must be at least max (1, columns).</td>
</tr>
</tbody>
</table>

**NOTE**
The values of ldap used in mkl_?geunpack_compact must be consistent with the values used in mkl_?get_size_compact and mkl_?gepack_compact.

format

Specifies the format of the compact matrices. See Compact Format or mkl_get_format_compact for details.

nm

Total number of matrices that will be stored in Compact format.

**Output Parameters**

\( a \)

A standard format (row- or column-major, pointer-to-pointer) array, storing \( nm \) output \( A \) matrices.

<table>
<thead>
<tr>
<th>layout = MKL_COL_MAJOR</th>
<th>( a ) has size ( lda \times \text{columns} \times nm ).</th>
</tr>
</thead>
<tbody>
<tr>
<td>layout = MKL_ROW_MAJOR</td>

</tr>
</tbody>
</table>

**Inspector-executor Sparse BLAS Routines**

The inspector-executor API for Sparse BLAS divides operations into two stages: analysis and execution. During the initial analysis stage, the API inspects the matrix sparsity pattern and applies matrix structure changes. In the execution stage, subsequent routine calls reuse this information in order to improve performance.

The inspector-executor API supports key Sparse BLAS operations for iterative sparse solvers:

- Sparse matrix-vector multiplication
- Sparse matrix-matrix multiplication with a sparse or dense result
- Solution of triangular systems
- Sparse matrix addition

**Optimization Notice**

Intel’s compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804
### Naming conventions in Inspector-executor Sparse BLAS Routines

The Inspector-executor Sparse BLAS API routine names use the following convention:

\[
mkl\_sparse\_[<\text{character}>]_<\text{operation}>\_[<\text{format}>]
\]

The `<character>` field indicates the data type:

- `s`: real, single precision
- `c`: complex, single precision
- `d`: real, double precision
- `z`: complex, double precision

The data type is included in the name only if the function accepts dense matrix or scalar floating point parameters.

The `<operation>` field indicates the type of operation:

- `create`: create matrix handle
- `copy`: create a copy of matrix handle
- `convert`: convert matrix between sparse formats
- `export`: export matrix from internal representation to CSR or BSR format
- `destroy`: frees memory allocated for matrix handle
- `set_<op>_hint`: provide information about number of upcoming compute operations and operation type for optimization purposes, where `<op>` is `mv`, `sv`, `mm`, `sm`, `dotmv`, `symgs`, or `memory`
- `optimize`: analyze the matrix using hints and store optimization information in matrix handle
- `mv`: compute sparse matrix-vector product
- `mm`: compute sparse matrix by dense matrix product (batch mv)
- `set_value`: change a value in a matrix
- `spmm/spmd`: compute sparse matrix by sparse matrix product and store the result as a sparse/dense matrix
- `trsv`: solve a triangular system
- `trsm`: solve a triangular system with multiple right-hand sides
- `add`: compute sum of two sparse matrices
- `symgs`: compute a symmetric Gauss-Zeidel preconditioner
- `symgs_mv`: compute a symmetric Gauss-Zeidel preconditioner with a final matrix-vector multiplication
- `sypr`: compute the symmetric or Hermitian product of sparse matrices and store the result as a sparse matrix
- `syprd`: compute the symmetric or Hermitian product of sparse and dense matrices and store the result as a dense matrix
- `syrk`: compute the product of sparse matrix with its transposed matrix and store the result as a sparse matrix
syrkd: compute the product of sparse matrix with its transposed matrix and store the result as a dense matrix.

order: perform ordering of column indexes of the matrix in CSR format.

dotmv: compute a sparse matrix-vector product with dot product.

The `<format>` field indicates the sparse matrix storage format:

- coo: coordinate format
- bsr: block sparse row format plus variations. Fill out either `rows_start` and `rows_end` (for 4-arrays representation) or `rowIndex` array (for 3-array BSR/CSR).
- csr: compressed sparse row format plus variations. Fill out either `rows_start` and `rows_end` (for 4-arrays representation) or `rowIndex` array (for 3-array BSR/CSR).
- csc: compressed sparse column format plus variations. Fill out either `cols_start` and `cols_end` (for 4-arrays representation) or `colIndex` array (for 3-array CSC).

The format is included in the function name only if the function parameters include an explicit sparse matrix in one of the conventional sparse matrix formats.

**Sparse Matrix Storage Formats for Inspector-executor Sparse BLAS Routines**

Inspector-executor Sparse BLAS routines support four conventional sparse matrix storage formats:

- compressed sparse row format (CSR) plus variations
- compressed sparse column format (CSC) plus variations
- coordinate format (COO)
- block sparse row format (BSR) plus variations

Computational routines operate on a matrix handle that stores a matrix in CSR or BSR formats. Other formats should be converted to CSR or BSR format before calling any computational routines. For more information see [Sparse Matrix Storage Formats](#).

**Supported Inspector-executor Sparse BLAS Operations**

The Inspector-executor Sparse BLAS API can perform several operations involving sparse matrices. These notations are used in the description of the operations:

- $A$, $G$, $V$ are sparse matrices
- $B$ and $C$ are dense matrices
- $x$ and $y$ are dense vectors
- $alpha$ and $beta$ are scalars

$op(A)$ represents a possible transposition of matrix $A$

- $op(A) = A$
- $op(A) = A^T$ - transpose of $A$
- $op(A) = A^H$ - conjugate transpose of $A$

$op(A)^{-1}$ denotes the inverse of $op(A)$.

The Inspector-executor Sparse BLAS routines support the following operations:

- computing the vector product between a sparse matrix and a dense vector:
  
  $y := alpha*op(A)*x + beta*y$

- solving a single triangular system:
  
  $y := alpha*inv(op(A))*x$
• computing a product between a sparse matrix and a dense matrix:

\[ C := \alpha \cdot \text{op}(A) \cdot B + \beta \cdot C \]

• computing a product between sparse matrices with a sparse result:

\[ V := \alpha \cdot \text{op}(A) \cdot \text{op}(G) \]

• computing a product between sparse matrices with a dense result:

\[ C := \alpha \cdot \text{op}(A) \cdot \text{op}(G) \]

• computing a sum of sparse matrices with a sparse result:

\[ V := \alpha \cdot \text{op}(A) + G \]

• solving a sparse triangular system with multiple right-hand sides:

\[ C := \alpha \cdot \text{inv} \left( \text{op}(A) \right) \cdot B \]

Two-stage Algorithm for Inspector-executor Sparse BLAS routines

You can use a two-stage algorithm for Inspector-executor Sparse BLAS routines which produce a sparse matrix. The applicable routines are:

- `mkl_sparse_sp2m` (BSR/CSR/CSC formats)
- `mkl_sparse_sypr` (CSR format)
- `mkl_sparse_syrk` (CSR format) through the `mkl_sparse_sypr` interface.

In the two-stage algorithm:

1. The first stage constructs the structure of the output matrix.
   - For the BSR/CSR storage formats, fill out `rows_start` and either `rows_end` or `rowIndex` arrays for 4 or 3 array.
   - For the CSC storage format, fill out `cols_start` and either `cols_end` or `colIndex` arrays for 4 or 3 array.

   This stage also allows the user to estimate memory required for the desired operation.

2. The second stage constructs other arrays and performs the desired operation.

You can separate the calls for each stage. You can also perform the entire computation in a single call using the `sparse_request_t` parameter:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>SPARSE_STAGE_NNZ_COUNT</code></td>
<td>In the first stage, the algorithm computes only the row (CSR/BSR format) or column (CSC format) pointer array of the matrix storage format. The computed number of non-zeroes in the output matrix helps to calculate the amount of memory required.</td>
</tr>
<tr>
<td><code>SPARSE_STAGE_FINALIZE_MULT</code></td>
<td>In the second stage, the algorithm computes the remaining column (CSR/BSR format) or row (CSC format) index and value arrays for the output matrix. Use this value only after calling the function with <code>SPARSE_STAGE_NNZ_COUNT</code> first.</td>
</tr>
<tr>
<td><code>SPARSE_STAGE_FULL_MULT</code></td>
<td>Combine the two stages by performing the entire computation in a single step.</td>
</tr>
</tbody>
</table>

This example uses the two-stage algorithm for `mkl_sparse_sp2m` routine with a matrix in CSR format:

**First stage** (`sparse_request_t = SPARSE_STAGE_NNZ_COUNT`)

1. The algorithm calls the `mkl_sparse_sp2m` routine with the request parameter set to `SPARSE_STAGE_NNZ_COUNT`.
2. The algorithm exports the computed `rows_start` and `rows_end` arrays using the `mkl_sparse_x_export_csr` routine.
3. These arrays are used to calculate the number of non-zeroes (nnz) of the resulting output matrix.
Note that at this stage, the arrays related to column index and values for the output matrix have not been computed.

```c
status = mkl_sparse_sp2m (opA, descrA, csrA, opB, descrB, csrB, SPARSE_STAGE_NNZ_COUNT, &csrC);
/* optional calculation of nnz of resulting output matrix for computing memory requirement */
status = mkl_sparse_x_export_csr (csrC, &indexing, &rows, &cols, &rows_start, &rows_end, &col_indx, &values);
MKL_INT nnz = rows_end[rows-1] - rows_start[0];
```

**Second stage (sparse_request_t = SPARSE_STAGE_FINALIZE_MULT)**

The algorithm computes the remaining storage arrays (related to column index and values for the output matrix) and performs the desired operation.

```c
status = mkl_sparse_sp2m (opA, descrA, csrA, opB, descrB, csrB, SPARSE_STAGE_FINALIZE_MULT, &csrC);
```

Alternatively, you can perform both operations in a single step:

**Single stage operation (sparse_request_t = SPARSE_STAGE_FULL_MULT)**

```c
status = mkl_sparse_sp2m (opA, descrA, csrA, opB, descrB, csrB, SPARSE_STAGE_FULL_MULT, &csrC);
```

### Routine or Function Group | Data Types | Description
--- | --- | ---
mkl_sparse_?_export_bsr  | s, d, c, z  | Exports BSR matrix from internal representation.
mkl_sparse_?_set_value  | s, d, c, z  | Changes a single value of matrix in internal representation.
mkl_sparse_?_update_values  | s, d, c, z  | Changes all or selected matrix values in internal representation.
mkl_sparse_order  | NA  | Performs ordering of column indexes of the matrix in CSR format.

#### mkl_sparse_?_create_csr

Creates a handle for a CSR-format matrix.

**Syntax**

```c
sparse_status_t mkl_sparse_s_create_csr (sparse_matrix_t *A, const sparse_index_base_t indexing, const MKL_INT rows, const MKL_INT cols, MKL_INT *rows_start, MKL_INT *rows_end, MKL_INT *col_indx, float *values);
sparse_status_t mkl_sparse_d_create_csr (sparse_matrix_t *A, const sparse_index_base_t indexing, const MKL_INT rows, const MKL_INT cols, MKL_INT *rows_start, MKL_INT *rows_end, MKL_INT *col_indx, double *values);
sparse_status_t mkl_sparse_c_create_csr (sparse_matrix_t *A, const sparse_index_base_t indexing, const MKL_INT rows, const MKL_INT cols, MKL_INT *rows_start, MKL_INT *rows_end, MKL_INT *col_indx, MKL_Complex8 *values);
sparse_status_t mkl_sparse_z_create_csr (sparse_matrix_t *A, const sparse_index_base_t indexing, const MKL_INT rows, const MKL_INT cols, MKL_INT *rows_start, MKL_INT *rows_end, MKL_INT *col_indx, MKL_Complex16 *values);
```

**Include Files**

- mkl_spblas.h

**Description**

The `mkl_sparse_?_create_csr` routine creates a handle for an \( m \)-by-\( k \) matrix \( A \) in CSR format.

**NOTE**

The input arrays provided are left unchanged except for the call to `mkl_sparse_order`, which performs ordering of column indexes of the matrix. To avoid any changes to the input data, use `mkl_sparse_copy`.

**Input Parameters**

- **indexing**
  
  Indicates how input arrays are indexed.

  - **SPARSE_INDEX_BASE_ZERO**  
    Zero-based (C-style) indexing: indices start at 0.

  - **SPARSE_INDEX_BASE_ONE**  
    One-based (Fortran-style) indexing: indices start at 1.
Number of rows of matrix A.

Number of columns of matrix A.

Array of length at least \( m \). This array contains row indices, such that \( \text{rows}_\text{start}[i] \) - indexing is the first index of row \( i \) in the arrays \( \text{values} \) and \( \text{col}_\text{indx} \). The value of indexing is 0 for zero-based indexing and 1 for one-based indexing.

Refer to \( \text{pointerB} \) array description in CSR Format for more details.

Array of at least length \( m \). This array contains row indices, such that \( \text{rows}_\text{end}[i] \) - indexing - 1 is the last index of row \( i \) in the arrays \( \text{values} \) and \( \text{col}_\text{indx} \). The value of indexing is 0 for zero-based indexing and 1 for one-based indexing.

Refer to \( \text{pointerE} \) array description in CSR Format for more details.

For one-based indexing, array containing the column indices plus one for each non-zero element of the matrix A. For zero-based indexing, array containing the column indices for each non-zero element of the matrix A. Its length is at least \( \text{rows}_\text{end}[\text{rows} - 1] \) - indexing.

The value of indexing is 0 for zero-based indexing and 1 for one-based indexing.

Array containing non-zero elements of the matrix A. Its length is equal to length of the \( \text{col}_\text{indx} \) array.

Refer to \( \text{values} \) array description in CSR Format for more details.

**Output Parameters**

**A** Handle containing internal data for subsequent Inspector-executor Sparse BLAS operations.

**Return Values**

The function returns a value indicating whether the operation was successful or not, and why.

**SPARSE_STATUS_SUCCESS** The operation was successful.

**SPARSE_STATUS_NOT_INITIALIZED** The routine encountered an empty handle or matrix array.

**SPARSE_STATUS_ALLOC_FAILED** Internal memory allocation failed.

**SPARSE_STATUS_INVALID_VALUE** The input parameters contain an invalid value.

**SPARSE_STATUS_EXECUTION_FAILED** Execution failed.

**SPARSE_STATUS_INTERNAL_ERROR** An error in algorithm implementation occurred.

**SPARSE_STATUS_NOT_SUPPORTED** The requested operation is not supported.

**mkl_sparse_?_create_csc**

*Creates a handle for a CSC format matrix.*
Syntax

sparse_status_t mkl_sparse_s_create_csc (sparse_matrix_t *A, const sparse_index_base_t indexing, const MKL_INT rows, const MKL_INT cols, MKL_INT *cols_start, MKL_INT *cols_end, MKL_INT *row_indx, float *values);
sparse_status_t mkl_sparse_d_create_csc (sparse_matrix_t *A, const sparse_index_base_t indexing, const MKL_INT rows, const MKL_INT cols, MKL_INT *cols_start, MKL_INT *cols_end, MKL_INT *row_indx, double *values);
sparse_status_t mkl_sparse_c_create_csc (sparse_matrix_t *A, const sparse_index_base_t indexing, const MKL_INT rows, const MKL_INT cols, MKL_INT *cols_start, MKL_INT *cols_end, MKL_INT *row_indx, MKL_Complex8 *values);
sparse_status_t mkl_sparse_z_create_csc (sparse_matrix_t *A, const sparse_index_base_t indexing, const MKL_INT rows, const MKL_INT cols, MKL_INT *cols_start, MKL_INT *cols_end, MKL_INT *row_indx, MKL_Complex16 *values);

Include Files

• mkl_spblas.h

Description

The mkl_sparse_?_create_csc routine creates a handle for an $m$-by-$k$ matrix $A$ in CSC format.

NOTE

The input arrays provided are left unchanged except for the call to mkl_sparse_order, which performs ordering of column indexes of the matrix. To avoid any changes to the input data, use mkl_sparse_copy.

Input Parameters

indexing

Indicates how input arrays are indexed.

SPARSE_INDEX_BASE_ZERO

Zero-based (C-style) indexing: indices start at 0.

SPARSE_INDEX_BASE_ONE

One-based (Fortran-style) indexing: indices start at 1.

rows

Number of rows of the matrix $A$.

cols

Number of columns of the matrix $A$.

cols_start

Array of length at least $m$. This array contains col indices, such that cols_start[i] - ind is the first index of col $i$ in the arrays values and row_indx.ind takes 0 for zero-based indexing and 1 for one-based indexing.

Refer to pointerB array description in CSC Format for more details.

cols_end

Array of at least length $m$. This array contains col indices, such that cols_end[i] - ind - 1 is the last index of col $i$ in the arrays values and row_indx.ind takes 0 for zero-based indexing and 1 for one-based indexing.

Refer to pointerE array description in CSC Format for more details.
row_indx

For one-based indexing, array containing the row indices plus one for each non-zero element of the matrix A. For zero-based indexing, array containing the row indices for each non-zero element of the matrix A. Its length is at least \( cols \) \( \text{cols} - 1 \) \( \text{ind} \). \( \text{ind} \) takes 0 for zero-based indexing and 1 for one-based indexing.

values

Array containing non-zero elements of the matrix A. Its length is equal to length of the row_indx array.

Refer to values array description in CSC Format for more details.

Output Parameters

A

Handle containing internal data.

Return Values

The function returns a value indicating whether the operation was successful or not, and why.

SPARSE_STATUS_SUCCESS The operation was successful.

SPARSE_STATUS_NOT_INITIALIZED The routine encountered an empty handle or matrix array.

SPARSE_STATUS_ALLOC_FAILED Internal memory allocation failed.

SPARSE_STATUS_INVALID_VALUE The input parameters contain an invalid value.

SPARSE_STATUS_EXECUTION_FAILED Execution failed.

SPARSE_STATUS_INTERNAL_ERROR An error in algorithm implementation occurred.

SPARSE_STATUS_NOT_SUPPORTED The requested operation is not supported.

mkl_sparse_?_create_coo

Creates a handle for a matrix in COO format.

Syntax

sparse_status_t mkl_sparse_s_create_coo (sparse_matrix_t *A, const sparse_index_base_t indexing, const MKL_INT rows, const MKL_INT cols, const MKL_INT nnz, MKL_INT *row indx, MKL_INT * col indx, float *values);

sparse_status_t mklsparse_d_create_coo (sparse_matrix_t *A, const sparse_index_base_t indexing, const MKL_INT rows, const MKL_INT cols, const MKL_INT nnz, MKL_INT *row indx, MKL_INT * col indx, double *values);

sparse_status_t mkl_sparse_c_create_coo (sparse_matrix_t *A, const sparse_index_base_t indexing, const MKL_INT rows, const MKL_INT cols, const MKL_INT nnz, MKL_INT *row indx, MKL_INT * col indx, MKL_Complex8 *values);

sparse_status_t mkl_sparse_z_create_coo (sparse_matrix_t *A, const sparse_index_base_t indexing, const MKL_INT rows, const MKL_INT cols, const MKL_INT nnz, MKL_INT *row indx, MKL_INT * col indx, MKL_Complex16 *values);

Include Files

• mkl_spblas.h
Description

The `mkl_sparse_?_create_coo` routine creates a handle for an \( m \)-by-\( k \) matrix \( A \) in COO format.

**NOTE**
The input arrays provided are left unchanged except for the call to `mkl_sparse_order`, which performs ordering of column indexes of the matrix. To avoid any changes to the input data, use `mkl_sparse_copy`.

**Input Parameters**

- **indexing**
  Indicating how input arrays are indexed.
  - `SPARSE_INDEX_BASE_ZERO` Zero-based (C-style) indexing: indices start at 0.
  - `SPARSE_INDEX_BASE_ONE` One-based (Fortran-style) indexing: indices start at 1.

- **rows**
  Number of rows of matrix \( A \).

- **cols**
  Number of columns of matrix \( A \).

- **nnz**
  Specifies the number of non-zero elements of the matrix \( A \).
  Refer to `nnz` description in Coordinate Format for more details.

- **row_indx**
  Array of length \( nnz \), containing the row indices for each non-zero element of matrix \( A \).
  Refer to `rows` array description in Coordinate Format for more details.

- **col_indx**
  Array of length \( nnz \), containing the column indices for each non-zero element of matrix \( A \).
  Refer to `columns` array description in Coordinate Format for more details.

- **values**
  Array of length \( nnz \), containing the non-zero elements of matrix \( A \) in arbitrary order.
  Refer to `values` array description in Coordinate Format for more details.

**Output Parameters**

- **A**
  Handle containing internal data.

**Return Values**
The function returns a value indicating whether the operation was successful or not, and why.

- `SPARSE_STATUS_SUCCESS` The operation was successful.
- `SPARSE_STATUS_NOT_INITIALIZED` The routine encountered an empty handle or matrix array.
- `SPARSE_STATUS_ALLOC_FAILED` Internal memory allocation failed.
- `SPARSE_STATUS_INVALID_VALUE` The input parameters contain an invalid value.
- `SPARSE_STATUS_EXECUTION_FAILED` Execution failed.
SPARSE_STATUS_INTERNAL_ERROR  An error in algorithm implementation occurred.
SPARSE_STATUS_NOT_SUPPORTED The requested operation is not supported.

**mkl_sparse_?_create_bsr**

*Creates a handle for a matrix in BSR format.*

**Syntax**

```c
sparse_status_t mkl_sparse_s_create_bsr (sparse_matrix_t *A, const sparse_index_base_t indexing, const sparse_layout_t block_layout, const MKL_INT rows, const MKL_INT cols, const MKL_INT block_size, MKL_INT *rows_start, MKL_INT *rows_end, MKL_INT *col_indx, float *values);

sparse_status_t mkl_sparse_d_create_bsr (sparse_matrix_t *A, const sparse_index_base_t indexing, const sparse_layout_t block_layout, const MKL_INT rows, const MKL_INT cols, const MKL_INT block_size, MKL_INT *rows_start, MKL_INT *rows_end, MKL_INT *col_indx, double *values);

sparse_status_t mkl_sparse_c_create_bsr (sparse_matrix_t *A, const sparse_index_base_t indexing, const sparse_layout_t block_layout, const MKL_INT rows, const MKL_INT cols, const MKL_INT block_size, MKL_INT *rows_start, MKL_INT *rows_end, MKL_INT *col_indx, MKL_Complex8 *values);

sparse_status_t mkl_sparse_z_create_bsr (sparse_matrix_t *A, const sparse_index_base_t indexing, const sparse_layout_t block_layout, const MKL_INT rows, const MKL_INT cols, const MKL_INT block_size, MKL_INT *rows_start, MKL_INT *rows_end, MKL_INT *col_indx, MKL_Complex16 *values);
```

**Include Files**

- mkl_spblas.h

**Description**

The `mkl_sparse_?_create_bsr` routine creates a handle for an \( m \)-by-\( k \) matrix \( A \) in BSR format.

**NOTE**

The input arrays provided are left unchanged except for the call to `mkl_sparse_order`, which performs ordering of column indexes of the matrix. To avoid any changes to the input data, use `mkl_sparse_copy`.

**Input Parameters**

- **indexing**
  Indicates how input arrays are indexed.
  - SPARSE_INDEX_BASE_ZERO  Zero-based (C-style) indexing: indices start at 0.
  - SPARSE_INDEX_BASE_ONE  One-based (Fortran-style) indexing: indices start at 1.

- **block_layout**
  Specifies layout of blocks:
  - SPARSE_LAYOUT_ROW_MAJ  Storage of elements of blocks uses row major layout.
Storage of elements of blocks uses column major layout.

**rows**

Number of block rows of matrix A.

**cols**

Number of block columns of matrix A.

**block_size**

Size of blocks in matrix A.

**rows_start**

Array of length \( m \). This array contains row indices, such that \( \text{rows_start}[i] - \text{ind} \) is the first index of block row \( i \) in the arrays \( \text{values} \) and \( \text{col_indx} \). \( \text{ind} \) takes 0 for zero-based indexing and 1 for one-based indexing.

Refer to pointerB array description in CSR Format for more details.

**rows_end**

Array of length \( m \). This array contains row indices, such that \( \text{rows_end}[i] - \text{ind} - 1 \) is the last index of block row \( i \) in the arrays \( \text{values} \) and \( \text{col_indx} \). \( \text{ind} \) takes 0 for zero-based indexing and 1 for one-based indexing.

Refer to pointerE array description in CSR Format for more details.

**col_indx**

For one-based indexing, array containing the column indices plus one for each non-zero block of the matrix A. For zero-based indexing, array containing the column indices for each non-zero block of the matrix A. Its length is \( \text{rows_end}[\text{rows} - 1] - \text{ind} \). \( \text{ind} \) takes 0 for zero-based indexing and 1 for one-based indexing.

**values**

Array containing non-zero elements of the matrix A. Its length is equal to length of the \( \text{col_indx} \) array multiplied by \( \text{block_size} \times \text{block_size} \).

Refer to the \( \text{values} \) array description in BSR Format for more details.

**Output Parameters**

**A**

Handle containing internal data.

**Return Values**

The function returns a value indicating whether the operation was successful or not, and why.

- **SPARSE_STATUS_SUCCESS**
  The operation was successful.

- **SPARSE_STATUS_NOT_INITIALIZED**
  The routine encountered an empty handle or matrix array.

- **SPARSE_STATUS_ALLOC_FAILED**
  Internal memory allocation failed.

- **SPARSE_STATUS_INVALID_VALUE**
  The input parameters contain an invalid value.

- **SPARSE_STATUS_EXECUTION_FAILED**
  Execution failed.

- **SPARSE_STATUS_INTERNAL_ERROR**
  An error in algorithm implementation occurred.

- **SPARSE_STATUS_NOT_SUPPORTED**
  The requested operation is not supported.

**mkl_sparse_copy**

Creates a copy of a matrix handle.
Syntax

```c
sparse_status_t mkl_sparse_copy (const sparse_matrix_t source, const struct matrix_descr descr, sparse_matrix_t *dest);
```

Include Files

- mkl_spblas.h

Description

The `mkl_sparse_copy` routine creates a copy of a matrix handle.

Input Parameters

- `source` Specifies handle containing internal data.
- `descr` Structure specifying sparse matrix properties.

- `sparse_matrix_type_t type` - Specifies the type of a sparse matrix:
  - `SPARSE_MATRIX_TYPE_GENERAL` The matrix is processed as is.
  - `SPARSE_MATRIX_TYPE_SYM MMETRIC` The matrix is symmetric (only the requested triangle is processed).
  - `SPARSE_MATRIX_TYPE_HERM ITIAN` The matrix is Hermitian (only the requested triangle is processed).
  - `SPARSE_MATRIX_TYPE_TRI ANGULAR` The matrix is triangular (only the requested triangle is processed).
  - `SPARSE_MATRIX_TYPE_DIAG ONAL` The matrix is diagonal (only diagonal elements are processed).
  - `SPARSE_MATRIX_TYPE_BLOCK_TRI ANGULAR` The matrix is block-triangular (only requested triangle is processed). Applies to BSR format only.
  - `SPARSE_MATRIX_TYPE_BLOCK_DIA GONAL` The matrix is block-diagonal (only diagonal blocks are processed). Applies to BSR format only.

- `sparse_fill_mode_t mode` - Specifies the triangular matrix part for symmetric, Hermitian, triangular, and block-triangular matrices:
  - `SPARSE_FILL_MODE_LOWER` The lower triangular matrix part is processed.
  - `SPARSE_FILL_MODE_UPPER` The upper triangular matrix part is processed.

- `sparse_diag_type_t diag` - Specifies diagonal type for non-general matrices:
  - `SPARSE_DIAG_NON_UNIT` Diagonal elements might not be equal to one.
  - `SPARSE_DIAG_UNIT` Diagonal elements are equal to one.
Output Parameters

\textit{dest} \hspace{1cm} Handle containing internal data.

Return Values

The function returns a value indicating whether the operation was successful or not, and why.

- \textbf{SPARSE\_STATUS\_SUCCESS} \hspace{1cm} The operation was successful.
- \textbf{SPARSE\_STATUS\_NOT\_INITIALIZED} \hspace{1cm} The routine encountered an empty handle or matrix array.
- \textbf{SPARSE\_STATUS\_ALLOC\_FAILED} \hspace{1cm} Internal memory allocation failed.
- \textbf{SPARSE\_STATUS\_INVALID\_VALUE} \hspace{1cm} The input parameters contain an invalid value.
- \textbf{SPARSE\_STATUS\_EXECUTION\_FAILED} \hspace{1cm} Execution failed.
- \textbf{SPARSE\_STATUS\_INTERNAL\_ERROR} \hspace{1cm} An error in algorithm implementation occurred.
- \textbf{SPARSE\_STATUS\_NOT\_SUPPORTED} \hspace{1cm} The requested operation is not supported.

\textbf{mkl\_sparse\_destroy}

\textit{Frees memory allocated for matrix handle.}

Syntax

\begin{verbatim}
sparse_status_t mkl_sparse_destroy (sparse_matrix_t A);
\end{verbatim}

Include Files

- \textit{mkl\_spblas.h}

Description

The \textbf{mkl\_sparse\_destroy} routine frees memory allocated for matrix handle.

\textbf{NOTE}

You must free memory allocated for matrices after completing use of them. The mkl\_sparse\_destroy routine provides a utility to do so.

Input Parameters

\textit{A} \hspace{1cm} Handle containing internal data.

Return Values

The function returns a value indicating whether the operation was successful or not, and why.

- \textbf{SPARSE\_STATUS\_SUCCESS} \hspace{1cm} The operation was successful.
- \textbf{SPARSE\_STATUS\_NOT\_INITIALIZED} \hspace{1cm} The routine encountered an empty handle or matrix array.
- \textbf{SPARSE\_STATUS\_ALLOC\_FAILED} \hspace{1cm} Internal memory allocation failed.
- \textbf{SPARSE\_STATUS\_INVALID\_VALUE} \hspace{1cm} The input parameters contain an invalid value.
- \textbf{SPARSE\_STATUS\_EXECUTION\_FAILED} \hspace{1cm} Execution failed.
mkl_sparse_convert_csr
Converts internal matrix representation to CSR format.

Syntax
sparse_status_t mkl_sparse_convert_csr (const sparse_matrix_t source, const sparse_operation_t operation, sparse_matrix_t *dest);

Include Files
• mkl_spblas.h

Description
The mkl_sparse_convert_csr routine converts internal matrix representation to CSR format.

Input Parameters
source
Handle containing internal data.

operation
Specifies operation \( \text{op}() \) on input matrix.

- SPARSE_OPERATION_NON_TRANSPOSE Non-transpose, \( \text{op}(A) = A \).
- SPARSE_OPERATION_TRANSPOSE Transpose, \( \text{op}(A) = A^T \).
- SPARSE_OPERATION_CONJUGATE_TRANSPOSE Conjugate transpose, \( \text{op}(A) = A^H \).

Output Parameters
dest
Handle containing internal data.

Return Values
The function returns a value indicating whether the operation was successful or not, and why.

- SPARSE_STATUS_SUCCESS The operation was successful.
- SPARSE_STATUS_NOT_INITIALIZED The routine encountered an empty handle or matrix array.
- SPARSE_STATUS_ALLOC_FAILED Internal memory allocation failed.
- SPARSE_STATUS_INVALID_VALUE The input parameters contain an invalid value.
- SPARSE_STATUS_EXECUTION_FAILED Execution failed.
- SPARSE_STATUS_INTERNAL_ERROR An error in algorithm implementation occurred.
- SPARSE_STATUS_NOT_SUPPORTED The requested operation is not supported.
mkl_sparse_convert_bsr

Converts internal matrix representation to BSR format or changes BSR block size.

Syntax

sparse_status_t mkl_sparse_convert_bsr (const sparse_matrix_t source, const MKL_INT block_size, const sparse_layout_t block_layout, const sparse_operation_t operation, sparse_matrix_t *dest);

Include Files

• mkl_spblas.h

Description

The mkl_sparse_convert_bsr routine converts internal matrix representation to BSR format or changes BSR block size.

Input Parameters

source

Handle containing internal data.

block_size

Size of the block in the output structure.

block_layout

Specifies layout of blocks:

- SPARSE_LAYOUT_ROW_MAJOR
  - Storage of elements of blocks uses row major layout.
- SPARSE_LAYOUT_COLUMN_MAJOR
  - Storage of elements of blocks uses column major layout.

operation

Specifies operation op() on input matrix.

- SPARSE_OPERATION_NON_TRANSPOSE
  - Non-transpose, op(A) = A.
- SPARSE_OPERATION_TRANSPOSE
  - Transpose, op(A) = A^T.
- SPARSE_OPERATION_CONJ_TRANSPOSE
  - Conjugate transpose, op(A) = A^H.

Output Parameters

dest

Handle containing internal data.

Return Values

The function returns a value indicating whether the operation was successful or not, and why.

- SPARSE_STATUS_SUCCESS
  - The operation was successful.
- SPARSE_STATUS_NOT_INITIALIZED
  - The routine encountered an empty handle or matrix array.
- SPARSE_STATUS_ALLOC_FAILED
  - Internal memory allocation failed.
- SPARSE_STATUS_INVALID_VALUE
  - The input parameters contain an invalid value.
SPARSE_STATUS_EXECUTION_FAILED  Execution failed.
SPARSE_STATUS_INTERNAL_ERROR  An error in algorithm implementation occurred.
SPARSE_STATUS_NOT_SUPPORTED  The requested operation is not supported.

**mkl_sparse_?_export_csr**
Exports CSR matrix from internal representation.

**Syntax**

```c
sparse_status_t mkl_sparse_s_export_csr (const sparse_matrix_t source, sparse_index_base_t *indexing, MKL_INT *rows, MKL_INT *cols, MKL_INT **rows_start, MKL_INT **rows_end, MKL_INT **col_indx, float **values);
sparse_status_t mkl_sparse_d_export_csr (const sparse_matrix_t source, sparse_index_base_t *indexing, MKL_INT *rows, MKL_INT *cols, MKL_INT **rows_start, MKL_INT **rows_end, MKL_INT **col_indx, double **values);
sparse_status_t mkl_sparse_c_export_csr (const sparse_matrix_t source, sparse_index_base_t *indexing, MKL_INT *rows, MKL_INT *cols, MKL_INT **rows_start, MKL_INT **rows_end, MKL_INT **col_indx, MKL_Complex8 **values);
sparse_status_t mkl_sparse_z_export_csr (const sparse_matrix_t source, sparse_index_base_t *indexing, MKL_INT *rows, MKL_INT *cols, MKL_INT **rows_start, MKL_INT **rows_end, MKL_INT **col_indx, MKL_Complex16 **values);
```

**Include Files**

- mkl_spblas.h

**Description**

If the matrix specified by the `source` handle is in CSR format, the `mkl_sparse_?_export_csr` routine exports an \( m \)-by-\( k \) matrix \( A \) in CSR format matrix from the internal representation. The routine returns pointers to the internal representation and does not allocate additional memory.

If the matrix is not already in CSR format, the routine returns `SPARSE_STATUS_INVALID_VALUE`.

**Input Parameters**

- `source`: Handle containing internal data.

**Output Parameters**

- `indexing`: Indicates how input arrays are indexed.
  - `SPARSE_INDEX_BASE_ZERO`: Zero-based (C-style) indexing: indices start at 0.
  - `SPARSE_INDEX_BASE_ONE`: One-based (Fortran-style) indexing: indices start at 1.

- `rows`: Number of rows of the matrix `source`.

- `cols`: Number of columns of the matrix `source`.  

288
**rows_start**

Pointer to array of length \( m \). This array contains row indices, such that \( \text{rows_start}[i] - \text{ind} \) is the first index of row \( i \) in the arrays \( \text{values} \) and \( \text{col_indx} \). \( \text{ind} \) takes 0 for zero-based indexing and 1 for one-based indexing.

Refer to \( \text{pointerB} \) array description in CSR Format for more details.

**rows_end**

Pointer to array of length \( m \). This array contains row indices, such that \( \text{rows_end}[i] - \text{ind} - 1 \) is the last index of row \( i \) in the arrays \( \text{values} \) and \( \text{col_indx} \). \( \text{ind} \) takes 0 for zero-based indexing and 1 for one-based indexing.

Refer to \( \text{pointerE} \) array description in CSR Format for more details.

**col_indx**

For one-based indexing, pointer to array containing the column indices plus one for each non-zero element of the matrix \( \text{source} \). For zero-based indexing, pointer to array containing the column indices for each non-zero element of the matrix \( \text{source} \). Its length is \( \text{rows_end}[\text{rows} - 1] - \text{ind} \). \( \text{ind} \) takes 0 for zero-based indexing and 1 for one-based indexing.

**values**

Pointer to array containing non-zero elements of the matrix \( A \). Its length is equal to length of the \( \text{col_indx} \) array.

Refer to \( \text{values} \) array description in CSR Format for more details.

**Return Values**

The function returns a value indicating whether the operation was successful or not, and why.

- **SPARSE_STATUS_SUCCESS**
  - The operation was successful.
- **SPARSE_STATUS_NOT_INITIALIZED**
  - The routine encountered an empty handle or matrix array.
- **SPARSE_STATUS_ALLOC_FAILED**
  - Internal memory allocation failed.
- **SPARSE_STATUS_INVALID_VALUE**
  - The input parameters contain an invalid value.
- **SPARSE_STATUS_EXECUTION_FAILED**
  - Execution failed.
- **SPARSE_STATUS_INTERNAL_ERROR**
  - An error in algorithm implementation occurred.
- **SPARSE_STATUS_NOT_SUPPORTED**
  - The requested operation is not supported.

**mkl_sparse_?_export_csc**

Exports CSC matrix from internal representation.

**Syntax**

```c
sparse_status_t mkl_sparse_s_export_csc (const sparse_matrix_t source,
spatial_index_base_t *indexing, MKL_INT *rows, MKL_INT *cols, MKL_INT **cols_start,
MKL_INT **cols_end, MKL_INT **row_indx, float **values);

sparse_status_t mkl_sparse_d_export_csc (const sparse_matrix_t source,
spatial_index_base_t *indexing, MKL_INT *rows, MKL_INT *cols, MKL_INT **cols_start,
MKL_INT **cols_end, MKL_INT **row_indx, double **values);

sparse_status_t mkl_sparse_c_export_csc (const sparse_matrix_t source,
spatial_index_base_t *indexing, MKL_INT *rows, MKL_INT *cols, MKL_INT **cols_start,
MKL_INT **cols_end, MKL_INT **row_indx, MKL_Complex8 **values);
```
sparse_status_t mkl_sparse_z_export_csc (const sparse_matrix_t source,
    sparse_index_base_t *indexing, MKL_INT *rows, MKL_INT *cols, MKL_INT **cols_start,
    MKL_INT **cols_end, MKL_INT **row_indx, MKL_Complex16 **values);

**Include Files**

- mkl_spblas.h

**Description**
If the matrix specified by the `source` handle is in CSC format, the `mkl_sparse_?_export_csc` routine exports an \( m \)-by-\( k \) matrix \( A \) in CSC format matrix from the internal representation. The routine returns pointers to the internal representation and does not allocate additional memory.

If the matrix is not already in CSC format, the routine returns `SPARSE_STATUS_INVALID_VALUE`.

**Input Parameters**

- `source`  
  Handle containing internal data.

**Output Parameters**

- `indexing`  
  Indicates how input arrays are indexed.
  - `SPARSE_INDEX_BASE_ZER0`  
    Zero-based (C-style) indexing: indices start at 0.
  - `SPARSE_INDEX_BASE_ONE`  
    One-based (Fortran-style) indexing: indices start at 1.

- `rows`  
  Number of rows of the matrix `source`.

- `cols`  
  Number of columns of the matrix `source`.

- `cols_start`  
  Array of length \( m \). This array contains column indices, such that \( \text{cols}_\text{start}[i] - \text{cols}_\text{start}[0] \) is the first index of column \( i \) in the arrays `values` and `row_indx`.

  Refer to `pointerb` array description in `csc Format` for more details.

- `cols_end`  
  Pointer to array of length \( m \). This array contains row indices, such that \( \text{cols}_\text{end}[i] - \text{cols}_\text{start}[0] - 1 \) is the last index of column \( i \) in the arrays `values` and `row_indx`.

  Refer to `pointerE` array description in `csc Format` for more details.

- `row_indx`  
  For one-based indexing, pointer to array containing the row indices plus one for each non-zero element of the matrix `source`. For zero-based indexing, pointer to array containing the row indices for each non-zero element of the matrix `source`. Its length is \( \text{cols}_\text{end}[\text{cols} - 1] - \text{cols}_\text{start}[0] \).

- `values`  
  Pointer to array containing non-zero elements of the matrix \( A \). Its length is equal to length of the `row_indx` array.

  Refer to `values` array description in `csc Format` for more details.

**Return Values**
The function returns a value indicating whether the operation was successful or not, and why.
The operation was successful.
The routine encountered an empty handle or matrix array.
Internal memory allocation failed.
The input parameters contain an invalid value.
Execution failed.
An error in algorithm implementation occurred.
The requested operation is not supported.

**mkl_sparse_?_export_bsr**

*Exports BSR matrix from internal representation.*

**Syntax**

```c
sparse_status_t mkl_sparse_s_export_bsr (const sparse_matrix_t source,
sparse_index_base_t *indexing, sparse_layout_t *block_layout, MKL_INT *rows, MKL_INT *cols,
MKL_INT *block_size, MKL_INT **rows_start, MKL_INT **rows_end, MKL_INT **col_index, float **values);

sparse_status_t mkl_sparse_d_export_bsr (const sparse_matrix_t source,
sparse_index_base_t *indexing, sparse_layout_t *block_layout, MKL_INT *rows, MKL_INT *cols,
MKL_INT *block_size, MKL_INT **rows_start, MKL_INT **rows_end, MKL_INT **col_index, double **values);

sparse_status_t mkl_sparse_c_export_bsr (const sparse_matrix_t source,
sparse_index_base_t *indexing, sparse_layout_t *block_layout, MKL_INT *rows, MKL_INT *cols,
MKL_INT *block_size, MKL_INT **rows_start, MKL_INT **rows_end, MKL_INT **col_index, MKL_Complex8 **values);

sparse_status_t mkl_sparse_z_export_bsr (const sparse_matrix_t source,
sparse_index_base_t *indexing, sparse_layout_t *block_layout, MKL_INT *rows, MKL_INT *cols,
MKL_INT *block_size, MKL_INT **rows_start, MKL_INT **rows_end, MKL_INT **col_index, MKL_Complex16 **values);
```

**Include Files**

- mkl_spblas.h

**Description**

If the matrix specified by the `source` handle is in BSR format, the `mkl_sparse_?_export_bsr` routine exports an $m$-by-$k$ matrix $A$ in BSR format from the internal representation. The routine returns pointers to the internal representation and does not allocate additional memory.

If the matrix is not already in BSR format, the routine returns `SPARSE_STATUS_INVALID_VALUE`.

**Input Parameters**

- `source` Handle containing internal data.

**Output Parameters**

- `indexing` Indicates how input arrays are indexed.
Zero-based (C-style) indexing: indices start at 0.

One-based (Fortran-style) indexing: indices start at 1.

**block_layout**

Specifies layout of blocks:

- **SPARSE_LAYOUT_ROW_MAJOR** Storage of elements of blocks uses row major layout.
- **SPARSE_LAYOUT_COLUMN_MAJOR** Storage of elements of blocks uses column major layout.

**rows**

Number of block rows of the matrix `source`.

**cols**

Number of columns of the matrix `source`. Number of block columns of matrix `source`.

**block_size**

Size of the block in matrix `source`.

**rows_start**

Pointer to array of length `m`. This array contains row indices, such that `rows_start[i] - ind` is the first index of block row `i` in the arrays `values` and `col_ind`. `ind` takes 0 for zero-based indexing and 1 for one-based indexing.

Refer to `pointerB` array description in CSR Format for more details.

**rows_end**

Pointer to array of length `m`. This array contains row indices, such that `rows_end[i] - ind - 1` is the last index of block row `i` in the arrays `values` and `col_ind`. `ind` takes 0 for zero-based indexing and 1 for one-based indexing.

Refer to `pointerE` array description in CSR Format for more details.

**col_ind**

For one-based indexing, pointer to array containing the column indices plus one for each non-zero blocks of the matrix `source`. For zero-based indexing, pointer to array containing the column indices for each non-zero blocks of the matrix `source`. Its length is `rows_end[m - 1] - ind[0]`. `ind` takes 0 for zero-based indexing and 1 for one-based indexing.

**values**

Pointer to array containing non-zero elements of matrix `source`. Its length is equal to length of the `col_ind` array multiplied by `block_size*block_size`.

Refer to the `values` array description in BSR Format for more details.

**Return Values**

The function returns a value indicating whether the operation was successful or not, and why.

- **SPARSE_STATUS_SUCCESS** The operation was successful.
- **SPARSE_STATUS_NOT_INITIALIZED** The routine encountered an empty handle or matrix array.
- **SPARSE_STATUS_ALLOC_FAILED** Internal memory allocation failed.
- **SPARSE_STATUS_INVALID_VALUE** The input parameters contain an invalid value.
- **SPARSE_STATUS_EXECUTION_FAILED** Execution failed.
SPARSE_STATUS_INTERNAL_ERROR
An error in algorithm implementation occurred.

SPARSE_STATUS_NOT_SUPPORTED
The requested operation is not supported.

\textbf{mkl_sparse\_?\_set_value}

Changes a single value of matrix in internal representation.

\textbf{Syntax}

sparse_status_t mkl_sparse_s_set_value (const sparse_matrix_t A, const MKL_INT row, const MKL_INT col, const float value);

sparse_status_t mkl_sparse_d_set_value (const sparse_matrix_t A, const MKL_INT row, const MKL_INT col, const double value);

sparse_status_t mkl_sparse_c_set_value (const sparse_matrix_t A, const MKL_INT row, const MKL_INT col, const MKL_Complex8 value);

sparse_status_t mkl_sparse_z_set_value (const sparse_matrix_t A, const MKL_INT row, const MKL_INT col, const MKL_Complex16 value);

\textbf{Include Files}

- mkl_spblas.h

\textbf{Description}

Use the \texttt{mkl_sparse\_?\_set_value} routine to change a single value of a matrix in the internal Inspector-executor Sparse BLAS format. The value should already be presented in a matrix structure.

\textbf{Input Parameters}

- \texttt{A} Specifies handle containing internal data.
- \texttt{row} Indicates row of matrix in which to set value.
- \texttt{col} Indicates column of matrix in which to set value.
- \texttt{value} Indicates value

\textbf{Output Parameters}

- \texttt{A} Handle containing modified internal data.

\textbf{Return Values}

The function returns a value indicating whether the operation was successful or not, and why.

- SPARSE_STATUS_SUCCESS The operation was successful.
- SPARSE_STATUS_NOT_INITIALIZED The routine encountered an empty handle or matrix array.
- SPARSE_STATUS_INVALID_VALUE The input parameters contain an invalid value.
- SPARSE_STATUS_INTERNAL_ERROR An error in algorithm implementation occurred.

\textbf{mkl_sparse\_?\_update_values}

Changes all or selected matrix values in internal representation.
Syntax

**NOTE**
This routine is supported for sparse matrices in BSR format only.

```c
sparse_status_t mkl_sparse_s_update_values (sparse_matrix_t A, MKL_INT nvalues, MKL_INT *indx, MKL_INT *indy, float *values);
sparse_status_t mkl_sparse_d_update_values (sparse_matrix_t A, MKL_INT nvalues, MKL_INT *indx, MKL_INT *indy, double *values);
sparse_status_t mkl_sparse_c_update_values (sparse_matrix_t A, MKL_INT nvalues, MKL_INT *indx, MKL_INT *indy, MKL_Complex8 *values);
sparse_status_t mkl_sparse_z_update_values (sparse_matrix_t A, MKL_INT nvalues, MKL_INT *indx, MKL_INT *indy, MKL_Complex16 *values);
```

Include Files
- mkl_spblas.h

Description

Use the `mkl_sparse_?_update_values` routine to change all or selected values of a matrix in the internal Inspector-Executor Sparse BLAS format.

The values to be updated should already be present in the matrix structure.

- To change selected values, you must provide an array values (with new values) and also the corresponding row and column indices for each value via `indx` and `indy` arrays as well as the overall number of changed elements `nvalues`.

  So that, for example, to change A(0, 0) to 1 and A(0, 1) to 2, pass the following input parameters: `nvalues = 2, indx = {0, 0}, indy = {0, 1}` and `values = {1, 2}`.

- To change all the values in the matrix, one can simply provide the `values` array, no need to supply `indx` and `indy` arrays.

Input Parameters

- **A**: Specifies handle containing internal data.
- **nvalues**: Total number of elements changed.
- **indx**: Row indices for the new values.
- **indy**: Column indices for the new values.
- **values**: New values.

Output Parameters

- **A**: Handle containing modified internal data.

Return Values

The function returns a value indicating whether the operation was successful or not, and why.

- `SPARSE_STATUS_SUCCESS`: The operation was successful.
- `SPARSE_STATUS_NOT_INITIALIZED`: The routine encountered an empty handle or matrix array.
SPARSE_STATUS_ALLOC_FAILED     Internal memory allocation failed.
SPARSE_STATUS_INVALID_VALUE     The input parameters contain an invalid value.
SPARSE_STATUS_EXECUTION_FAILED Execution failed.
SPARSE_STATUS_INTERNAL_ERROR   An error in algorithm implementation occurred.
SPARSE_STATUS_NOT_SUPPORTED    The requested operation is not supported.

mkl_sparse_order
Performs ordering of column indexes of the matrix in CSR format

Syntax
sparse_status_t mkl_sparse_order (const sparse_matrix_t csrA);

Include Files
• mkl_spblas.h

Description
Use the mkl_sparse_order routine to perform ordering of column indexes of the matrix in CSR format.

Input Parameters
csrA                  CSR data

Output Parameters
csrA                  Handle containing modified internal data.

Return Values
The function returns a value indicating whether the operation was successful or not, and why.

SPARSE_STATUS_SUCCESS     The operation was successful.
SPARSE_STATUS_NOT_INITIALIZED The routine encountered an empty handle or matrix array.
SPARSE_STATUS_INVALID_VALUE The input parameters contain an invalid value.
SPARSE_STATUS_INTERNAL_ERROR An error in algorithm implementation occurred.

**Optimization Notice**

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

**mkl_sparse_set_lu_smoother_hint**

*Provides an estimate of the number and type of upcoming calls to LU smoother functionality.*

**Syntax**

```c
sparse_status_t mkl_sparse_set_lu_smoother_hint (sparse_matrix_t A, const sparse_operation_t operation, struct matrix_descr descr, MKL_INT expected_calls);
```

**Include Files**

- mkl_spblas.h

**Description**

The `mkl_sparse_set_lu_smoother_hint` function provides subsequent Inspector-Executor Sparse BLAS calls an estimate of the number of upcoming calls to the `lu_smoother` routine that ultimately may influence the optimizations applied and specifies whether or not to perform an operation on the matrix.
Optimization Notice

Optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

Specifies the operation \( op() \) on input matrix.

- \texttt{SPARSE\_OPERATION\_NON\_TRANSPOSE}\n  Non-transpose, \( \text{op}(A) = A \).
- \texttt{SPARSE\_OPERATION\_TRANSPOSE}\n  Transpose, \( \text{op}(A) = A^T \).
- \texttt{SPARSE\_OPERATION\_CONJUGATE\_TRANSPOSE}\n  Conjugate transpose, \( \text{op}(A) = A^H \).

Structure specifying sparse matrix properties.

- \texttt{sparse\_matrix\_type\_t type}\n  Specifies the type of a sparse matrix:
  - \texttt{SPARSE\_MATRIX\_TYPE\_GENERAL}\n    The matrix is processed as is.
  - \texttt{SPARSE\_MATRIX\_TYPE\_SYMMETRIC}\n    The matrix is symmetric (only the requested triangle is processed).
  - \texttt{SPARSE\_MATRIX\_TYPE\_HERMITIAN}\n    The matrix is Hermitian (only the requested triangle is processed).
  - \texttt{SPARSE\_MATRIX\_TYPE\_TRIANGULAR}\n    The matrix is triangular (only the requested triangle is processed).
  - \texttt{SPARSE\_MATRIX\_TYPE\_DIAGONAL}\n    The matrix is diagonal (only diagonal elements are processed).
  - \texttt{SPARSE\_MATRIX\_TYPE\_BLOCK\_TRIANGULAR}\n    The matrix is block-triangular (only the requested triangle is processed). Applies to BSR format only.
  - \texttt{SPARSE\_MATRIX\_TYPE\_BLOCK\_DIAGONAL}\n    The matrix is block-diagonal (only diagonal blocks are processed). Applies to BSR format only.

- \texttt{sparse\_fill\_mode\_t mode}\n  Specifies the triangular matrix part for symmetric, Hermitian, triangular, and block-triangular matrices:
  - \texttt{SPARSE\_FILL\_MODE\_LOWER}\n    The lower triangular matrix part is processed.
  - \texttt{SPARSE\_FILL\_MODE\_UPPER}\n    The upper triangular matrix part is processed.

- \texttt{sparse\_diag\_type\_t diag}\n  Specifies the diagonal type for non-general matrices:
  - \texttt{SPARSE\_DIAG\_NON\_UNIT}\n    Diagonal elements might not be equal to one.
Diagonal elements are equal to one.

Number of expected calls to execution routine.

Handle containing internal data.

Return Values

The function returns a value indicating whether the operation was successful or not, and why.

- **SPARSE_STATUS_SUCCESS**: The operation was successful.
- **SPARSE_STATUS_NOT_INITIALIZED**: The routine encountered an empty handle or matrix array.
- **SPARSE_STATUS_ALLOC_FAILED**: Internal memory allocation failed.
- **SPARSE_STATUS_INVALID_VALUE**: The input parameters contain an invalid value.
- **SPARSE_STATUS_EXECUTION_FAILED**: Execution failed.
- **SPARSE_STATUS_INTERNAL_ERROR**: An error in algorithm implementation occurred.
- **SPARSE_STATUS_NOT_SUPPORTED**: The requested operation is not supported.

**mkl_sparse_set_mv_hint**

*Provides estimate of number and type of upcoming matrix-vector operations.*

**Syntax**

```c
sparse_status_t mkl_sparse_set_mv_hint (const sparse_matrix_t A, const sparse_operation_t operation, const struct matrix_descr descr, const MKL_INT expected_calls);
```

**Include Files**

- mkl_spblas.h

**Description**

Use the `mkl_sparse_set_mv_hint` routine to provide the Inspector-executor Sparse BLAS API an estimate of the number of upcoming matrix-vector multiplication operations for performance optimization, and specify whether or not to perform an operation on the matrix.

**Optimization Notice**

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804
**Input Parameters**

*operation*

Specifies operation $\text{op()}$ on input matrix.

- SPARSE_OPERATION_NON_TRANSPOSE Non-transpose, $\text{op}(A) = A$.
- SPARSE_OPERATION_TRANSPOSE Transpose, $\text{op}(A) = A^T$.
- SPARSE_OPERATION_CONJUGATE_TRANSPOSE Conjugate transpose, $\text{op}(A) = A^H$.

*descr*

Structure specifying sparse matrix properties.

- **sparse_matrix_type_t** *type* - Specifies the type of a sparse matrix:
  - SPARSE_MATRIX_TYPE_GENERAL The matrix is processed as is.
  - SPARSE_MATRIX_TYPE_SYMMETRIC The matrix is symmetric (only the requested triangle is processed).
  - SPARSE_MATRIX_TYPE_HERMITIAN The matrix is Hermitian (only the requested triangle is processed).
  - SPARSE_MATRIX_TYPE_TRIANGULAR The matrix is triangular (only the requested triangle is processed).
  - SPARSE_MATRIX_TYPE_DIAGONAL The matrix is diagonal (only diagonal elements are processed).
  - SPARSE_MATRIX_TYPE_BLOCK_TRIANGULAR The matrix is block-triangular (only requested triangle is processed). Applies to BSR format only.
  - SPARSE_MATRIX_TYPE_BLOCK_DIAGONAL The matrix is block-diagonal (only diagonal blocks are processed). Applies to BSR format only.

- **sparse_fill_mode_t** *mode* - Specifies the triangular matrix part for symmetric, Hermitian, triangular, and block-triangular matrices:
  - SPARSE_FILL_MODE_LOWER The lower triangular matrix part is processed.
  - SPARSE_FILL_MODE_UPPER The upper triangular matrix part is processed.

- **sparse_diag_type_t** *diag* - Specifies diagonal type for non-general matrices:
  - SPARSE_DIAG_NON_UNIT Diagonal elements might not be equal to one.
  - SPARSE_DIAG_UNIT Diagonal elements are equal to one.

*expected_calls*

Number of expected calls to execution routine.

**Output Parameters**

*A*

Handle containing internal data.
Return Values
The function returns a value indicating whether the operation was successful or not, and why.

- **SPARSE_STATUS_SUCCESS**: The operation was successful.
- **SPARSE_STATUS_NOT_INITIALIZED**: The routine encountered an empty handle or matrix array.
- **SPARSE_STATUS_ALLOC_FAILED**: Internal memory allocation failed.
- **SPARSE_STATUS_INVALID_VALUE**: The input parameters contain an invalid value.
- **SPARSE_STATUS_EXECUTION_FAILED**: Execution failed.
- **SPARSE_STATUS_INTERNAL_ERROR**: An error in algorithm implementation occurred.
- **SPARSE_STATUS_NOT_SUPPORTED**: The requested operation is not supported.

**mkl_sparse_set_sv_hint**
**Provides estimate of number and type of upcoming triangular system solver operations.**

**Syntax**
```
sparse_status_t mkl_sparse_set_sv_hint (const sparse_matrix_t A, const sparse_operation_t operation, const struct matrix_descr descr, const MKL_INT expected_calls);
```

**Include Files**
- mkl_spblas.h

**Description**
The **mkl_sparse_set_sv_hint** routine provides an estimate of the number of upcoming triangular system solver operations and type of these operations for performance optimization.

**Optimization Notice**
Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

**Input Parameters**

- **operation**: Specifies operation `op()` on input matrix.
  - **SPARSE_OPERATION_NON_TRANSPOSE**: Non-transpose, `op(A) = A`.
  - **SPARSE_OPERATION_TRANSPOSE**: Transpose, `op(A) = A^T`.
Conjugate transpose, \( \mathbf{op}(A) = A^H \).

Structure specifying sparse matrix properties.

- **type** - Specifies the type of a sparse matrix:
  - **SPARSE_MATRIX_TYPE_GENERAL** The matrix is processed as is.
  - **SPARSE_MATRIX_TYPE_SYMMETRIC** The matrix is symmetric (only the requested triangle is processed).
  - **SPARSE_MATRIX_TYPE_HERMITIAN** The matrix is Hermitian (only the requested triangle is processed).
  - **SPARSE_MATRIX_TYPE_TRIANGULAR** The matrix is triangular (only the requested triangle is processed).
  - **SPARSE_MATRIX_TYPE_DIAGONAL** The matrix is diagonal (only diagonal elements are processed).
  - **SPARSE_MATRIX_TYPE_BLOCK_TRIANGULAR** The matrix is block-triangular (only requested triangle is processed). Applies to BSR format only.
  - **SPARSE_MATRIX_TYPE_BLOCK_DIAGONAL** The matrix is block-diagonal (only diagonal blocks are processed). Applies to BSR format only.

- **mode** - Specifies the triangular matrix part for symmetric, Hermitian, triangular, and block-triangular matrices:
  - **SPARSE_FILL_MODE_LOWER** The lower triangular matrix part is processed.
  - **SPARSE_FILL_MODE_UPPER** The upper triangular matrix part is processed.

- **diag** - Specifies diagonal type for non-general matrices:
  - **SPARSE_DIAG_NON_UNIT** Diagonal elements might not be equal to one.
  - **SPARSE_DIAG_UNIT** Diagonal elements are equal to one.

**Output Parameters**

- **A** Handle containing internal data.

**Return Values**

The function returns a value indicating whether the operation was successful or not, and why.

- **SPARSE_STATUS_SUCCESS** The operation was successful.
- **SPARSE_STATUS_NOT_INITIALIZED** The routine encountered an empty handle or matrix array.
SPARSE_STATUS_ALLOC_FAILED  Internal memory allocation failed.
SPARSE_STATUS_INVALID_VALUE  The input parameters contain an invalid value.
SPARSE_STATUS_EXECUTION_FAILED  Execution failed.
SPARSE_STATUS_INTERNAL_ERROR  An error in algorithm implementation occurred.
SPARSE_STATUS_NOT_SUPPORTED  The requested operation is not supported.

**mkl_sparse_set_mm_hint**

Provides estimate of number and type of upcoming matrix-matrix multiplication operations.

**Syntax**

```c
sparse_status_t mkl_sparse_set_mm_hint(
    const sparse_matrix_t A,
    const sparse_operation_t operation,
    const struct matrix_descr descr,
    const sparse_layout_t layout,
    const MKL_INT dense_matrix_size,
    const MKL_INT expected_calls);
```

**Include Files**

- mkl_spblas.h

**Description**

The `mkl_sparse_set_mm_hint` routine provides an estimate of the number of upcoming matrix-matrix multiplication operations and type of these operations for performance optimization purposes.

**Optimization Notice**

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. Notice revision #20110804

**Input Parameters**

- **operation**
  Specifies operation \( \text{op}() \) on input matrix.
  - `SPARSE_OPERATION_NON_TRANSPOSE`  Non-transpose, \( \text{op}(A) = A \).
  - `SPARSE_OPERATION_TRANSPOSE`  Transpose, \( \text{op}(A) = A^T \).
  - `SPARSE_OPERATION_CONJUGATE_TRANSPOSE`  Conjugate transpose, \( \text{op}(A) = A^H \).

- **descr**
  Structure specifying sparse matrix properties.
  - `sparse_matrix_type_t type` - Specifies the type of a sparse matrix:
SPARSE_MATRIX_TYPE_GENERAL  The matrix is processed as is.
SPARSE_MATRIX_TYPE_SYMMETRIC  The matrix is symmetric (only the requested triangle is processed).
SPARSE_MATRIX_TYPE_HERMITIAN  The matrix is Hermitian (only the requested triangle is processed).
SPARSE_MATRIX_TYPE_TRIANGULAR  The matrix is triangular (only the requested triangle is processed).
SPARSE_MATRIX_TYPE_DIAGONAL  The matrix is diagonal (only diagonal elements are processed).
SPARSE_MATRIX_TYPE_BLOCK_TRIANGULAR  The matrix is block-triangular (only requested triangle is processed). Applies to BSR format only.
SPARSE_MATRIX_TYPE_BLOCK_DIAGONAL  The matrix is block-diagonal (only diagonal blocks are processed). Applies to BSR format only.

sparse_fill_mode_t mode - Specifies the triangular matrix part for symmetric, Hermitian, triangular, and block-triangular matrices:
SPARSE_FILL_MODE_LOWER  The lower triangular matrix part is processed.
SPARSE_FILL_MODE_UPPER  The upper triangular matrix part is processed.

sparse_diag_type_t diag - Specifies diagonal type for non-general matrices:
SPARSE_DIAG_NON_UNIT  Diagonal elements might not be equal to one.
SPARSE_DIAG_UNIT  Diagonal elements are equal to one.

layout

SPARSE_LAYOUT_COLUMN_MAJOR  Storage of elements uses column major layout.
SPARSE_LAYOUT_ROW_MAJOR  Storage of elements uses row major layout.

dense_matrix_size

Number of columns in dense matrix.

expected_calls

Number of expected calls to execution routine.

Output Parameters

A  Handle containing internal data.

Return Values

The function returns a value indicating whether the operation was successful or not, and why.
SPARSE_STATUS_SUCCESS  The operation was successful.
SPARSE_STATUS_NOT_INITIALIZED The routine encountered an empty handle or matrix array.

SPARSE_STATUS_ALLOC_FAILED Internal memory allocation failed.

SPARSE_STATUS_INVALID_VALUE The input parameters contain an invalid value.

SPARSE_STATUS_EXECUTION_FAILED Execution failed.

SPARSE_STATUS_INTERNAL_ERROR An error in algorithm implementation occurred.

SPARSE_STATUS_NOT_SUPPORTED The requested operation is not supported.

mkl_sparse_set_sm_hint
Provides estimate of number and type of upcoming triangular matrix solve with multiple right hand sides operations.

Syntax
sparse_status_t mkl_sparse_set_sm_hint (const sparse_matrix_t A, const sparse_operation_t operation, const struct matrix_descr descr, const sparse_layout_t layout, const MKL_INT dense_matrix_size, const MKL_INT expected_calls);

Include Files
• mkl_spblas.h

Description
The mkl_sparse_set_sm_hint routine provides an estimate of the number of upcoming triangular matrix solve with multiple right hand sides operations and type of these operations for performance optimization purposes.

Optimization Notice
Intel’s compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microarchitectures. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters
operation
Specifies operation op() on input matrix.

Sparse_operation_non_transpose, \( \text{op}(A) = A \)

Sparse_operation_transpose, \( \text{op}(A) = A^T \)

Sparse_operation_conjugate_transpose, \( \text{op}(A) = A^H \)

descr
Structure specifying sparse matrix properties.
sparse_matrix_type_t  type - Specifies the type of a sparse matrix:

SPARSE_MATRIX_TYPE_GENERAL
The matrix is processed as is.

SPARSE_MATRIX_TYPE_SYMMETRIC
The matrix is symmetric (only the requested triangle is processed).

SPARSE_MATRIX_TYPE_HERMITIAN
The matrix is Hermitian (only the requested triangle is processed).

SPARSE_MATRIX_TYPE_TRIANGULAR
The matrix is triangular (only the requested triangle is processed).

SPARSE_MATRIX_TYPE_DIAGONAL
The matrix is diagonal (only diagonal elements are processed).

SPARSE_MATRIX_TYPE_BLOCK_TRIANGULAR
The matrix is block-triangular (only requested triangle is processed). Applies to BSR format only.

SPARSE_MATRIX_TYPE_BLOCK_DIAGONAL
The matrix is block-diagonal (only diagonal blocks are processed). Applies to BSR format only.

sparse_fill_mode_t  mode - Specifies the triangular matrix part for symmetric, Hermitian, triangular, and block-triangular matrices:

SPARSE_FILL_MODE_LOWER
The lower triangular matrix part is processed.

SPARSE_FILL_MODE_UPPER
The upper triangular matrix part is processed.

sparse_diag_type_t  diag - Specifies diagonal type for non-general matrices:

SPARSE_DIAG_NON_UNIT
Diagonal elements might not be equal to one.

SPARSE_DIAG_UNIT
Diagonal elements are equal to one.

layout
Specifies layout of elements:

SPARSE_LAYOUT_COLUMN_MAJOR
Storage of elements uses column major layout.

SPARSE_LAYOUT_ROW_MAJOR
Storage of elements uses row major layout.

dense_matrix_size
Number of right-hand-side.

expected_calls
Number of expected calls to execution routine.

Output Parameters
A
Handle containing internal data.

Return Values
The function returns a value indicating whether the operation was successful or not, and why.
The operation was successful.

The routine encountered an empty handle or matrix array.

Internal memory allocation failed.

The input parameters contain an invalid value.

Execution failed.

An error in algorithm implementation occurred.

The requested operation is not supported.

**mkl_sparse_set_dotmv_hint**

Sets estimate of the number and type of upcoming matrix-vector operations.

**Syntax**

```c
sparse_status_t mkl_sparse_set_dotmv_hint (const sparse_matrix_t A, const
sparse_operation_t operation, const struct matrix_descr descr, const MKL_INT
expected_calls);
```

**Include Files**

• mkl_spblas.h

**Description**

Use the `mkl_sparse_set_dotmv_hint` routine to provide the Inspector-executor Sparse BLAS API an estimate of the number of upcoming matrix-vector multiplication operations for performance optimization, and specify whether or not to perform an operation on the matrix.

**Input Parameters**

- **operation**

  Specifies the operation performed on matrix \( A \).

  - If `operation` = SPARSE_OPERATION_NON_TRANSPOSE, \( \text{op}(A) = A \).
  - If `operation` = SPARSE_OPERATION_TRANSPOSE, \( \text{op}(A) = A^T \).
  - If `operation` = SPARSE_OPERATION_CONJUGATE_TRANSPOSE, \( \text{op}(A) = A^H \).

- **descr**

  Structure specifying sparse matrix properties.

  - `sparse_matrix_type_t type` - Specifies the type of a sparse matrix:
    - SPARSE_MATRIX_TYPE_GENERAL: The matrix is processed as is.
    - SPARSE_MATRIX_TYPE_SYMMETRIC: The matrix is symmetric (only the requested triangle is processed).
    - SPARSE_MATRIX_TYPE_HERMITIAN: The matrix is Hermitian (only the requested triangle is processed).
    - SPARSE_MATRIX_TYPE_TRIANGULAR: The matrix is triangular (only the requested triangle is processed).
    - SPARSE_MATRIX_TYPE_DIAGONAL: The matrix is diagonal (only diagonal elements are processed).
Sparse Matrix Types:

- **SPARSE_MATRIX_TYPE_BLOCK_TRIANGULAR**
  - The matrix is block-triangular (only requested triangle is processed). Applies to BSR format only.

- **SPARSE_MATRIX_TYPE_BLOCK.Diagonal**
  - The matrix is block-diagonal (only diagonal blocks are processed). Applies to BSR format only.

Sparse Fill Mode:

- `sparse_fill_mode_t mode` - Specifies the triangular matrix part for symmetric, Hermitian, triangular, and block-triangular matrices:
  - **SPARSE_FILL_MODE_LOWER**
    - The lower triangular matrix part is processed.
  - **SPARSE_FILL_MODE_UPPER**
    - The upper triangular matrix part is processed.

Sparse Diag Type:

- `sparse_diag_type_t diag` - Specifies diagonal type for non-general matrices:
  - **SPARSE_DIAG_NON_UNIT**
    - Diagonal elements might not be equal to one.
  - **SPARSE_DIAG_UNIT**
    - Diagonal elements are equal to one.

Output Parameters:

- **A**
  - Handle containing internal data.

Return Values:

The function returns a value indicating whether the operation was successful or not, and why.

- **SPARSE_STATUS_SUCCESS**
  - The operation was successful.
- **SPARSE_STATUS_NOT_INITIALIZED**
  - The routine encountered an empty handle or matrix array.
- **SPARSE_STATUS_ALLOC_FAILED**
  - Internal memory allocation failed.
- **SPARSE_STATUS_INVALID_VALUE**
  - The input parameters contain an invalid value.
- **SPARSE_STATUS_EXECUTION_FAILED**
  - Execution failed.
- **SPARSE_STATUS_INTERNAL_ERROR**
  - An error in algorithm implementation occurred.
- **SPARSE_STATUS_NOT_SUPPORTED**
  - The requested operation is not supported.

### mkl_sparse_set_symgs_hint

Syntax:

```c
sparse_status_t mkl_sparse_set_symgs_hint (const sparse_matrix_t A, const sparse_operation_t operation, const struct matrix_descr descr, const MKL_INT expected_calls);
```

Include Files:

- `mkl_spblas.h`
Description

Use the `mkl_sparse_set_symgs_hint` routine to provide the Inspector-executor Sparse BLAS API an estimate of the number of upcoming symmetric Gauss-Zeidel preconditioner operations for performance optimization, and specify whether or not to perform an operation on the matrix.

Input Parameters

`operation` Specifies the operation performed on matrix $A$.

- If $operation = SPARSE_OPERATION_NON_TRANSPOSE$, $\text{op}(A) = A$.
- If $operation = SPARSE_OPERATION_TRANSPOSE$, $\text{op}(A) = A^T$.
- If $operation = SPARSE_OPERATION_CONJUGATE_TRANSPOSE$, $\text{op}(A) = A^H$.

`descr` Structure specifying sparse matrix properties.

- `sparse_matrix_type_t type` - Specifies the type of a sparse matrix:
  - `SPARSE_MATRIX_TYPE_GENERAL` - The matrix is processed as is.
  - `SPARSE_MATRIX_TYPE_SYMMETRIC` - The matrix is symmetric (only the requested triangle is processed).
  - `SPARSE_MATRIX_TYPE_HERMITIAN` - The matrix is Hermitian (only the requested triangle is processed).
  - `SPARSE_MATRIX_TYPE_TRIANGULAR` - The matrix is triangular (only the requested triangle is processed).
  - `SPARSE_MATRIX_TYPE_DIAGONAL` - The matrix is diagonal (only diagonal elements are processed).
  - `SPARSE_MATRIX_TYPE_BLOCK_TRIANGULAR` - The matrix is block-triangular (only requested triangle is processed). Applies to BSR format only.
  - `SPARSE_MATRIX_TYPE_BLOCK_DIAGONAL` - The matrix is block-diagonal (only diagonal blocks are processed). Applies to BSR format only.

- `sparse_fill_mode_t mode` - Specifies the triangular matrix part for symmetric, Hermitian, triangular, and block-triangular matrices:
  - `SPARSE_FILL_MODE_LOWER` - The lower triangular matrix part is processed.
  - `SPARSE_FILL_MODE_UPPER` - The upper triangular matrix part is processed.

- `sparse_diag_type_t diag` - Specifies diagonal type for non-general matrices:
  - `SPARSE_DIAG_NON_UNIT` - Diagonal elements might not be equal to one.
  - `SPARSE_DIAG_UNIT` - Diagonal elements are equal to one.

`diag` Specifies diagonal type for non-general matrices.
mode Specifies the triangular matrix part for symmetric, Hermitian, triangular, and block-triangular matrices.

type Specifies the type of a sparse matrix.

expected_calls Estimate of the number to the execution routine.

Output Parameters

A Handle containing internal data.

Return Values

The function returns a value indicating whether the operation was successful or not, and why.

<table>
<thead>

mkl_sparse_set_memory_hint

Provides memory requirements for performance optimization purposes.

Syntax

```c
sparse_status_t mkl_sparse_set_memory_hint (const sparse_matrix_t A, const sparse_memory_usage_t policy);
```

Include Files

- mkl_spblas.h

Description

The mkl_sparse_set_memory_hint routine allocates additional memory for further performance optimization purposes.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804
Input Parameters

Specify memory utilization policy for optimization routine using these types:

- **SPARSE_MEMORY_NONE**: Routine can allocate memory only for auxiliary structures (such as for workload balancing); the amount of memory is proportional to vector size.

- **SPARSE_MEMORY_AGGRESSIVE**: Default. Routine can allocate memory up to the size of matrix $A$ for converting into the appropriate sparse format.

Output Parameters

- **A**: Handle containing internal data.

Return Values

The function returns a value indicating whether the operation was successful or not, and why.

- **SPARSE_STATUS_SUCCESS**: The operation was successful.
- **SPARSE_STATUS_NOT_INITIALIZED**: The routine encountered an empty handle or matrix array.
- **SPARSE_STATUS_ALLOC_FAILED**: Internal memory allocation failed.
- **SPARSE_STATUS_INVALID_VALUE**: The input parameters contain an invalid value.
- **SPARSE_STATUS_EXECUTION_FAILED**: Execution failed.
- **SPARSE_STATUS_INTERNAL_ERROR**: An error in algorithm implementation occurred.
- **SPARSE_STATUS_NOT_SUPPORTED**: The requested operation is not supported.

**mkl_sparse_optimize**

Analyzes matrix structure and performs optimizations using the hints provided in the handle.

**Syntax**

```c
sparse_status_t mkl_sparse_optimize (sparse_matrix_t A);
```

**Include Files**

- `mkl_spblas.h`

**Description**

The `mkl_sparse_optimize` routine analyzes matrix structure and performs optimizations using the hints provided in the handle. Generally, specifying a higher number of expected operations allows for more aggressive and time consuming optimizations.

**Optimization Notice**

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or

### mkl_sparse_?_lu_smoother

*Computes an action of a preconditioner which corresponds to the approximate matrix decomposition*

\[ A \approx (L + D) \times E \times (U + D) \]  
*for the system*  
\[ Ax = b \]  
*(see description below).*

#### Syntax

```c
sparse_status_t mkl_sparse_s_lu_smoother (const sparse_operation_t op, const sparse_matrix_t A, const struct matrix descr descr, const float *diag, const float *approx_diag_inverse, float *x, const float *b);
```

```c
sparse_status_t mkl_sparse_d_lu_smoother (const sparse_operation_t op, const sparse_matrix_t A, const struct matrix descr descr, const double *diag, const double *approx_diag_inverse, double *x, const double *b);
```

```c
sparse_status_t mkl_sparse_c_lu_smoother (const sparse_operation_t op, const sparse_matrix_t A, const struct matrix descr descr, const MKL_COMPLEX8 *diag, const MKL_COMPLEX8 *approx_diag_inverse, MKL_COMPLEX8 *x, const MKL_COMPLEX8 *b);
```

```c
sparse_status_t mkl_sparse_z_lu_smoother (const sparse_operation_t op, const sparse_matrix_t A, const struct matrix descr descr, const MKL_COMPLEX16 *diag, const MKL_COMPLEX16 *approx_diag_inverse, MKL_COMPLEX16 *x, const MKL_COMPLEX16 *b);
```

#### Include Files

- mkl_spblas.h
Description

This routine computes an update for an iterative solution \( x \) of the system \( Ax = b \) by means of applying one iteration of an approximate preconditioner which is based on the following approximation:

\[
A - (L + D) \ast E \ast (U + D),
\]
where \( E \) is an approximate inverse of the diagonal (using exact inverse will result in Gauss-Seidel preconditioner), \( L \) and \( U \) are lower/upper triangular parts of \( A \), \( D \) is the diagonal (block diagonal in case of BSR format) of \( A \).

The \texttt{mkl_sparse_?_lu_smoother} routine performs these operations:

\[
\begin{align*}
    r &= b - A \ast x & \text{ /* 1. Computes the residual */ } \\
    (L + D) \ast E \ast (U + D) \ast dx &= r & \text{ /* 2. Finds the update } dx \text{ by solving the system */ } \\
    y &= x + dx & \text{ /* 3. Performs an update */ }
\end{align*}
\]

**NOTE**

This routine is supported only for sparse matrices in BSR format, non-transpose operation and real data types.

Both diagonal values and approximate diagonal inverse arrays should be passed explicitly.

Input Parameters

**operation**

Specifies the operation performed on matrix \( A \).

\[
\text{SPARSE\_OPERATION\_NON\_TRANSPOSE, } \text{op}(A) := A
\]

**NOTE**

Transpose and conjugate transpose (\text{SPARSE\_OPERATION\_TRANSPOSE} and \text{SPARSE\_OPERATION\_CONJUGATE\_TRANSPOSE}) are not supported.

Non-transpose, \( \text{op}(A) = A \).

**A**

Handle which contains the sparse matrix \( A \).

**descr**

Structure specifying sparse matrix properties.

**sparse\_matrix\_type\_t type** - Specifies the type of a sparse matrix:

- \text{SPARSE\_MATRIX\_TYPE\_GENERAL} - The matrix is processed as is.

- \text{SPARSE\_MATRIX\_TYPE\_SYMMETRIC} - The matrix is symmetric (only the requested triangle is processed).

- \text{SPARSE\_MATRIX\_TYPE\_HERMITIAN} - The matrix is Hermitian (only the requested triangle is processed).

- \text{SPARSE\_MATRIX\_TYPE\_TRIANGULAR} - The matrix is triangular (only the requested triangle is processed).

- \text{SPARSE\_MATRIX\_TYPE\_DIAGONAL} - The matrix is diagonal (only diagonal elements are processed).
SPARSE_MATRIX_TYPE_BLOCK_TRIANGULAR  The matrix is block-triangular (only the requested triangle is processed). Applies to BSR format only.

SPARSE_MATRIX_TYPE_BLOCK_DIAGNOSTIC  The matrix is block-diagonal (only diagonal blocks are processed). Applies to BSR format only.

sparse_fill_mode_t mode - Specifies the triangular matrix part for symmetric, Hermitian, triangular, and block-triangular matrices:

SPARSE_FILL_MODE_LOWER  The lower triangular matrix part is processed.

SPARSE_FILL_MODE_UPPER  The upper triangular matrix part is processed.

sparse_diag_type_t diag - Specifies the diagonal type for non-general matrices:

SPARSE_DIAG_NON_UNIT  Diagonal elements might not be equal to one.

SPARSE_DIAG_UNIT  Diagonal elements are equal to one.

**NOTE**
Only SPARSE_MATRIX_TYPE_GENERAL is supported.

diag

Array of size at least \( m \), where \( m \) is the number of rows (or nrows * block_size * block_size in case of BSR format) of matrix \( A \).

The array diag must contain the diagonal values of matrix \( A \).

approx_diag_inverse

Array of size at least \( m \), where \( m \) is the number of rows (or the number of rows * block_size * block_size in case of BSR format) of matrix \( A \).

The array approx_diag_inverse will be used as \( E \), approximate inverse of the diagonal of the matrix \( A \).

x

Array of size at least \( k \), where \( k \) is the number of columns (or columns * block_size in case of BSR format) of matrix \( A \).

On entry, the array \( x \) must contain the input vector.

b

Array of size at least \( m \), where \( m \) is the number of rows (or rows * block_size in case of BSR format) of matrix \( A \). The array \( b \) must contain the values of the right-hand side of the system.

**Output Parameters**

\( x \)

Overwritten by the computed vector \( y \).

**Return Values**
The function returns a value indicating whether the operation was successful or not, and why.

SPARSE_STATUS_SUCCESS  The operation was successful.

SPARSE_STATUS_NOT_INITIALIZED  The routine encountered an empty handle or matrix array.
**SPARSE_STATUS_ALLOC_FAILED**
Internal memory allocation failed.

**SPARSE_STATUS_INVALID_VALUE**
The input parameters contain an invalid value.

**SPARSE_STATUS_EXECUTION_FAILED**
Execution failed.

**SPARSE_STATUS_INTERNAL_ERROR**
An error in algorithm implementation occurred.

**SPARSE_STATUS_NOT_SUPPORTED**
The requested operation is not supported.

---

**mkl_sparse_?_mv**
*Computes a sparse matrix-vector product.*

**Syntax**

```c
sparse_status_t mkl_sparse_s_mv(
    const sparse_operation_t operation,
    const float alpha,
    const sparse_matrix_t A,
    const struct matrix_descr descr,
    const float *x,
    const float beta,
    float *y);
```

```c
sparse_status_t mkl_sparse_d_mv(
    const sparse_operation_t operation,
    const double alpha,
    const sparse_matrix_t A,
    const struct matrix_descr descr,
    const double *x,
    const double beta,
    double *y);
```

```c
sparse_status_t mkl_sparse_c_mv(
    const sparse_operation_t operation,
    const MKL_Complex8 alpha,
    const sparse_matrix_t A,
    const struct matrix_descr descr,
    const MKL_Complex8 *x,
    const MKL_Complex8 beta,
    MKL_Complex8 *y);
```

```c
sparse_status_t mkl_sparse_z_mv(
    const sparse_operation_t operation,
    const MKL_Complex16 alpha,
    const sparse_matrix_t A,
    const struct matrix_descr descr,
    const MKL_Complex16 *x,
    const MKL_Complex16 beta,
    MKL_Complex16 *y);
```

**Include Files**

- mkl_spblas.h

**Description**

The *mkl_sparse_?_mv* routine computes a sparse matrix-vector product defined as

\[ y := \alpha \cdot \text{op}(A) \cdot x + \beta \cdot y \]

where:

- \( \alpha \) and \( \beta \) are scalars, \( x \) and \( y \) are vectors, and \( A \) is a sparse matrix handle of a matrix with \( m \) rows and \( k \) columns, and \( \text{op} \) is a matrix modifier for matrix \( A \).

**Input Parameters**

**operation**

- Specifies operation \( \text{op}() \) on input matrix.
  - `SPARSE_OPERATION_NON_TRANSPOSE` Non-transpose, \( \text{op}(A) = A \).
  - `SPARSE_OPERATION_TRANSPOSE` Transpose, \( \text{op}(A) = A^T \).
  - `SPARSE_OPERATION_CONJUGATE_TRANSPOSE` Conjugate transpose, \( \text{op}(A) = A^H \).

**alpha**

- Specifies the scalar \( \alpha \).

**A**

- Handle which contains the input matrix \( A \).
Structure specifying sparse matrix properties.

`sparse_matrix_type_t type` - Specifies the type of a sparse matrix:

- **SPARSE_MATRIX_TYPE_GENERAL**:
The matrix is processed as is.

- **SPARSE_MATRIX_TYPE_SYMMETRIC**:
The matrix is symmetric (only the requested triangle is processed).

- **SPARSE_MATRIX_TYPE_HERMITIAN**:
The matrix is Hermitian (only the requested triangle is processed).

- **SPARSE_MATRIX_TYPE_TRIANGULAR**:
The matrix is triangular (only the requested triangle is processed).

- **SPARSE_MATRIX_TYPE_DIAGONAL**:
The matrix is diagonal (only diagonal elements are processed).

- **SPARSE_MATRIX_TYPE_BLOCK_TRIANGULAR**:
The matrix is block-triangular (only requested triangle is processed). Applies to BSR format only.

- **SPARSE_MATRIX_TYPE_BLOCK_DIAGNOSTIC**:
The matrix is block-diagonal (only diagonal blocks are processed). Applies to BSR format only.

`sparse_fill_mode_t mode` - Specifies the triangular matrix part for symmetric, Hermitian, triangular, and block-triangular matrices:

- **SPARSE_FILL_MODE_LOWER**:
The lower triangular matrix part is processed.

- **SPARSE_FILL_MODE_UPPER**:
The upper triangular matrix part is processed.

`sparse_diag_type_t diag` - Specifies diagonal type for non-general matrices:

- **SPARSE_DIAG_NON_UNIT**:
  Diagonal elements might not be equal to one.

- **SPARSE_DIAG_UNIT**:
  Diagonal elements are equal to one.

Array of size equal to the number of columns, \( k \) of \( A \) if \( operation = SPARSE_OPERATION_NON_TRANSPOSE \) and at least the number of rows, \( m \), of \( A \) otherwise. On entry, the array must contain the vector \( x \).

Specifies the scalar \( beta \).

Array with size at least \( m \) if \( operation=SPARSE_OPERATION_NON_TRANSPOSE \) and at least \( k \) otherwise. On entry, the array \( y \) must contain the vector \( y \). Array of size equal to the number of rows, \( m \) of \( A \) if \( operation = SPARSE_OPERATION_NON_TRANSPOSE \) and at least the number of columns, \( k \), of \( A \) otherwise. On entry, the array \( y \) must contain the vector \( y \).

Output Parameters

\( y \) - Overwritten by the updated vector \( y \).
Return Values
The function returns a value indicating whether the operation was successful or not, and why.

- **SPARSE_STATUS_SUCCESS**: The operation was successful.
- **SPARSE_STATUS_NOT_INITIALIZED**: The routine encountered an empty handle or matrix array.
- **SPARSE_STATUS_ALLOC_FAILED**: Internal memory allocation failed.
- **SPARSE_STATUS_INVALID_VALUE**: The input parameters contain an invalid value.
- **SPARSE_STATUS_EXECUTION_FAILED**: Execution failed.
- **SPARSE_STATUS_INTERNAL_ERROR**: An error in algorithm implementation occurred.
- **SPARSE_STATUS_NOT_SUPPORTED**: The requested operation is not supported.

**mkl_sparse_?_trsv**
Solves a system of linear equations for a triangular sparse matrix.

Syntax

```c
sparse_status_t mkl_sparse_s_trsv (const sparse_operation_t operation, const float alpha, const sparse_matrix_t A, const struct matrix_descr descr, const float *x, float *y);
```

```c
sparse_status_t mkl_sparse_d_trsv (const sparse_operation_t operation, const double alpha, const sparse_matrix_t A, const struct matrix_descr descr, const double *x, double *y);
```

```c
sparse_status_t mkl_sparse_c_trsv (const sparse_operation_t operation, const MKL_Complex8 alpha, const sparse_matrix_t A, const struct matrix_descr descr, const MKL_Complex8 *x, MKL_Complex8 *y);
```

```c
sparse_status_t mkl_sparse_z_trsv (const sparse_operation_t operation, const MKL_Complex16 alpha, const sparse_matrix_t A, const struct matrix_descr descr, const MKL_Complex16 *x, MKL_Complex16 *y);
```

**Include Files**
- mkl_spblas.h

**Description**
The **mkl_sparse_?_trsv** routine solves a system of linear equations for a matrix:

```
op(A)*y = alpha * x
```

where **A** is a triangular sparse matrix, **op** is a matrix modifier for matrix **A**, **alpha** is a scalar, and **x** and **y** are vectors.

**NOTE**
For sparse matrices in the BSR format, the supported combinations of 
(indexing,block_layout) are:

- (SPARSE_INDEX_BASE_ZERO, SPARSE_LAYOUT_ROW_MAJOR)
- (SPARSE_INDEX_BASE_ONE, SPARSE_LAYOUT_COLUMN_MAJOR)
Input Parameters

**operation**

Specifies operation \( \text{op()} \) on input matrix.

- **SPARSE_OPERATION_NON_TRANSPOSE**  
  Non-transpose, \( \text{op}(A) = A \).
- **SPARSE_OPERATION_TRANSPOSE**  
  Transpose, \( \text{op}(A) = A^T \).
- **SPARSE_OPERATION_CONJ_TRANSPOSE**  
  Conjugate transpose, \( \text{op}(A) = A^H \).

**alpha**

Specifies the scalar \( \alpha \).

**A**

Handle which contains the input matrix \( A \).

**descr**

Structure specifying sparse matrix properties.

**sparse_matrix_type_t type** - Specifies the type of a sparse matrix:

- **SPARSE_MATRIX_TYPE_GENERAL**  
  The matrix is processed as is.
- **SPARSE_MATRIX_TYPE_SYMMETRIC**  
  The matrix is symmetric (only the requested triangle is processed).
- **SPARSE_MATRIX_TYPE_HERMITIAN**  
  The matrix is Hermitian (only the requested triangle is processed).
- **SPARSE_MATRIX_TYPE_TRIANGULAR**  
  The matrix is triangular (only the requested triangle is processed).
- **SPARSE_MATRIX_TYPE_DIAGONAL**  
  The matrix is diagonal (only diagonal elements are processed).
- **SPARSE_MATRIX_TYPE_BLOCK_TRIANGULAR**  
  The matrix is block-triangular (only requested triangle is processed). Applies to BSR format only.
- **SPARSE_MATRIX_TYPE_BLOCK_DIAGONAL**  
  The matrix is block-diagonal (only diagonal blocks are processed). Applies to BSR format only.

**sparse_fill_mode_t mode** - Specifies the triangular matrix part for symmetric, Hermitian, triangular, and block-triangular matrices:

- **SPARSE_FILL_MODE_LOWER**  
  The lower triangular matrix part is processed.
- **SPARSE_FILL_MODE_UPPER**  
  The upper triangular matrix part is processed.

**sparse_diag_type_t diag** - Specifies diagonal type for non-general matrices:

- **SPARSE_DIAG_NON_UNIT**  
  Diagonal elements might not be equal to one.
- **SPARSE_DIAG_UNIT**  
  Diagonal elements are equal to one.

**x**

Array of size at least \( m \), where \( m \) is the number of rows of matrix \( A \). On entry, the array must contain the vector \( x \).
Output Parameters

\[ y \]  
Array of size at least \( m \) containing the solution to the system of linear equations.

Return Values

The function returns a value indicating whether the operation was successful or not, and why.

- \texttt{SPARSE_STATUS_SUCCESS}  
The operation was successful.
- \texttt{SPARSE_STATUS_NOT_INITIALIZED}  
The routine encountered an empty handle or matrix array.
- \texttt{SPARSE_STATUS_ALLOC_FAILED}  
Internal memory allocation failed.
- \texttt{SPARSE_STATUS_INVALID_VALUE}  
The input parameters contain an invalid value.
- \texttt{SPARSE_STATUS_EXECUTION_FAILED}  
Execution failed.
- \texttt{SPARSE_STATUS_INTERNAL_ERROR}  
An error in algorithm implementation occurred.
- \texttt{SPARSE_STATUS_NOT_SUPPORTED}  
The requested operation is not supported.

\texttt{mkl_sparse_?_mm}

Computes the product of a sparse matrix and a dense matrix and stores the result as a dense matrix.

Syntax

\begin{verbatim}
sparse_status_t mkl_sparse_s_mm (const sparse_operation_t operation, const float alpha,  
const sparse_matrix_t A, const struct matrix_descr descr, const sparse_layout_t layout,  
const float *x, const MKL_INT columns, const MKL_INT idx, const float beta, float *y,  
const MKL_INT ldy);
sparse_status_t mkl_sparse_d_mm (const sparse_operation_t operation, const double alpha,  
const sparse_matrix_t A, const struct matrix_descr descr, const sparse_layout_t layout,  
const double *x, const MKL_INT columns, const MKL_INT idx, const double beta,  
double *y, const MKL_INT ldy);
sparse_status_t mkl_sparse_c_mm (const sparse_operation_t operation, const MKL_Complex8 alpha,  
const sparse_matrix_t A, const struct matrix_descr descr, const sparse_layout_t layout,  
const MKL_Complex8 *x, const MKL_INT columns, const MKL_INT idx, const MKL_Complex8 beta,  
MKL_Complex8 *y, const MKL_INT ldy);
sparse_status_t mkl_sparse_z_mm (const sparse_operation_t operation, const MKL_Complex16 alpha,  
const sparse_matrix_t A, const struct matrix_descr descr, const sparse_layout_t layout,  
const MKL_Complex16 *x, const MKL_INT columns, const MKL_INT idx, const MKL_Complex16 beta,  
MKL_Complex16 *y, const MKL_INT ldy);
\end{verbatim}

Include Files

- mkl_spblas.h

Description

The \texttt{mkl_sparse_?_mm} routine performs a matrix-matrix operation:

\[ Y := alpha \cdot \text{op}(A) \cdot X + beta \cdot Y \]
where \( \alpha \) and \( \beta \) are scalars, \( A \) is a sparse matrix, \( \text{op} \) is a matrix modifier for matrix \( A \), and \( X \) and \( Y \) are dense matrices.

The \texttt{mkl_sparse_?_mm} and \texttt{mkl_sparse_?_trsm} routines support these configurations:

<table>
<thead>
<tr>
<th>0-based sparse matrix:</th>
<th>Column-major dense matrix:</th>
<th>Row-major dense matrix:</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPARSE_INDEX_BASE_ZERO</td>
<td>( \text{layout} = ) SPARSE_LAYOUT_COLUMN_MAJOR</td>
<td>( \text{layout} = ) SPARSE_LAYOUT_ROW_MAJOR</td>
</tr>
<tr>
<td>CSR</td>
<td>All formats</td>
<td>CSR</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>1-based sparse matrix:</th>
<th>CSR</th>
<th>BSR: general non-transposed matrix multiplication only</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPARSE_INDEX_BASE_ONE</td>
<td>All formats</td>
<td>All formats</td>
</tr>
</tbody>
</table>

\textbf{NOTE}
For sparse matrices in the BSR format, the supported combinations of \((\text{indexing,block\_layout})\) are:

- \((\text{SPARSE\_INDEX\_BASE\_ZERO, SPARSE\_LAYOUT\_ROW\_MAJOR})\)
- \((\text{SPARSE\_INDEX\_BASE\_ONE, SPARSE\_LAYOUT\_COLUMN\_MAJOR})\)

\textbf{Input Parameters}

- \textit{operation} Specifies operation \( \text{op}() \) on input matrix.
  
  - \texttt{SPARSE\_OPERATION\_NON\_TRANSPOSE} Non-transpose, \( \text{op}(A) = A \).
  
  - \texttt{SPARSE\_OPERATION\_TRANSPOSE} Transpose, \( \text{op}(A) = A^T \).
  
  - \texttt{SPARSE\_OPERATION\_CONJUATE\_TRANSPOSE} Conjugate transpose, \( \text{op}(A) = A^H \).

- \textit{alpha} Specifies the scalar \( \alpha \).

- \textit{A} Handle which contains the sparse matrix \( A \).

- \textit{descr} Structure specifying sparse matrix properties.
  
  - \texttt{SPARSE\_MATRIX\_TYPE\_GENERAL} The matrix is processed as is.
  
  - \texttt{SPARSE\_MATRIX\_TYPE\_SYMMETRIC} The matrix is symmetric (only the requested triangle is processed).
  
  - \texttt{SPARSE\_MATRIX\_TYPE\_HERMITIAN} The matrix is Hermitian (only the requested triangle is processed).
  
  - \texttt{SPARSE\_MATRIX\_TYPE\_TRIANGULAR} The matrix is triangular (only the requested triangle is processed).
The matrix is diagonal (only diagonal elements are processed).

The matrix is block-triangular (only requested triangle is processed). Applies to BSR format only.

The matrix is block-diagonal (only diagonal blocks are processed). Applies to BSR format only.

**sparse_fill_mode_t**

- **mode** - Specifies the triangular matrix part for symmetric, Hermitian, triangular, and block-triangular matrices:
  - **SPARSE_FILL_MODE_LOWER** - The lower triangular matrix part is processed.
  - **SPARSE_FILL_MODE_UPPER** - The upper triangular matrix part is processed.

**sparse_diag_type_t**

- **diag** - Specifies diagonal type for non-general matrices:
  - **SPARSE_DIAG_NON_UNIT** - Diagonal elements might not be equal to one.
  - **SPARSE_DIAG_UNIT** - Diagonal elements are equal to one.

**layout**

Describes the storage scheme for the dense matrix:

- **SPARSE_LAYOUT_COLUMN_MAJOR** - Storage of elements uses column major layout.
- **SPARSE_LAYOUT_ROW_MAJOR** - Storage of elements uses row major layout.

**x**

Array of size at least rows*cols.

<table>
<thead>
<tr>
<th>rows (number of rows in x)</th>
<th>ldx</th>
</tr>
</thead>
</table>

If op(A) = A, number of columns in A.

If op(A) = Aᵀ, number of rows in A.

<table>
<thead>
<tr>
<th>columns (number of columns in x)</th>
<th>columns</th>
<th>ldx</th>
</tr>
</thead>
</table>

Number of columns of matrix Y.

Specifies the leading dimension of matrix X.

**beta**

Specifies the scalar beta

**y**

Array of size at least rows*cols, where
Output Parameters

\( y \)

Overwritten by the updated matrix \( Y \).

Return Values

The function returns a value indicating whether the operation was successful or not, and why.

- **SPARSE_STATUS_SUCCESS**
  - The operation was successful.
- **SPARSE_STATUS_NOT_INITIALIZED**
  - The routine encountered an empty handle or matrix array.
- **SPARSE_STATUS_ALLOC_FAILED**
  - Internal memory allocation failed.
- **SPARSE_STATUS_INVALID_VALUE**
  - The input parameters contain an invalid value.
- **SPARSE_STATUS_EXECUTION_FAILED**
  - Execution failed.
- **SPARSE_STATUS_INTERNAL_ERROR**
  - An error in algorithm implementation occurred.
- **SPARSE_STATUS_NOT_SUPPORTED**
  - The requested operation is not supported.

**mkl_sparse_?_trsm**

Solves a system of linear equations with multiple right hand sides for a triangular sparse matrix.

**Syntax**

```c
sparse_status_t mkl_sparse_s_trsm (const sparse_operation_t operation, const float alpha, const sparse_matrix_t A, const struct matrix_descr descr, const sparse_layout_t layout, const float *x, const MKL_INT columns, const MKL_INT ldx, float *y, const MKL_INT ldy);

sparse_status_t mkl_sparse_d_trsm (const sparse_operation_t operation, const double alpha, const sparse_matrix_t A, const struct matrix_descr descr, const sparse_layout_t layout, const double *x, const MKL_INT columns, const MKL_INT ldx, double *y, const MKL_INT ldy);

sparse_status_t mkl_sparse_c_trsm (const sparse_operation_t operation, const MKL_Complex8 alpha, const sparse_matrix_t A, const struct matrix_descr descr, const sparse_layout_t layout, const MKL_Complex8 *x, const MKL_INT columns, const MKL_INT ldx, MKL_Complex8 *y, const MKL_INT ldy);
```
sparse_status_t mkl_sparse_z_trsm (const sparse_operation_t operation, const MKL_Complex16 alpha, const sparse_matrix_t A, const struct matrix_descr descr, const sparse_layout_t layout, const MKL_Complex16 *x, const MKL_INT columns, const MKL_INT ldx, MKL_Complex16 *y, const MKL_INT ldy);

Include Files

- mkl_spblas.h

Description

The mkl_sparse_?_trsm routine solves a system of linear equations with multiple right hand sides for a triangular sparse matrix:

\[ Y := alpha \cdot \text{inv}(\text{op}(A)) \cdot X \]

where:

- \( alpha \) is a scalar,
- \( X \) and \( Y \) are dense matrices,
- \( A \) is a sparse matrix, and
- \( \text{op} \) is a matrix modifier for matrix \( A \).

The mkl_sparse_?_mm and mkl_sparse_?_trsm routines support these configurations:

<table>
<thead>
<tr>
<th>Column-major dense matrix:</th>
<th>Row-major dense matrix:</th>
<th>0-based sparse matrix:</th>
<th>1-based sparse matrix:</th>
</tr>
</thead>
<tbody>
<tr>
<td>layout = SPARSE_LAYOUT_COLUMN_MAJOR</td>
<td>layout = SPARSE_LAYOUT_ROW_MAJOR</td>
<td>CSR</td>
<td>CSR</td>
</tr>
<tr>
<td>CSR: general non-transposed matrix multiplication only</td>
<td>All formats</td>
<td>All formats</td>
<td>BSR: general non-transposed matrix multiplication only</td>
</tr>
</tbody>
</table>

**NOTE**

For sparse matrices in the BSR format, the supported combinations of (indexing,block_layout) are:

- (SPARSE_INDEX_BASE_ZERO, SPARSE_LAYOUT_ROW_MAJOR)
- (SPARSE_INDEX_BASE_ONE, SPARSE_LAYOUT_COLUMN_MAJOR)

Input Parameters

**operation**

Specifies operation \( \text{op()} \) on input matrix.

- SPARSE_OPERATION_NON_TRANSPOSE Non-transpose, \( \text{op}(A) = A \).
- SPARSE_OPERATION_TRANSPOSE Transpose, \( \text{op}(A) = A^T \).
- SPARSE_OPERATION_CONJUGATE_TRANSPOSE Conjugate transpose, \( \text{op}(A) = A^H \).

**alpha**

Specifies the scalar \( alpha \).

**A**

Handle which contains the sparse matrix \( A \).
Structure specifying sparse matrix properties.

`sparse_matrix_type_t type` - Specifies the type of a sparse matrix:

- `SPARSE_MATRIX_TYPE_GENERAL` - The matrix is processed as is.
- `SPARSE_MATRIX_TYPE_SYMMETRIC` - The matrix is symmetric (only the requested triangle is processed).
- `SPARSE_MATRIX_TYPE_HERMITIAN` - The matrix is Hermitian (only the requested triangle is processed).
- `SPARSE_MATRIX_TYPE_TRIANGULAR` - The matrix is triangular (only the requested triangle is processed).
- `SPARSE_MATRIX_TYPE_DIAGONAL` - The matrix is diagonal (only diagonal elements are processed).
- `SPARSE_MATRIX_TYPE_BLOCK_TRIANGULAR` - The matrix is block-triangular (only requested triangle is processed). Applies to BSR format only.
- `SPARSE_MATRIX_TYPE_BLOCK_DIAGONAL` - The matrix is block-diagonal (only diagonal blocks are processed). Applies to BSR format only.

`sparse_fill_mode_t mode` - Specifies the triangular matrix part for symmetric, Hermitian, triangular, and block-triangular matrices:

- `SPARSE_FILL_MODE_LOWER` - The lower triangular matrix part is processed.
- `SPARSE_FILL_MODE_UPPER` - The upper triangular matrix part is processed.

`sparse_diag_type_t diag` - Specifies diagonal type for non-general matrices:

- `SPARSE_DIAG_NON_UNIT` - Diagonal elements might not be equal to one.
- `SPARSE_DIAG_UNIT` - Diagonal elements are equal to one.

Describes the storage scheme for the dense matrix:

- `SPARSE_LAYOUT_COLUMN_MAJOR` - Storage of elements uses column major layout.
- `SPARSE_LAYOUT_ROW_MAJOR` - Storage of elements uses row major layout.

Array of size at least `rows*cols`.

<table>
<thead>
<tr>
<th>layout</th>
<th>rows (number of rows in x)</th>
<th>idx</th>
<th>number of rows in A</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>SPARSE_LAYOUT_COLUMN_MAJOR</code></td>
<td><code>rows</code></td>
<td><code>idx</code></td>
<td><code>number of rows in A</code></td>
</tr>
<tr>
<td><code>SPARSE_LAYOUT_ROW_MAJOR</code></td>
<td><code>rows</code></td>
<td><code>idx</code></td>
<td><code>number of rows in A</code></td>
</tr>
</tbody>
</table>
On entry, the array \( x \) must contain the matrix \( X \).

**Number of columns in matrix \( Y \).**

**Specifies the leading dimension of matrix \( X \).**

**Array of size at least rows*cols, where**

<table>
<thead>
<tr>
<th>cols (number of columns in ( x ))</th>
<th>columns</th>
<th>ldx</th>
</tr>
</thead>
<tbody>
<tr>
<td>columns</td>
<td></td>
<td></td>
</tr>
<tr>
<td>ldx</td>
<td></td>
<td></td>
</tr>
<tr>
<td>y</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Output Parameters**

**\( y \)**

Overwritten by the updated matrix \( Y \).

**Return Values**

The function returns a value indicating whether the operation was successful or not, and why.

- **SPARSE_STATUS_SUCCESS**
  - The operation was successful.
- **SPARSE_STATUS_NOT_INITIALIZED**
  - The routine encountered an empty handle or matrix array.
- **SPARSE_STATUS_ALLOC_FAILED**
  - Internal memory allocation failed.
- **SPARSE_STATUS_INVALID_VALUE**
  - The input parameters contain an invalid value.
- **SPARSE_STATUS_EXECUTION_FAILED**
  - Execution failed.
- **SPARSE_STATUS_INTERNAL_ERROR**
  - An error in algorithm implementation occurred.
- **SPARSE_STATUS_NOT_SUPPORTED**
  - The requested operation is not supported.

**mkl_sparse_?_add**

*Computes the sum of two sparse matrices. The result is stored in a newly allocated sparse matrix.*

**Syntax**

```c
sparse_status_t mkl_sparse_s_add (const sparse_operation_t operation, const sparse_matrix_t A, const float alpha, const sparse_matrix_t B, sparse_matrix_t *C);
sparse_status_t mkl_sparse_d_add (const sparse_operation_t operation, const sparse_matrix_t A, const double alpha, const sparse_matrix_t B, sparse_matrix_t *C);
sparse_status_t mkl_sparse_c_add (const sparse_operation_t operation, const sparse_matrix_t A, const MKL_Complex8 alpha, const sparse_matrix_t B, sparse_matrix_t *C);
```
sparse_status_t mkl_sparse_z_add (const sparse_operation_t operation, const sparse_matrix_t A, const MKL_Complex16 alpha, const sparse_matrix_t B, sparse_matrix_t *C);

Include Files

- mkl_spblas.h

Description

The mkl_sparse_?_add routine performs a matrix-matrix operation:

\[ C := \alpha \cdot \text{op}(A) + B \]

where \( \alpha \) is a scalar, \( \text{op} \) is a matrix modifier, and \( A, B, \) and \( C \) are sparse matrices.

NOTE

This routine is only supported for sparse matrices in CSR and BSR formats. It is not supported for COO or CSC formats.

Input Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>Handle which contains the sparse matrix ( A ).</td>
</tr>
<tr>
<td>alpha</td>
<td>Specifies the scalar ( \alpha ).</td>
</tr>

<td>The requested operation is not supported.</td>
</tr>
</tbody>
</table>
mkl_sparse_spmm

Computes the product of two sparse matrices. The result is stored in a newly allocated sparse matrix.

Syntax

sparse_status_t mkl_sparse_spmm (const sparse_operation_t operation, const sparse_matrix_t A, const sparse_matrix_t B, sparse_matrix_t *C);

Include Files

• mkl_spblas.h

Description

The mkl_sparse_spmm routine performs a matrix-matrix operation:

\[ C := \text{op}(A) \times B \]

where \( A \), \( B \), and \( C \) are sparse matrices and \( \text{op} \) is a matrix modifier for matrix \( A \).

NOTE

This routine is only supported for sparse matrices in CSC, CSR, and BSR formats. It is not supported for sparse matrices in COO format.

Input Parameters

- \( operation \): Specifies operation \( \text{op}() \) on input matrix.
  - \text{SPARSE_OPERATION_NON_TRANSPOSE}: Non-transpose, \( \text{op}(A) = A \).
  - \text{SPARSE_OPERATION_TRANSPOSE}: Transpose, \( \text{op}(A) = A^T \).
  - \text{SPARSE_OPERATION_CONJ_TRANSPOSE}: Conjugate transpose, \( \text{op}(A) = A^H \).

- \( A \): Handle which contains the sparse matrix \( A \).

- \( B \): Handle which contains the sparse matrix \( B \).

Output Parameters

- \( C \): Handle which contains the resulting sparse matrix.

Return Values

The function returns a value indicating whether the operation was successful or not, and why.

- \text{SPARSE_STATUS_SUCCESS}: The operation was successful.
- \text{SPARSE_STATUS_NOT_INITIALIZED}: The routine encountered an empty handle or matrix array.
- \text{SPARSE_STATUS_ALLOC_FAILED}: Internal memory allocation failed.
- \text{SPARSE_STATUS_INVALID_VALUE}: The input parameters contain an invalid value.
- \text{SPARSE_STATUS_EXECUTION_FAILED}: Execution failed.
mkl_sparse_?_spmm

**Computes the product of two sparse matrices and stores the result as a dense matrix.**

**Syntax**

```c
sparse_status_t mkl_sparse_s_spmm (const sparse_operation_t operation, const sparse_matrix_t A, const sparse_matrix_t B, const sparse_layout_t layout, float *C, const MKL_INT ldc);

sparse_status_t mkl_sparse_d_spmm (const sparse_operation_t operation, const sparse_matrix_t A, const sparse_matrix_t B, const sparse_layout_t layout, double *C, const MKL_INT ldc);

sparse_status_t mkl_sparse_c_spmm (const sparse_operation_t operation, const sparse_matrix_t A, const sparse_matrix_t B, const sparse_layout_t layout, MKL_Complex8 *C, const MKL_INT ldc);

sparse_status_t mkl_sparse_z_spmm (const sparse_operation_t operation, const sparse_matrix_t A, const sparse_matrix_t B, const sparse_layout_t layout, MKL_Complex16 *C, const MKL_INT ldc);
```

**Include Files**

- mkl_spblas.h

**Description**

The `mkl_sparse_?_spmm` routine performs a matrix-matrix operation:

\[ C := \text{op}(A) \times B \]

where A and B are sparse matrices, \( \text{op} \) is a matrix modifier for matrix A, and C is a dense matrix.

**NOTE**

This routine is not supported for sparse matrices in the COO format. For sparse matrices in BSR format, these combinations of (indexing, block_layout) are supported:

- \((\text{SPARSE_INDEX_BASE_ZERO}, \text{SPARSE_LAYOUT_ROW_MAJOR})\)
- \((\text{SPARSE_INDEX_BASE_ONE}, \text{SPARSE_LAYOUT_COLUMN_MAJOR})\)

**Input Parameters**

- **operation**
  - Specifies operation \( \text{op}(\cdot) \) on input matrix.
  - `SPARSE_OPERATION_NON_TRANSPOSE` Non-transpose, \( \text{op}(A) = A \).
  - `SPARSE_OPERATION_TRANSPOSE` Transpose, \( \text{op}(A) = A^T \).
  - `SPARSE_OPERATION_CONJUGATE_TRANSPOSE` Conjugate transpose, \( \text{op}(A) = A^H \).
A Handle which contains the sparse matrix $A$.

B Handle which contains the sparse matrix $B$.

layout Describes the storage scheme for the dense matrix:

SPARSE_LAYOUT_COLUMN_MAJOR Storage of elements uses column major layout.

SPARSE_LAYOUT_ROW_MAJOR Storage of elements uses row major layout.

ldC Leading dimension of matrix $C$.

Output Parameters

$C$ Resulting dense matrix.

Return Values

The function returns a value indicating whether the operation was successful or not, and why.

SPARSE_STATUS_SUCCESS The operation was successful.

SPARSE_STATUS_NOT_INITIALIZED The routine encountered an empty handle or matrix array.

SPARSE_STATUS_ALLOC FAILED Internal memory allocation failed.

SPARSE_STATUS_INVALID_VALUE The input parameters contain an invalid value.

SPARSE_STATUS_EXECUTION FAILED Execution failed.

SPARSE_STATUS_INTERNAL_ERROR An error in algorithm implementation occurred.

SPARSE_STATUS_NOT_SUPPORTED The requested operation is not supported.

mkl_sparse_sp2m

Computes the product of two sparse matrices. The result is stored in a newly allocated sparse matrix.

Syntax

sparse_status_t mkl_sparse_sp2m (const sparse_operation_t transA, const struct matrix_descr descrA, const sparse_matrix_t A, const sparse_operation_t transB, const struct matrix_descr descrB, const sparse_matrix_t B, const sparse_request_t request, sparse_matrix_t *C);

Include Files

• mkl_spblas.h

Description

The mkl_sparse_sp2m routine performs a matrix-matrix operation:

$$ C := \text{op}(A) \ast \text{op}(B) $$

where $A$, $B$, and $C$ are sparse matrices, $\text{op}(A)$ and $\text{op}(B)$ are matrix modifiers for matrices $A$ and $B$, respectively.
### Input Parameters

**opA**

Specifies operation on input matrix.

<table>
<thead>
<tr>
<th>Operation Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPARSE_OPERATION_NON_TRANSPOSE</td>
<td>Non-transpose, ( \text{op}(A)=A )</td>
</tr>
<tr>
<td>SPARSE_OPERATION_TRANSPOSE</td>
<td>Transpose, ( \text{op}(A)=A^T )</td>
</tr>
<tr>
<td>SPARSE_OPERATION_CONJUGATE_TRANSPOSE</td>
<td>Conjugate transpose, ( \text{op}(A)=A^H )</td>
</tr>
</tbody>
</table>

**opB**

Specifies operation on input matrix.

<table>
<thead>
<tr>
<th>Operation Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPARSE_OPERATION_NON_TRANSPOSE</td>
<td>Non-transpose, ( \text{op}(B)=B )</td>
</tr>
<tr>
<td>SPARSE_OPERATION_TRANSPOSE</td>
<td>Transpose, ( \text{op}(B)=B^T )</td>
</tr>
<tr>
<td>SPARSE_OPERATION_CONJUGATE_TRANSPOSE</td>
<td>Conjugate transpose, ( \text{op}(B)=B^H )</td>
</tr>
</tbody>
</table>

**descrA**

Structure that specifies sparse matrix properties.

**NOTE** Currently, only SPARSE_MATRIX_TYPE_GENERAL is supported.

**sparse_matrix_type_t type** specifies the type of sparse matrix.

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPARSE_MATRIX_TYPE_GENERAL</td>
<td>The matrix is processed as is.</td>
</tr>
<tr>
<td>SPARSE_MATRIX_TYPE_SYMMETRIC</td>
<td>The matrix is symmetric (only the requested triangle is processed).</td>
</tr>
<tr>
<td>SPARSE_MATRIX_TYPE_HERMITIAN</td>
<td>The matrix is Hermitian (only the requested triangle is processed).</td>
</tr>
<tr>
<td>SPARSE_MATRIX_TYPE_TRIANGULAR</td>
<td>The matrix is triangular (only the requested triangle is processed).</td>
</tr>
<tr>
<td>SPARSE_MATRIX_TYPE_DIAGONAL</td>
<td>The matrix is diagonal (only diagonal elements are processed).</td>
</tr>
<tr>
<td>SPARSE_MATRIX_TYPE_BLOCK_TRIANGULAR</td>
<td>The matrix is block-triangular (only the requested triangle is processed). This applies to BSR format only.</td>
</tr>
<tr>
<td>SPARSE_MATRIX_TYPE_BLOCK_DIAGONAL</td>
<td>The matrix is block-diagonal (only the requested triangle is processed). This applies to BSR format only.</td>
</tr>
</tbody>
</table>

**sparse_fill_mode_t mode** specifies the triangular matrix portion for symmetric, Hermitian, triangular, and block-triangular matrices.

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPARSE_FILL_MODE_LOWER</td>
<td>The lower triangular matrix is processed.</td>
</tr>
</tbody>
</table>
The upper triangular matrix is processed.

**sparse_diag_type_t** `diag` specifies the type of diagonal for non-general matrices.

<table>
<thead>
<tr>
<th>Enum</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPARSE_DIAG_NON_UNIT</td>
<td>Diagonal elements must not be equal to 1.</td>
</tr>
<tr>
<td>SPARSE_DIAG_UNIT</td>
<td>Diagonal elements are equal to 1.</td>
</tr>
</tbody>
</table>

Structure that specifies sparse matrix properties.

**NOTE** Currently, only SPARSE_MATRIX_TYPE_GENERAL is supported.

**sparse_matrix_type_t** `type` specifies the type of sparse matrix.

<table>
<thead>
<tr>
<th>Enum</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPARSE_MATRIX_TYPE_GENERAL</td>
<td>The matrix is processed as is.</td>
</tr>
<tr>
<td>SPARSE_MATRIX_TYPE_SYMMETRIC</td>
<td>The matrix is symmetric (only the requested triangle is processed).</td>
</tr>
<tr>
<td>SPARSE_MATRIX_TYPE_HERMITIAN</td>
<td>The matrix is Hermitian (only the requested triangle is processed).</td>
</tr>
<tr>
<td>SPARSE_MATRIX_TYPE_TRIANGULAR</td>
<td>The matrix is triangular (only the requested triangle is processed).</td>
</tr>
<tr>
<td>SPARSE_MATRIX_TYPE_DIAGONAL</td>
<td>The matrix is diagonal (only diagonal elements are processed).</td>
</tr>
<tr>
<td>SPARSE_MATRIX_TYPE_BLOCK_TRIANGULAR</td>
<td>The matrix is block-triangular (only the requested triangle is processed). This applies to BSR format only.</td>
</tr>
<tr>
<td>SPARSE_MATRIX_TYPE_BLOCK_DIAGONAL</td>
<td>The matrix is block-diagonal (only the requested triangle is processed). This applies to BSR format only.</td>
</tr>
</tbody>
</table>

**sparse_fill_mode_t** `mode` specifies the triangular matrix portion for symmetric, Hermitian, triangular, and block-triangular matrices.

<table>
<thead>
<tr>
<th>Enum</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPARSE_FILL_MODE_LOWER</td>
<td>The lower triangular matrix is processed.</td>
</tr>
<tr>
<td>SPARSE_FILL_MODE_UPPER</td>
<td>The upper triangular matrix is processed.</td>
</tr>
</tbody>
</table>

**sparse_diag_type_t** `diag` specifies the type of diagonal for non-general matrices.

<table>
<thead>
<tr>
<th>Enum</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPARSE_DIAG_NON_UNIT</td>
<td>Diagonal elements must not be equal to 1.</td>
</tr>
</tbody>
</table>
**SPARSE_DIAG_UNIT**

Diagonal elements are equal to 1.

Handle which contains the sparse matrix \( A \).

Handle which contains the sparse matrix \( B \).

Specifies whether the full computations are performed at once or using the two-stage algorithm. See Two-stage Algorithm for Inspector-executor Sparse BLAS Routines.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPARSE_STAGE_NNZ_COUNT</td>
<td>Only rowIndex (BSR/CSR format) or colIndex (CSC format) array of the matrix is computed internally. The computation can be extracted to measure the memory required for full operation.</td>
</tr>
<tr>
<td>SPARSE_STAGE_FINALIZE_MULT_NO_VAL</td>
<td>Finalize computations of the matrix structure (values will not be computed). Use only after the call with SPARSE_STAGE_NNZ_COUNT parameter.</td>
</tr>
<tr>
<td>SPARSE_STAGE_FINALIZE_MULT</td>
<td>Finalize computation. Can also be used when the matrix structure remains unchanged and only values of the resulting matrix ( C ) need to be recomputed.</td>
</tr>
<tr>
<td>SPARSE_STAGE_FULL_MULT_NO_VAL</td>
<td>Perform computations of the matrix structure.</td>
</tr>
<tr>
<td>SPARSE_STAGE_FULL_MULT</td>
<td>Perform the entire computation in a single step.</td>
</tr>
</tbody>
</table>

**Output Parameters**

\( C \)

Handle which contains the resulting sparse matrix.

**Return Values**

The function returns a value indicating whether the operation was successful, or the reason why it failed.

- **SPARSE_STATUS_SUCCESS**
  - The operation was successful.

- **SPARSE_STATUS_NOT_INITIALIZED**
  - The routine encountered an empty handle or matrix array.

- **SPARSE_STATUS_ALLOC_FAILED**
  - The internal memory allocation failed.

- **SPARSE_STATUS_INVALID_VALUE**
  - The input parameters contain an invalid value.

- **SPARSE_STATUS_EXECUTION_FAILED**
  - The execution failed.

- **SPARSE_STATUS_INTERNAL_ERROR**
  - An error occurred in the implementation of the algorithm.

- **SPARSE_STATUS_NOT_SUPPORTED**
  - The requested operation is not supported.
mkl_sparse_sypr

Computes the symmetric product of three sparse matrices and stores the result in a newly allocated sparse matrix.

Syntax

```c
sparse_status_t mkl_sparse_sypr (const sparse_operation_t operation, const sparse_matrix_t A, const sparse_matrix_t B, const struct matrix_descr B, sparse_matrix_t *C, const sparse_request_t request);
```

Include Files

- mkl_spblas.h

Description

The `mkl_sparse_sypr` routine performs a multiplication of three sparse matrices that results in a symmetric or Hermitian matrix, `C`.

\[ C = A \times B \times \text{op}(A) \]

or

\[ C = \text{op}(A) \times B \times A \]

depending on the matrix modifier `operation`.

Here, `A`, `B`, and `C` are sparse matrices, where `A` has a general structure while `B` and `C` are symmetric or Hermitian matrices. \text{op}A is the transpose (real precision) or conjugate transpose (complex precision) operator.

**NOTE**

This routine is not supported for sparse matrices in COO or CSC formats. This routine supports only CSR and BSR formats. In addition, it supports only the sorted CSR and sorted BSR formats for the input matrix. If the data is unsorted, call the `mkl_sparse_order` routine before either `mkl_sparse_sypr` or `mkl_sparse_\*syprd`.

Input Parameters

<table>
<thead>
<tr>
<th>operation</th>
<th>Specifies operation on the input sparse matrices.</th>
</tr>
</thead>
</table>
| SPARSE_OPERATION_NON_TRANSPOSE | Non-transpose case.  
\[ C = A \times B \times (A^T) \] for real precision  
\[ C = A \times B \times (A^H) \] for complex precision. |
| SPARSE_OPERATION_TRANSPOSE | Transpose case. This is not supported for complex matrices.  
\[ C = (A^T) \times B \times A \] |
SPARSE_OPERATION_CONJUGATE_TRANSPOSE

Conjugate transpose case. This is not supported for real matrices.
\[
C = (A^H)^*B*A
\]

A
Handle which contains the sparse matrix A.

B
Handle which contains the sparse matrix B.

descrB
Structure specifying properties of the sparse matrix.

sparse_matrix_type_t type specifies the type of a sparse matrix

<table>
<thead>
<tr>
<th>SPARSE_MATRIX_TYPE_SYMMETRIC</th>
<th>The matrix is symmetric (only the specified triangle is processed).</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPARSE_MATRIX_TYPE_HERMITIAN</td>
<td>The matrix is Hermitian (only the specified triangle is processed).</td>
</tr>
</tbody>
</table>

sparse_fill_mode_t mode specifies the triangular matrix part.

| SPARSE_FILL_MODE_LOWER       | The lower triangular matrix part is processed.                   |
| SPARSE_FILL_MODE_UPPER      | The upper triangular matrix part is processed.                   |

sparse_diag_type_t diag specifies the type of diagonal.

| SPARSE_DIAG_NON_UNIT        | Diagonal elements cannot be equal to one.                        |

NOTE
This routine also supports \( C = AA^T, H \) with these parameters:

descrB.type=SPARSE_MATRIX_TYPE_DIAGONAL
descrB.diag=SPARSE_DIAG_UNIT

In this case, you do not need to allocate structure B. Use the routine as a 2-stage version of mkl_sparse_syrk.

request
Use this routine to specify if the computations should be performed in a single step or using the two-stage algorithm. See Two-stage Algorithm for Inspector-executor Sparse BLAS Routines for more information.

| SPARSE_STAGE_NNZ_COUNT | Only rowIndex (BSR/CSR format) or colIndex (CSC format) array of the matrix is computed internally. The computation can be extracted to measure the memory required for full operation. |
### Output Parameters

**C**

Handle which contains the resulting sparse matrix. Only the upper-triangular part of the matrix is computed.

### Return Values

The function returns a value indicating whether the operation was successful, or the reason why it failed.

- **SPARSE_STATUS_SUCCESS**: The operation was successful.
- **SPARSE_STATUS_NOT_INITIALIZED**: The routine encountered an empty handle or matrix array.
- **SPARSE_STATUS_ALLOC_FAILED**: Internal memory allocation failed.
- **SPARSE_STATUS_INVALID_VALUE**: The input parameters contain an invalid value.
- **SPARSE_STATUS_EXECUTION_FAILED**: Execution failed.
- **SPARSE_STATUS_INTERNAL_ERROR**: An error in algorithm implementation occurred.
- **SPARSE_STATUS_NOT_SUPPORTED**: The requested operation is not supported.

### mkl_sparse_?_syprd

*Computes the symmetric triple product of a sparse matrix and a dense matrix and stores the result as a dense matrix.*

#### Syntax

```c
sparse_status_t mkl_sparse_s_syprd (const sparse_operation_t op, const sparse_matrix_t A, const float *B, const sparse_layout_t layoutB, const MKL_INT ldb, const float alpha, const float *C, const sparse_layout_t layoutC, const MKL_INT ldc);
```

```c
sparse_status_t mkl_sparse_d_syprd (const sparse_operation_t op, const sparse_matrix_t A, const double *B, const sparse_layout_t layoutB, const MKL_INT ldb, const double alpha, const double beta, double *C, const sparse_layout_t layoutC, const MKL_INT ldc);
```
sparse_status_t mkl_sparse_c_syprd (const sparse_operation_t op, const sparse_matrix_t A, const MKL_Complex8 *B, const sparse_layout_t layoutB, const MKL_INT ldb, const MKL_Complex8 alpha, const MKL_Complex8 *C, const sparse_layout_t layoutC, const MKL_INT ldc);

sparse_status_t mkl_sparse_z_syprd (const sparse_operation_t op, const sparse_matrix_t A, const MKL_Complex16 *B, const sparse_layout_t layoutB, const MKL_INT ldb, const MKL_Complex16 alpha, const MKL_Complex16 *C, const sparse_layout_t layoutC, const MKL_INT ldc);

Include Files
• mkl_spblas.h

Description
The mkl_sparse_?_syprd routine performs a multiplication of three sparse matrices that results in a symmetric or Hermitian matrix, C.

\[ C = \alpha A B \text{op}(A) + \beta C \] or

\[ C = \alpha \text{op}(A) B A + \beta C \]

depending on the matrix modifier operation. Here A is a sparse matrix, B and C are dense and symmetric (or Hermitian) matrices.

op is the transpose (real precision) or conjugate transpose (complex precision) operator.

NOTE
This routine is not supported for sparse matrices in COO or CSC formats. It supports only CSR and BSR formats. In addition, this routine supports only the sorted CSR and sorted BSR formats for the input matrix. If the data is unsorted, call the mkl_sparse_order routine before either mkl_sparse_sypr or mkl_sparse_?_syprd.

Input Parameters

operation

Specifies operation on the input sparse matrix.

<table>
<thead>
<tr>
<th>Sparse Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPARSE_OPERATION_NON_TRANSPOSE</td>
<td>Non-transpose case. [ C = \alpha A B \text{op}(A) + \beta C ] for real precision. [ C = \alpha \text{op}(A) B A + \beta C ] for complex precision.</td>
</tr>
<tr>
<td>SPARSE_OPERATION_TRANSPOSE</td>
<td>Transpose case. This is not supported for complex matrices. [ C = \alpha (A^T) B A + \beta C ]</td>
</tr>
</tbody>
</table>
**SPARSE_OPERATION_CONJUGATE_TRANSPOSE**

Conjugate transpose case. This is not supported for real matrices.

\[ C := \alpha (A^H) B^* A + \beta C \]

**A**

Handle which contains the sparse matrix \( A \).

**B**

Input dense matrix. Only the upper triangular part of the matrix is used for computation.

**denselayoutB**

Structure that describes the storage scheme for the dense matrix.

<table>
<thead>
<tr>
<th>SPARSE_LAYOUT_COLUMN_MAJOR</th>
<th>Store elements in a column-major layout.</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPARSE_LAYOUT_ROW_MAJOR</td>
<td>Store elements in a row-major layout.</td>
</tr>
</tbody>
</table>

**ldb**

Leading dimension of matrix \( B \).

**alpha**

Scalar parameter.

**beta**

Scalar parameter.

**NOTE**

Since the upper triangular part of matrix \( C \) is the only portion that is processed, set real values of \( \alpha \) and \( \beta \) in the complex case to obtain the Hermitian matrix.

**denselayoutC**

Structure that describes the storage scheme for the dense matrix.

<table>
<thead>
<tr>
<th>SPARSE_LAYOUT_COLUMN_MAJOR</th>
<th>Store elements in a column-major layout.</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPARSE_LAYOUT_ROW_MAJOR</td>
<td>Store elements in a row-major layout.</td>
</tr>
</tbody>
</table>

**ldc**

Leading dimension of matrix \( C \).

**Output Parameters**

**C**

Handle which contains the resulting dense matrix. Only the upper-triangular part of the matrix is computed.

**Return Values**

The function returns a value indicating whether the operation was successful, or the reason why it failed.

- **SPARSE_STATUS_SUCCESS**
  The operation was successful.

- **SPARSE_STATUS_NOT_INITIALIZED**
  The routine encountered an empty handle or matrix array.

- **SPARSE_STATUS_ALLOC_FAILED**
  The internal memory allocation failed.
The input parameters contain an invalid value.
The execution failed.
An error occurred in the implementation of the algorithm.
The requested operation is not supported.

**mkl_sparse_?_symgs**

*Computes a symmetric Gauss-Seidel preconditioner.*

**Syntax**

```c
sparse_status_t mkl_sparse_s_symgs (const sparse_operation_t operation, const sparse_matrix_t A, const struct matrix_descr descr, const float alpha, const float *b, float *x);
sparse_status_t mkl_sparse_d_symgs (const sparse_operation_t operation, const sparse_matrix_t A, const struct matrix_descr descr, const double alpha, const double *b, double *x);
sparse_status_t mkl_sparse_c_symgs (const sparse_operation_t operation, const sparse_matrix_t A, const struct matrix_descr descr, const MKL_Complex8 alpha, const MKL_Complex8 *b, MKL_Complex8 *x);
sparse_status_t mkl_sparse_z_symgs (const sparse_operation_t operation, const sparse_matrix_t A, const struct matrix_descr descr, const MKL_Complex16 alpha, const MKL_Complex16 *b, MKL_Complex16 *x);
```

**Include Files**

- mkl_spblas.h

**Description**

The **mkl_sparse_?_symgs** routine performs this operation:

\[
x_0 := x \cdot \alpha;
(L + D) \cdot x_1 = b - U \cdot x_0;
(U + D) \cdot x = b - L \cdot x_1;
\]

where \( A = L + D + U. \)

**NOTE**

This routine is not supported for sparse matrices in BSR, COO, or CSC formats. It supports only the CSR format. Additionally, only symmetric matrices are supported, so the desc.type must be SPARSE_MATRIX_TYPE_SYMMETRIC.

**Input Parameters**

- **operation**
  Specifies the operation performed on matrix \( A. \)

  \( \text{SPARSE OPERATION NON_TRANSPOSE}, \) \( \text{op}(A) := A. \)
NOTE

Transpose (SPARSE_OPERATION_TRANSPOSE) and conjugate transpose (SPARSE_OPERATION_CONJUGATE_TRANSPOSE) are not supported.

A
alpha
descr

Handle which contains the sparse matrix $A$.

Specifies the scalar $alpha$.

Structure specifying sparse matrix properties.

```c
sppr`Matrix_type_t type - Specifies the type of a sparse matrix:

SPARSE_MATRIX_TYPE_GENERAL
The matrix is processed as is.

SPARSE_MATRIX_TYPE_SYMMETRIC
The matrix is symmetric (only the requested triangle is processed).

SPARSE_MATRIX_TYPE_HERMITIAN
The matrix is Hermitian (only the requested triangle is processed).

SPARSE_MATRIX_TYPE_TRIANGULAR
The matrix is triangular (only the requested triangle is processed).

SPARSE_MATRIX_TYPE_DIAGONAL
The matrix is diagonal (only diagonal elements are processed).

SPARSE_MATRIX_TYPE_BLOCK_TRIANGULAR
The matrix is block-triangular (only requested triangle is processed). Applies to BSR format only.

SPARSE_MATRIX_TYPE_BLOCK_DIAGONAL
The matrix is block-diagonal (only diagonal blocks are processed). Applies to BSR format only.

sppr_fill_mode_t mode - Specifies the triangular matrix part for symmetric, Hermitian, triangular, and block-triangular matrices:

SPARSE_FILL_MODE_LOWER
The lower triangular matrix part is processed.

SPARSE_FILL_MODE_UPPER
The upper triangular matrix part is processed.

sppr_diag_type_t diag - Specifies diagonal type for non-general matrices:

SPARSE_DIAG_NON_UNIT
Diagonal elements might not be equal to one.

SPARSE_DIAG_UNIT
Diagonal elements are equal to one.
```

x

Array of size at least $m$, where $m$ is the number of rows of matrix $A$.

On entry, the array $x$ must contain the vector $x$.

b

Array of size at least $m$, where $m$ is the number of rows of matrix $A$.

On entry, the array $b$ must contain the vector $b$. 
Output Parameters

- **x**: Overwritten by the computed vector x.

Return Values

The function returns a value indicating whether the operation was successful or not, and why.

- **SPARSE_STATUS_SUCCESS**: The operation was successful.
- **SPARSE_STATUS_NOT_INITIALIZED**: The routine encountered an empty handle or matrix array.
- **SPARSE_STATUS_ALLOC_FAILED**: Internal memory allocation failed.
- **SPARSE_STATUS_INVALID_VALUE**: The input parameters contain an invalid value.
- **SPARSE_STATUS_EXECUTION_FAILED**: Execution failed.
- **SPARSE_STATUS_INTERNAL_ERROR**: An error in algorithm implementation occurred.
- **SPARSE_STATUS_NOT_SUPPORTED**: The requested operation is not supported.

### mkl_sparse_?_symgs_mv

*Computes a symmetric Gauss-Seidel preconditioner followed by a matrix-vector multiplication.*

#### Syntax

```c
sparse_status_t mkl_sparse_s_symgs_mv (const sparse_operation_t operation, const
sparse_matrix_t A, const struct matrix_descr descr, const float alpha, const float *b, float *x, float *y);
```

```c
sparse_status_t mkl_sparse_d_symgs_mv (const sparse_operation_t operation, const
sparse_matrix_t A, const struct matrix_descr descr, const double alpha, const double *b, double *x, double *y);
```

```c
sparse_status_t mkl_sparse_c_symgs_mv (const sparse_operation_t operation, const
sparse_matrix_t A, const struct matrix_descr descr, const MKL_Complex8 alpha, const
MKL_Complex8 *b, MKL_Complex8 *x, MKL_Complex8 *y);
```

```c
sparse_status_t mkl_sparse_z_symgs_mv (const sparse_operation_t operation, const
sparse_matrix_t A, const struct matrix_descr descr, const MKL_Complex16 alpha, const
MKL_Complex16 *b, MKL_Complex16 *x, MKL_Complex16 *y);
```

#### Include Files

- mkl_spblas.h

#### Description

The `mkl_sparse_?_symgs_mv` routine performs this operation:

\[
\begin{align*}
x_0 & := x^*\alpha; \\
(L + D) x_1 &= b - U x_0; \\
(U + D) x &= b - L x_1; \\
y & := A x
\end{align*}
\]

where \( A = L + D + U \)
NOTE
This routine is not supported for sparse matrices in BSR, COO, or CSC formats. It supports only the CSR format. Additionally, only symmetric matrices are supported, so the desc.type must be SPARSE_MATRIX_TYPE_SYMMETRIC.

Input Parameters

operation

Specifies the operation performed on input matrix.

SPARSE_OPERATION_NON_TRANSPOSE, op(A) = A.

NOTE
Transpose (SPARSE_OPERATION_TRANSPOSE) and conjugate transpose (SPARSE_OPERATION_CONJUGATE_TRANSPOSE) are not supported.

A

Handle which contains the sparse matrix A.

alpha

Specifies the scalar alpha.

descr

Structure specifying sparse matrix properties.

sparse_matrix_type_t type - Specifies the type of a sparse matrix:

SPARSE_MATRIX_TYPE_GENERAL The matrix is processed as is.

SPARSE_MATRIX_TYPE_SYMMETRIC The matrix is symmetric (only the requested triangle is processed).

SPARSE_MATRIX_TYPE_HERMITIAN The matrix is Hermitian (only the requested triangle is processed).

SPARSE_MATRIX_TYPE_TRIANGULAR The matrix is triangular (only the requested triangle is processed).

SPARSE_MATRIX_TYPE_DIAGONAL The matrix is diagonal (only diagonal elements are processed).

SPARSE_MATRIX_TYPE_BLOCK_TRIANGULAR The matrix is block-triangular (only requested triangle is processed). Applies to BSR format only.

SPARSE_MATRIX_TYPE_BLOCK_DIAGONAL The matrix is block-diagonal (only diagonal blocks are processed). Applies to BSR format only.

sparse_fill_mode_t mode - Specifies the triangular matrix part for symmetric, Hermitian, triangular, and block-triangular matrices:

SPARSE_FILL_MODE_LOWER The lower triangular matrix part is processed.

SPARSE_FILL_MODE_UPPER The upper triangular matrix part is processed.

sparse_diag_type_t diag - Specifies diagonal type for non-general matrices:
SPARSE_DIAG_NON_UNIT  Diagonal elements might not be equal to one.
SPARSE_DIAG_UNIT    Diagonal elements are equal to one.

x
Array of size at least \( m \), where \( m \) is the number of rows of matrix \( A \).
On entry, the array \( x \) must contain the vector \( x \).

b
Array of size at least \( m \), where \( m \) is the number of rows of matrix \( A \).
On entry, the array \( b \) must contain the vector \( b \).

**Output Parameters**

\( x \)
Overwritten by the computed vector \( x \).

\( y \)
Array of size at least \( m \), where \( m \) is the number of rows of matrix \( A \).
Overwritten by the computed vector \( y \).

**Return Values**
The function returns a value indicating whether the operation was successful or not, and why.

SPARSE_STATUS_SUCCESS  The operation was successful.
SPARSE_STATUS_NOT_INITIALIZED  The routine encountered an empty handle or matrix array.
SPARSE_STATUS_ALLOC_FAILED  Internal memory allocation failed.
SPARSE_STATUS_INVALID_VALUE  The input parameters contain an invalid value.
SPARSE_STATUS_EXECUTION_FAILED  Execution failed.
SPARSE_STATUS_INTERNAL_ERROR  An error in algorithm implementation occurred.
SPARSE_STATUS_NOT_SUPPORTED  The requested operation is not supported.

**mkl_sparse_syrk**

*Computes the product of sparse matrix with its transpose (or conjugate transpose) and stores the result in a newly allocated sparse matrix.*

**Syntax**

```c
sparse_status_t mkl_sparse_syrk (const sparse_operation_t operation, const sparse_matrix_t A, sparse_matrix_t *C);
```

**Include Files**
- mkl_spblas.h

**Description**
The mkl_sparse_syrk routine performs a sparse matrix-matrix operation which results in a sparse matrix \( C \) that is either Symmetric (real) or Hermitian (complex):

\[ C := A \ast op(A) \]

where \( op(\ast) \) is the transpose for real matrices and conjugate transpose for complex matrices OR

\[ C := op(A) \ast A \]
depending on the matrix modifier \( op \) which can be the transpose for real matrices or conjugate transpose for complex matrices.

Here, \( A \) and \( C \) are sparse matrices.

**NOTE** This routine is not supported for sparse matrices in COO or CSC formats. It supports only CSR and BSR formats. Additionally, this routine supports only the sorted CSR and sorted BSR formats for the input matrix. If data is unsorted, call the `mkl_sparse_order` routine before either `mkl_sparse_syrk` or `mkl_sparse_\?_syrkd`.

### Input Parameters

**operation**

Specifies the operation \( op() \) on input matrix.

- `SPARSE_OPERATION_NON_TRANSPOSE`, Non-transpose, \( C := A \cdot op(A) \) where \( op(*) \) is the transpose for real matrices and conjugate transpose for complex matrices
- `SPARSE_OPERATION_TRANSPOSE`, Transpose, \( C := (A^T) \cdot A \) for real matrix \( A \)
- `SPARSE_OPERATION_CONJUGATE_TRANSPOSE`, Conjugate transpose, \( C := (A^H) \cdot A \) for complex matrix \( A \).

**A**

Handle which contains the sparse matrix \( A \).

### Output Parameters

**C**

Handle which contains the resulting sparse matrix. Only the upper-triangular part of the matrix is computed.

### Return Values

The function returns a value indicating whether the operation was successful or not, and why.

- `SPARSE_STATUS_SUCCESS` The operation was successful.
- `SPARSE_STATUS_NOT_INITIALIZED` The routine encountered an empty handle or matrix array.
- `SPARSE_STATUS_ALLOC_FAILED` Internal memory allocation failed.
- `SPARSE_STATUS_INVALID_VALUE` The input parameters contain an invalid value.
- `SPARSE_STATUS_EXECUTION_FAILED` Execution failed.
- `SPARSE_STATUS_INTERNAL_ERROR` An error in algorithm implementation occurred.
- `SPARSE_STATUS_NOT_SUPPORTED` The requested operation is not supported.

### mkl_sparse_\?_syrkd

Computes the product of sparse matrix with its transpose (or conjugate transpose) and stores the result as a dense matrix.

**Syntax**

```c
sparse_status_t mkl_sparse_s_syrkd(sparse_operation_t operation, const sparse_matrix_t A, float alpha, float beta, float *C, sparse_layout_t layout, MKL_INT ldc);
```
sparse_status_t mkl_sparse_d_syrkd (sparse_operation_t operation, const sparse_matrix_t A, double alpha, double beta, double *C, sparse_layout_t layout, MKL_INT ldc);
sparse_status_t mkl_sparse_c_syrkd (sparse_operation_t operation, const sparse_matrix_t A, const MKL_Complex8 alpha, MKL_Complex8 beta, MKL_Complex8 *C, sparse_layout_t layout, MKL_INT ldc);
sparse_status_t mkl_sparse_z_syrkd (sparse_operation_t operation, const sparse_matrix_t A, MKL_Complex16 alpha, MKL_Complex16 beta, MKL_Complex16 *C, sparse_layout_t layout, const MKL_INT ldc);

Include Files

- mkl_spblas.h

Description

The mkl_sparse_?_syrkd routine performs a sparse matrix-matrix operation which results in a dense matrix \( C \) that is either symmetric (real case) or Hermitian (complex case):

\[
C := \beta C + \alpha A \cdot \text{op}(A)
\]

or

\[
C := \beta C + \alpha \cdot \text{op}(A) \cdot A
\]

depending on the matrix modifier \( \text{op} \) which can be the transpose for real matrices or conjugate transpose for complex matrices. Here, \( A \) is a sparse matrix and \( C \) is a dense matrix.

**NOTE** This routine is not supported for sparse matrices in COO or CSC formats. It supports only CSR and BSR formats. Additionally, this routine supports only the sorted CSR and sorted BSR formats for the input matrix. If data is unsorted, call the mkl_sparse_order routine before either mkl_sparse_syrk or mkl_sparse_?_syrkd.

Input Parameters

- **operation**: Specifies the operation \( \text{op()} \) performed on the input matrix.
  
  \( \text{SPARSE_OPERATION_NON_TRANSPOSE} \), Non-transpose, \( C := \beta C + \alpha A \cdot \text{op}(A) \) where \( \text{op}(*) \) is the transpose (real matrices) or conjugate transpose (complex matrices).

  \( \text{SPARSE_OPERATION_TRANSPOSE} \), Transpose, \( C := \beta C + \alpha A^T \cdot A \) for real matrix \( A \).

  \( \text{SPARSE_OPERATION_CONJUGATE_TRANSPOSE} \), Conjugate transpose, \( C := \beta C + \alpha A^H \cdot A \) for complex matrix \( A \).

- **A**: Handle which contains the sparse matrix \( A \).

- **alpha**: Scalar parameter \( \alpha \).

- **beta**: Scalar parameter \( \beta \).

- **layout**: Describes the storage scheme for the dense matrix.
  
  \( \text{layout} = \text{SPARSE_LAYOUT_COLUMN_MAJOR} \) Storage of elements uses column-major layout.
Storage of elements uses row-major layout.

leadc

Leading dimension of matrix C.

NOTE
Only the upper triangular part of matrix C is processed. Therefore, you must set real values of alpha and beta for complex matrices in order to obtain a Hermitian matrix.

Output Parameters

C

Resulting dense matrix. Only the upper triangular part of the matrix is computed.

Return Values

The function returns a value indicating whether the operation was successful or not, and why.

SPARSE_STATUS_SUCCESS
The operation was successful.

SPARSE_STATUS_NOT_INITIALIZED
The routine encountered an empty handle or matrix array.

SPARSE_STATUS_ALLOC_FAILED
Internal memory allocation failed.

SPARSE_STATUS_INVALID_VALUE
The input parameters contain an invalid value.

SPARSE_STATUS_EXECUTION_FAILED
Execution failed.

SPARSE_STATUS_INTERNAL_ERROR
An error in algorithm implementation occurred.

SPARSE_STATUS_NOT_SUPPORTED
The requested operation is not supported.

mkl_sparse_?_dotmv
Computes a sparse matrix-vector product followed by a dot product.

Syntax

sparse_status_t mkl_sparse_s_dotmv (const sparse_operation_t operation, const float alpha, const sparse_matrix_t A, const struct matrix_descr descr, const float *x, const float beta, float *y, float *d);
sparse_status_t mkl_sparse_d_dotmv (const sparse_operation_t operation, const double alpha, const sparse_matrix_t A, const struct matrix_descr descr, const double *x, const double beta, double *y, double *d);
sparse_status_t mkl_sparse_c_dotmv (const sparse_operation_t operation, const MKL_Complex8 alpha, const sparse_matrix_t A, const struct matrix_descr descr, const MKL_Complex8 *x, const MKL_Complex8 beta, MKL_Complex8 *y, MKL_Complex8 *d);
sparse_status_t mkl_sparse_z_dotmv (const sparse_operation_t operation, const MKL_Complex16 alpha, const sparse_matrix_t A, const struct matrix_descr descr, const MKL_Complex16 *x, const MKL_Complex16 beta, MKL_Complex16 *y, MKL_Complex16 *d);

Include Files

- mkl_spblas.h
Description
The mkl_sparse_?_dotmv routine computes a sparse matrix-vector product and dot product:

\[ y := \alpha \cdot \text{op}(A) \cdot x + \beta \cdot y \]
\[ d := \sum_i \text{conj}(x_i) \cdot y_i \] (real case)
\[ d := \sum_i x_i \cdot y_i \] (complex case)

where
- \( \alpha \) and \( \beta \) are scalars.
- \( x \) and \( y \) are vectors.
- \( A \) is an \( m \)-by-\( k \) matrix.
- \( \text{conj} \) represents complex conjugation.
- \( \text{op}(A) \) is a matrix modifier.

Available options for \( \text{op}(A) \) are \( A \), \( A^T \), or \( A^H \).

NOTE
For sparse matrices in the BSR format, the supported combinations of \( \text{(indexing,block\_layout)} \) are:
- \( \text{(SPARSE\_INDEX\_BASE\_ZERO, SPARSE\_LAYOUT\_ROW\_MAJOR) } \)
- \( \text{(SPARSE\_INDEX\_BASE\_ONE, SPARSE\_LAYOUT\_COLUMN\_MAJOR) } \)

Input Parameters

- **operation**
  Specifies the operation performed on matrix \( A \).
  - If \( \text{operation} = \text{SPARSE\_OPERATION\_NON\_TRANSPOSE} \), \( \text{op}(A) = A \).
  - If \( \text{operation} = \text{SPARSE\_OPERATION\_TRANSPOSE} \), \( \text{op}(A) = A^T \).
  - If \( \text{operation} = \text{SPARSE\_OPERATION\_CONJUGATE\_TRANSPOSE} \), \( \text{op}(A) = A^H \).

- **alpha**
  Specifies the scalar \( \alpha \).

- **A**
  Handle which contains the sparse matrix \( A \).

- **descr**
  Structure specifying sparse matrix properties.
  - **type** - Specifies the type of a sparse matrix:
    - \( \text{SPARSE\_MATRIX\_TYPE\_GENERAL} \) - The matrix is processed as is.
    - \( \text{SPARSE\_MATRIX\_TYPE\_SYMMETRIC} \) - The matrix is symmetric (only the requested triangle is processed).
    - \( \text{SPARSE\_MATRIX\_TYPE\_HERMITIAN} \) - The matrix is Hermitian (only the requested triangle is processed).
    - \( \text{SPARSE\_MATRIX\_TYPE\_TRIANGULAR} \) - The matrix is triangular (only the requested triangle is processed).
    - \( \text{SPARSE\_MATRIX\_TYPE\_DIAGONAL} \) - The matrix is diagonal (only diagonal elements are processed).
    - \( \text{SPARSE\_MATRIX\_TYPE\_BLOCK\_TRIANGULAR} \) - The matrix is block-triangular (only requested triangle is processed). Applies to BSR format only.
SPARSE_MATRIX_TYPE_BLOCK_DIAGONAL The matrix is block-diagonal (only diagonal blocks are processed). Applies to BSR format only.

sparse_fill_mode_t mode - Specifies the triangular matrix part for symmetric, Hermitian, triangular, and block-triangular matrices:
- SPARSE_FILL_MODE_LOWER The lower triangular matrix part is processed.
- SPARSE_FILL_MODE_UPPER The upper triangular matrix part is processed.

sparse_diag_type_t diag - Specifies diagonal type for non-general matrices:
- SPARSE_DIAG_NON_UNIT Diagonal elements might not be equal to one.
- SPARSE_DIAG_UNIT Diagonal elements are equal to one.

If operation = SPARSE_OPERATION_NON_TRANSPOSE, array of size at least \( k \), where \( k \) is the number of columns of matrix \( A \).
Otherwise, array of size at least \( m \), where \( m \) is the number of rows of matrix \( A \).
On entry, the array \( x \) must contain the vector \( x \).

beta Specifies the scalar \( \beta \).

If operation = SPARSE_OPERATION_NON_TRANSPOSE, array of size at least \( m \), where \( m \) is the number of rows of matrix \( A \).
Otherwise, array of size at least \( k \), where \( k \) is the number of columns of matrix \( A \).
On entry, the array \( y \) must contain the vector \( y \).

Output Parameters
- \( y \) Overwritten by the updated vector \( y \).
- \( d \) Overwritten by the dot product of \( x \) and \( y \).

Return Values
The function returns a value indicating whether the operation was successful or not, and why.
- SPARSE_STATUS_SUCCESS The operation was successful.
- SPARSE_STATUS_NOT_INITIALIZED The routine encountered an empty handle or matrix array.
- SPARSE_STATUS_ALLOC_FAILED Internal memory allocation failed.
- SPARSE_STATUS_INVALID_VALUE The input parameters contain an invalid value.
- SPARSE_STATUS_EXECUTION_FAILED Execution failed.
- SPARSE_STATUS_INTERNAL_ERROR An error in algorithm implementation occurred.
- SPARSE_STATUS_NOT_SUPPORTED The requested operation is not supported.
## BLAS-like Extensions

provides C and Fortran routines to extend the functionality of the BLAS routines. These include routines to compute vector products, matrix-vector products, and matrix-matrix products.

also provides routines to perform certain data manipulation, including matrix in-place and out-of-place transposition operations combined with simple matrix arithmetic operations. Transposition operations are Copy As Is, Conjugate transpose, Transpose, and Conjugate. Each routine adds the possibility of scaling during the transposition operation by giving some \( \alpha \) and/or \( \beta \) parameters. Each routine supports both row-major orderings and column-major orderings.

Table "BLAS-like Extensions" lists these routines.

The \(<\? >\) symbol in the routine short names is a precision prefix that indicates the data type:

\[
\begin{align*}
  s & \quad \text{float} \\
  d & \quad \text{double} \\
  c & \quad \text{MKL Complex8} \\
  z & \quad \text{MKL Complex16}
\end{align*}
\]

</table>
### Routine | Data Types | Description
--- | --- | ---
`cblas_?gemm_pack` | s, d | Performs scaling and packing of the matrix into the previously allocated buffer.
`cblas_gemm_*_pack` | integer | Pack the matrix into the buffer allocated previously.
`cblas_?gemm_compute` | s, d | Computes a matrix-matrix product with general matrices where one or both input matrices are stored in a packed data structure and adds the result to a scalar-matrix product.
`cblas_gemm_*_compute` | integer | Computes a matrix-matrix product with general integer matrices where one or both input matrices are stored in a packed data structure and adds the result to a scalar-matrix product.
`cblas_?gemm_free` | s, d | Frees the storage previously allocated for the packed matrix.
`cblas_gemm_*` | integer | Computes a matrix-matrix product with general integer matrices.

### cblas_?axpby

**Scales two vectors, adds them to one another and stores result in the vector.**

#### Syntax

```c
void cblas_saxpby (const MKL_INT n, const float a, const float *x, const MKL_INT incx, const float b, float *y, const MKL_INT incy);
void cblas_daxpby (const MKL_INT n, const double a, const double *x, const MKL_INT incx, const double b, double *y, const MKL_INT incy);
void cblas_caxpby (const MKL_INT n, const void *a, const void *x, const MKL_INT incx, const void *b, void *y, const MKL_INT incy);
void cblas_zaxpby (const MKL_INT n, const void *a, const void *x, const MKL_INT incx, const void *b, void *y, const MKL_INT incy);
```

#### Include Files

- mkl.h

#### Description

The ?axpby routines perform a vector-vector operation defined as

\[ y := a \cdot x + b \cdot y \]

where:

- `a` and `b` are scalars
- `x` and `y` are vectors each with `n` elements.

#### Input Parameters

- `n` Specifies the number of elements in vectors `x` and `y`. 
a  
Specifies the scalar \( a \).

x  
Array, size at least \((1 + (n-1) \times \text{abs(incx)})\).

\( \text{incx} \)  
Specifies the increment for the elements of \( x \).

b  
Specifies the scalar \( b \).

y  
Array, size at least \((1 + (n-1) \times \text{abs(incy)})\).

\( \text{incy} \)  
Specifies the increment for the elements of \( y \).

Output Parameters

\( y \)  
Contains the updated vector \( y \).

Example

For examples of routine usage, see these code examples in the Intel® MKL installation directory:

- cblas_saxpby: examples\cblas\source\cblas_saxpbyx.c
- cblas_daxpby: examples\cblas\source\cblas_daxpbyx.c
- cblas_caxpby: examples\cblas\source\cblas_caxpbyx.c
- cblas_zaxpby: examples\cblas\source\cblas_zaxpbyx.c

\textbf{cblas} \_\textbf{?}gemmt}  
\textit{Computes a matrix-matrix product with general matrices but updates only the upper or lower triangular part of the result matrix.}

\textbf{Syntax}

\begin{verbatim}

const void *alpha, const void *a, const MKL_INT lda, const void *b, const MKL_INT 
ldb, const void *beta, void *c, const MKL_INT ldc);
\end{verbatim}

\textbf{Include Files}

- mkl.h
Description

The ?gemmt routines compute a scalar-matrix-matrix product with general matrices and add the result to the upper or lower part of a scalar-matrix product. These routines are similar to the ?gemm routines, but they only access and update a triangular part of the square result matrix (see Application Notes below).

The operation is defined as

\[ C := \alpha \cdot \text{op}(A) \cdot \text{op}(B) + \beta \cdot C, \]

where:

- \( \text{op}(X) \) is one of \( \text{op}(X) = X \), or \( \text{op}(X) = X^T \), or \( \text{op}(X) = X^H \),
- \( \alpha \) and \( \beta \) are scalars,
- \( A \), \( B \) and \( C \) are matrices:
  - \( \text{op}(A) \) is an \( n \)-by-\( k \) matrix,
  - \( \text{op}(B) \) is a \( k \)-by-\( n \) matrix,
  - \( C \) is an \( n \)-by-\( n \) upper or lower triangular matrix.

Input Parameters

- **Layout**
  Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).

- **uplo**
  Specifies whether the upper or lower triangular part of the array \( c \) is used. If \( \text{uplo} = \text{'CblasUpper'} \), then the upper triangular part of the array \( c \) is used. If \( \text{uplo} = \text{'CblasLower'} \), then the lower triangular part of the array \( c \) is used.

- **transa**
  Specifies the form of \( \text{op}(A) \) used in the matrix multiplication:
  - if \( \text{transa} = \text{'CblasNoTrans'} \), then \( \text{op}(A) = A \);
  - if \( \text{transa} = \text{'CblasTrans'} \), then \( \text{op}(A) = A^T \);
  - if \( \text{transa} = \text{'CblasConjTrans'} \), then \( \text{op}(A) = A^H \).

- **transb**
  Specifies the form of \( \text{op}(B) \) used in the matrix multiplication:
  - if \( \text{transb} = \text{'CblasNoTrans'} \), then \( \text{op}(B) = B \);
  - if \( \text{transb} = \text{'CblasTrans'} \), then \( \text{op}(B) = B^T \);
  - if \( \text{transb} = \text{'CblasConjTrans'} \), then \( \text{op}(B) = B^H \).

- **n**
  Specifies the order of the matrix \( C \). The value of \( n \) must be at least zero.

- **k**
  Specifies the number of columns of the matrix \( \text{op}(A) \) and the number of rows of the matrix \( \text{op}(B) \). The value of \( k \) must be at least zero.

- **alpha**
  Specifies the scalar \( \alpha \).

- **a**

\hline
\end{array}
\]

\text{beta}

Specifies the scalar } beta \text{. When } beta \text{ is equal to zero, then } c \text{ need not be set on input.

\text{c}

Array, size } ldc \text{ by } n.
When \( \beta \) is equal to zero, \( c \) need not be set on input.

<table>
<thead>
<tr>
<th>( \text{uplo} = 'CblasUpper' )</th>
<th>( \text{uplo} = 'CblasLower' )</th>
</tr>
</thead>
<tbody>
<tr>
<td>The leading ( n )-by-( n ) upper triangular part of the array ( c ) must contain the upper triangular part of the matrix ( C ) and the strictly lower triangular part of ( c ) is not referenced.</td>
<td>The leading ( n )-by-( n ) lower triangular part of the array ( c ) must contain the lower triangular part of the matrix ( C ) and the strictly upper triangular part of ( c ) is not referenced.</td>
</tr>
</tbody>
</table>

\( \text{ldc} \)

Specifies the leading dimension of \( c \) as declared in the calling (sub)program. The value of \( \text{ldc} \) must be at least \( \max(1, n) \).

### Output Parameters

\( c \)

- When \( \text{uplo} = 'CblasUpper' \), the upper triangular part of the array \( c \) is overwritten by the upper triangular part of the updated matrix.
- When \( \text{uplo} = 'CblasLower' \), the lower triangular part of the array \( c \) is overwritten by the lower triangular part of the updated matrix.

### Application Notes

These routines only access and update the upper or lower triangular part of the result matrix. This can be useful when the result is known to be symmetric; for example, when computing a product of the form \( C := \alpha A S B^T + \beta C \), where \( S \) and \( C \) are symmetric matrices and \( B \) is a general matrix. In this case, first compute \( A := B S \) (which can be done using the corresponding \(?\text{symm}\) routine), then compute \( C := \alpha A B^T + \beta C \) using the \(?\text{gemm}\) routine.

### \text{cblas}\_?gemm3m

**Computes a scalar-matrix-matrix product using matrix multiplications and adds the result to a scalar-matrix product.**

### Syntax

```c
void cblas_cgemm3m (const CBLAS_LAYOUT Layout, const CBLAS_TRANSPOSE transa, const CBLAS_TRANSPOSE transb, const MKL_INT m, const MKL_INT n, const MKL_INT k, const void *alpha, const void *a, const MKL_INT lda, const void *b, const MKL_INT ldb, const void *beta, void *c, const MKL_INT ldc);

void cblas_zgemm3m (const CBLAS_LAYOUT Layout, const CBLAS_TRANSPOSE transa, const CBLAS_TRANSPOSE transb, const MKL_INT m, const MKL_INT n, const MKL_INT k, const void *alpha, const void *a, const MKL_INT lda, const void *b, const MKL_INT ldb, const void *beta, void *c, const MKL_INT ldc);
```

### Include Files

- \text{mkl.h}

### Description

The \(?\text{gemm3m}\) routines perform a matrix-matrix operation with general complex matrices. These routines are similar to the \(?\text{gemm}\) routines, but they use fewer matrix multiplication operations (see \text{Application Notes} below).
The operation is defined as
\[ C := \alpha \cdot \text{op}(A) \cdot \text{op}(B) + \beta \cdot C, \]

where:
- \( \text{op}(x) \) is one of \( \text{op}(x) = x \), or \( \text{op}(x) = x' \), or \( \text{op}(x) = \text{conjg}(x') \),
- \( \alpha \) and \( \beta \) are scalars,
- \( A \), \( B \), and \( C \) are matrices:
  - \( \text{op}(A) \) is an \( m \)-by-\( k \) matrix,
  - \( \text{op}(B) \) is a \( k \)-by-\( n \) matrix,
  - \( C \) is an \( m \)-by-\( n \) matrix.

**Input Parameters**

**Layout**

Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).

**transa**

Specifies the form of \( \text{op}(A) \) used in the matrix multiplication:
- if \( \text{transa} = \text{CblasNoTrans} \), then \( \text{op}(A) = A \);
- if \( \text{transa} = \text{CblasTrans} \), then \( \text{op}(A) = A' \);
- if \( \text{transa} = \text{CblasConjTrans} \), then \( \text{op}(A) = \text{conjg}(A') \).

**transb**

Specifies the form of \( \text{op}(B) \) used in the matrix multiplication:
- if \( \text{transb} = \text{CblasNoTrans} \), then \( \text{op}(B) = B \);
- if \( \text{transb} = \text{CblasTrans} \), then \( \text{op}(B) = B' \);
- if \( \text{transb} = \text{CblasConjTrans} \), then \( \text{op}(B) = \text{conjg}(B') \).

**m**

Specifies the number of rows of the matrix \( \text{op}(A) \) and of the matrix \( C \). The value of \( m \) must be at least zero.

**n**

Specifies the number of columns of the matrix \( \text{op}(B) \) and the number of columns of the matrix \( C \).

The value of \( n \) must be at least zero.

**k**

 Specifies the number of columns of the matrix \( \text{op}(A) \) and the number of rows of the matrix \( \text{op}(B) \).

The value of \( k \) must be at least zero.

**alpha**

Specifies the scalar \( \alpha \).

**a**

<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>CblasRowMajor</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Output Parameters

- c
  Overwritten by the m-by-n matrix \((\alpha \cdot \text{op}(A) \cdot \text{op}(B) + \beta \cdot C)\).

Application Notes

These routines perform a complex matrix multiplication by forming the real and imaginary parts of the input matrices. This uses three real matrix multiplications and five real matrix additions instead of the conventional four real matrix multiplications and two real matrix additions. The use of three real matrix multiplications reduces the time spent in matrix operations by 25%, resulting in significant savings in compute time for large matrices.

If the errors in the floating point calculations satisfy the following conditions:

\[ f_l(x \text{ op } y) = (x \text{ op } y)(1 + \delta), |\delta| \leq u, \text{ op} = \times, /, f_l(x \pm y) = x(1 + \alpha) \pm y(1 + \beta), |\alpha|, |\beta| \leq u \]

then for an n-by-n matrix \( \hat{C} = f_l(C_1 + iC_2) = f_l((A_1 + iA_2)(B_1 + iB_2)) = C_1 + iC_2 \), the following bounds are satisfied:

\[ \|C_1 - \hat{C}_1\| \leq 2(n+1)u\|A\|_\infty\|B\|_\infty + O(u^2), \]
\[ \|C_2 - \hat{C}_2\| \leq 4(n+4)u\|A\|_\infty\|B\|_\infty + O(u^2), \]

where \( \|A\|_\infty = \max(\|A_1\|_\infty, \|A_2\|_\infty) \), and \( \|B\|_\infty = \max(\|B_1\|_\infty, \|B_2\|_\infty) \).

Thus the corresponding matrix multiplications are stable.

cblas_?gemm_batch

*Computes scalar-matrix-matrix products and adds the results to scalar matrix products for groups of general matrices.*

Syntax

```c
void cblas_sgemm_batch (const CBLAS_LAYOUT Layout, const CBLAS_TRANSPOSE* transa_array, const CBLAS_TRANSPOSE* transb_array, const MKL_INT* m_array, const MKL_INT* n_array, const MKL_INT* k_array, const float* alpha_array, const float **a_array, const MKL_INT*...

Include Files
• mkl.h

Description
The ?gemm_batch routines perform a series of matrix-matrix operations with general matrices. They are
similar to the ?gemm routine counterparts, but the ?gemm_batch routines perform matrix-matrix operations
with groups of matrices, processing a number of groups at once. The groups contain matrices with the same
parameters.

The operation is defined as

```c
idx = 0
for i = 0..group_count - 1
    alpha and beta in alpha_array[i] and beta_array[i]
    for j = 0..group_size[i] - 1
        A, B, and C matrix in a_array[idx], b_array[idx], and c_array[idx]
        C := alpha*op(A)*op(B) + beta*C,
        idx = idx + 1
    end for
end for
```

where:

- \( \text{op}(X) \) is one of \( \text{op}(X) = X, \text{op}(X) = X^T, \) or \( \text{op}(X) = X^H, \)
- \( \alpha \) and \( \beta \) are scalar elements of \( \text{alpha_array} \) and \( \text{beta_array} \),
- \( A, B \) and \( C \) are matrices such that for \( m, n, \) and \( k \) which are elements of \( m_array, n_array, \) and \( k_array \):
  - \( \text{op}(A) \) is an \( m \)-by-\( k \) matrix,
  - \( \text{op}(B) \) is a \( k \)-by-\( n \) matrix,
  - \( C \) is an \( m \)-by-\( n \) matrix.
A, B, and C represent matrices stored at addresses pointed to by a_array, b_array, and c_array, respectively. The number of entries in a_array, b_array, and c_array is total_batch_count = the sum of all of the group_size entries.

See also gemm for a detailed description of multiplication for general matrices and ?gemm3m_batch, BLAS-like extension routines for similar matrix-matrix operations.

NOTE
Error checking is not performed for Windows* single dynamic libraries for the ?gemm_batch routines.

Input Parameters

Layout
Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).

tansa_array
Array of size group_count. For the group i, transa_i = transa_array[i] specifies the form of op(A) used in the matrix multiplication:

if transa_i = CblasNoTrans, then op(A) = A;
if transa_i = CblasTrans, then op(A) = A^T;
if transa_i = CblasConjTrans, then op(A) = A^H.

transb_array
Array of size group_count. For the group i, transb_i = transb_array[i] specifies the form of op(B_i) used in the matrix multiplication:

if transb_i = CblasNoTrans, then op(B) = B;
if transb_i = CblasTrans, then op(B) = B^T;
if transb_i = CblasConjTrans, then op(B) = B^H.

m_array
Array of size group_count. For the group i, m_i = m_array[i] specifies the number of rows of the matrix op(A) and of the matrix C.

The value of each element of m_array must be at least zero.

n_array
Array of size group_count. For the group i, n_i = n_array[i] specifies the number of columns of the matrix op(B) and the number of columns of the matrix C.

The value of each element of n_array must be at least zero.

k_array
Array of size group_count. For the group i, k_i = k_array[i] specifies the number of columns of the matrix op(A) and the number of rows of the matrix op(B).

The value of each element of k_array must be at least zero.

alpha_array
Array of size group_count. For the group i, alpha_array[i] specifies the scalar alpha_i.

a_array
Array, size total_batch_count, of pointers to arrays used to store A matrices.
lda_array

Array of size group_count. For the group i, lda_i = lda_array[i] specifies the leading dimension of the array storing matrix A as declared in the calling (sub)program.

<table>
<thead>
<tr>
<th></th>
<th>transa_i=CblasNoTrans</th>
<th>transa_i=CblasTrans or transa_i=CblasConjTrans</th>
</tr>
</thead>
<tbody>
<tr>
<td>Layout = CblasColMajor</td>
<td>lda_i must be at least max(1, m_i).</td>
<td>lda_i must be at least max(1, k_i).</td>
</tr>
<tr>
<td>Layout = CblasRowMajor</td>
<td>lda_i must be at least max(1, k_i).</td>
<td>lda_i must be at least max(1, m_i).</td>
</tr>
</tbody>
</table>

b_array

Array, size total_batch_count, of pointers to arrays used to store B matrices.

ldb_array

Array of size group_count. For the group i, ldb_i = ldb_array[i] specifies the leading dimension of the array storing matrix B as declared in the calling (sub)program.

<table>
<thead>
<tr>
<th></th>
<th>transb_i=CblasNoTrans</th>
<th>transb_i=CblasTrans or transb_i=CblasConjTrans</th>
</tr>
</thead>
<tbody>
<tr>
<td>Layout = CblasColMajor</td>
<td>ldb_i must be at least max(1, k_i).</td>
<td>ldb_i must be at least max(1, n_i).</td>
</tr>
<tr>
<td>Layout = CblasRowMajor</td>
<td>ldb_i must be at least max(1, n_i).</td>
<td>ldb_i must be at least max(1, k_i).</td>
</tr>
</tbody>
</table>

beta_array

Array of size group_count. For the group i, beta_array[i] specifies the scalar beta_i.

When beta_i is equal to zero, then C matrices in group i need not be set on input.

c_array

Array, size total_batch_count, of pointers to arrays used to store C matrices.

ldc_array

Array of size group_count. For the group i, ldc_i = ldc_array[i] specifies the leading dimension of all arrays storing matrix C in group i as declared in the calling (sub)program.

When Layout = CblasColMajor ldc_i must be at least max(1, m_i).

When Layout = CblasRowMajor ldc_i must be at least max(1, n_i).

group_count

Specifies the number of groups. Must be at least 0.

group_size

Array of size group_count. The element group_size[i] specifies the number of matrices in group i. Each element in group_size must be at least 0.

Output Parameters

c_array

Output buffer, overwritten by total_batch_count matrix multiply operations of the form alpha*op(A)*op(B) + beta*C.
**cblas_?gemm3m_batch**

Computes scalar-matrix-matrix products and adds the results to scalar matrix products for groups of general matrices.

**Syntax**

```c
void cblas_cgemm3m_batch
(const CBLAS_LAYOUT Layout,
 const CBLAS_TRANSPOSE* transa_array,
 const CBLAS_TRANSPOSE* transb_array,

**Description**

The ?gemm3m_batch routines perform a series of matrix-matrix operations with general matrices. They are similar to the ?gemm3m routine counterparts, but the ?gemm3m_batch routines perform matrix-matrix operations with groups of matrices, processing a number of groups at once. The groups contain matrices with the same parameters. The ?gemm3m_batch routines use fewer matrix multiplications than the ?gemm_batch routines, as described in the Application Notes.

The operation is defined as

```c
idx = 0
for i = 0..group_count - 1
    alpha and beta in alpha_array[i] and beta_array[i]
    for j = 0..group_size[i] - 1
        A, B, and C matrix in a_array[idx], b_array[idx], and c_array[idx]
        C := alpha*op(A)*op(B) + beta*C,
        idx = idx + 1
    end for
end for
```

where:

- \( \text{op}(X) \) is one of \( \text{op}(X) = X, \text{op}(X) = X^T, \text{or} \ \text{op}(X) = X^H \),
- \( \alpha \) and \( \beta \) are scalar elements of \( \text{alpha_array} \) and \( \text{beta_array} \),
- \( A, B \) and \( C \) are matrices such that for \( m, n, \) and \( k \) which are elements of \( \text{m_array}, \text{n_array}, \) and \( \text{k_array} \):
  - \( \text{op}(A) \) is an \( m\times k \) matrix,
  - \( \text{op}(B) \) is a \( k\times n \) matrix,
  - \( C \) is an \( m\times n \) matrix.
$A$, $B$, and $C$ represent matrices stored at addresses pointed to by $a\_array$, $b\_array$, and $c\_array$, respectively. The number of entries in $a\_array$, $b\_array$, and $c\_array$ is $total\_batch\_count = \text{the sum of all the group size entries}$.

See also gemm for a detailed description of multiplication for general matrices and gemm\_batch, BLAS-like extension routines for similar matrix-matrix operations.

**NOTE**

Error checking is not performed for Intel® MKL Windows® single dynamic libraries for the ?gemm3m\_batch routines.

### Input Parameters

**Layout**

Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).

**transa\_array**

Array of size $group\_count$. For the group $i$, $transa_i = transa\_array[i]$ specifies the form of $\text{op} (A)$ used in the matrix multiplication:

- if $transa_i = \text{CblasNoTrans}$, then $\text{op} (A) = A$;
- if $transa_i = \text{CblasTrans}$, then $\text{op} (A) = A^T$;
- if $transa_i = \text{CblasConjTrans}$, then $\text{op} (A) = A^H$.

**transb\_array**

Array of size $group\_count$. For the group $i$, $transb_i = transb\_array[i]$ specifies the form of $\text{op} (B_i)$ used in the matrix multiplication:

- if $transb_i = \text{CblasNoTrans}$, then $\text{op} (B) = B$;
- if $transb_i = \text{CblasTrans}$, then $\text{op} (B) = B^T$;
- if $transb_i = \text{CblasConjTrans}$, then $\text{op} (B) = B^H$.

**m\_array**

Array of size $group\_count$. For the group $i$, $m_i = m\_array[i]$ specifies the number of rows of the matrix $\text{op} (A)$ and of the matrix $C$.

The value of each element of $m\_array$ must be at least zero.

**n\_array**

Array of size $group\_count$. For the group $i$, $n_i = n\_array[i]$ specifies the number of columns of the matrix $\text{op} (B)$ and the number of columns of the matrix $C$.

The value of each element of $n\_array$ must be at least zero.

**k\_array**

Array of size $group\_count$. For the group $i$, $k_i = k\_array[i]$ specifies the number of columns of the matrix $\text{op} (A)$ and the number of rows of the matrix $\text{op} (B)$.

The value of each element of $k\_array$ must be at least zero.

**alpha\_array**

Array of size $group\_count$. For the group $i$, $alpha\_array[i]$ specifies the scalar $alpha_i$.

**a\_array**

Array, size $total\_batch\_count$, of pointers to arrays used to store $A$ matrices.
lda_array

Array of size `group_count`. For the group `i`, `lda_i = lda_array[i]` specifies the leading dimension of the array storing matrix `A` as declared in the calling (sub)program.

<table>
<thead>
<tr>
<th>transa&lt;sub&gt;i&lt;/sub&gt;=CblasNoTrans</th>
<th>transa&lt;sub&gt;i&lt;/sub&gt;=CblasTrans or transa&lt;sub&gt;i&lt;/sub&gt;=CblasConjTrans</th>
</tr>
</thead>
<tbody>
<tr>
<td>Layout = CblasColMajor</td>

<td><code>lda_i</code> must be at least <code>max(1, m_i)</code>.</td>
</tr>
</tbody>
</table>

b_array

Array, size `total_batch_count`, of pointers to arrays used to store `B` matrices.

lbd_array

Array of size `group_count`. For the group `i`, `ldb_i = ldb_array[i]` specifies the leading dimension of the array storing matrix `B` as declared in the calling (sub)program.

<table>
<thead>
<tr>
<th>transb&lt;sub&gt;i&lt;/sub&gt;=CblasNoTrans</th>
<th>transb&lt;sub&gt;i&lt;/sub&gt;=CblasTrans or transb&lt;sub&gt;i&lt;/sub&gt;=CblasConjTrans</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td></td>
<td><code>ldb_i</code> must be at least <code>max(1, k_i)</code>.</td>
</tr>
</tbody>
</table>

beta_array

For the group `i`, `beta_array[i]` specifies the scalar `beta<sub>i</sub>`. When `beta<sub>i</sub>` is equal to zero, then `C` matrices in group `i` need not be set on input.

c_array

Array, size `total_batch_count`, of pointers to arrays used to store `C` matrices.

ldc_array

Array of size `group_count`. For the group `i`, `ldc<sub>i</sub> = ldc_array[i]` specifies the leading dimension of all arrays storing matrix `C` in group `i` as declared in the calling (sub)program.

When `Layout = CblasColMajor` `ldc<sub>i</sub>` must be at least `max(1, m_i)`. When `Layout = CblasRowMajor` `ldc<sub>i</sub>` must be at least `max(1, n_i)`.

group_count

Specifies the number of groups. Must be at least 0.

group_size

Array of size `group_count`. The element `group_size[i]` specifies the number of matrices in group `i`. Each element in `group_size` must be at least 0.

Output Parameters

`c_array`

Overwritten by the `m_i`-by-`n_i` matrix `(alpha<sub>i</sub>*op(A)*op(B) + beta<sub>i</sub>*C)` for group `i`. 
Application Notes

These routines perform a complex matrix multiplication by forming the real and imaginary parts of the input matrices. This uses three real matrix multiplications and five real matrix additions instead of the conventional four real matrix multiplications and two real matrix additions. The use of three real matrix multiplications reduces the time spent in matrix operations by 25%, resulting in significant savings in compute time for large matrices.

If the errors in the floating point calculations satisfy the following conditions:

\[ fl(x \text{ op} y) = (x \text{ op} y)(1+\delta), |\delta| \leq u, \quad \text{op=x, /, fl}(x \pm y) = x(1+\alpha) \pm y(1+\beta), |\alpha|, |\beta| \leq u \]

then for an \( n \)-by-\( n \) matrix \( \hat{C} = fl(C_1 + iC_2) = fl((A_1 + iA_2)(B_1 + iB_2)) = \hat{C}_1 + i\hat{C}_2 \), the following bounds are satisfied:

\[ \| \hat{C}_1 - C_1 \| \leq 2(n+1)u \|A\|_\infty \|B\|_\infty + O(u^2), \]
\[ \| \hat{C}_2 - C_2 \| \leq 4(n+4)u \|A\|_\infty \|B\|_\infty + O(u^2), \]

where \( \|A\|_\infty = \max(\|A_1\|_\infty, \|A_2\|_\infty) \), and \( \|B\|_\infty = \max(\|B_1\|_\infty, \|B_2\|_\infty) \).

Thus the corresponding matrix multiplications are stable.

cblas_?trsm_batch

Solves a triangular matrix equation for a group of matrices.

Description

BLAS and Sparse BLAS Routines
The `trsm_batch` routines solve a series of matrix equations. They are similar to the `trsm` routines except that they operate on groups of matrices which have the same parameters. The `trsm_batch` routines process a number of groups at once.

```plaintext
idx = 0
for i = 0..group_count - 1
    alpha in alpha_array[i]
    for j = 0..group_size[i] - 1
        A and B matrix in a_array[idx] and b_array[idx]
        Solve op(A)*X = alpha*B
        or
        Solve X*op(A) = alpha*B
        idx = idx + 1
    end for
end for
```

where:

- `alpha` is a scalar element of `alpha_array`,
- `X` and `B` are `m`-by-`n` matrices for `m` and `n` which are elements of `m_array` and `n_array`, respectively,
- `A` is a unit, or non-unit, upper or lower triangular matrix,
- and `op(A)` is one of `op(A) = A`, or `op(A) = A^T`, or `op(A) = conjg(A^T)`.
- `A` and `B` represent matrices stored at addresses pointed to by `a_array` and `b_array`, respectively. There are `total_batch_count` entries in each of `a_array` and `b_array`, where `total_batch_count` is the sum of all the `group_size` entries.

**Input Parameters**

- **Layout**
  Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).

- **side_array**
  Array of size `group_count`. For group `i`, `0 ≤ i < group_count`, `side[i]` specifies whether `op(A)` appears on the left or right of `X` in the equation:
  - if `side[i]` = CblasLeft, then `op(A)*X = alpha*B`;
  - if `side[i]` = CblasRight, then `X*op(A) = alpha*B`.

- **uplo_array**
  Array of size `group_count`. For group `i`, `0 ≤ i < group_count`, `uplo[i]` specifies whether the matrix `A` is upper or lower triangular:
  - `uplo[i]` = CblasUpper if `uplo[i]` = CblasLower, then the matrix is lower triangular.

- **transa_array**
  Array of size `group_count`. For group `i`, `0 ≤ i < group_count`, `transa[i]` specifies the form of `op(A)` used in the matrix multiplication:
  - if `transa[i]` = CblasNoTrans, then `op(A) = A`;
  - if `transa[i]` = CblasTrans;
  - if `transa[i]` = CblasConjTrans, then `op(A) = conjg(A')`.

- **diag_array**
  Array of size `group_count`. For group `i`, `0 ≤ i < group_count`, `diag[i]` specifies whether the matrix `A` is unit triangular:
  - if `diag[i]` = CblasUnit then the matrix is unit triangular;
if $diag_i = \text{CblasNonUnit}$, then the matrix is not unit triangular.

$m\_array$

Array of size $group\_count$. For group $i$, $0 \leq i < group\_count$, $m_i = m\_array[i]$ specifies the number of rows of $B$. The value of $m_i$ must be at least zero.

$n\_array$

Array of size $group\_count$. For group $i$, $0 \leq i < group\_count$, $n_i = n\_array[i]$ specifies the number of columns of $B$. The value of $n_i$ must be at least zero.

$alpha\_array$

Array of size $group\_count$. For group $i$, $0 \leq i < group\_count$, $alpha\_array[i]$ specifies the scalar $alpha_i$.

$a\_array$

Array, size $total\_batch\_count$, of pointers to arrays used to store $A$ matrices.

For group $i$, $0 \leq i < group\_count$, $k$ is $m_i$ when $side_i = \text{CblasLeft}$ and is $n_i$ when $side_i = \text{CblasRight}$ and $a$ is any of the $group\_size[i]$ arrays starting with $a\_array[group\_size[0] + group\_size[1] + \ldots + group\_size(i - 1)]$.

Before entry with $uplo_i = \text{CblasUpper}$, the leading $k$ by $k$ upper triangular part of the array $a$ must contain the upper triangular matrix and the strictly lower triangular part of $a$ is not referenced.

Before entry with $uplo_i = \text{CblasLower}$ lower triangular part of the array $a$ must contain the lower triangular matrix and the strictly upper triangular part of $a$ is not referenced.

When $diag_i = \text{CblasUnit}$, the diagonal elements of $a$ are not referenced either, but are assumed to be unity.

$lda\_array$

Array of size $group\_count$. For group $i$, $0 \leq i < group\_count$, $lda_i = lda\_array[i]$ specifies the leading dimension of $a$ as declared in the calling (sub)program. When $side_i = \text{CblasLeft}$, then $lda_i$ must be at least $\max(1, m_i)$, when $side_i = \text{CblasRight}$, then $lda_i$ must be at least $\max(1, n_i)$.

$b\_array$

Array, size $total\_batch\_count$, of pointers to arrays used to store $B$ matrices.

For group $i$, $0 \leq i < group\_count$, $b$ is any of the $group\_size[i]$ arrays starting with $b\_array[group\_size[0] + group\_size[1] + \ldots + group\_size(i - 1)]$.

For $Layout = \text{CblasColMajor}$: before entry, the leading $m_i$-by-$n_i$ part of the array $b$ must contain the matrix $B$.

For $Layout = \text{CblasRowMajor}$: before entry, the leading $n_i$-by-$m_i$ part of the array $b$ must contain the matrix $B$.

$ldb\_array$

Array of size $group\_count$. Specifies the leading dimension of $b$ as declared in the calling (sub)program. When $Layout = \text{CblasColMajor}$, $ldb$ must be at least $\max(1, m)$; otherwise, $ldb$ must be at least $\max(1, n)$.

Array of size $group\_count$. For group $i$, $0 \leq i < group\_count$, $ldb_i = ldb\_array[i]$ specifies the leading dimension of $b$ as declared in the calling (sub)program. When $Layout = \text{CblasColMajor}$, $ldb_i$ must be at least $\max(1, m_i)$; otherwise, $ldb_i$ must be at least $\max(1, n_i)$.
**group_count**

Specifies the number of groups. Must be at least 0.

**group_size**

Array of size group_count. The element group_size[i] specifies the number of matrices in group i. Each element in group_size must be at least 0.

**Output Parameters**

**b_array**

Overwritten by the solution matrix X.

---

**mkl_?imatcopy**

*Performs scaling and in-place transposition/copying of matrices.*

**Syntax**

```c
void mkl_simatcopy (const char ordering, const char trans, size_t rows, size_t cols, const float alpha, float * AB, size_t lda, size_t ldb);
void mkl_dimatcopy (const char ordering, const char trans, size_t rows, size_t cols, const double alpha, double * AB, size_t lda, size_t ldb);
void mkl_cimatcopy (const char ordering, const char trans, size_t rows, size_t cols, const MKL_Complex8 alpha, MKL_Complex8 * AB, size_t lda, size_t ldb);
void mkl_zimatcopy (const char ordering, const char trans, size_t rows, size_t cols, const MKL_Complex16 alpha, MKL_Complex16 * AB, size_t lda, size_t ldb);
```

**Include Files**

- mkl.h

**Description**

The mkl_?imatcopy routine performs scaling and in-place transposition/copying of matrices. A transposition operation can be a normal matrix copy, a transposition, a conjugate transposition, or just a conjugation. The operation is defined as follows:

\[ AB := \alpha \cdot \text{op}(AB). \]

**NOTE**

Different arrays must not overlap.

**Input Parameters**

**ordering**

Ordering of the matrix storage.

If ordering = 'R' or 'r', the ordering is row-major.

If ordering = 'C' or 'c', the ordering is column-major.

**trans**

Parameter that specifies the operation type.

If trans = 'N' or 'n', \( \text{op}(AB) = AB \) and the matrix AB is assumed unchanged on input.
If $\text{trans} = 'T'$ or 't', it is assumed that $AB$ should be transposed.

If $\text{trans} = 'C'$ or 'c', it is assumed that $AB$ should be conjugate transposed.

If $\text{trans} = 'R'$ or 'r', it is assumed that $AB$ should be only conjugated.

If the data is real, then $\text{trans} = 'R'$ is the same as $\text{trans} = 'N'$, and $\text{trans} = 'C'$ is the same as $\text{trans} = 'T'$.

**rows**

The number of rows in matrix $AB$ before the transpose operation.

**cols**

The number of columns in matrix $AB$ before the transpose operation.

**ab**

Array.

**alpha**

This parameter scales the input matrix by $\alpha$.

**lda**

Distance between the first elements in adjacent columns (in the case of the column-major order) or rows (in the case of the row-major order) in the source matrix; measured in the number of elements.

This parameter must be at least $\text{rows}$ if $\text{ordering} = 'C'$ or 'c', and $\max(1, \text{cols})$ otherwise.

**ldb**

Distance between the first elements in adjacent columns (in the case of the column-major order) or rows (in the case of the row-major order) in the destination matrix; measured in the number of elements.

To determine the minimum value of $\text{ldb}$ on output, consider the following guideline:

If $\text{ordering} = 'C'$ or 'c', then

- If $\text{trans} = 'T'$ or 't' or 'C' or 'c', this parameter must be at least $\max(1, \text{cols})$
- If $\text{trans} = 'N'$ or 'n' or 'R' or 'r', this parameter must be at least $\max(1, \text{rows})$

If $\text{ordering} = 'R'$ or 'r', then

- If $\text{trans} = 'T'$ or 't' or 'C' or 'c', this parameter must be at least $\max(1, \text{rows})$
- If $\text{trans} = 'N'$ or 'n' or 'R' or 'r', this parameter must be at least $\max(1, \text{cols})$

**Output Parameters**

**ab**

Array.

Contains the matrix $AB$.

**Interfaces**

**mkl_?omatcopy**

*Performs scaling and out-place transposition/copying of matrices.*
Syntax

```c
void mkl_somatcopy (char ordering, char trans, size_t rows, size_t cols, const float alpha, const float * A, size_t lda, float * B, size_t ldb);
void mkl_domatcopy (char ordering, char trans, size_t rows, size_t cols, const double alpha, const double * A, size_t lda, double * B, size_t ldb);
void mkl_comatcopy (char ordering, char trans, size_t rows, size_t cols, const MKL_Complex8 alpha, const MKL_Complex8 * A, size_t lda, MKL_Complex8 * B, size_t ldb);
void mkl_zomatcopy (char ordering, char trans, size_t rows, size_t cols, const MKL_Complex16 alpha, const MKL_Complex16 * A, size_t lda, MKL_Complex16 * B, size_t ldb);
```

Include Files

- mkl.h

Description

The mkl_?omatcopy routine performs scaling and out-of-place transposition/copying of matrices. A transposition operation can be a normal matrix copy, a transposition, a conjugate transposition, or just a conjugation. The operation is defined as follows:

\[ B := \alpha \cdot \text{op}(A) \]

**NOTE**

Different arrays must not overlap.

Input Parameters

- **ordering**
  
  Ordering of the matrix storage.
  
  If `ordering = 'R'` or `r'`, the ordering is row-major.
  
  If `ordering = 'C'` or `c'`, the ordering is column-major.

- **trans**
  
  Parameter that specifies the operation type.
  
  If `trans = 'N'` or `n'`, `\text{op}(A) = A` and the matrix `A` is assumed unchanged on input.
  
  If `trans = 'T'` or `t'`, it is assumed that `A` should be transposed.
  
  If `trans = 'C'` or `c'`, it is assumed that `A` should be conjugate transposed.
  
  If `trans = 'R'` or `r'`, it is assumed that `A` should be only conjugated.
  
  If the data is real, then `trans = 'R'` is the same as `trans = 'N'`, and `trans = 'C'` is the same as `trans = 'T'`.

- **rows**
  
  The number of rows in matrix `B` (the source matrix).

- **cols**
  
  The number of columns in matrix `B` (the source matrix).

- **alpha**
  
  This parameter scales the input matrix by `alpha`.

- **a**
  
  Array.
lda

If ordering = 'R' or 'r', lda represents the number of elements in array a between adjacent rows of matrix A; lda must be at least equal to the number of columns of matrix A.

If ordering = 'C' or 'c', lda represents the number of elements in array a between adjacent columns of matrix A; lda must be at least equal to the number of row in matrix A.

b

If ordering = 'R' or 'r', ldb represents the number of elements in array b between adjacent rows of matrix B.

• If trans = 'T' or 't' or 'C' or 'c', ldb must be at least equal to rows.
• If trans = 'N' or 'n' or 'R' or 'r', ldb must be at least equal to cols.

If ordering = 'C' or 'c', ldb represents the number of elements in array b between adjacent columns of matrix B.

• If trans = 'T' or 't' or 'C' or 'c', ldb must be at least equal to cols.
• If trans = 'N' or 'n' or 'R' or 'r', ldb must be at least equal to rows.

Output Parameters

b

Array, size at least m.

Contains the destination matrix.

Interfaces

mkl_somatcopy2
Performs two-strided scaling and out-of-place transposition/copying of matrices.

Syntax

void mkl_somatcopy2 (char ordering, char trans, size_t rows, size_t cols, const float * A, size_t lda, size_t stridea, float * B, size_t ldb, size_t strideb);

void mkl_domatcopy2 (char ordering, char trans, size_t rows, size_t cols, const double * A, size_t lda, size_t stridea, double * B, size_t ldb, size_t strideb);

void mkl_comatcopy2 (char ordering, char trans, size_t rows, size_t cols, const MKL_Complex8 alpha, const MKL_Complex8 * A, size_t lda, size_t stridea, MKL_Complex8 * B, size_t ldb, size_t strideb);

void mkl_zomatcopy2 (char ordering, char trans, size_t rows, size_t cols, const MKL_Complex16 alpha, const MKL_Complex16 * A, size_t lda, size_t stridea, MKL_Complex16 * B, size_t ldb, size_t strideb);
Include Files
- mkl.h

Description

The mkl_omatcopy2 routine performs two-strided scaling and out-of-place transposition/copying of matrices. A transposition operation can be a normal matrix copy, a transposition, a conjugate transposition, or just a conjugation. The operation is defined as follows:

\[ B := \alpha \cdot \text{op}(A) \]

Normally, matrices in the BLAS or LAPACK are specified by a single stride index. For instance, in the column-major order, \( A(2,1) \) is stored in memory one element away from \( A(1,1) \), but \( A(1,2) \) is a leading dimension away. The leading dimension in this case is at least the number of rows of the source matrix. If a matrix has two strides, then both \( A(2,1) \) and \( A(1,2) \) may be an arbitrary distance from \( A(1,1) \).

**NOTE**
Different arrays must not overlap.

Input Parameters

- **ordering**
  Ordering of the matrix storage.
  - If \( \text{ordering} = 'R' \) or \( 'r' \), the ordering is row-major.
  - If \( \text{ordering} = 'C' \) or \( 'c' \), the ordering is column-major.

- **trans**
  Parameter that specifies the operation type.
  - If \( \text{trans} = 'N' \) or \( 'n' \), \( \text{op}(A) = A \) and the matrix \( A \) is assumed unchanged on input.
  - If \( \text{trans} = 'T' \) or \( 't' \), it is assumed that \( A \) should be transposed.
  - If \( \text{trans} = 'C' \) or \( 'c' \), it is assumed that \( A \) should be conjugate transposed.
  - If \( \text{trans} = 'R' \) or \( 'r' \), it is assumed that \( A \) should be only conjugated.
  - If the data is real, then \( \text{trans} = 'R' \) is the same as \( \text{trans} = 'N' \), and \( \text{trans} = 'C' \) is the same as \( \text{trans} = 'T' \).

- **rows**
  The number of rows in matrix \( B \) (the source matrix).

- **cols**
  The number of columns in matrix \( B \) (the source matrix).

- **alpha**
  This parameter scales the input matrix by \( \alpha \).

- **a**
  Array.

- **lda**
  If \( \text{ordering} = 'R' \) or \( 'r' \), \( lda \) represents the number of elements in array \( a \) between adjacent rows of matrix \( A \); \( lda \) must be at least equal to the number of columns of matrix \( A \).
  - If \( \text{ordering} = 'C' \) or \( 'c' \), \( lda \) represents the number of elements in array \( a \) between adjacent columns of matrix \( A \); \( lda \) must be at least 1 and not more than the number of columns in matrix \( A \).
If `ordering = 'R'` or `r'`, `stridea` represents the number of elements in array `a` between adjacent columns of matrix `A`. `stridea` must be at least 1 and not more than the number of columns in matrix `A`.

If `ordering = 'C'` or `c'`, `stridea` represents the number of elements in array `a` between adjacent rows of matrix `A`. `stridea` must be at least equal to the number of columns in matrix `A`.

Array `b`.

If `ordering = 'R'` or `r'`, `ldb` represents the number of elements in array `b` between adjacent rows of matrix `B`.

- If `trans = 'T'` or `t'` or `C'` or `c'`, `ldb` must be at least equal to `rows/strideb`.
- If `trans = 'N'` or `n'` or `R'` or `r'`, `ldb` must be at least equal to `cols/strideb`.

If `ordering = 'C'` or `c'`, `ldb` represents the number of elements in array `b` between adjacent columns of matrix `B`.

- If `trans = 'T'` or `t'` or `C'` or `c'`, `ldb` must be at least 1 and not more than `rows/strideb`.
- If `trans = 'N'` or `n'` or `R'` or `r'`, `ldb` must be at least 1 and not more than `cols/strideb`.

Array, size at least `m`.

Contains the destination matrix.

Output Parameters

Parameters

`b` Array, size at least `m`.

Contains the destination matrix.

Interfaces

`mkl_?omatadd`

Scales and sums two matrices including in addition to performing out-of-place transposition operations.
Syntax

void mkl_somatadd (char ordering, char transa, char transb, size_t m, size_t n, const float alpha, const float * A, size_t lda, const float beta, const float * B, size_t ldb, float * C, size_t ldc);

void mkl_domatadd (char ordering, char transa, char transb, size_t m, size_t n, const double alpha, const double * A, size_t lda, const double beta, const double * B, size_t ldb, double * C, size_t ldc);

void mkl_comatadd (char ordering, char transa, char transb, size_t m, size_t n, const MKL_Complex8 alpha, const MKL_Complex8 * A, size_t lda, const MKL_Complex8 beta, const MKL_Complex8 * B, size_t ldb, MKL_Complex8 * C, size_t ldc);

void mkl_zomatadd (char ordering, char transa, char transb, size_t m, size_t n, const MKL_Complex16 alpha, const MKL_Complex16 * A, size_t lda, const MKL_Complex16 beta, const MKL_Complex16 * B, size_t ldb, MKL_Complex16 * C, size_t ldc);

Include Files

• mkl.h

Description

The mkl_omatadd routine scales and adds two matrices, as well as performing out-of-place transposition operations. A transposition operation can be no operation, a transposition, a conjugate transposition, or a conjugation (without transposition). The following out-of-place memory movement is done:

\[ C := \alpha \cdot \text{op}(A) + \beta \cdot \text{op}(B) \]

where the \( \text{op}(A) \) and \( \text{op}(B) \) operations are transpose, conjugate-transpose, conjugate (no transpose), or no transpose, depending on the values of \( \text{transa} \) and \( \text{transb} \). If no transposition of the source matrices is required, \( m \) is the number of rows and \( n \) is the number of columns in the source matrices \( A \) and \( B \). In this case, the output matrix \( C \) is \( m \)-by-\( n \).

\[ \text{NOTE} \]
Note that different arrays must not overlap.

Input Parameters

ordering

Ordering of the matrix storage.
- If \( \text{ordering} = 'R' \) or \( 'r' \), the ordering is row-major.
- If \( \text{ordering} = 'C' \) or \( 'c' \), the ordering is column-major.

transa

Parameter that specifies the operation type on matrix \( A \).
- If \( \text{transa} = 'N' \) or \( 'n' \), \( \text{op}(A) = A \) and the matrix \( A \) is assumed unchanged on input.
- If \( \text{transa} = 'T' \) or \( 't' \), it is assumed that \( A \) should be transposed.
- If \( \text{transa} = 'C' \) or \( 'c' \), it is assumed that \( A \) should be conjugate transposed.
- If \( \text{transa} = 'R' \) or \( 'r' \), it is assumed that \( A \) should be conjugated (and not transposed).
If the data is real, then \( \text{transa} = 'R' \) is the same as \( \text{transa} = 'N' \), and \( \text{transa} = 'C' \) is the same as \( \text{transa} = 'T' \).

\( \text{transb} \)

Parameter that specifies the operation type on matrix \( B \).

If \( \text{transb} = 'N' \) or \( 'n' \), \( \text{op}(B) = B \) and the matrix \( B \) is assumed unchanged on input.

If \( \text{transb} = 'T' \) or \( 't' \), it is assumed that \( B \) should be transposed.

If \( \text{transb} = 'C' \) or \( 'c' \), it is assumed that \( B \) should be conjugate transposed.

If \( \text{transb} = 'R' \) or \( 'r' \), it is assumed that \( B \) should be conjugated (and not transposed).

If the data is real, then \( \text{transb} = 'R' \) is the same as \( \text{transb} = 'N' \), and \( \text{transb} = 'C' \) is the same as \( \text{transb} = 'T' \).

\( m \)

The number of matrix rows in \( \text{op}(A) \), \( \text{op}(B) \), and \( C \).

\( n \)

The number of matrix columns in \( \text{op}(A) \), \( \text{op}(B) \), and \( C \).

\( \alpha \)

This parameter scales the input matrix by \( \alpha \).

\( a \)

Array.

\( \text{lda} \)

Distance between the first elements in adjacent columns (in the case of the column-major order) or rows (in the case of the row-major order) in the source matrix \( A \); measured in the number of elements.

For \( \text{ordering} = 'C' \) or \( 'c' \): when \( \text{transa} = 'N', 'n', 'R', \) or \( 'r' \), \( \text{lda} \) must be at least \( \max(1, m) \); otherwise \( \text{lda} \) must be \( \max(1, n) \).

For \( \text{ordering} = 'R' \) or \( 'r' \): when \( \text{transa} = 'N', 'n', 'R', \) or \( 'r' \), \( \text{lda} \) must be at least \( \max(1, n) \); otherwise \( \text{lda} \) must be \( \max(1, m) \).

\( \beta \)

This parameter scales the input matrix by \( \beta \).

\( b \)

Array.

\( \text{ldb} \)

Distance between the first elements in adjacent columns (in the case of the column-major order) or rows (in the case of the row-major order) in the source matrix \( B \); measured in the number of elements.

For \( \text{ordering} = 'C' \) or \( 'c' \): when \( \text{transa} = 'N', 'n', 'R', \) or \( 'r' \), \( \text{ldb} \) must be at least \( \max(1, m) \); otherwise \( \text{ldb} \) must be \( \max(1, n) \).

For \( \text{ordering} = 'R' \) or \( 'r' \): when \( \text{transa} = 'N', 'n', 'R', \) or \( 'r' \), \( \text{ldb} \) must be at least \( \max(1, n) \); otherwise \( \text{ldb} \) must be \( \max(1, m) \).

\( \text{ldc} \)

Distance between the first elements in adjacent columns (in the case of the column-major order) or rows (in the case of the row-major order) in the destination matrix \( C \); measured in the number of elements.

If \( \text{ordering} = 'C' \) or \( 'c' \), then \( \text{ldc} \) must be at least \( \max(1, m) \), otherwise \( \text{ldc} \) must be at least \( \max(1, n) \).

**Output Parameters**

\( c \)

Array.
Interfaces

**cblas_?gemm_pack_get_size, cblas_gemm_*_pack_get_size**

*Returns the number of bytes required to store the packed matrix.*

**Syntax**

```
size_t cblas_sgemm_pack_get_size (const CBLAS_IDENTIFIER identifier, const MKL_INT m, const MKL_INT n, const MKL_INT k)
size_t cblas_dgemm_pack_get_size (const CBLAS_IDENTIFIER identifier, const MKL_INT m, const MKL_INT n, const MKL_INT k)
size_t cblas_gemm_s8u8s32_pack_get_size (const CBLAS_IDENTIFIER identifier, const MKL_INT m, const MKL_INT n, const MKL_INT k)
size_t cblas_gemm_s16s16s32_pack_get_size (const CBLAS_IDENTIFIER identifier, const MKL_INT m, const MKL_INT n, const MKL_INT k)
```

**Include Files**

- mkl.h

**Description**

The `cblas_?gemm_pack_get_size` and `cblas_gemm_*_pack_get_size` routines belong to a set of related routines that enable the use of an internal packed storage. Call the `cblas_?gemm_pack_get_size` and `cblas_gemm_*_pack_get_size` routines first to query the size of storage required for a packed matrix structure to be used in subsequent calls. Ultimately, the packed matrix structure is used to compute

\[
C := \alpha \cdot \text{op}(\ A) \cdot \text{op}(\ B) + \beta C
\]

for single and double precision or

\[
C := \alpha \cdot (\text{op}(\ A + A_{\text{offset}})) \cdot (\text{op}(\ B + B_{\text{offset}})) + \beta C + C_{\text{offset}}
\]

for integer type.

where:

- \(\text{op}(X)\) is one of the operations \(\text{op}(X) = X\) or \(\text{op}(X) = X^T\)
- \(\alpha\) and \(\beta\) are scalars,
- \(A, A_{\text{offset}}, B, B_{\text{offset}}, C,\) and \(C_{\text{offset}}\) are matrices
- \(\text{op}(A)\) is an \(m\)-by-\(k\) matrix,
- \(\text{op}(B)\) is a \(k\)-by-\(n\) matrix,
- \(C\) is an \(m\)-by-\(n\) matrix.
- \(A_{\text{offset}}\) is an \(m\)-by-\(k\) matrix.
- \(B_{\text{offset}}\) is an \(k\)-by-\(n\) matrix.
- \(C_{\text{offset}}\) is an \(m\)-by-\(n\) matrix.

**Input Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>identifier</td>
<td>CBLAS_IDENTIFIER</td>
<td>Specifies which matrix is to be packed: If (\text{identifier} = \text{CblasAMatrix}), the size returned is the size required to store matrix (A) in an internal format.</td>
</tr>
</tbody>
</table>
If \( \texttt{identifier} = \texttt{CblasBMatrix} \), the size returned is the size required to store matrix \( B \) in an internal format.

- \( m \) \( \text{MKL_INT} \): Specifies the number of rows of matrix \( \text{op}(A) \) and of the matrix \( C \). The value of \( m \) must be at least zero.

- \( n \) \( \text{MKL_INT} \): Specifies the number of columns of matrix \( \text{op}(B) \) and the number of columns of matrix \( C \). The value of \( n \) must be at least zero.

- \( k \) \( \text{MKL_INT} \): Specifies the number of columns of matrix \( \text{op}(A) \) and the number of rows of matrix \( \text{op}(B) \). The value of \( k \) must be at least zero.

**See Also**

- \texttt{cblas\_?gemm\_pack} and \texttt{cblas\_gemm\_\*\_pack}
  - to pack the matrix into a buffer allocated previously.
- \texttt{cblas\_?gemm\_compute} and \texttt{cblas\_gemm\_\*\_compute}
  - to compute a matrix-matrix product with general matrices (where one or both input matrices are stored in a packed data structure) and add the result to a scalar-matrix product.

**\texttt{cblas\_?gemm\_alloc}**

*Allocates storage for a packed matrix (deprecated).*

**Syntax**

- \( \text{float}^* \texttt{cblas\_sgemm\_alloc} (\text{const} \text{CBLAS\_IDENTIFIER} \texttt{identifier}, \text{const} \text{MKL\_INT} \texttt{m}, \text{const} \text{MKL\_INT} \texttt{n}, \text{const} \text{MKL\_INT} \texttt{k}); \)
- \( \text{double}^* \texttt{cblas\_dgemm\_alloc} (\text{const} \text{CBLAS\_IDENTIFIER} \texttt{identifier}, \text{const} \text{MKL\_INT} \texttt{m}, \text{const} \text{MKL\_INT} \texttt{n}, \text{const} \text{MKL\_INT} \texttt{k}); \)

**Include Files**

- \texttt{mkl\_h}
Description

The `cblas_?gemm_alloc` routine is one of a set of related routines that enable use of an internal packed storage. Call the `cblas_?gemm_alloc` routine first to allocate storage for a packed matrix structure to be used in subsequent calls, ultimately to compute

\[ C := \alpha \cdot \text{op}(A) \cdot \text{op}(B) + \beta \cdot C, \]

where:

- \( \text{op}(X) \) is one of the operations \( \text{op}(X) = X, \text{op}(X) = X^T, \) or \( \text{op}(X) = X^H, \)
- \( \alpha \) and \( \beta \) are scalars,
- \( A, B, \) and \( C \) are matrices:
  - \( \text{op}(A) \) is an \( m \)-by-\( k \) matrix,
  - \( \text{op}(B) \) is a \( k \)-by-\( n \) matrix,
  - \( C \) is an \( m \)-by-\( n \) matrix.

Notice

The `cblas_?gemm_alloc` routine is not supported on Windows* OS for the IA-32 architecture with single dynamic library linking.

Input Parameters

- \textit{identifier} Specifies which matrix is to be packed:
  - If \textit{identifier} = CblasAMatrix, the routine allocates storage to pack matrix \( A. \)
  - If \textit{identifier} = CblasBMatrix, the routine allocates storage to pack matrix \( B. \)
- \textit{m} Specifies the number of rows of matrix \( \text{op}(A) \) and of the matrix \( C. \) The value of \( m \) must be at least zero.
- \textit{n} Specifies the number of columns of matrix \( \text{op}(B) \) and the number of columns of matrix \( C. \) The value of \( n \) must be at least zero.
- \textit{k} Specifies the number of columns of matrix \( \text{op}(A) \) and the number of rows of matrix \( \text{op}(B). \) The value of \( k \) must be at least zero.

Return Values

The function returns the allocated storage.

See Also

- `cblas_?gemm_pack` Performs scaling and packing of the matrix into the previously allocated buffer.
- `cblas_?gemm_compute` Computes a matrix-matrix product with general matrices where one or both input matrices are stored in a packed data structure and adds the result to a scalar-matrix product.
- `cblas_?gemm_free` Frees the storage previously allocated for the packed matrix (deprecated).
- `cblas_?gemm` for a detailed description of general matrix multiplication.
**cblas_?gemm_pack**  
Performs scaling and packing of the matrix into the previously allocated buffer.

**Syntax**

```c
void cblas_sgemm_pack(  
    const CBLAS_LAYOUT Layout,  
    const CBLAS_IDENTIFIER identifier,  
    const CBLAS_TRANSPOSE trans,  
    const MKL_INT m,  
    const MKL_INT n,  
    const MKL_INT k,  
    const float alpha,  
    const float *src,  
    const MKL_INT ld,  
    float *dest);
```

```c
void cblas_dgemm_pack(  
    const CBLAS_LAYOUT Layout,  
    const CBLAS_IDENTIFIER identifier,  
    const CBLAS_TRANSPOSE trans,  
    const MKL_INT m,  
    const MKL_INT n,  
    const MKL_INT k,  
    const double alpha,  
    const double *src,  
    const MKL_INT ld,  
    double *dest);
```

**Include Files**

- mkl.h

**Description**

The `cblas_?gemm_pack` routine is one of a set of related routines that enable use of an internal packed storage. Call `cblas_?gemm_pack` after you allocate a buffer whose size is given by `cblas_?gemm_pack_getsize`. The `cblas_?gemm_pack` routine scales the identified matrix by alpha and packs it into the buffer allocated previously.

The `cblas_?gemm_pack` routine performs this operation:

\[ \text{dest} := \text{alpha} \cdot \text{op(src)} \text{ as part of the computation } C := \alpha \cdot \text{op}(A) \cdot \text{op}(B) + \beta \cdot C \]

where:

- `op(X)` is one of the operations \( X \), \( X^T \), or \( X^H \),
- `alpha` and `beta` are scalars,
- `src` is a matrix,
- `A`, `B`, and `C` are matrices
- `op(src)` is an \( m \)-by-\( k \) matrix if `identifier` = `CblasAMatrix`,
- `op(src)` is a \( k \)-by-\( n \) matrix if `identifier` = `CblasBMatrix`,
- `dest` is an internal packed storage buffer.

**NOTE**

You must use the same value of the `Layout` parameter for the entire sequence of related `cblas_?gemm_pack` and `cblas_?gemm_compute` calls.

For best performance, use the same number of threads for packing and for computing.

If packing for both `A` and `B` matrices, you must use the same number of threads for packing `A` as for packing `B`.

**Input Parameters**

- **Layout**
  Specifies whether two-dimensional array storage is row-major (`CblasRowMajor`) or column-major (`CblasColMajor`).

- **identifier**
  Specifies which matrix is to be packed:
If \( \text{identifier} = \text{CblasAMatrix} \), the routine allocates storage to pack matrix \( A \).

If \( \text{identifier} = \text{CblasBMatrix} \), the routine allocates storage to pack matrix \( B \).

\( \text{trans} \) Specifies the form of \( \text{op} (\text{src}) \) used in the packing:

If \( \text{trans} = \text{CblasNoTrans} \) \( \text{op} (\text{src}) = \text{src} \).

If \( \text{trans} = \text{CblasTrans} \) \( \text{op} (\text{src}) = \text{src}^T \).

If \( \text{trans} = \text{CblasConjTrans} \) \( \text{op} (\text{src}) = \text{src}^H \).

\( m \) Specifies the number of rows of the matrix \( \text{op}(A) \) and of the matrix \( C \). The value of \( m \) must be at least zero.

\( n \) Specifies the number of columns of the matrix \( \text{op}(B) \) and the number of columns of the matrix \( C \). The value of \( n \) must be at least zero.

\( k \) Specifies the number of columns of the matrix \( \text{op}(A) \) and the number of rows of the matrix \( \text{op}(B) \). The value of \( k \) must be at least zero.

\( \alpha \) Specifies the scalar \( \alpha \).

\( \text{src} \) Array:

Scaled and packed internal storage buffer.

**Output Parameters**

dest

Overwritten by the matrix alpha*op(src).

**See Also**

- cblas_gemm_pack_get_size: Returns the number of bytes required to store the packed matrix.
- cblas_gemm_compute: Computes a matrix-matrix product with general matrices where one or both input matrices are stored in a packed data structure and adds the result to a scalar-matrix product.
cblas_gemm
for a detailed description of general matrix multiplication.

cblas_gemm_*_pack
Pack the matrix into the buffer allocated previously.

Syntax
void cblas_gemm_s8u8s32_pack (const CBLAS_LAYOUT Layout, const CBLAS_IDENTIFIER identifier, const CBLAS_TRANSPOSE trans, const MKL_INT m, const MKL_INT n, const MKL_INT k, const void *src, const MKL_INT ld, void *dest);
void cblas_gemm_s16s16s32_pack (const CBLAS_LAYOUT Layout, const CBLAS_IDENTIFIER identifier, const CBLAS_TRANSPOSE trans, const MKL_INT m, const MKL_INT n, const MKL_INT k, const MKL_INT16 *src, const MKL_INT ld, MKL_INT16 *dest);

Include Files
• mkl.h

Description
The cblas_gemm_*_pack routine is one of a set of related routines that enable the use of an internal packed storage. Call cblas_gemm_*_pack after you allocate a buffer whose size is given by cblas_gemm_*_pack_get_size. The cblas_gemm_*_pack routine packs the identified matrix into the buffer allocated previously.

The cblas_gemm_*_pack routine performs this operation:
\[ \text{dest} := \text{op} (\text{src}) \text{ as part of the computation } C := \alpha \cdot (\text{op} (A) + A_{\text{offset}}) \cdot (\text{op} (B) + B_{\text{offset}}) + \beta C + C_{\text{offset}} \]

where:
- \( \text{op}(X) \) is one of the operations \( \text{op}(X) = X \) or \( \text{op}(X) = X^T \)
- \( \alpha \) and \( \beta \) are scalars,
- \( \text{src} \) is a matrix,
- \( A, A_{\text{offset}}, B, B_{\text{offset}}, C, \text{and } C_{\text{offset}} \) are matrices
- \( \text{op}(\text{src}) \) is a m-by-k matrix if \( \text{identifier} = \text{CblasAMatrix} \),
- \( \text{op}(\text{src}) \) is a k-by-n matrix if \( \text{identifier} = \text{CblasBMatrix} \),
- \( \text{dest} \) is the buffer previously allocated to store the matrix packed into an internal format
- \( A_{\text{offset}} \) is an m-by-k matrix.
- \( B_{\text{offset}} \) is an k-by-n matrix.
- \( C_{\text{offset}} \) is an m-by-n matrix.

NOTE
You must use the same value of the Layout parameter for the entire sequence of related cblas_gemm_*_pack and cblas_gemm_*_compute calls.

For best performance, use the same number of threads for packing and for computing.

If packing for both \( A \) and \( B \) matrices, you must use the same number of threads for packing \( A \) as for packing \( B \).
Input Parameters

CBLAS_LAYOUT
Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).

identifier
CBLAS_IDENTIFIER
Specifies which matrix is to be packed:
If identifier = CblasAMatrix, the A matrix is packed.
If identifier = CblasBMatrix, the B matrix is packed.

trans
CBLAS_TRANSPOSE
Specifies the form of \( \text{op}(\text{src}) \) used in the packing:
If trans = CblasNoTrans \( \text{op}(\text{src}) = \text{src} \).
If trans = CblasTrans \( \text{op}(\text{src}) = \text{src}^T \).

m
MKL_INT
Specifies the number of rows of matrix \( \text{op}(A) \) and of the matrix C. The value of \( m \) must be at least zero.

n
MKL_INT
Specifies the number of columns of matrix \( \text{op}(B) \) and the number of columns of matrix C. The value of \( n \) must be at least zero.

k
MKL_INT
Specifies the number of columns of matrix \( \text{op}(A) \) and the number of rows of matrix \( \text{op}(B) \). The value of \( k \) must be at least zero.

src
void* for cblas_gemm_s8u8s32_pack and MKL_INT16* for cblas_gemm_s16s16s32_pack

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

MKL_INT specifies the leading dimension of src as declared in the calling (sub)program.
**Output Parameters**

- `dest` `void*` for `cblas_gemm_s8u8s32_pack` and `MKL_INT16*` for `cblas_gemm_s16s16s32_pack`

  Overwritten by the matrix `op(src)` stored in a format internal to Intel® MKL.

**Example**

See the following examples in the MKL installation directory to understand the use of these routines:

- `cblas_gemm_s8u8s32_pack`: examples\blas\source\cblas_gemm_s8u8s32_computex.c
- `cblas_gemm_s16s16s32_pack`: examples\blas\source\cblas_gemm_s16s16s32_computex.c

**Application Notes**

When using `cblas_gemm_s8u8s32_pack` with row-major layout, the data types of \(A\) and \(B\) must be swapped. That is, you must provide an 8-bit unsigned integer array for matrix \(A\) and an 8-bit signed integer array for matrix \(B\).

**See Also**

- `cblas_gemm_*_pack_get_size`
  - to return the number of bytes needed to store the packed matrix.
- `cblas_gemm_*_compute`
  - to compute a matrix-matrix product with general integer matrices (where one or both input matrices are stored in a packed data structure) and add the result to a scalar-matrix product.
**cblas_gemm_compute**

Computes a matrix-matrix product with general matrices where one or both input matrices are stored in a packed data structure and adds the result to a scalar-matrix product.

**Syntax**

```c
void cblas_sgemm_compute(
    const CBLAS_LAYOUT Layout,
    const MKL_INT transa,
    const MKL_INT transb,
    const MKL_INT m,
    const MKL_INT n,
    const MKL_INT k,
    const float *a,
    const MKL_INT lda,
    const float *b,
    const MKL_INT ldb,
    const float beta,
    float *c,
    const MKL_INT ldc);

void cblas_dgemm_compute(
    const CBLAS_LAYOUT Layout,
    const MKL_INT transa,
    const MKL_INT transb,

    const double *a,
    const MKL_INT lda,
    const double *b,
    const MKL_INT ldb,
    const double beta,
    double *c,
    const MKL_INT ldc);
```

**Include Files**

- mkl.h

**Description**

The `cblas_gemm_compute` routine is one of a set of related routines that enable use of an internal packed storage. After calling `cblas_gemm_pack` call `cblas_gemm_compute` to compute

\[ C := \text{op}(A) \ast \text{op}(B) + \beta \ast C, \]

where:

- \( \text{op}(X) \) is one of the operations \( \text{op}(X) = X, \text{op}(X) = X^T, \) or \( \text{op}(X) = X^H, \)
- \( \beta \) is a scalar,
- \( A, B, \) and \( C \) are matrices:
  - \( \text{op}(A) \) is an \( m \)-by-\( k \) matrix,
  - \( \text{op}(B) \) is a \( k \)-by-\( n \) matrix,
  - \( C \) is an \( m \)-by-\( n \) matrix.

**NOTE**

You must use the same value of the `Layout` parameter for the entire sequence of related `cblas_gemm_pack` and `cblas_gemm_compute` calls.

For best performance, use the same number of threads for packing and for computing.

If packing for both \( A \) and \( B \) matrices, you must use the same number of threads for packing \( A \) as for packing \( B \).

**Input Parameters**

- **Layout**
  Specifies whether two-dimensional array storage is row-major (`CblasRowMajor`) or column-major (`CblasColMajor`).

- **transa**
  Specifies the form of \( \text{op}(A) \) used in the matrix multiplication, one of the `CBLAS_TRANSPOSE` or `CBLAS_STORAGE` enumerated types:

  - If `transa = CblasNoTrans` \( \text{op}(A) = A \).
If \( \text{transa} = \text{CblasTrans} \) \( \text{op}(A) = A^T \).

If \( \text{transa} = \text{CblasConjTrans} \) \( \text{op}(A) = A^H \).

If \( \text{transa} = \text{CblasPacked} \) the matrix in array \( a \) is packed and \( lda \) is ignored.

\( \text{transb} \) specifies the form of \( \text{op}(B) \) used in the matrix multiplication, one of the \text{CUBLAS_TRANSPOSE} or \text{CUBLAS_STORAGE} enumerated types:

If \( \text{transb} = \text{CblasNoTrans} \) \( \text{op}(B) = B \).

If \( \text{transb} = \text{CblasTrans} \) \( \text{op}(B) = B^T \).

If \( \text{transb} = \text{CblasConjTrans} \) \( \text{op}(B) = B^H \).

If \( \text{transb} = \text{CblasPacked} \) the matrix in array \( b \) is packed and \( ldb \) is ignored.

\( m \) specifies the number of rows of the matrix \( \text{op}(A) \) and of the matrix \( C \). The value of \( m \) must be at least zero.

\( n \) specifies the number of columns of the matrix \( \text{op}(B) \) and the number of columns of the matrix \( C \). The value of \( n \) must be at least zero.

\( k \) specifies the number of columns of the matrix \( \text{op}(A) \) and the number of rows of the matrix \( \text{op}(B) \). The value of \( k \) must be at least zero.

</table>

<table>
<thead>
<tr>
<th>$ldb$ must be at least $\max(1, n)$</th>
<th>$ldb$ must be at least $\max(1, k)$.</th>
<th>$ldb$ is ignored.</th>
</tr>
</thead>
</table>

### $beta$

Specifies the scalar $beta$. When $beta$ is equal to zero, then $c$ need not be set on input.
Before entry, the leading m-by-n part of the array c must contain the matrix C, except when beta is equal to zero, in which case c need not be set on entry.

Before entry, the leading n-by-m part of the array c must contain the matrix C, except when beta is equal to zero, in which case c need not be set on entry.

Specifies the leading dimension of c as declared in the calling (sub)program.

Overwritten by the m-by-n matrix op(A)*op(B) + beta*C.

See Also

```
Include Files
- mkl.h

Description
The `cblas_gemm_*_compute` routine is one of a set of related routines that enable use of an internal packed storage. After calling `cblas_gemm_*_pack` call `cblas_gemm_*_compute` to compute

\[ C := \alpha(\text{op}(A) + A_{\text{offset}})(\text{op}(B) + B_{\text{offset}}) + \beta C + C_{\text{offset}}, \]

where:
- \( \text{op}(X) \) is either \( \text{op}(X) = X \) or \( \text{op}(X) = X^T \)
- \( \alpha \) and \( \beta \) are scalars
- \( A, B, \) and \( C \) are matrices:
  - \( \text{op}(A) \) is an \( m \)-by-\( k \) matrix,
  - \( \text{op}(B) \) is a \( k \)-by-\( n \) matrix,
  - \( C \) is an \( m \)-by-\( n \) matrix.
- \( A_{\text{offset}} \) is an \( m \)-by-\( k \) matrix with every element equal to the value \( \text{oa} \).
- \( B_{\text{offset}} \) is a \( k \)-by-\( n \) matrix with every element equal to the value \( \text{ob} \).
- \( C_{\text{offset}} \) is an \( m \)-by-\( n \) matrix defined by the \( \text{oc} \) array as described in the description of the \( \text{offsetc} \) parameter.

**NOTE**
You must use the same value of the `Layout` parameter for the entire sequence of related `cblas_*gemm_pack` and `cblas_*gemm_compute` calls.

For best performance, use the same number of threads for packing and for computing.

If you are packing for both \( A \) and \( B \) matrices, you must use the same number of threads for packing \( A \) as for packing \( B \).

Input Parameters

- **Layout**
  - CBLAS_LAYOUT
    - Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major(CblasColMajor).

- **transa**
  - MKL_INT
    - Specifies the form of \( \text{op}(A) \) used in the packing:
      - If \( \text{transa} = \text{CblasNoTrans} \) \( \text{op}(A) = A \).
      - If \( \text{transa} = \text{CblasTrans} \) \( \text{op}(A) = A^T \).
      - If \( \text{transa} = \text{CblasPacked} \) the matrix in array \( a \) is packed into a format internal to Intel® MKL and \( lda \) is ignored.

- **transb**
  - MKL_INT
    - Specifies the form of \( \text{op}(B) \) used in the packing:
      - If \( \text{transb} = \text{CblasNoTrans} \) \( \text{op}(B) = B \).
      - If \( \text{transb} = \text{CblasTrans} \) \( \text{op}(B) = B^T \).
      - If \( \text{transb} = \text{CblasPacked} \) the matrix in array \( b \) is packed into a format internal to Intel® MKL and \( ldb \) is ignored.

- **offsetc**
  - CBLAS_OFFSET
    - Specifies the form of \( C_{\text{offset}} \) used in the matrix multiplication.
If \( \text{offsetc}=\text{CblasFixOffset} \), \( \text{oc} \) has a single element and every element of \( \text{C_offset} \) is equal to this element.

If \( \text{offsetc}=\text{CblasColOffset} \), \( \text{oc} \) has a size of \( m \) and every element of \( \text{C_offset} \) is equal to \( \text{oc} \).

If \( \text{offsetc}=\text{CblasRowOffset} \), \( \text{oc} \) has a size of \( n \) and every element of \( \text{C_offset} \) is equal to \( \text{oc} \).

**\( m \)** MKL_INT Specifies the number of rows of the matrix \( \text{op}(A) \) and of the matrix \( C \). The value of \( m \) must be at least zero.

**\( n \)** MKL_INT Specifies the number of columns of the matrix \( \text{op}(B) \) and the number of columns of the matrix \( C \). The value of \( n \) must be at least zero.

**\( k \)** MKL_INT Specifies the number of columns of the matrix \( \text{op}(A) \) and the number of rows of the matrix \( \text{op}(B) \). The value of \( k \) must be at least zero.

**\( \alpha \)** float Specifies the scalar \( \alpha \).

**\( \text{a} \)** void* for \( \text{gemm}\_s8u8s32\_compute \)

**MKL\_INT16** for \( \text{gemm}\_s16s16s32\_compute \)

<table>

\(\text{MKL\_INT16}\) for \(\text{cblas_gemm}_s16s16s32\_compute\)

\(\text{Specifies the scalar offset value for the matrix } B.\)

#### \(beta\)

\(\text{float}\)

\(\text{Specifies the scalar } beta.\)

#### \(c\)

\(\text{MKL\_INT32}\)

\(\text{Array:}\)

<table>
<thead>
<tr>
<th>Layout = CblasColMajor</th>
<th>Array, size (ldc\times n). Before entry, the leading (m)-by-(n) part of the array (c) must contain the matrix (C), except when (beta) is equal to zero, in which case (c) need not be set on entry.</th>
</tr>
</thead>
<tbody>
<tr>
<td>(\text{layout} = \text{CblasRowMajor})</td>
<td>Array, size (ldc\times m).</td>
</tr>
</tbody>
</table>
Before entry, the leading \( n \)-by-\( m \) part of the array \( c \) must contain the matrix \( C \), except when \( \beta \) is equal to zero, in which case \( c \) need not be set on entry.

### ldc
MKL_INT Specifies the leading dimension of \( c \) as declared in the calling (sub)program.

<table>
<thead>
<tr>
<th>Layout = CblasColMajor</th>
<th>( \text{ldc must be at least max}(1, m) )</th>
</tr>
</thead>
<tbody>
<tr>
<td>Layout = CblasRowMajor</td>
<td>( \text{ldc must be at least max}(1, n) )</td>
</tr>
</tbody>
</table>

### oc
MKL_INT32*
Array, size \( \text{len} \). Specifies the scalar offset value for the matrix \( C \).

- If \( \text{offsetc} = \text{CblasFixOffset} \), \( \text{len} \) must be at least 1.
- If \( \text{offsetc} = \text{CblasColOffset} \), \( \text{len} \) must be at least \( \text{max}(1, m) \).
- If \( \text{offsetc} = \text{CblasRowOffset} \), \( \text{len} \) must be at least \( \text{max}(1, n) \).

### Output Parameters
MKL_INT32*
Overwritten by the matrix \( \alpha \cdot (\text{op}(A) + A_{\text{offset}}) \cdot (\text{op}(B) + B_{\text{offset}}) + \beta \cdot C + C_{\text{offset}} \).

### Example
See the following examples in the MKL installation directory to understand the use of these routines:
- cblas_gemm_s8u8s32_compute: examples\cblas\source\cblas_gemm_s8u8s32_computex.c
- cblas_gemm_s16s16s32_compute: examples\cblas\source\cblas_gemm_s16s16s32_computex.c

### Application Notes
You can expand the matrix-matrix product in this manner:

\[
(\text{op}(A) + A_{\text{offset}}) \cdot (\text{op}(B) + B_{\text{offset}}) = \text{op}(A) \cdot \text{op}(B) + \text{op}(A) \cdot B_{\text{offset}} + A_{\text{offset}} \cdot \text{op}(B) + A_{\text{offset}} \cdot B_{\text{offset}}
\]

After computing these four multiplication terms separately, they are summed from left to right. The results from the matrix-matrix product and the \( C \) matrix are scaled with \( \alpha \) and \( \beta \) floating-point values respectively using double-precision arithmetic. Before storing the results to the output \( c \) array, the floating-point values are rounded to the nearest integers.

In the event of overflow or underflow, the results depend on the architecture. The results are either unsaturated (wrapped) or saturated to maximum or minimum representable integer values for the data type of the output matrix.

When using cblas_gemm_s8u8s32_compute with row-major layout, the data types of \( A \) and \( B \) must be swapped. That is, you must provide an 8-bit unsigned integer array for matrix \( A \) and an 8-bit signed integer array for matrix \( B \).

### See Also
- cblas_gemm_*_pack_get_size
to return the number of bytes needed to store the packed matrix.
- cblas_gemm_*_pack
to pack the matrix into the buffer allocated previously.

**cblas_?gemm_free**

Frees the storage previously allocated for the packed matrix (deprecated).

**Syntax**

```c
void cblas_sgemm_free (float *dest);
void cblas_dgemm_free (double *dest);
```

**Include Files**

- mkl.h

**Description**

The cblas_?gemm_free routine is one of a set of related routines that enable use of an internal packed storage. Call the cblas_?gemm_free routine last to release storage for the packed matrix structure allocated with cblas_?gemm_alloc.

**Input Parameters**

- `dest`: Previously allocated storage.

**Output Parameters**

- `dest`: The freed buffer.

**See Also**

- cblas_?gemm_alloc: Allocates storage for a packed matrix (deprecated).
- cblas_?gemm_pack: Performs scaling and packing of the matrix into the previously allocated buffer.
- cblas_?gemm_compute: Computes a matrix-matrix product with general matrices where one or both input matrices are stored in a packed data structure and adds the result to a scalar-matrix product.
- cblas_?gemm: for a detailed description of general matrix multiplication.

**cblas_gemm_***

Computes a matrix-matrix product with general integer matrices.

**Syntax**

```c
void cblas_gemm_s8u8s32 (const CBLAS_LAYOUT Layout, const CBLAS_TRANSPOSE transa, const CBLAS_TRANSPOSE transb, const CBLAS_OFFSET offsetc, const MKL_INT m, const MKL_INT n, const MKL_INT k, const float alpha, const void *a, const MKL_INT lda, const MKL_INT8 oa, const void *b, const MKL_INT ldb, const MKL_INT8 ob, const float beta, MKL_INT32 *c, const MKL_INT ldc, const MKL_INT32 *oc);

void cblas_gemm_s16s16s32 (const CBLAS_LAYOUT Layout, const CBLAS_TRANSPOSE transa, const CBLAS_TRANSPOSE transb, const CBLAS_OFFSET offsetc, const MKL_INT m, const MKL_INT n, const MKL_INT k, const float alpha, const MKL_INT16 *a, const MKL_INT lda, const MKL_INT16 oa, const MKL_INT16 *b, const MKL_INT ldb, const MKL_INT16 ob, const float beta, MKL_INT32 *c, const MKL_INT ldc, const MKL_INT32 *oc);
```
Include Files

- mkl.h

Description

The cblas_gemm_* routines compute a scalar-matrix-matrix product and adds the result to a scalar-matrix product. To get the final result, a vector is added to each row or column of the output matrix. The operation is defined as:

\[ C := \alpha \cdot (\text{op}(A) + A\text{\_offset}) \cdot (\text{op}(B) + B\text{\_offset}) + \beta \cdot C + C\text{\_offset} \]

where:

- \( \text{op}(X) \) is either \( \text{op}(X) = X \) or \( \text{op}(X) = X^T \),
- \( A\text{\_offset} \) is an \( m \)-by-\( k \) matrix with every element equal to the value \( a \),
- \( B\text{\_offset} \) is a \( k \)-by-\( n \) matrix with every element equal to the value \( b \),
- \( C\text{\_offset} \) is an \( m \)-by-\( n \) matrix defined by the \( oc \) array as described in the description of the \( offsetc \) parameter,
- \( \alpha \) and \( \beta \) are scalars,
- \( A \) is a matrix such that \( \text{op}(A) \) is \( m \)-by-\( k \),
- \( B \) is a matrix such that \( \text{op}(B) \) is \( k \)-by-\( n \),
- and \( C \) is an \( m \)-by-\( n \) matrix.

Input Parameters

- **Layout**
  Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).

- **transa**
  Specifies the form of \( \text{op}(A) \) used in the matrix multiplication:
  - if \( transa=CblasNoTrans \), then \( \text{op}(A) = A \);
  - if \( transa=CblasTrans \), then \( \text{op}(A) = A^T \).

- **transb**
  Specifies the form of \( \text{op}(B) \) used in the matrix multiplication:
  - if \( transb=CblasNoTrans \), then \( \text{op}(B) = B \);
  - if \( transb=CblasTrans \), then \( \text{op}(B) = B^T \).

- **offsetc**
  Specifies the form of \( C\text{\_offset} \) used in the matrix multiplication.
  - \( offsetc = CblasFixOffset \): \( oc \) has a single element and every element of \( C\text{\_offset} \) is equal to this element.
  - \( offsetc = CblasColOffset \): \( oc \) has a size of \( m \) and every column of \( C\text{\_offset} \) is equal to \( oc \).
  - \( offsetc = CblasRowOffset \): \( oc \) has a size of \( n \) and every row of \( C\text{\_offset} \) is equal to \( oc \).

- **m**
  Specifies the number of rows of the matrix \( \text{op}(A) \) and of the matrix \( C \). The value of \( m \) must be at least zero.

- **n**
  Specifies the number of columns of the matrix \( \text{op}(B) \) and the number of columns of the matrix \( C \). The value of \( n \) must be at least zero.

- **k**
  Specifies the number of columns of the matrix \( \text{op}(A) \) and the number of rows of the matrix \( \text{op}(B) \). The value of \( k \) must be at least zero.
alpha

Specifies the scalar $\alpha$.

<td></td>
</tr>
</tbody>
</table>

**ob**

Specifies the scalar offset value for matrix $B$.

**beta**

Specifies the scalar $beta$. When $beta$ is equal to zero, then $c$ need not be set on input.

**c**

Array, size $ldc$ by $n$. Before entry, the leading $m$-by-$n$ part of the array $c$ must contain the matrix $C$, except when $beta$ is equal to zero, in which case $c$ need not be set on entry.

Array, size $ldc$ by $m$. Before entry, the leading $n$-by-$m$ part of the array $c$ must contain the matrix $C$, except when $beta$ is equal to zero, in which case $c$ need not be set on entry.

**ldc**

Specifies the leading dimension of $c$ as declared in the calling (sub)program.

<table>
<thead>
<tr>
<th>Layout = CblasColMajor</th>
<th>ldc must be at least max(1, m).</th>
</tr>
</thead>
<tbody>
<tr>
<td>Layout = CblasRowMajor</td>
<td>ldc must be at least max(1, n).</td>
</tr>
</tbody>
</table>

**oc**

Array, size $len$. Specifies the offset values for matrix $C$.

- If $offsetc = CblasFixOffset$, $len$ must be at least 1.
- If $offsetc = CblasColOffset$, $len$ must be at least max(1, $m$).
- If $offsetc = CblasRowOffset$, $oc$ must be at least max(1, $n$).
Output Parameters

Overwritten by $alpha \cdot (\text{op}(A) + A\_\text{offset}) \cdot (\text{op}(B) + B\_\text{offset}) + beta \cdot C + C\_\text{offset}$.

Example

For examples of routine usage, see the code in the Intel® MKL installation directory:

- cblas_gemm_s8u8s32: examples\cblas\source\cblas_gemm_s8u8s32x.c
- cblas_gemm_s16s16s32: examples\cblas\source\cblas_gemm_s16s16s32x.c

Application Notes

The matrix-matrix product can be expanded:

$$(\text{op}(A) + A\_\text{offset}) \cdot (\text{op}(B) + B\_\text{offset})$$

$$= \text{op}(A) \cdot \text{op}(B) + \text{op}(A) \cdot B\_\text{offset} + A\_\text{offset} \cdot \text{op}(B) + A\_\text{offset} \cdot B\_\text{offset}$$

After computing these four multiplication terms separately, they are summed from left to right. The results from the matrix-matrix product and the $C$ matrix are scaled with $alpha$ and $beta$ floating-point values respectively using double-precision arithmetic. Before storing the results to the output $c$ array, the floating-point values are rounded to the nearest integers. In the event of overflow or underflow, the results depend on the architecture. The results are either unsaturated (wrapped) or saturated to maximum or minimum representable integer values for the data type of the output matrix.

When using cblas_gemm_s8u8s32 with row-major layout, the data types of $A$ and $B$ must be swapped. That is, you must provide an 8-bit unsigned integer array for matrix $A$ and an 8-bit signed integer array for matrix $B$.

Intermediate integer computations in cblas_gemm_s8u8s32 on 64-bit Intel® Advanced Vector Extensions 2 (Intel® AVX2) and Intel® Advanced Vector Extensions 512 (Intel® AVX-512) architectures without Vector Neural Network Instructions (VNNI) extensions can saturate. This is because only 16-bits are available for the accumulation of intermediate results. You can avoid integer saturation by maintaining all integer elements of $A$ or $B$ matrices under 8 bits.
LAPACK Routines

This chapter describes the Intel® Math Kernel Library (Intel® MKL) implementation of routines from the LAPACK package that are used for solving systems of linear equations, linear least squares problems, eigenvalue and singular value problems, and performing a number of related computational tasks. The library includes LAPACK routines for both real and complex data. Routines are supported for systems of equations with the following types of matrices:

- General
- Banded
- Symmetric or Hermitian positive-definite (full, packed, and rectangular full packed (RFP) storage)
- Symmetric or Hermitian positive-definite banded
- Symmetric or Hermitian indefinite (both full and packed storage)
- Symmetric or Hermitian indefinite banded
- Triangular (full, packed, and RFP storage)
- Triangular banded
- Tridiagonal
- Diagonally dominant tridiagonal.

**NOTE**
Different arrays used as parameters to Intel® MKL LAPACK routines must not overlap.

**Warning**
LAPACK routines assume that input matrices do not contain IEEE 754 special values such as \(\text{INF}\) or NaN values. Using these special values may cause LAPACK to return unexpected results or become unstable.

Choosing a LAPACK Routine

Intel® MKL offers many LAPACK routines, and many perform similar operations. The Intel® Math Kernel Library LAPACK Function Finding Advisor helps you understand the differences between routines so that you can choose the appropriate routine for your task:

C Interface Conventions for LAPACK Routines

The C interfaces are implemented for most of the Intel® MKL LAPACK driver and computational routines.

**NaN checking in LAPACKE**

NaN checking can affect the performance of an application. By default, it is ON.

See the **Support Functions** section for details on the methods and options to turn NaN check off or back on with LAPACKE:

**Function Prototypes**

Intel® MKL supports four distinct floating-point precisions. Each corresponding prototype looks similar, usually differing only in the data type. C interface LAPACK function names follow the form `<fmt><name>`, where `<fmt>` is:
• LAPACKE_s for float
• LAPACKE_d for double
• LAPACKE_c for lapack_complex_float
• LAPACKE_z for lapack_complex_double

A specific example follows. To solve a system of linear equations with a packed Cholesky-factored Hermitian positive-definite matrix with complex precision, use the following:

```c
lapack_int LAPACKE_cpptrs(int matrix_layout, char uplo, lapack_int n, lapack_int nrhs,
const lapack_complex_float* ap, lapack_complex_float* b, lapack_int ldb);
```

**Workspace Arrays**

In contrast to the Fortran interface, the LAPACK C interface omits workspace parameters because workspace is allocated during runtime and released upon completion of the function operation.

If you prefer to allocate workspace arrays yourself, the LAPACK C interface provides alternate interfaces with `work` parameters. The name of the alternate interface is the same as the LAPACK C interface with `_work` appended. For example, the syntax for the singular value decomposition of a real bidiagonal matrix is:

**Fortran:**
```
call sbdsdc ( uplo, compq, n, d, e, u, ldu, vt, ldvt, q, iq,
             work, iwork, info )
```

**C LAPACK interface:**
```
lapack_int LAPACKE_sbdsdc ( int matrix_layout, char uplo, char
                           compq, lapack_int n, float* d, float* e, float* u, lapack_int
                           ldu, float* vt, lapack_int ldvt, float* q, lapack_int* iq );
```

**Alternate C LAPACK interface with `work` parameters:**
```
lapack_int LAPACKE_sbdsdc_work( int matrix_layout, char uplo,
                            char compq, lapack_int n, float* d, float* e, float* u,
                            lapack_int ldu, float* vt, lapack_int ldvt, float* q, lapack_int*
                            iq, float* work, lapack_int* iwork );
```

See the `install_dir/include/mkl_lapacke.h` file for the full list of alternative C LAPACK interfaces.

The Intel® MKL Fortran-specific documentation contains details about workspace arrays.

**Mapping Fortran Data Types against C Data Types**

<table>
<thead>
<tr>
<th>FORTRAN</th>
<th>C</th>

</tbody>
</table>

**C Type Definitions**

You can find type definitions specific to Intel® MKL such as `MKL_INT`, `MKL_Complex8`, and `MKL_Complex16` in `install_dir/mkl_types.h`. 
C types

```c
#ifndef lapack_int
#define lapack_int MKL_INT
#endif

#ifndef lapack_logical
#define lapack_logical lapack_int
#endif
```

Complex Type Definitions

Complex type for single precision:

```c
#ifndef lapack_complex_float
#define lapack_complex_float MKL_Complex8
#endif
```

Complex type for double precision:

```c
#ifndef lapack_complex_double
#define lapack_complex_double MKL_Complex16
#endif
```

Matrix Layout Definitions

```c
#define LAPACK_ROW_MAJOR  101
#define LAPACK_COL_MAJOR  102
```

See Matrix Layout for LAPACK Routines for an explanation of row-major order and column-major order storage.

Error Code Definitions

```c
#define LAPACK_WORK_MEMORY_ERROR       -1010  /* Failed to allocate memory for a working array */
#define LAPACK_TRANSPOSE_MEMORY_ERROR  -1011  /* Failed to allocate memory for transposed matrix */
```

## Matrix Layout for LAPACK Routines

There are two general methods of storing a two dimensional matrix in linear (one dimensional) memory: column-wise (column major order) or row-wise (row major order). Consider an $M$-by-$N$ matrix $A$:

\[
A = \begin{bmatrix}
    a_{11} & a_{12} & \cdots & a_{1L_1} & a_{1L_1+1} & a_{1L_1+2} & \cdots & a_{1L_1+L-1} & a_{1L_1+L} & \cdots & a_{1N} \\
    a_{21} & a_{22} & \cdots & a_{2L_2} & a_{2L_2+1} & a_{2L_2+2} & \cdots & a_{2L_2+L-1} & a_{2L_2+L} & \cdots & a_{2N} \\
    \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\
    a_{b+1L_1} & a_{b+1L_1+1} & a_{b+1L_1+2} & \cdots & a_{b+1L_1+L-1} & a_{b+1L_1+L} & \cdots & a_{b+1L_1+L-1} & a_{b+1L_1+L} & \cdots & a_{b+1N} \\
    a_{b+2L_1} & a_{b+2L_1+1} & a_{b+2L_1+2} & \cdots & a_{b+2L_1+L-1} & a_{b+2L_1+L} & \cdots & a_{b+2L_1+L-1} & a_{b+2L_1+L} & \cdots & a_{b+2N} \\
    \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\
    a_{b+K-L_1} & a_{b+K-L_1+1} & a_{b+K-L_1+2} & \cdots & a_{b+K-L_1+L-1} & a_{b+K-L_1+L} & \cdots & a_{b+K-L_1+L-1} & a_{b+K-L_1+L} & \cdots & a_{b+K-N} \\
    a_{b+K} & a_{b+K+1} & \cdots & a_{b+K+K-1} & a_{b+K+K} & a_{b+K+K+1} & \cdots & a_{b+K+K} & a_{b+K+K+1} & \cdots & a_{b+K+K-N} \\
    \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\
    a_{M+1} & a_{M+2} & \cdots & a_{M,L_2} & a_{M,L_2+1} & a_{M,L_2+2} & \cdots & a_{M,L_2+L-1} & a_{M,L_2+L} & \cdots & a_{M,N} \\
\end{bmatrix}
\]
**Column Major Layout**

In column major layout the first index, $i$, of matrix elements $a_{ij}$ changes faster than the second index when accessing sequential memory locations. In other words, for $1 \leq i < M$, if the element $a_{ij}$ is stored in a specific location in memory, the element $a_{i+1,j}$ is stored in the next location, and, for $1 \leq j < N$, the element $a_{M,j}$ is stored in the location previous to element $a_{1,j+1}$. So the matrix elements are located in memory according to this sequence:

$$\{a_{1,1}, a_{2,1}, \ldots, a_{M,1}, a_{1,2}, \ldots, a_{M,2}, \ldots, a_{1,N}, a_{2,N}, \ldots, a_{M,N}\}$$

**Row Major Layout**

In row major layout the second index, $j$, of matrix elements $a_{ij}$ changes faster than the first index when accessing sequential memory locations. In other words, for $1 \leq j < N$, if the element $a_{ij}$ is stored in a specific location in memory, the element $a_{i,j+1}$ is stored in the next location, and, for $1 \leq i < M$, the element $a_{i,N}$ is stored in the location previous to element $a_{i+1,1}$. So the matrix elements are located in memory according to this sequence:

$$\{a_{1,1}, a_{1,2}, \ldots, a_{1,N}, a_{2,1}, a_{2,2}, \ldots, a_{2,N}, \ldots, a_{M,1}, a_{M,2}, \ldots, a_{M,N}\}$$

**Leading Dimension Parameter**

A leading dimension parameter allows use of LAPACK routines on a submatrix of a larger matrix. For example, the submatrix $B$ can be extracted from the original matrix $A$ defined previously:

$$B = \begin{bmatrix}
    a_{b+1,j_0+1} & a_{b+1,j_0+2} & \cdots & a_{b+1,j_0+L-1} & a_{b+1,j_0+L} \\
    a_{b+2,j_0+1} & a_{b+2,j_0+2} & \cdots & a_{b+2,j_0+L-1} & a_{b+2,j_0+L} \\
    \vdots & \vdots & \ddots & \vdots & \vdots \\
    a_{b+K-1,j_0+1} & a_{b+K-1,j_0+2} & \cdots & a_{b+K-1,j_0+L-1} & a_{b+K-1,j_0+L} \\
    a_{b+K,j_0+1} & a_{b+K,j_0+2} & \cdots & a_{b+K,j_0+L-1} & a_{b+K,j_0+L}
\end{bmatrix}$$

$B$ is formed from rows with indices $i_0 + 1$ to $i_0 + K$ and columns $j_0 + 1$ to $j_0 + L$ of matrix $A$. To specify matrix $B$, LAPACK routines require four parameters:

- the number of rows $K$;
- the number of columns $L$;
- a pointer to the start of the array containing elements of $B$;
- the leading dimension of the array containing elements of $B$.

The leading dimension depends on the layout of the matrix:

- **Column major layout**
  
  Leading dimension $ldb=M$, the number of rows of matrix $A$.

  Starting address: offset by $i_0 + j_0*ldb$ from $a_{1,1}$.

  $j_0*M + i_0$

  \[
  \begin{array}{cccc}
  a_{1,1} & \cdots & a_{b+1,j_0+1} & a_{b+2,j_0+1} \\
  \downarrow & & \downarrow & \downarrow \\
  a_{b+1,j_0+2} & \cdots & a_{b+K-1,j_0+1} & a_{b+K,j_0+1} \\
  \end{array}
  \]

- **Row major layout**
Leading dimension \( ldb = N \), the number of columns of matrix \( A \).

Starting address: offset by \( i_0 \times ldb + j_0 \) from \( a_{1,1} \).

Matrix Storage Schemes for LAPACK Routines

LAPACK routines use the following matrix storage schemes:

- Full Storage
- Packed Storage
- Band Storage
- Rectangular Full Packed (RFP) Storage

**Full Storage**

Consider an \( m \)-by-\( n \) matrix \( A \):

\[
A = \begin{pmatrix}
a_{1,1} & a_{1,2} & a_{1,3} & \cdots & a_{1,n} \\
a_{2,1} & a_{2,2} & a_{2,3} & \cdots & a_{2,n} \\
a_{3,1} & a_{3,2} & a_{3,3} & \cdots & a_{3,n} \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
a_{m,1} & a_{m,2} & a_{m,3} & \cdots & a_{m,n}
\end{pmatrix}
\]

It is stored in a one-dimensional array \( a \) of length at least \( lda \times n \) for column major layout or \( m \times lda \) for row major layout. Element \( a_{i,j} \) is stored as array element \( a[k] \) where the mapping of \( k(i, j) \) is defined as

- column major layout: \( k(i, j) = i - 1 + (j - 1) \times lda \)
- row major layout: \( k(i, j) = (i - 1) \times lda + j - 1 \)

**NOTE**

Although LAPACK accepts parameter values of zero for matrix size, in general the size of the array used to store an \( m \)-by-\( n \) matrix \( A \) with leading dimension \( lda \) should be greater than or equal to \( \max(1, n \times lda) \) for column major layout and \( \max(1, m \times lda) \) for row major layout.

**NOTE**

Even though the array used to store a matrix is one-dimensional, for simplicity the documentation sometimes refers parts of the array such as rows, columns, upper and lower triangular part, and diagonals. These refer to the parts of the matrix stored within the array. For example, the lower triangle of array \( a \) is defined as the subset of elements \( a[k(i,j)] \) with \( k(i,j) \).
Packed Storage

The packed storage format compactly stores matrix elements when only one part of the matrix, the upper or lower triangle, is necessary to determine all of the elements of the matrix. This is the case when the matrix is upper triangular, lower triangular, symmetric, or Hermitian. For an \( n \times n \) matrix of one of these types, a linear array \( a_p \) of length \( n(n + 1)/2 \) is adequate. Two parameters define the storage scheme: \( \text{matrix\_layout} \), which specifies column major (with the value \( \text{LAPACK\_COL\_MAJOR} \)) or row major (with the value \( \text{LAPACK\_ROW\_MAJOR} \)) matrix layout, and \( \text{uplo} \), which specifies that the upper triangle (with the value ‘U’) or the lower triangle (with the value ‘L’) is stored.

Element \( a_{ij} \) is stored as array element \( a[k] \) where the mapping of \( k(i, j) \) is defined as

<table>
<thead>
<tr>
<th>( \text{uplo} )</th>
<th>( \text{matrix_layout} = \text{LAPACK_COL_MAJOR} )</th>
<th>( \text{matrix_layout} = \text{LAPACK_ROW_MAJOR} )</th>
</tr>
</thead>
<tbody>
<tr>
<td>‘U’</td>
<td>( k(i, j) = i - 1 + j*(j - 1)/2 )</td>
<td>( k(i, j) = j - 1 + (i - 1)<em>(2</em>n - i)/2 )</td>
</tr>
<tr>
<td>‘L’</td>
<td>( k(i, j) = i - 1 + (j - 1)<em>(2</em>n - j)/2 )</td>
<td>( k(i, j) = j - 1 + i*(i - 1)/2 )</td>
</tr>
</tbody>
</table>

NOTE

Although LAPACK accepts parameter values of zero for matrix size, in general the size of the array should be greater than or equal to \( \max(1, nx(n + 1)/2) \).

Band Storage

When the non-zero elements of a matrix are confined to diagonal bands, it is possible to store the elements more efficiently using band storage. For example, consider an \( m \times n \) band matrix \( A \) with \( kl \) subdiagonals and \( ku \) superdiagonals:

\[
A = \begin{pmatrix}
a_{1,1} & a_{1,2} & \cdots & a_{1,k_u + 1} \\
\vdots & \vdots & \ddots & \vdots \\
a_{k_l + 1,1} & a_{k_l + 1,2} & \cdots & a_{k_l + 1,k_u + 1} \\
a_{k_l + 2,2} & \ddots & \ddots & \ddots \\
\vdots & \ddots & \ddots & \ddots \\
a_{k_l + j,j} & a_{k_l + j,j + 1} & \cdots & a_{k_l + j,k_l + k_u + j}
\end{pmatrix}
\]

This matrix can be stored compactly in a one dimensional array \( ab \). There are two operations involved in storing the matrix: packing the band matrix into matrix \( AB \), and converting the packed matrix to a one-dimensional array.

- Packing the Band Matrix: How the band matrix is packed depends on the matrix layout.
  - Column major layout: matrix \( A \) is packed in an \( ldab \)-by-\( n \) matrix \( AB \) column-wise so that the diagonals of \( A \) become rows of array \( AB \).
Converting the Packed Matrix to a One-Dimensional Array: The packed matrix in column major layout:

\[ AB = \begin{pmatrix}
  a_{1,1} & a_{1,2} & \cdots & a_{1,k_u + 1} \\
  \vdots & \vdots & \ddots & \vdots \\
  a_{k_l + 1,1} & a_{k_l + 1,2} & \cdots & a_{k_l + 1, k_l + 1} \\
  a_{k_l + 2,1} & a_{k_l + 2,2} & \cdots & a_{k_l + 2, k_l + 2} \\
  \vdots & \vdots & \ddots & \vdots \\
  a_{k_l + k_u,1} & a_{k_l + k_u,2} & \cdots & a_{k_l + k_u, k_l + k_u + 1}
\end{pmatrix} \]

The number of rows of \( AB \cdot ldab \geq kl + ku + 1 \), and the number of columns of \( AB \) is \( n \).

- Row major layout: matrix \( A \) is packed in an \( m \)-by-\( ldab \) matrix \( AB \) row-wise so that the diagonals of \( A \) become columns of \( AB \).

\[ AB = \begin{pmatrix}
  a_{1,1} & a_{1,2} & \cdots & a_{1,k_u + 1} \\
  a_{2,1} & a_{2,2} & \cdots & a_{2,k_u + 2} \\
  a_{3,1} & a_{3,2} & \cdots & a_{3,k_u + 3} \\
  \vdots & \vdots & \ddots & \vdots \\
  a_{k_l + 1,1} & a_{k_l + 1,2} & \cdots & a_{k_l + 1, k_l + 1} \\
  a_{k_l + 2,1} & a_{k_l + 2,2} & \cdots & a_{k_l + 2, k_l + 2} \\
  a_{k_l + 3,1} & a_{k_l + 3,2} & \cdots & a_{k_l + 3, k_l + 3} \\
  \vdots & \vdots & \ddots & \vdots \\
  a_{k_l + k_u,1} & a_{k_l + k_u,2} & \cdots & a_{k_l + k_u, k_l + k_u + 1}
\end{pmatrix} \]

The number of columns of \( AB \cdot ldab \geq kl + ku + 1 \), and the number of rows of \( AB \) is \( m \).

**NOTE**

For both column major and row major layout, elements of the upper left triangle of \( AB \) are not used. Depending on the relationship of the dimensions \( m, n, kl, \) and \( ku \), the lower right triangle might not be used.

- Converting the Packed Matrix to a One-Dimensional Array: The packed matrix \( AB \) is stored in a linear array \( ab \) as described in **Full Storage**. The size of \( ab \) should be greater than or equal to the total number of elements of matrix \( AB: ldab \cdot n \) for column major layout or \( ldab \cdot m \) for row major layout. The leading dimension of \( ab, ldab \), must be greater than or equal to \( kl + ku + 1 \) (and some routines require it to be even larger).

Element \( a_{ij} \) is stored as array element \( a[k(i, j)] \) where the mapping of \( k(i, j) \) is defined as

- column major layout: \( k(i, j) = i + ku - j + (j - 1) \cdot ldab; 1 \leq j \leq n, \max(1, j - ku) \leq k \leq \min(m, j + kl) \)
- row major layout: \( k(i,j) = j - i + k_l + (i - 1)(k_u + 1), 1 \leq i \leq m, \max(1, i - k_l) \leq j \leq \min(n, i + k_u) \)

**NOTE**

Although LAPACK accepts parameter values of zero for matrix size, in general the size of the array should be greater than or equal to \( \max(1, n \cdot ldab) \) for column major layout and \( \max(1, m \cdot ldab) \) for row major layout.
Rectangular Full Packed Storage

A combination of full and packed storage, rectangular full packed storage can be used to store the upper or lower triangle of a matrix which is upper triangular, lower triangular, symmetric, or Hermitian. It offers the storage savings of packed storage plus the efficiency of using full storage Level 3 BLAS and LAPACK routines. Three parameters define the storage scheme: matrix_layout, which specifies column major (with the value LAPACK_COL_MAJOR) or row major (with the value LAPACK_ROW_MAJOR) matrix layout; uplo, which specifies that the upper triangle (with the value 'U') or the lower triangle (with the value 'L') is stored; and transr, which specifies normal (with the value 'N'), transpose (with the value 'T'), or conjugate transpose (with the value 'C') operation on the matrix.

Consider an $N$ by $N$ matrix $A$:

$$ A = \begin{pmatrix} a_{0,0} & a_{0,1} & a_{0,2} & \cdots & a_{0,N-1} \\ a_{1,0} & a_{1,1} & a_{1,2} & \cdots & a_{1,N-1} \\ a_{2,0} & a_{2,1} & a_{2,2} & \cdots & a_{2,N-1} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{N-1,0} & a_{N-1,1} & a_{N-1,2} & \cdots & a_{N-1,N-1} \end{pmatrix} $$

The upper or lower triangle of $A$ can be stored in the array $ap$ of length $N^2(N + 1)/2$.

Additionally, define $k$ as the integer part of $N/2$, such that $N=2k$ if $N$ is even, and $N=2k + 1$ if $N$ is odd.

Storing the matrix involves packing the matrix into a rectangular matrix, and then storing the matrix in a one-dimensional array. The size of rectangular matrix $AP$ required for the $N$ by $N$ matrix $A$ is $N + 1$ by $N/2$ for even $N$, and $N$ by $(N + 1)/2$ for odd $N$.

These examples illustrate the rectangular full packed storage method.

- **Upper triangular** - $uplo = 'U'$

  Consider a matrix $A$ with $N = 6$:

  $$ A = \begin{pmatrix} a_{0,0} & a_{0,1} & a_{0,2} & a_{0,3} & a_{0,4} & a_{0,5} \\ a_{1,0} & a_{1,1} & a_{1,2} & a_{1,3} & a_{1,4} & a_{1,5} \\ a_{2,0} & a_{2,1} & a_{2,2} & a_{2,3} & a_{2,4} & a_{2,5} \\ a_{3,0} & a_{3,1} & a_{3,2} & a_{3,3} & a_{3,4} & a_{3,5} \\ a_{4,0} & a_{4,1} & a_{4,2} & a_{4,3} & a_{4,4} & a_{4,5} \\ a_{5,0} & a_{5,1} & a_{5,2} & a_{5,3} & a_{5,4} & a_{5,5} \end{pmatrix} $$

- **Not transposed** - $transr = 'N'$

  The elements of the upper triangle of $A$ can be packed in a matrix with the dimensions $(N + 1)$ by $(N/2) = 7$ by $3$:

  $$ AP = \begin{pmatrix} a_{0,0} & a_{0,1} & a_{0,2} \\ a_{1,0} & a_{1,1} & a_{1,2} \\ a_{2,0} & a_{2,1} & a_{2,2} \\ a_{3,0} & a_{3,1} & a_{3,2} \\ a_{4,0} & a_{4,1} & a_{4,2} \\ a_{5,0} & a_{5,1} & a_{5,2} \end{pmatrix} $$

- **Transposed or conjugate transposed** - $transr = 'T'$ or $transr = 'C'$

The elements of the upper triangle of $A$ can be packed in a matrix with the dimensions $(N/2)$ by $(N + 1) = 3$ by 7:

$$
AP = \begin{pmatrix}
a_{0,3} & a_{1,3} & a_{2,3} & a_{3,3} & a_{0,0} & a_{0,1} & a_{0,2} \\
a_{0,4} & a_{1,4} & a_{2,4} & a_{3,4} & a_{4,4} & a_{1,1} & a_{1,2} \\
a_{0,5} & a_{1,5} & a_{2,5} & a_{3,5} & a_{4,5} & a_{5,5} & a_{2,2}
\end{pmatrix}
$$

Consider a matrix $A$ with $N = 5$:

$$
A = \begin{pmatrix}
a_{0,0} & a_{0,1} & a_{0,2} & a_{0,3} & a_{0,4} \\
a_{1,0} & a_{1,1} & a_{1,2} & a_{1,3} & a_{1,4} \\
a_{2,0} & a_{2,1} & a_{2,2} & a_{2,3} & a_{2,4} \\
a_{3,0} & a_{3,1} & a_{3,2} & a_{3,3} & a_{3,4} \\
a_{4,0} & a_{4,1} & a_{4,2} & a_{4,3} & a_{4,4}
\end{pmatrix}
$$

- **Not transposed - $\text{transr} = 'N'$**

  The elements of the upper triangle of $A$ can be packed in a matrix with the dimensions $(N)$-by-$(N + 1)/2) = 5$ by 3:

  $$
  AP = \begin{pmatrix}
a_{0,2} & a_{0,3} & a_{0,4} \\
a_{1,2} & a_{1,3} & a_{1,4} \\
a_{2,2} & a_{2,3} & a_{2,4} \\
a_{0,0} & a_{3,3} & a_{3,4} \\
a_{0,1} & a_{4,1} & a_{4,4}
  \end{pmatrix}
  $$

- **Transposed or conjugate transposed - $\text{transr} = 'T'$ or $\text{transr} = 'C'$**

  The elements of the upper triangle of $A$ can be packed in a matrix with the dimensions $(N+1)/2)$ by $(N) = 5$ by 3:

  $$
  AP = \begin{pmatrix}
a_{0,2} & a_{1,2} & a_{2,3} & a_{0,0} & a_{0,1} \\
a_{0,3} & a_{1,3} & a_{2,3} & a_{3,3} & a_{1,1} \\
a_{0,4} & a_{1,4} & a_{2,4} & a_{3,4} & a_{4,4}
  \end{pmatrix}
  $$

- **Lower triangular - $\text{uplo} = 'L'$**

  Consider a matrix $A$ with $N = 6$:

  $$
  A = \begin{pmatrix}
a_{0,0} & a_{0,1} & a_{0,2} & a_{0,3} & a_{0,4} & a_{0,5} \\
a_{1,0} & a_{1,1} & a_{1,2} & a_{1,3} & a_{1,4} & a_{1,5} \\
a_{2,0} & a_{2,1} & a_{2,2} & a_{2,3} & a_{2,4} & a_{2,5} \\
a_{3,0} & a_{3,1} & a_{3,2} & a_{3,3} & a_{3,4} & a_{3,5} \\
a_{4,0} & a_{4,1} & a_{4,2} & a_{4,3} & a_{4,4} & a_{4,5} \\
a_{5,0} & a_{5,1} & a_{5,2} & a_{5,3} & a_{5,4} & a_{5,5}
  \end{pmatrix}
  $$

- **Not transposed - $\text{transr} = 'N'$**

  The elements of the lower triangle of $A$ can be packed in a matrix with the dimensions $(N + 1)$-by-$(N/2) = 7$ by 3:
The elements of the lower triangle of $A$ can be packed in a matrix with the dimensions $(N/2) \times (N + 1) = 3 \times 7$:

$$AP = \begin{pmatrix}
a_{3,3} & a_{4,3} & a_{5,3} \\
a_{0,0} & a_{1,4} & a_{5,4} \\
a_{1,0} & a_{1,1} & a_{5,5}
\end{pmatrix}$$

- Transposed or conjugate transposed - $\text{transr} = 'T'$ or $\text{transr} = 'C'$

The elements of the lower triangle of $A$ can be packed in a matrix with the dimensions $(N/2) \times (N + 1) = 3 \times 7$:

$$AP = \begin{pmatrix}
a_{3,3} & a_{0,0} & a_{1,0} & a_{2,0} & a_{3,0} & a_{4,0} & a_{5,0} \\
a_{4,3} & a_{4,4} & a_{1,1} & a_{2,1} & a_{3,1} & a_{4,1} & a_{5,1} \\
a_{5,3} & a_{5,4} & a_{5,5} & a_{2,2} & a_{3,2} & a_{4,2} & a_{5,2}
\end{pmatrix}$$

Consider a matrix $A$ with $N = 5$:

$$A = \begin{pmatrix}
a_{0,0} & a_{0,1} & a_{0,2} & a_{0,3} & a_{0,4} \\
a_{1,0} & a_{1,1} & a_{1,2} & a_{1,3} & a_{1,4} \\
a_{2,0} & a_{2,1} & a_{2,2} & a_{2,3} & a_{2,4} \\
a_{3,0} & a_{3,1} & a_{3,2} & a_{3,3} & a_{3,4} \\
a_{4,0} & a_{4,1} & a_{4,2} & a_{4,3} & a_{4,4}
\end{pmatrix}$$

- Not transposed - $\text{transr} = 'N'$

The elements of the lower triangle of $A$ can be packed in a matrix with the dimensions $(N) \times ((N + 1)/2) = 5 \times 3$:

$$AP = \begin{pmatrix}
a_{0,0} & a_{3,3} & a_{4,3} \\
a_{1,0} & a_{1,1} & a_{4,4} \\
a_{2,0} & a_{2,1} & a_{2,2} \\
a_{3,0} & a_{3,1} & a_{3,2} \\
a_{4,0} & a_{4,1} & a_{4,2}
\end{pmatrix}$$

- Transposed or conjugate transposed - $\text{transr} = 'T'$ or $\text{transr} = 'C'$

The elements of the lower triangle of $A$ can be packed in a matrix with the dimensions $((N+1)/2) \times (N) = 5 \times 3$:

$$AP = \begin{pmatrix}
a_{0,0} & a_{1,0} & a_{2,0} & a_{3,0} & a_{4,0} \\
a_{3,3} & a_{1,1} & a_{2,1} & a_{3,1} & a_{4,1} \\
a_{4,3} & a_{4,4} & a_{2,2} & a_{3,2} & a_{4,2}
\end{pmatrix}$$

The packed matrix $AP$ can be stored using column major layout or row major layout.
NOTE
The `matrix_layout` and `transr` parameters can specify the same storage scheme: for example, the storage scheme for `matrix_layout = LAPACK_COL_MAJOR` and `transr = 'N'` is the same as that for `matrix_layout = LAPACK_ROW_MAJOR` and `transr = 'T'`.

Element $a_{ij}$ is stored as array element $ap[l]$ where the mapping of $(i,j)$ is defined in the following tables.

- **Column major layout:** `matrix_layout = LAPACK_COL_MAJOR`

<table>
<thead>
<tr>
<th>transr</th>
<th>uplo</th>
<th>N</th>
<th>$l(i, j) =$</th>
<th>$i$</th>
<th>$j$</th>
</tr>

</tr>
</tbody>
</table>

**NOTE**

Although LAPACK accepts parameter values of zero for matrix size, in general the size of the array should be greater than or equal to max(1, $N^*(N + 1)/2$).
For an \( M \)-by-\( N \) matrix \( A \), denotes the conjugate transposed \( N \)-by-\( M \) matrix with elements:

\[
A_H^{H} = \overline{A_{ij}}
\]

For a real-valued matrix, \( A^H = A^T \).

The dot product of two vectors, defined as:

\[
x \cdot y = \sum_{i} x_i y_i
\]

Ax = b

A system of linear equations with an \( n \)-by-\( n \) matrix \( A = \{a_{ij}\} \), a right-hand side vector \( b = \{b_j\} \), and an unknown vector \( x = \{x_i\} \).

AX = B

A set of systems with a common matrix \( A \) and multiple right-hand sides. The columns of \( B \) are individual right-hand sides, and the columns of \( X \) are the corresponding solutions.

|\( x |\)

the vector with elements |\( x_i |\) (absolute values of \( x_i \)).

|\( A |\)

the matrix with elements |\( a_{ij} |\) (absolute values of \( a_{ij} \)).

|\( |\sum_{i} x_i |\)\( \infty \ginfty\) = max |\( x_i |\)

The infinity-norm of the vector \( x \).

|\( |\sum_{i} a_{ij} |\)\( \infty \ginfty\) = max |\( a_{ij} |\)

The infinity-norm of the matrix \( A \).

|\( |\sum_{i} |\sum_{j} a_{ij} |\)\( \infty \ginfty\) = max |\( a_{ij} |\)

The one-norm of the matrix \( A \).

|\( |\sum_{i} x_i |\)\( 2 \ginfty\) = (\( \sum_{i} |x_i |^2 \))^{1/2}

The 2-norm of the vector \( x \): |\( x |\)\( 2 \ginfty\) = |\( x \) (see the definition for Euclidean norm in this section).

|\( |\sum_{i} x_i |\)\( 2 \ginfty\) = (\( \sum_{i} |x_i |^2 \))^{1/2}

The 2-norm (or spectral norm) of the matrix \( A \).

\[
|A|_2 = \max_{\|\mathbf{x}\| = 1} \|A\mathbf{x}\|_2
\]

The Euclidean norm of the matrix \( A \): \( |A|_E = (\sum_{i} |a_{ij} |^2)^{1/2} \).

\( \kappa (A) = |\|A\| \cdot |\|A^{-1}\|| \)

The condition number of the matrix \( A \).

\( \lambda_i \)

Eigenvalues of the matrix \( A \) (for the definition of eigenvalues, see Eigenvalue Problems).

\( \sigma_i \)

Singular values of the matrix \( A \). They are equal to square roots of the eigenvalues of \( A^T A \). (For more information, see Singular Value Decomposition).

---

**Error Analysis**

In practice, most computations are performed with rounding errors. Besides, you often need to solve a system \( Ax = b \) where the data (the elements of \( A \) and \( b \)) are not known exactly. Therefore, it is important to understand how the data errors and rounding errors can affect the solution \( x \).

**Data perturbations.** If \( x \) is the exact solution of \( Ax = b \), and \( x + \delta x \) is the exact solution of a perturbed problem \( (A + \delta A)(x + \delta x) = (b + \delta b) \), then this estimate, given up to linear terms of perturbations, holds:
where $A + \delta A$ is nonsingular and

$$\frac{\|\delta x\|}{\|x\|} \leq \kappa(A) \left( \frac{\|\delta A\|}{\|A\|} + \frac{\|\delta b\|}{\|b\|} \right)$$

In other words, relative errors in $A$ or $b$ may be amplified in the solution vector $x$ by a factor $\kappa(A) = \|A\|\|A^{-1}\|$ called the condition number of $A$.

Rounding errors have the same effect as relative perturbations $c(n)\epsilon$ in the original data. Here $\epsilon$ is the machine precision, defined as the smallest positive number $x$ such that $1 + x > 1$; and $c(n)$ is a modest function of the matrix order $n$. The corresponding solution error is

$$\|\delta x\|/\|x\| \leq c(n)\kappa(A)\epsilon.$$ (The value of $c(n)$ is seldom greater than $10n$.)

**NOTE**

Machine precision depends on the data type used. For example, it is usually defined in the `float.h` file as `FLT_EPSILON` the float datatype and `DBL_EPSILON` for the double datatype.

Thus, if your matrix $A$ is ill-conditioned (that is, its condition number $\kappa(A)$ is very large), then the error in the solution $x$ can also be large; you might even encounter a complete loss of precision. LAPACK provides routines that allow you to estimate $\kappa(A)$ (see Routines for Estimating the Condition Number) and also give you a more precise estimate for the actual solution error (see Refining the Solution and Estimating Its Error).

**LAPACK Linear Equation Routines**

This section describes routines for performing the following computations:
- factoring the matrix (except for triangular matrices)
- equilibrating the matrix (except for RFP matrices)
- solving a system of linear equations
- estimating the condition number of a matrix (except for RFP matrices)
- refining the solution of linear equations and computing its error bounds (except for RFP matrices)
- inverting the matrix.

To solve a particular problem, you can call two or more computational routines or call a corresponding driver routine that combines several tasks in one call. For example, to solve a system of linear equations with a general matrix, call `?getrf` (LU factorization) and then `?getrs` (computing the solution). Then, call `?gerfs` to refine the solution and get the error bounds. Alternatively, use the driver routine `?gesvx` that performs all these tasks in one call.

**LAPACK Linear Equation Computational Routines**

Table "Computational Routines for Systems of Equations with Real Matrices" lists the LAPACK computational routines for factorizing, equilibrating, and inverting real matrices, estimating their condition numbers, solving systems of equations with real matrices, refining the solution, and estimating its error. Table "Computational Routines for Systems of Equations with Complex Matrices" lists similar routines for complex matrices.

LAPACK Routines
Matrix Factorization: LAPACK Computational Routines

This section describes the LAPACK routines for matrix factorization. The following factorizations are supported:

- LU factorization
- Cholesky factorization of real symmetric positive-definite matrices
- Cholesky factorization of real symmetric positive-definite matrices with pivoting
- Cholesky factorization of Hermitian positive-definite matrices
- Cholesky factorization of Hermitian positive-definite matrices with pivoting
- Bunch-Kaufman factorization of real and complex symmetric matrices
- Bunch-Kaufman factorization of Hermitian matrices.

You can compute:

- the LU factorization using full and band storage of matrices
- the Cholesky factorization using full, packed, RFP, and band storage
- the Bunch-Kaufman factorization using full and packed storage.

`?getrf`

*Computes the LU factorization of a general m-by-n matrix.*

**Syntax**

```c
lapack_int LAPACKE_sgetrf (int matrix_layout, lapack_int m, lapack_int n, float * a, lapack_int lda, lapack_int * ipiv);
lapack_int LAPACKE_dgetrf (int matrix_layout, lapack_int m, lapack_int n, double * a, lapack_int lda, lapack_int * ipiv);
lapack_int LAPACKE_cgetrf (int matrix_layout, lapack_int m, lapack_int n, lapack_complex_float * a, lapack_int lda, lapack_int * ipiv);
lapack_int LAPACKE_zgetrf (int matrix_layout, lapack_int m, lapack_int n, lapack_complex_double * a, lapack_int lda, lapack_int * ipiv);
```

**Include Files**

- mkl.h

**Description**

The routine computes the LU factorization of a general m-by-n matrix $A$ as

$$A = P*L*U,$$

where $P$ is a permutation matrix, $L$ is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$) and $U$ is upper triangular (upper trapezoidal if $m < n$). The routine uses partial pivoting, with row interchanges.

**NOTE**

This routine supports the Progress Routine feature. See Progress Functions section for details.

**Input Parameters**

- `matrix_layout`: Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
m
n
a
lda

The number of rows in the matrix A (m≥ 0).
The number of columns in A; n≥ 0.
Array, size at least \( \max(1, lda\cdot n) \) for column-major layout or \( \max(1, lda\cdot m) \) for row-major layout. Contains the matrix A.
The leading dimension of array a, which must be at least \( \max(1, m) \) for column-major layout or \( \max(1, n) \) for row-major layout.

Output Parameters

a
Overwritten by L and U. The unit diagonal elements of L are not stored.
ipiv
Array, size at least \( \max(1, \min(m, n)) \). Contains the pivot indices; for \( 1 \leq i \leq \min(m, n) \), row i was interchanged with row ipiv(i).

Return Values

This function returns a value info.
If info=0, the execution is successful.
If info = -i, parameter i had an illegal value.
If info = i, \( u_{ii} \) is 0. The factorization has been completed, but U is exactly singular. Division by 0 will occur if you use the factor U for solving a system of linear equations.

Application Notes

The computed L and U are the exact factors of a perturbed matrix A + E, where

\[
|E| \leq c(\min(m,n))\epsilon \|L\|\|U\|
\]

\( c(n) \) is a modest linear function of n, and \( \epsilon \) is the machine precision.

The approximate number of floating-point operations for real flavors is

\[
\begin{align*}
(2/3)n^3 & \quad \text{If } m = n, \\
(1/3)n^2(3m-n) & \quad \text{If } m>n, \\
(1/3)m^2(3n-m) & \quad \text{If } m<n.
\end{align*}
\]

The number of operations for complex flavors is four times greater.

After calling this routine with \( m = n \), you can call the following:

?-getrs to solve \( A^r X = B \) or \( A^t X = B \) or \( A^H X = B \)

?-gecon to estimate the condition number of A

?-getri to compute the inverse of A.

See Also

mkl_progress

Matrix Storage Schemes
mkl_getrfnp
Computes the LU factorization of a general m-by-n matrix without pivoting.

Syntax

```c
lapack_int LAPACKE_mkl_sgetrfnp (int matrix_layout, lapack_int m, lapack_int n,
                         float * a, lapack_int lda);

lapack_int LAPACKE_mkl_dgetrfnp (int matrix_layout, lapack_int m, lapack_int n,
                         double * a, lapack_int lda);

lapack_int LAPACKE_mkl_cgetrfnp (int matrix_layout, lapack_int m, lapack_int n,
                         lapack_complex_float * a, lapack_int lda);

lapack_int LAPACKE_mkl_zgetrfnp (int matrix_layout, lapack_int m, lapack_int n,
                         lapack_complex_double * a, lapack_int lda);
```

Include Files

- mkl.h

Description

The routine computes the LU factorization of a general m-by-n matrix A as

\[ A = L*U, \]

where L is lower triangular with unit-diagonal elements (lower trapezoidal if \( m > n \)) and U is upper triangular (upper trapezoidal if \( m < n \)). The routine does not use pivoting.

Input Parameters

- `matrix_layout`
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- `m`
  The number of rows in the matrix A \((m \geq 0)\).

- `n`
  The number of columns in A; \( n \geq 0 \).

- `a`
  Array, size at least max(1, \( lda*n \)) for column-major layout or max(1, \( lda*m \)) for row-major layout. Contains the matrix A.

- `lda`
  The leading dimension of array a, which must be at least max(1, \( m \)) for column-major layout or max(1, \( n \)) for row-major layout.

Output Parameters

- `a`
  Overwritten by L and U. The unit diagonal elements of L are not stored.

Return Values

This function returns a value `info`.

If \( info=0 \), the execution is successful.

If \( info = -i \), parameter \( i \) had an illegal value.

If \( info = i \), \( u_{ii} \) is 0. The factorization has been completed, but U is exactly singular. Division by 0 will occur if you use the factor U for solving a system of linear equations.
Application Notes

The approximate number of floating-point operations for real flavors is

\[(2/3)n^3\]  \quad \text{If } m = n,

\[(1/3)n^2(3m-n)\]  \quad \text{If } m > n,

\[(1/3)m^2(3n-m)\]  \quad \text{If } m < n.

The number of operations for complex flavors is four times greater.

After calling this routine with \(m = n\), you can call the following:

mkl\_?getrinp to compute the inverse of \(A\)

See Also

mkl\_progress

Matrix Storage Schemes

mkl\_?getrfnpi

Performs LU factorization (complete or incomplete) of a general matrix without pivoting.

Syntax

\[
\begin{align*}
\text{lapack_int LAPACKE_mkl_sgetrfnpi (int matrix_layout, lapack_int m, lapack_int n,}\ \\
\text{lapack_int nfact, float* a, lapack_int lda);}
\text{lapack_int LAPACKE_mkl_dgetrfnpi (int matrix_layout, lapack_int m, lapack_int n,}\ \\
\text{lapack_int nfact, double* a, lapack_int lda);}
\text{lapack_int LAPACKE_mkl_cgetrfnpi (int matrix_layout, lapack_int m, lapack_int n,}\ \\
\text{lapack_int nfact, lapack_complex_float* a, lapack_int lda);}
\text{lapack_int LAPACKE_mkl_zgetrfnpi (int matrix_layout, lapack_int m, lapack_int n,}\ \\
\text{lapack_int nfact, lapack_complex_double* a, lapack_int lda);}\
\end{align*}
\]

Include Files

- mkl.h

Description

The routine computes the LU factorization of a general \(m\)-by-\(n\) matrix \(A\) without using pivoting. It supports incomplete factorization. The factorization has the form:

\[A = L^*U,\]

where \(L\) is lower triangular with unit diagonal elements (lower trapezoidal if \(m > n\)) and \(U\) is upper triangular (upper trapezoidal if \(m < n\)).

Incomplete factorization has the form:

\[A = L \ast U + \hat{A}\]

where \(L\) is lower trapezoidal with unit diagonal elements, \(U\) is upper trapezoidal, and \(\hat{A}\) is the unfactored part of matrix \(A\). See the application notes section for further details.
NOTE
Use \texttt{?getrf} if it is possible that the matrix is not diagonal dominant.

**Input Parameters**

\begin{itemize}
  \item \texttt{matrix\_layout} 
    Specifies whether matrix storage layout is row major (\texttt{LAPACK\_ROW\_MAJOR}) or column major (\texttt{LAPACK\_COL\_MAJOR}).
  \item \texttt{m} 
    The number of rows in matrix \(A\); \(m \geq 0\).
  \item \texttt{n} 
    The number of columns in matrix \(A\); \(n \geq 0\).
  \item \texttt{nfact} 
    The number of rows and columns to factor; \(0 \leq nfact \leq \min(m, n)\). Note that if \(nfact < \min(m, n)\), incomplete factorization is performed.
  \item \texttt{a} 
    Array of size at least \(lda\ast n\) for column major layout and at least \(lda\ast m\) for row major layout. Contains the matrix \(A\).
  \item \texttt{lda} 
    The leading dimension of array \(a\). \(lda \geq \max(1, m)\) for column major layout and \(lda \geq \max(1, n)\) for row major layout.
\end{itemize}

**Output Parameters**

\texttt{a} 
Overwritten by \(L\) and \(U\). The unit diagonal elements of \(L\) are not stored.

When incomplete factorization is specified by setting \(nfact < \min(m, n)\), a also contains the unfactored submatrix \(\tilde{A}_{22}\). See the application notes section for further details.

**Return Values**

This function returns a value \(info\).

If \(info=0\), the execution is successful.

If \(info = -i\), the \(i\)-th parameter had an illegal value.

If \(info = i\), \(u_i\) is 0. The requested factorization has been completed, but \(U\) is exactly singular. Division by 0 will occur if factorization is completed and factor \(U\) is used for solving a system of linear equations.

**Application Notes**

The computed \(L\) and \(U\) are the exact factors of a perturbed matrix \(A + E\), with

\[ |E| \leq c(n) \varepsilon |L||U| \]

where \(c(n)\) is a modest linear function of \(n\), and \(\varepsilon\) is the machine precision.

The approximate number of floating-point operations for real flavors is

\begin{align*}
(2/3)n^3 & \quad \text{if} \quad m = n = nfact \\
(1/3)n^2(3m-n) & \quad \text{if} \quad m > n = nfact \\
(1/3)m^2(3n-m) & \quad \text{if} \quad m = nfact < n \\
(2/3)n^3 - (n-nfact)^3 & \quad \text{if} \quad m = n, nfact < \min(m, n)
\end{align*}
The number of operations for complex flavors is four times greater.

When incomplete factorization is specified, the first \( n_{\text{fact}} \) rows and columns are factored, with the update of the remaining rows and columns of \( A \) as follows:

If matrix \( A \) is represented as a block 2-by-2 matrix:

\[
A = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}
\]

where

- \( A_{11} \) is a square matrix of order \( n_{\text{fact}} \),
- \( A_{21} \) is an \((m - n_{\text{fact}})\)-by-\( n_{\text{fact}} \) matrix,
- \( A_{12} \) is an \( n_{\text{fact}} \)-by-\((n - n_{\text{fact}})\) matrix, and
- \( A_{22} \) is an \((m - n_{\text{fact}})\)-by-\((n - n_{\text{fact}})\) matrix.

The result is

\[
A = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix} = \begin{bmatrix} L_1 \\ L_2 \end{bmatrix} \begin{bmatrix} U_1 & U_2 \\ 0 & 0 \end{bmatrix} + \begin{bmatrix} 0 \\ 0 \end{bmatrix}
\]

\( L_1 \) is a lower triangular square matrix of order \( n_{\text{fact}} \) with unit diagonal and \( U_1 \) is an upper triangular square matrix of order \( n_{\text{fact}} \). \( L_1 \) and \( U_1 \) result from LU factorization of matrix \( A_{11} \): \( A_{11} = L_1 U_1 \).

\( L_2 \) is an \((m - n_{\text{fact}})\)-by-\( n_{\text{fact}} \) matrix and \( L_2 = A_{21} U_1^{-1} \). \( U_2 \) is an \( n_{\text{fact}} \)-by-\((n - n_{\text{fact}})\) matrix and \( U_2 = L_1^{-1} A_{12} \).

\( A_{22} \) is an \((m - n_{\text{fact}})\)-by-\((n - n_{\text{fact}})\) matrix and \( \tilde{A}_{22} = A_{22} - L_2 U_2 \).
On exit, elements of the upper triangle \( U_1 \) are stored in place of the upper triangle of block \( A_{11} \) in array \( a \); elements of the lower triangle \( L_1 \) are stored in the lower triangle of block \( A_{11} \) in array \( a \) (unit diagonal elements are not stored). Elements of \( L_2 \) replace elements of \( A_{21} \); \( U_2 \) replaces elements of \( A_{12} \) and \( \tilde{A}_{22} \) replaces elements of \( A_{22} \).

\[ \begin{array}{c}
\text{input} \quad \begin{array}{ccc}
A_{11} & A_{12} \\
A_{21} & A_{22}
\end{array} \\
\downarrow \quad m \\
\downarrow \quad n \\
\end{array} \quad \begin{array}{ccc}
\text{output} \\
U_1 & \ \ \ \ \ \ \ \ \ \ U_2 \\
L_1 & \ \ \ \ \ \ \ \ \ \ \ L_2 \\
& \tilde{A}_{22}
\end{array} \]\n
`getrf2`

*Computes LU factorization using partial pivoting with row interchanges.*

**Syntax**

```c
lapack_int LAPACKE_sgetrf2 (int matrix_layout, lapack_int m, lapack_int n, float * a, lapack_int lda, lapack_int * ipiv);
```

```c
lapack_int LAPACKE_dgetrf2 (int matrix_layout, lapack_int m, lapack_int n, double * a, lapack_int lda, lapack_int * ipiv);
```

```c
lapack_int LAPACKE_cgetrf2 (int matrix_layout, lapack_int m, lapack_int n, lapack_complex_float * a, lapack_int lda, lapack_int * ipiv);
```

```c
lapack_int LAPACKE_zgetrf2 (int matrix_layout, lapack_int m, lapack_int n, lapack_complex_double * a, lapack_int lda, lapack_int * ipiv);
```

**Include Files**

- mkl.h

**Description**

`getrf2` computes an LU factorization of a general \( m \)-by-\( n \) matrix \( A \) using partial pivoting with row interchanges.

The factorization has the form

\[
A = P \cdot L \cdot U
\]

where \( P \) is a permutation matrix, \( L \) is lower triangular with unit diagonal elements (lower trapezoidal if \( m > n \)), and \( U \) is upper triangular (upper trapezoidal if \( m < n \)).

This is the recursive version of the algorithm. It divides the matrix into four submatrices:

\[
A = \begin{pmatrix}
A_{11} & A_{12} \\
A_{21} & A_{22}
\end{pmatrix}
\]
where $A_{11}$ is $n_1$ by $n_1$ and $A_{22}$ is $n_2$ by $n_2$ with $n_1 = \min(m, n)$, and $n_2 = n - n_1$.

The subroutine calls itself to factor $\begin{pmatrix} A_{11} \\ A_{12} \end{pmatrix}$, do the swaps on $\begin{pmatrix} A_{12} \\ A_{22} \end{pmatrix}$, solve $A_{12}$, update $A_{22}$, then it calls itself to factor $A_{22}$ and do the swaps on $A_{21}$.

**Input Parameters**

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **$m$**
  The number of rows of the matrix A. $m \geq 0$.

- **$n$**
  The number of columns of the matrix A. $n \geq 0$.

- **$a$**
  Array, size $lda \times n$.
  On entry, the $m$-by-$n$ matrix to be factored.

- **$lda$**
  The leading dimension of the array $a$. $lda \geq \max(1, m)$.

**Output Parameters**

- **$a$**
  On exit, the factors $L$ and $U$ from the factorization $A = P \times L \times U$; the unit diagonal elements of $L$ are not stored.

- **$ipiv$**
  Array, size $(\min(m, n))$.
  The pivot indices; for $1 \leq i \leq \min(m, n)$, row $i$ of the matrix was interchanged with row $ipiv[i - 1]$.

**Return Values**

This function returns a value $info$.

- $= 0$: successful exit
- $< 0$: if $info = -i$, the $i$-th argument had an illegal value.
- $> 0$: if $info = i$, $U_{ii}$ is exactly zero. The factorization has been completed, but the factor $U$ is exactly singular, and division by zero will occur if it is used to solve a system of equations.

`gbtrf`

*Computes the LU factorization of a general $m$-by-$n$ band matrix.*

**Syntax**

```c
lapack_int LAPACKE_sgbtrf (int matrix_layout, lapack_int m, lapack_int n, lapack_int kl, lapack_int ku, float * ab, lapack_int ldab, lapack_int * ipiv);
lapack_int LAPACKE_dgbtrf (int matrix_layout, lapack_int m, lapack_int n, lapack_int kl, lapack_int ku, double * ab, lapack_int ldab, lapack_int * ipiv);
lapack_int LAPACKE_cgbtrf (int matrix_layout, lapack_int m, lapack_int n, lapack_int kl, lapack_int ku, lapack_complex_float * ab, lapack_int ldab, lapack_int * ipiv);
lapack_int LAPACKE_zgbtrf (int matrix_layout, lapack_int m, lapack_int n, lapack_int kl, lapack_int ku, lapack_complex_double * ab, lapack_int ldab, lapack_int * ipiv);
```
Include Files

- mkl.h

Description

The routine forms the $LU$ factorization of a general $m$-by-$n$ band matrix $A$ with $kl$ non-zero subdiagonals and $ku$ non-zero superdiagonals, that is,

$$ A = P*L*U, $$

where $P$ is a permutation matrix; $L$ is lower triangular with unit diagonal elements and at most $kl$ non-zero elements in each column; $U$ is an upper triangular band matrix with $kl + ku$ superdiagonals. The routine uses partial pivoting, with row interchanges (which creates the additional $kl$ superdiagonals in $U$).

**NOTE**

This routine supports the Progress Routine feature. See Progress Function section for details.

Input Parameters

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **m**
  The number of rows in matrix $A$; $m \geq 0$.

- **n**
  The number of columns in matrix $A$; $n \geq 0$.

- **kl**
  The number of subdiagonals within the band of $A$; $kl \geq 0$.

- **ku**
  The number of superdiagonals within the band of $A$; $ku \geq 0$.

- **ab**
  Array, size at least max(1, $ldab*n$) for column-major layout or max(1, $ldab*m$) for row-major layout. The array $ab$ contains the matrix $A$ in band storage as described in Band Storage.

- **ldab**
  The leading dimension of the array $ab$. ($ldab \geq 2*kl + ku + 1$)

Output Parameters

- **ab**
  Overwritten with elements of $L$ and $U$. $U$ is stored as an upper triangular band matrix with $kl + ku$ superdiagonals, and $L$ is stored as a lower triangular band matrix with $kl$ subdiagonals (diagonal unit values are not stored). Since the output array has more nonzero elements than the initial matrix $A$, there are limitations on the value of $ldab$ and the placement of elements of $A$ in array $ab$.

  See Application Notes below for further details.

- **ipiv**
  Array, size at least max(1, min($m$, $n$)). The pivot indices; for $1 \leq i \leq \min(m, n)$, row $i$ was interchanged with row $ipiv(i)$.

Return Values

This function returns a value $info$.

If $info = 0$, the execution is successful.
If $info = -i$, parameter $i$ had an illegal value.

If $info = i$, $u_{ii}$ is 0. The factorization has been completed, but $U$ is exactly singular. Division by 0 will occur if you use the factor $U$ for solving a system of linear equations.

**Application Notes**

The computed $L$ and $U$ are the exact factors of a perturbed matrix $A + E$, where

$$|E| \leq c(kl+ku+1)\epsilon P \|L\|\|U\|$$

$c(k)$ is a modest linear function of $k$, and $\epsilon$ is the machine precision.

The total number of floating-point operations for real flavors varies between approximately $2n(ku+1)kl$ and $2n(kl+ku+1)kl$. The number of operations for complex flavors is four times greater. All these estimates assume that $kl$ and $ku$ are much less than $\min(m,n)$.

As described in Band Storage, storage of a band matrix can be considered in two steps: packing band matrix elements into a matrix $AB$, then storing the elements in a linear array $ab$ using a full storage scheme. The effect of the ?gbtrf routine on matrix $AB$ is illustrated by this example, for $m = n = 6, kl = 2, ku = 1$.

- **matrix_layout = LAPACK_COL_MAJOR**

On entry:

$$AB = \begin{bmatrix}
* & * & * & + & + & + \\
* & * & + & + & + & + \\
* & a_{12} & a_{23} & a_{34} & a_{45} & a_{56} \\
a_{11} & a_{22} & a_{33} & a_{44} & a_{55} & a_{65} \\
a_{21} & a_{32} & a_{43} & a_{54} & a_{64} & * \\
a_{31} & a_{42} & a_{53} & a_{64} & * & * \\
\end{bmatrix}$$

On exit:

$$AB = \begin{bmatrix}
* & * & * & u_{14} & u_{25} & u_{36} \\
* & u_{13} & u_{24} & u_{35} & u_{45} & u_{56} \\
* & u_{12} & u_{23} & u_{34} & u_{44} & u_{55} & u_{65} \\
* & u_{11} & u_{22} & u_{33} & u_{44} & u_{55} & u_{66} \\
* & l_{12} & l_{23} & l_{34} & l_{44} & l_{54} & l_{66} \\
* & l_{11} & l_{22} & l_{33} & l_{43} & l_{53} & l_{64} \\
\end{bmatrix}$$

- **matrix_layout = LAPACK_ROW_MAJOR**

On entry:

$$AB = \begin{bmatrix}
* & * & a_{11} & a_{12} & + & + \\
* & a_{21} & a_{22} & a_{23} & + & + \\
a_{31} & a_{32} & a_{33} & a_{34} & + & + \\
a_{42} & a_{43} & a_{44} & a_{45} & + & * \\
a_{53} & a_{54} & a_{55} & a_{56} & * & * \\
a_{64} & a_{65} & a_{66} & * & * & * \\
\end{bmatrix}$$

On exit:

$$AB = \begin{bmatrix}
* & * & u_{11} & u_{12} & u_{13} & u_{14} \\
* & l_{21} & u_{22} & u_{23} & u_{24} & u_{25} \\
* & l_{31} & l_{32} & u_{33} & u_{34} & u_{35} & u_{36} \\
* & l_{42} & l_{43} & u_{44} & u_{45} & u_{46} & * \\
* & l_{53} & l_{54} & u_{55} & u_{56} & * & * \\
* & l_{64} & l_{65} & u_{66} & * & * & * \\
\end{bmatrix}$$

Elements marked * are not used; elements marked + need not be set on entry, but are required by the routine to store elements of $U$ because of fill-in resulting from the row interchanges.

After calling this routine with $m = n$, you can call the following routines:

- **gbtrs** to solve $A*X = B$ or $A^T*X = B$ or $A^H*X = B$
- **gbcon** to estimate the condition number of $A$.

lapack_int LAPACKE_zgttrf (lapack_int n, lapack_complex_double * dl, lapack_complex_double * d, lapack_complex_double * du, lapack_complex_double * du2, lapack_int * ipiv);
\end{verbatim}

\textbf{Include Files}

- mkl.h

\textbf{Description}

The routine computes the \textit{LU} factorization of a real or complex tridiagonal matrix $A$ using elimination with partial pivoting and row interchanges.

The factorization has the form

$$A = L \cdot U,$$

where $L$ is a product of permutation and unit lower bidiagonal matrices and $U$ is upper triangular with nonzeros in only the main diagonal and first two superdiagonals.

\textbf{Input Parameters}

- \textit{n}
  - The order of the matrix $A$; \(n \geq 0\).

- \textit{dl, d, du}
  - Arrays containing elements of $A$.
  - The array \textit{dl} of dimension \((n - 1)\) contains the subdiagonal elements of $A$.
  - The array \textit{d} of dimension \(n\) contains the diagonal elements of $A$.
  - The array \textit{du} of dimension \((n - 1)\) contains the superdiagonal elements of $A$.

\textbf{Output Parameters}

- \textit{dl}
  - Overwritten by the \((n-1)\) multipliers that define the matrix $L$ from the \textit{LU} factorization of $A$.

- \textit{d}
  - Overwritten by the \(n\) diagonal elements of the upper triangular matrix $U$ from the \textit{LU} factorization of $A$.

- \textit{du}
  - Overwritten by the \((n-1)\) elements of the first superdiagonal of $U$. 
du2

Array, dimension \((n-2)\). On exit, \(du2\) contains \((n-2)\) elements of the second superdiagonal of \(U\).

ipiv

Array, dimension \((n)\). The pivot indices: for \(1 \leq i \leq n\), row \(i\) was interchanged with row \(ipiv[i-1]\). \(ipiv[i-1]\) is always \(i\) or \(i+1\); \(ipiv[i-1] = i\) indicates a row interchange was not required.

Return Values

This function returns a value \(info\).

If \(info = 0\), the execution is successful.

If \(info = -i\), parameter \(i\) had an illegal value.

If \(info = i\), \(u_{ii}\) is 0. The factorization has been completed, but \(U\) is exactly singular. Division by zero will occur if you use the factor \(U\) for solving a system of linear equations.

Application Notes

\(?\)gbtrs

to solve \(A^{}X = B\) or \(A^T\cdot X = B\) or \(A^H\cdot X = B\)

\(?\)gbcon

to estimate the condition number of \(A\).

\(?\)dttrfb

**Computes the factorization of a diagonally dominant tridiagonal matrix.**

Syntax

```c
void sdttrfb (const MKL_INT * n , float * dl , float * d , const float * du , MKL_INT * info );
void ddttrfb (const MKL_INT * n , double * dl , double * d , const double * du , MKL_INT * info );
void cdttrfb (const MKL_INT * n , MKL_Complex8 * dl , MKL_Complex8 * d , const MKL_Complex8 * du , MKL_INT * info );
void zdttrfb_ (const MKL_INT * n , MKL_Complex16 * dl , MKL_Complex16 * d , const MKL_Complex16 * du , MKL_INT * info );
```

Include Files

- mkl.h

Description

The \(?\)dttrfb routine computes the factorization of a real or complex tridiagonal matrix \(A\) with the BABE (Burning At Both Ends) algorithm without pivoting. The factorization has the form

\[
A = L_1 \cdot U \cdot L_2
\]

where

- \(L_1\) and \(L_2\) are unit lower bidiagonal with \(k\) and \(n - k - 1\) subdiagonal elements, respectively, where \(k = n/2\), and
- \(U\) is an upper bidiagonal matrix with nonzeros in only the main diagonal and first superdiagonal.
Input Parameters

\( n \)  
The order of the matrix \( A \); \( n \geq 0 \).

\( dl, d, du \)  
Arrays containing elements of \( A \).

The array \( dl \) of dimension \((n - 1)\) contains the subdiagonal elements of \( A \).

The array \( d \) of dimension \( n \) contains the diagonal elements of \( A \).

The array \( du \) of dimension \((n - 1)\) contains the superdiagonal elements of \( A \).

Output Parameters

\( dl \)  
Overwritten by the \((n - 1)\) multipliers that define the matrix \( L \) from the \( LU \) factorization of \( A \).

\( d \)  
Overwritten by the \( n \) diagonal element reciprocals of the upper triangular matrix \( U \) from the factorization of \( A \).

\( du \)  
Overwritten by the \((n-1)\) elements of the superdiagonal of \( U \).

\( info \)  
If \( info = 0 \), the execution is successful.

If \( info = -i \), the \( i \)-th parameter had an illegal value.

If \( info = i \), \( u_{ii} \) is 0. The factorization has been completed, but \( U \) is exactly singular. Division by zero will occur if you use the factor \( U \) for solving a system of linear equations.

Application Notes

A diagonally dominant tridiagonal system is defined such that \(|d_i| > |dl_{i-1}| + |du_i|\) for any \( i \):

\[
1 < i < n, \text{ and } |d_1| > |du_1|, |d_n| > |dl_{n-1}|
\]

The underlying BABE algorithm is designed for diagonally dominant systems. Such systems are free from the numerical stability issue unlike the canonical systems that use elimination with partial pivoting (see \(?gttrf\)). The diagonally dominant systems are much faster than the canonical systems.

**NOTE**

- The current implementation of BABE has a potential accuracy issue on very small or large data close to the underflow or overflow threshold respectively. Scale the matrix before applying the solver in the case of such input data.
- Applying the \(?dttrfb\) factorization to non-diagonally dominant systems may lead to an accuracy loss, or false singularity detected due to no pivoting.

\?potrf

*Computes the Cholesky factorization of a symmetric (Hermitian) positive-definite matrix.*

**Syntax**

```c
lapack_int LAPACKE_spotrf (int matrix_layout , char uplo , lapack_int n , float * a , lapack_int lda );
```
lapack_int LAPACKE_dpotrf (int matrix_layout, char uplo, lapack_int n, double * a, lapack_int lda);
lapack_int LAPACKE_cpotrf (int matrix_layout, char uplo, lapack_int n, lapack_complex_float * a, lapack_int lda);
lapack_int LAPACKE_zpotrf (int matrix_layout, char uplo, lapack_int n, lapack_complex_double * a, lapack_int lda);

Include Files
• mkl.h

Description
The routine forms the Cholesky factorization of a symmetric positive-definite or, for complex data, Hermitian positive-definite matrix $A$:

- $A = U^T \cdot U$ for real data, $A = U^H \cdot U$ for complex data if $\text{uplo} = 'U'$
- $A = L \cdot L^T$ for real data, $A = L \cdot L^H$ for complex data if $\text{uplo} = 'L'$

where $L$ is a lower triangular matrix and $U$ is upper triangular.

NOTE
This routine supports the Progress Routine feature. See Progress Function section for details.

Input Parameters
matrix_layout Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
uplo Must be 'U' or 'L'.
Indicates whether the upper or lower triangular part of $A$ is stored and how $A$ is factored:
- If $\text{uplo} = 'U'$, the array $a$ stores the upper triangular part of the matrix $A$, and the strictly lower triangular part of the matrix is not referenced.
- If $\text{uplo} = 'L'$, the array $a$ stores the lower triangular part of the matrix $A$, and the strictly upper triangular part of the matrix is not referenced.
n Specifies the order of the matrix $A$. The value of $n$ must be at least zero.
a Array, size $\text{max}(1, \text{lda} \cdot n)$. The array $a$ contains either the upper or the lower triangular part of the matrix $A$ (see $\text{uplo}$).
lda The leading dimension of $a$. Must be at least $\text{max}(1, n)$.

Output Parameters
a The upper or lower triangular part of $a$ is overwritten by the Cholesky factor $U$ or $L$, as specified by $\text{uplo}$.

Return Values
This function returns a value $\text{info}$.
If info=0, the execution is successful.
If info = -i, parameter i had an illegal value.
If info = i, the leading minor of order i (and therefore the matrix A itself) is not positive-definite, and the factorization could not be completed. This may indicate an error in forming the matrix A.

**Application Notes**

If uplo = 'U', the computed factor U is the exact factor of a perturbed matrix A + E, where

\[
|E| \leq c(n)\varepsilon |U^H| |U|, |e_{ij}| \leq c(n)\varepsilon \sqrt{a_{ii}a_{jj}}
\]

\(c(n)\) is a modest linear function of \(n\), and \(\varepsilon\) is the machine precision.

A similar estimate holds for uplo = 'L'.

The total number of floating-point operations is approximately \((1/3)n^3\) for real flavors or \((4/3)n^3\) for complex flavors.

After calling this routine, you can call the following routines:

- ?potrs to solve \(A^*X = B\)
- ?pocon to estimate the condition number of \(A\)
- ?potri to compute the inverse of \(A\).

**See Also**

mkl_progress

**Matrix Storage Schemes**

??potrf2

Computes Cholesky factorization using a recursive algorithm.

**Syntax**

```c
lapack_int LAPACKE_spotrf2 (int matrix_layout, char uplo, lapack_int n, float * a, lapack_int lda);
lapack_int LAPACKE_dpotrf2 (int matrix_layout, char uplo, lapack_int n, double * a, lapack_int lda);
lapack_int LAPACKE_cpotrf2 (int matrix_layout, char uplo, lapack_int n, lapack_complex_float * a, lapack_int lda);
lapack_int LAPACKE_zpotrf2 (int matrix_layout, char uplo, lapack_int n, lapack_complex_double * a, lapack_int lda);
```

**Include Files**

- mkl.h

**Description**

??potrf2 computes the Cholesky factorization of a real or complex symmetric positive definite matrix A using the recursive algorithm.

The factorization has the form for real flavors:
\[ A = U^T U, \text{ if } \text{uplo} = 'U', \text{ or } \]
\[ A = L \ast L^T, \text{ if } \text{uplo} = 'L', \]
for complex flavors:
\[ A = U^H U, \text{ if } \text{uplo} = 'U', \]
\[ \text{or } A = L \ast L^H, \text{ if } \text{uplo} = 'L', \]
where \( U \) is an upper triangular matrix and \( L \) is lower triangular.

This is the recursive version of the algorithm. It divides the matrix into four submatrices:
\[
A = \begin{pmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{pmatrix}
\]
where \( A_{11} \) is \( n_1 \) by \( n_1 \) and \( A_{22} \) is \( n_2 \) by \( n_2 \), with \( n_1 = n/2 \) and \( n_2 = n-n_1 \).

The subroutine calls itself to factor \( A_{11} \). Update and scale \( A_{21} \) or \( A_{12} \), update \( A_{22} \) then call itself to factor \( A_{22} \).

**Input Parameters**

\[ \text{matrix\_layout} \]
Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

\[ \text{uplo} \]
= 'U': Upper triangle of \( A \) is stored;
= 'L': Lower triangle of \( A \) is stored.

\[ n \]
The order of the matrix \( A \).
\( n \geq 0 \).

\[ a \]
Array, size (\( \text{lda} \ast n \)).
On entry, the symmetric matrix \( A \).
If \( \text{uplo} = 'U' \), the leading \( n \)-by-\( n \) upper triangular part of \( a \) contains the upper triangular part of the matrix \( A \), and the strictly lower triangular part of \( a \) is not referenced.
If \( \text{uplo} = 'L' \), the leading \( n \)-by-\( n \) lower triangular part of \( a \) contains the lower triangular part of the matrix \( A \), and the strictly upper triangular part of \( a \) is not referenced.

\[ \text{lda} \]
The leading dimension of the array \( a \).
\( \text{lda} \geq \max(1,n) \).

**Output Parameters**

\[ a \]
On exit, if \( \text{info} = 0 \), the factor \( U \) or \( L \) from the Cholesky factorization.
For real flavors:
\[ A = U^T U \text{ or } A = L \ast L^T; \]
For complex flavors:
\[ A = U^H U \text{ or } A = L \ast L^H. \]

**Return Values**
This function returns a value \( \text{info} \).
= 0: successful exit
< 0: if info = -i, the i-th argument had an illegal value
> 0: if info = i, the leading minor of order i is not positive definite, and the factorization could not be completed.

*pstrf
Computes the Cholesky factorization with complete pivoting of a real symmetric (complex Hermitian) positive semidefinite matrix.

Syntax

```c
lapack_int LAPACKE_spstrf( int matrix_layout, char uplo, lapack_int n, float* a, lapack_int lda, lapack_int* piv, lapack_int* rank, float tol);

lapack_int LAPACKE_dpstrf( int matrix_layout, char uplo, lapack_int n, double* a, lapack_int lda, lapack_int* piv, lapack_int* rank, double tol);

lapack_int LAPACKE_cpstrf( int matrix_layout, char uplo, lapack_int n, lapack_complex_float* a, lapack_int lda, lapack_int* piv, lapack_int* rank, float tol);

lapack_int LAPACKE_zpstrf( int matrix_layout, char uplo, lapack_int n, lapack_complex_double* a, lapack_int lda, lapack_int* piv, lapack_int* rank, double tol);
```

Include Files

- mkl.h

Description

The routine computes the Cholesky factorization with complete pivoting of a real symmetric (complex Hermitian) positive semidefinite matrix. The form of the factorization is:

- \( P^T \cdot A \cdot P = U^T \cdot U \) for real flavors, where \( P \) is a permutation matrix stored as vector \( \text{piv} \), and \( U \) is an upper triangular matrix.

- \( P^T \cdot A \cdot P = U^H \cdot U \) for complex flavors.

- \( P^T \cdot A \cdot P = L \cdot L^T \) for real flavors.

- \( P^T \cdot A \cdot P = L \cdot L^H \) for complex flavors.

where \( P \) is a permutation matrix stored as vector \( \text{piv} \), and \( U \) and \( L \) are upper and lower triangular matrices, respectively.

This algorithm does not attempt to check that \( A \) is positive semidefinite. This version of the algorithm calls level 3 BLAS.

Input Parameters

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **uplo**
  Must be 'U' or 'L'.
  Indicates whether the upper or lower triangular part of \( A \) is stored:
  If \( \text{uplo} = 'U' \), the array \( a \) stores the upper triangular part of the matrix \( A \), and the strictly lower triangular part of the matrix is not referenced.
If uplo = 'L', the array \( a \) stores the lower triangular part of the matrix \( A \), and the strictly upper triangular part of the matrix is not referenced.

\( n \)

The order of matrix \( A \); \( n \geq 0 \).

\( a \)

Array \( a \), size \( \max(1,lda\ast n) \). The array \( a \) contains either the upper or the lower triangular part of the matrix \( A \) (see uplo).

\( tol \)

User defined tolerance. If \( tol < 0 \), then \( n\ast\varepsilon\ast\max(A_{k,k}) \), where \( \varepsilon \) is the machine precision, will be used (see Error Analysis for the definition of machine precision). The algorithm terminates at the \((k-1)\)-st step, if the pivot \( \leq tol \).

\( lda \)

The leading dimension of \( a \); at least \( \max(1, n) \).

**Output Parameters**

\( a \)

If info = 0, the factor \( U \) or \( L \) from the Cholesky factorization is as described in Description.

\( piv \)

Array, size at least \( \max(1, n) \). The array \( piv \) is such that the nonzero entries are \( P_{piv[k-1],k} \) \((1 \leq k \leq n)\).

\( rank \)

The rank of \( a \) given by the number of steps the algorithm completed.

**Return Values**

This function returns a value info.

If info = 0, the execution is successful.

If info = -k, the k-th argument had an illegal value.

If info > 0, the matrix \( A \) is either rank deficient with a computed rank as returned in rank, or is not positive semidefinite.

• mkl.h

Description

The routine forms the Cholesky factorization of a symmetric positive-definite or, for complex data, a
Hermitian positive-definite matrix \( A \):

\[
A = U^T U \quad \text{for real data,} \quad A = U^H U \quad \text{for complex data}
\]

\[
A = L^T L \quad \text{for real data,} \quad A = L^H L \quad \text{for complex data}
\]

if \( \text{uplo} = 'U' \)

where \( L \) is a lower triangular matrix and \( U \) is upper triangular.

The matrix \( A \) is in the Rectangular Full Packed (RFP) format. For the description of the RFP format, see Matrix Storage Schemes.

This is the block version of the algorithm, calling Level 3 BLAS.

Input Parameters

matrix_layout

Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

transr

Must be 'N', 'T' (for real data) or 'C' (for complex data).

If \( \text{transr} = 'N' \), the Normal \( \text{transr} \) of RFP \( A \) is stored.

If \( \text{transr} = 'T' \), the Transpose \( \text{transr} \) of RFP \( A \) is stored.

If \( \text{transr} = 'C' \), the Conjugate-Transpose \( \text{transr} \) of RFP \( A \) is stored.

uplo

Must be 'U' or 'L'.

Indicates whether the upper or lower triangular part of \( A \) is stored:

If \( \text{uplo} = 'U' \), the array \( a \) stores the upper triangular part of the matrix \( A \).

If \( \text{uplo} = 'L' \), the array \( a \) stores the lower triangular part of the matrix \( A \).

n

The order of the matrix \( A \); \( n \geq 0 \).

a

Array, size \( (n^2 + n + 1)/2 \). The array \( a \) contains the matrix \( A \) in the RFP format.

Output Parameters

\( a \) is overwritten by the Cholesky factor \( U \) or \( L \), as specified by \( \text{uplo} \) and \( \text{trans} \).

Return Values

This function returns a value \( \text{info} \).

If \( \text{info} = 0 \), the execution is successful.

If \( \text{info} = -i \), parameter \( i \) had an illegal value.

If \( \text{info} = i \), the leading minor of order \( i \) (and therefore the matrix \( A \) itself) is not positive-definite, and the factorization could not be completed. This may indicate an error in forming the matrix \( A \).

Matrix Storage Schemes

?pptrf
Computes the Cholesky factorization of a symmetric (Hermitian) positive-definite matrix using packed storage.

Syntax

```
lapack_int LAPACKE_spptrf (int matrix_layout, char uplo, lapack_int n, float * ap);
lapack_int LAPACKE_dpptrf (int matrix_layout, char uplo, lapack_int n, double * ap);
lapack_int LAPACKE_cpptrf (int matrix_layout, char uplo, lapack_int n, lapack_complex_float * ap);
lapack_int LAPACKE_zpptrf (int matrix_layout, char uplo, lapack_int n, lapack_complex_double * ap);
```

Include Files

- mkl.h

Description

The routine forms the Cholesky factorization of a symmetric positive-definite or, for complex data, Hermitian positive-definite packed matrix \( A \):

\[
A = U^T U \quad \text{for real data}, \quad A = U^H U \quad \text{for complex data}
\]

where \( L \) is a lower triangular matrix and \( U \) is upper triangular.

\[
A = L L^T \quad \text{for real data}, \quad A = L L^H \quad \text{for complex data}
\]

Input Parameters

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **uplo**
  Must be 'U' or 'L'.

  Indicates whether the upper or lower triangular part of \( A \) is packed in the array \( ap \), and how \( A \) is factored:

  - If \( uplo = 'U' \), the array \( ap \) stores the upper triangular part of the matrix \( A \), and \( A \) is factored as \( U^T U \).
  - If \( uplo = 'L' \), the array \( ap \) stores the lower triangular part of the matrix \( A \); \( A \) is factored as \( L L^T \).

- **n**
  The order of matrix \( A \); \( n \geq 0 \).
Array, size at least max(1, n(n+1)/2). The array \( ap \) contains either the upper or the lower triangular part of the matrix \( A \) (as specified by \( uplo \)) in packed storage (see Matrix Storage Schemes).

**Output Parameters**

\( ap \) Overwritten by the Cholesky factor \( U \) or \( L \), as specified by \( uplo \).

**Return Values**

This function returns a value \( info \).

If \( info=0 \), the execution is successful.

If \( info = -i \), parameter \( i \) had an illegal value.

If \( info = i \), the leading minor of order \( i \) (and therefore the matrix \( A \) itself) is not positive-definite, and the factorization could not be completed. This may indicate an error in forming the matrix \( A \).

**Application Notes**

If \( uplo = 'U' \), the computed factor \( U \) is the exact factor of a perturbed matrix \( A + E \), where

\[
|E| \leq c(n) \epsilon \|U\| \|U^T\|, \quad |e_{ij}| \leq c(n) \epsilon \sqrt{a_{ii}a_{jj}}
\]

\( c(n) \) is a modest linear function of \( n \), and \( \epsilon \) is the machine precision.

A similar estimate holds for \( uplo = 'L' \).

The total number of floating-point operations is approximately \((1/3) n^3\) for real flavors and \((4/3) n^3\) for complex flavors.

After calling this routine, you can call the following routines:

- \( ?pptrs \) to solve \( A^*X = B \)
- \( ?ppcon \) to estimate the condition number of \( A \)
- \( ?pptri \) to compute the inverse of \( A \).

Include Files
• mkl.h

Description
The routine forms the Cholesky factorization of a symmetric positive-definite or, for complex data, Hermitian positive-definite band matrix \( A \):
\[
A = U^T U \quad \text{for real data,} \quad A = U^H U \quad \text{for complex data}
\]
\[
A = L L^T \quad \text{for real data,} \quad A = L L^H \quad \text{for complex data}
\]
where \( L \) is a lower triangular matrix and \( U \) is upper triangular.

NOTE
This routine supports the Progress Routine feature. See Progress Function section for details.

Input Parameters

\textbf{matrix_layout}

Specifies whether matrix storage layout is row major \texttt{(LAPACK\_ROW\_MAJOR)} or column major \texttt{(LAPACK\_COL\_MAJOR)}.

\textbf{uplo}

Must be \texttt{'U'} or \texttt{'L'}.

Indicates whether the upper or lower triangular part of \( A \) is stored in the array \( ab \), and how \( A \) is factored:
- If \( uplo = 'U' \), the upper triangle of \( A \) is stored.
- If \( uplo = 'L' \), the lower triangle of \( A \) is stored.

\textbf{n}

The order of matrix \( A \); \( n \geq 0 \).

\textbf{kd}

The number of superdiagonals or subdiagonals in the matrix \( A \); \( kd \geq 0 \).

\textbf{ab}

Array, size \( \max(1, ldab \times n) \). The array \( ab \) contains either the upper or the lower triangular part of the matrix \( A \) (as specified by \texttt{uplo}) in band storage (see Matrix Storage Schemes).

\textbf{ldab}

The leading dimension of the array \( ab \). \( (ldab \geq kd + 1) \)

Output Parameters

\textbf{ab}

The upper or lower triangular part of \( A \) (in band storage) is overwritten by the Cholesky factor \( U \) or \( L \), as specified by \texttt{uplo}.

Return Values

This function returns a value \texttt{info}.

If \( info = 0 \), the execution is successful.

If \( info = -i \), parameter \( i \) had an illegal value.

If \( info = i \), the leading minor of order \( i \) (and therefore the matrix \( A \) itself) is not positive-definite, and the factorization could not be completed. This may indicate an error in forming the matrix \( A \).
Application Notes

If uplo = 'U', the computed factor $U$ is the exact factor of a perturbed matrix $A + E$, where

$$
|E| \leq c(kd + 1)\varepsilon \left|U^H |U| \right|, \quad |E_{i,j}| \leq c(kd + 1)\varepsilon \sqrt{a_{i,i}a_{j,j}}
$$

$c(n)$ is a modest linear function of $n$, and $\varepsilon$ is the machine precision.

A similar estimate holds for uplo = 'L'.

The total number of floating-point operations for real flavors is approximately $n(kd+1)^2$. The number of operations for complex flavors is 4 times greater. All these estimates assume that $kd$ is much less than $n$.

After calling this routine, you can call the following routines:

- ?pbtrs to solve $A^tX = B$
- ?pbcon to estimate the condition number of $A$.

Matrix Storage Schemes

?pttrf
Computes the factorization of a symmetric (Hermitian) positive-definite tridiagonal matrix.

Syntax

```c
lapack_int LAPACKE_spttrf( lapack_int n, float* d, float* e );
lapack_int LAPACKE_dpttrf( lapack_int n, double* d, double* e );
lapack_int LAPACKE_cpttrf( lapack_int n, float* d, lapack_complex_float* e );
lapack_int LAPACKE_zpttrf( lapack_int n, double* d, lapack_complex_double* e );
```

Include Files

- mkl.h

Description

The routine forms the factorization of a symmetric positive-definite or, for complex data, Hermitian positive-definite tridiagonal matrix $A$:

- $A = L^*D*L^T$ for real flavors, or
- $A = L^*D*L^H$ for complex flavors,

where $D$ is diagonal and $L$ is unit lower bidiagonal. The factorization may also be regarded as having the form

- $A = U^*D*U$ for real flavors, or $A = U^H*D*U$ for complex flavors, where $U$ is unit upper bidiagonal.

Input Parameters

- $n$ The order of the matrix $A$; $n \geq 0$.
- $d$ Array, dimension ($n$). Contains the diagonal elements of $A$.
- $e$ Array, dimension ($n - 1$). Contains the subdiagonal elements of $A$. 
Output Parameters

d
Overwritten by the $n$ diagonal elements of the diagonal matrix $D$ from the $L^*D*L^T$ (for real flavors) or $L^*D*L^H$ (for complex flavors) factorization of $A$.

e
Overwritten by the $(n - 1)$ sub-diagonal elements of the unit bidiagonal factor $L$ or $U$ from the factorization of $A$.

Return Values

This function returns a value $info$.

If $info = 0$, the execution is successful.

If $info = -i$, parameter $i$ had an illegal value.

If $info = i$, the leading minor of order $i$ (and therefore the matrix $A$ itself) is not positive-definite; if $i < n$, the factorization could not be completed, while if $i = n$, the factorization was completed, but $d[n - 1] \leq 0$.

?sytrf
Computes the Bunch-Kaufman factorization of a symmetric matrix.

Syntax

lapack_int LAPACKE_ssytrf (int matrix_layout, char uplo, lapack_int n, float * a, lapack_int lda, lapack_int * ipiv);

lapack_int LAPACKE_dsytrf (int matrix_layout, char uplo, lapack_int n, double * a, lapack_int lda, lapack_int * ipiv);

lapack_int LAPACKE_csytrf (int matrix_layout, char uplo, lapack_int n, lapack_complex_float * a, lapack_int lda, lapack_int * ipiv);

lapack_int LAPACKE_zsytrf (int matrix_layout, char uplo, lapack_int n, lapack_complex_double * a, lapack_int lda, lapack_int * ipiv);

Include Files

• mkl.h

Description

The routine computes the factorization of a real/complex symmetric matrix $A$ using the Bunch-Kaufman diagonal pivoting method. The form of the factorization is:

- if $uplo='U'$, $A = U^*D*U^T$
- if $uplo='L'$, $A = L^*D*L^T$

where $A$ is the input matrix, $U$ and $L$ are products of permutation and triangular matrices with unit diagonal (upper triangular for $U$ and lower triangular for $L$), and $D$ is a symmetric block-diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks. $U$ and $L$ have 2-by-2 unit diagonal blocks corresponding to the 2-by-2 blocks of $D$.

NOTE This routine supports the Progress Routine feature. See Progress Routines section for details.
Input Parameters

matrix_layout
- Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

uplo
- Must be 'U' or 'L'.
- Indicates whether the upper or lower triangular part of A is stored and how A is factored:
  - If uplo = 'U', the array a stores the upper triangular part of the matrix A, and A is factored as $U^TDU^T$.
  - If uplo = 'L', the array a stores the lower triangular part of the matrix A, and A is factored as $LDL^T$.

n
- The order of matrix A; $n \geq 0$.

a
- Array, size max(1, lda*n). The array a contains either the upper or the lower triangular part of the matrix A (see uplo).

lda
- The leading dimension of a; at least max(1, n).

Output Parameters

a
- The upper or lower triangular part of a is overwritten by details of the block-diagonal matrix D and the multipliers used to obtain the factor U (or L).

ipiv
- Array, size at least max(1, n). Contains details of the interchanges and the block structure of D. If $ipiv[i-1] = k > 0$, then $d_{ii}$ is a 1-by-1 block, and the i-th row and column of A was interchanged with the k-th row and column.
  - If uplo = 'U' and $ipiv[i] = ipiv[i-1] = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i+1$, and i-th row and column of A was interchanged with the m-th row and column.
  - If uplo = 'L' and $ipiv[i] = ipiv[i-1] = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i+1$, and ($i+1$)-th row and column of A was interchanged with the m-th row and column.

Return Values

This function returns a value info.

- If info = 0, the execution is successful.
- If info = -i, parameter i had an illegal value.
- If info = i, $D_{ii}$ is 0. The factorization has been completed, but D is exactly singular. Division by 0 will occur if you use D for solving a system of linear equations.

Application Notes

- The 2-by-2 unit diagonal blocks and the unit diagonal elements of U and L are not stored. The remaining elements of U and L are stored in the corresponding columns of the array a, but additional row interchanges are required to recover U or L explicitly (which is seldom necessary).
- If $ipiv[i-1] = i$ for all $i = 1 \ldots n$, then all off-diagonal elements of U (L) are stored explicitly in the corresponding elements of the array a.
If \( \text{uplo} = 'U' \), the computed factors \( U \) and \( D \) are the exact factors of a perturbed matrix \( A + E \), where
\[
|E| \leq c(n)\varepsilon |U||D| |U^T| |P|
\]
c\( (n) \) is a modest linear function of \( n \), and \( \varepsilon \) is the machine precision. A similar estimate holds for the computed \( L \) and \( D \) when \( \text{uplo} = 'L' \).

The total number of floating-point operations is approximately \( (1/3)n^3 \) for real flavors or \( (4/3)n^3 \) for complex flavors.

After calling this routine, you can call the following routines:

- \( ?\text{sytrs} \) to solve \( AX = B \)
- \( ?\text{sycon} \) to estimate the condition number of \( A \)
- \( ?\text{sytri} \) to compute the inverse of \( A \).

If \( \text{uplo} = 'U' \), then \( A = U^TDU^T \), where
\[
U = P(n)^*U(n)^* ... P(k)^*U(k)^* ...,\] that is, \( U \) is a product of terms \( P(k)^*U(k) \), where
- \( k \) decreases from \( n \) to 1 in steps of 1 and 2.
- \( D \) is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks \( D(k) \).
- \( P(k) \) is a permutation matrix as defined by \( \text{ipiv}[k-1] \).
- \( U(k) \) is a unit upper triangular matrix, such that if the diagonal block \( D(k) \) is of order \( s \) (\( s = 1 \) or 2), then
\[
U(k) = \begin{bmatrix}
I & V & 0 & & & & & \\
0 & I & 0 & & & & & \\
0 & 0 & I & & & & & \\
& & & I & 0 & & & \\
& & & & I & 0 & & \\
& & & & & I & 0 & \\
& & & & & & I & 0 \\
& & & & & & & I
\end{bmatrix}
\]
If \( s = 1 \), \( D(k) \) overwrites \( A(k,k) \), and \( V \) overwrites \( A(1:k-1,k) \).

If \( s = 2 \), the upper triangle of \( D(k) \) overwrites \( A(k-1,k-1), A(k-1,k) \) and \( A(k,k) \), and \( V \) overwrites \( A(1:k-2,k-1:k) \).

If \( \text{uplo} = 'L' \), then \( A = L^TDL^T \), where
\[
L = P(1)^*L(1)^* ... P(k)^*L(k)^* ...,\] that is, \( L \) is a product of terms \( P(k)^*L(k) \), where
- \( k \) increases from 1 to \( n \) in steps of 1 and 2.
- \( D \) is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks \( D(k) \).
- \( P(k) \) is a permutation matrix as defined by \( \text{ipiv}(k) \).
- \( L(k) \) is a unit lower triangular matrix, such that if the diagonal block \( D(k) \) is of order \( s \) (\( s = 1 \) or 2), then
If $s = 1$, $D(k)$ overwrites $A(k,k)$, and $v$ overwrites $A(k+1:n,k)$.

If $s = 2$, the lower triangle of $D(k)$ overwrites $A(k,k)$, $A(k+1,k)$, and $A(k+1,k+1)$, and $v$ overwrites $A(k+2:n,k:k+1)$.

?sytrf_aa

*Computes the factorization of a symmetric matrix using Aasen's algorithm.*

```c
lapack_int LAPACKE_ssytrf_aa (int matrix_layout, char uplo, lapack_int n, float * A, lapack_int lda, lapack_int * ipiv);

lapack_int LAPACKE_dsytrf_aa (int matrix_layout, char uplo, lapack_int n, double * A, lapack_int lda, lapack_int * ipiv);

lapack_int LAPACKE_csytrf_aa (int matrix_layout, char uplo, lapack_int n, lapack_complex_float * A, lapack_int lda, lapack_int * ipiv);

lapack_int LAPACKE_zsytrf_aa (int matrix_layout, char uplo, lapack_int n, lapack_complex_double * A, lapack_int lda, lapack_int * ipiv);
```

**Description**

?sytrf_aa computes the factorization of a symmetric matrix $A$ using Aasen's algorithm. The form of the factorization is $A = U^*T*U$ or $A = L^*T*L$ where $U$ (or $L$) is a product of permutation and unit upper (lower) triangular matrices, and $T$ is a complex symmetric tridiagonal matrix.

This is the blocked version of the algorithm, calling Level 3 BLAS.

**Input Parameters**

- **matrix_layout**
  
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **uplo**
  
  - `'U'`: The upper triangle of $A$ is stored.
  - `'L'`: The lower triangle of $A$ is stored.

- **n**
  
  The order of the matrix $A$. $n \geq 0$.

- **A**
  
  Array of size max(1, lda*n). The array $A$ contains either the upper or the lower triangular part of the matrix $A$ (see uplo).

- **lda**
  
  The leading dimension of the array $A$. 

\[
L(k) = \begin{pmatrix}
  I & 0 & 0 & k-1 \\
  0 & I & 0 & s \\
  0 & v & I & n-k-s+1 \\
  k-1 & s & n-k-s+1
\end{pmatrix}
\]
Output Parameters

\( A \)

On exit, the tridiagonal matrix is stored in the diagonals and the subdiagonals of \( A \) just below (or above) the diagonals, and \( L \) is stored below (or above) the subdiagonals, when \( \text{uplo} \) is 'L' (or 'U').

\( \text{ipiv} \)

Array of size \( n \). On exit, it contains the details of the interchanges; that is, the row and column \( k \) of \( A \) were interchanged with the row and column \( \text{ipiv}(k) \).

Return Values

This function returns a value \( \text{info} \).

\( = 0 \): Successful exit.

\( < 0 \): If \( \text{info} = -i \), the \( i \)th argument had an illegal value.

\( > 0 \): If \( \text{info} = i \), \( D(i,i) \) is exactly zero. The factorization has been completed, but the block diagonal matrix \( D \) is exactly singular, and division by zero will occur if it is used to solve a system of equations.

\textbf{sytrf_rook}

Computes the bounded Bunch-Kaufman factorization of a symmetric matrix.

Syntax

```c
lapack_int LAPACKE_ssytrf_rook (int matrix_layout, char uplo, lapack_int n, float * a, lapack_int lda, lapack_int * ipiv);
lapack_int LAPACKE_dsytrf_rook (int matrix_layout, char uplo, lapack_int n, double * a, lapack_int lda, lapack_int * ipiv);
lapack_int LAPACKE_csytrf_rook (int matrix_layout, char uplo, lapack_int n, lapack_complex_float * a, lapack_int lda, lapack_int * ipiv);
lapack_int LAPACKE_zsytrf_rook (int matrix_layout, char uplo, lapack_int n, lapack_complex_double * a, lapack_int lda, lapack_int * ipiv);
```

Include Files

- mkl.h

Description

The routine computes the factorization of a real/complex symmetric matrix \( A \) using the bounded Bunch-Kaufman ("rook") diagonal pivoting method. The form of the factorization is:

\[
\begin{align*}
\text{if } \text{uplo} = 'U', & \quad A = U^* D U^T \\
\text{if } \text{uplo} = 'L', & \quad A = L^* D L^T,
\end{align*}
\]

where \( A \) is the input matrix, \( U \) and \( L \) are products of permutation and triangular matrices with unit diagonal (upper triangular for \( U \) and lower triangular for \( L \)), and \( D \) is a symmetric block-diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks. \( U \) and \( L \) have 2-by-2 unit diagonal blocks corresponding to the 2-by-2 blocks of \( D \).

Input Parameters

\( \text{matrix_layout} \)

Specifies whether matrix storage layout for array \( b \) is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
uplo

Must be 'U' or 'L'.

Indicates whether the upper or lower triangular part of $A$ is stored and how $A$ is factored:

If $\text{uplo} = 'U'$, the array $a$ stores the upper triangular part of the matrix $A$, and $A$ is factored as $U*D*U^T$.

If $\text{uplo} = 'L'$, the array $a$ stores the lower triangular part of the matrix $A$, and $A$ is factored as $L*D*L^T$.

$n$

The order of matrix $A$; $n \geq 0$.

$a$

Array, size $lda*n$. The array $a$ contains either the upper or the lower triangular part of the matrix $A$ (see $\text{uplo}$).

$lda$

The leading dimension of $a$; at least $\max(1, n)$.

Output Parameters

The upper or lower triangular part of $a$ is overwritten by details of the block-diagonal matrix $D$ and the multipliers used to obtain the factor $U$ (or $L$).

$ipiv$

If $\text{ipiv}(k) > 0$, then rows and columns $k$ and $\text{ipiv}(k)$ were interchanged and $D_{k,k}$ is a 1-by-1 diagonal block.

If $\text{uplo} = 'U'$ and $\text{ipiv}(k) < 0$ and $\text{ipiv}(k - 1) < 0$, then rows and columns $k$ and $-\text{ipiv}(k)$ were interchanged, rows and columns $k - 1$ and $-\text{ipiv}(k - 1)$ were interchanged, and $D_{k-1:k, k-1:k}$ is a 2-by-2 diagonal block.

If $\text{uplo} = 'L'$ and $\text{ipiv}(k) < 0$ and $\text{ipiv}(k + 1) < 0$, then rows and columns $k$ and $-\text{ipiv}(k)$ were interchanged, rows and columns $k + 1$ and $-\text{ipiv}(k + 1)$ were interchanged, and $D_{k:k+1, k:k+1}$ is a 2-by-2 diagonal block.

Return Values

This function returns a value $\text{info}$.

If $\text{info} = 0$, the execution is successful.

If $\text{info} = -i$, the $i$-th parameter had an illegal value.

If $\text{info} = i$, $D_{ii}$ is 0. The factorization has been completed, but $D$ is exactly singular. Division by 0 will occur if you use $D$ for solving a system of linear equations.

Application Notes

The total number of floating-point operations is approximately $\frac{1}{3}n^3$ for real flavors or $\frac{4}{3}n^3$ for complex flavors.

After calling this routine, you can call the following routines:

$\text{?sytrs_rook}$ to solve $A*X = B$

$\text{?sycon_rook}$ (Fortran only) to estimate the condition number of $A$

$\text{?sytri_rook}$ (Fortran only) to compute the inverse of $A$.
If `uplo` = 'U', then $A = U*\mathcal{D}*U'$, where

$$U = P(n)*U(n)* \ldots *P(k)*U(k)*\ldots,$$

that is, $U$ is a product of terms $P(k)*U(k)$, where

- $k$ decreases from $n$ to 1 in steps of 1 and 2.
- $\mathcal{D}$ is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks $\mathcal{D}(k)$.
- $P(k)$ is a permutation matrix as defined by `ipiv[k-1].`
- $U(k)$ is a unit upper triangular matrix, such that if the diagonal block $\mathcal{D}(k)$ is of order $s$ ($s = 1$ or 2), then

$$U(k) = \begin{pmatrix}
  I & v & 0 \\
  0 & I & 0 \\
  0 & 0 & I \\
\end{pmatrix}
\begin{pmatrix}
  k-s & s & n-k \\
\end{pmatrix}$$

If $s = 1$, $\mathcal{D}(k)$ overwrites $A(k,k)$, and $v$ overwrites $A(1:k-1,k)$.

If $s = 2$, the upper triangle of $\mathcal{D}(k)$ overwrites $A(k-1,k-1), A(k-1,k)$ and $A(k,k)$, and $v$ overwrites $A(1:k-2,k-1:k)$.

If `uplo` = 'L', then $A = L*\mathcal{D}*L'$, where

$$L = P(1)*L(1)* \ldots *P(k)*L(k)*\ldots,$$

that is, $L$ is a product of terms $P(k)*L(k)$, where

- $k$ increases from 1 to $n$ in steps of 1 and 2.
- $\mathcal{D}$ is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks $\mathcal{D}(k)$.
- $P(k)$ is a permutation matrix as defined by `ipiv(k).`
- $L(k)$ is a unit lower triangular matrix, such that if the diagonal block $\mathcal{D}(k)$ is of order $s$ ($s = 1$ or 2), then

$$L(k) = \begin{pmatrix}
  I & 0 & 0 \\
  0 & I & 0 \\
  0 & v & I \\
\end{pmatrix}
\begin{pmatrix}
  k-1 & s & n-k-s+1 \\
\end{pmatrix}$$

If $s = 1$, $\mathcal{D}(k)$ overwrites $A(k,k)$, and $v$ overwrites $A(k+1:n,k)$.

If $s = 2$, the lower triangle of $\mathcal{D}(k)$ overwrites $A(k,k), A(k+1,k)$, and $A(k+1,k+1)$, and $v$ overwrites $A(k+2:n,k+1)$.

?-sytrf_rk

*Computes the factorization of a real or complex symmetric indefinite matrix using the bounded Bunch-Kaufman (rook) diagonal pivoting method (BLAS3 blocked algorithm).*
lapack_int LAPACKE_ssytrf_rk (int matrix_layout, char uplo, lapack_int n, float * A, lapack_int lda, float * e, lapack_int * ipiv);

lapack_int LAPACKE_dsytrf_rk (int matrix_layout, char uplo, lapack_int n, double * A, lapack_int lda, double * e, lapack_int * ipiv);

lapack_int LAPACKE_csytrf_rk (int matrix_layout, char uplo, lapack_int n, lapack_complex_float * A, lapack_int lda, lapack_complex_float * e, lapack_int * ipiv);

lapack_int LAPACKE_zsytrf_rk (int matrix_layout, char uplo, lapack_int n, lapack_complex_double * A, lapack_int lda, lapack_complex_double * e, lapack_int * ipiv);

Description

?sytrf_rk computes the factorization of a real or complex symmetric matrix A using the bounded Bunch-Kaufman (rook) diagonal pivoting method: A = P*U*D*(U^T)(P^T) or A = P*L*D*(L^T)(P^T), where U (or L) is unit upper (or lower) triangular matrix, U^T (or L^T) is the transpose of U (or L), P is a permutation matrix, P^T is the transpose of P, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the blocked version of the algorithm, calling Level-3 BLAS.

Input Parameters

matrix_layout

Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

uplo

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored:
- = 'U': Upper triangular
- = 'L': Lower triangular

n

The order of the matrix A. n ≥ 0.

A

Array of size max(1, lda*n). On entry, the symmetric matrix A. If uplo = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If uplo = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

lda

The leading dimension of the array A.

Output Parameters

A

On exit, contains:
- Only diagonal elements of the symmetric block diagonal matrix D on the diagonal of A; that is, D(k,k) = A(k,k); (superdiagonal (or subdiagonal) elements of D are stored on exit in array e).
- If uplo = 'U', factor U in the superdiagonal part of A. If uplo = 'L', factor L in the subdiagonal part of A.

e

Array of size n. On exit, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks. If uplo = 'U', e(i) = D(i-1,i), i=2:N, and e(1) is set to 0. If uplo = 'L', e(i) = D(i+1,i), i=1:N-1, and e(n) is set to 0.
NOTE For 1-by-1 diagonal block $D(k)$, where $1 \leq k \leq n$, the element $e[k-1]$ is set to 0 in both the $\text{uplo} = 'U'$ and $\text{uplo} = 'L'$ cases.

Array of size $n$. $\text{ipiv}$ describes the permutation matrix $P$ in the factorization of matrix $A$ as follows: The absolute value of $\text{ipiv}(k)$ represents the index of the row and column that were interchanged with the $k^{th}$ row and column. The value of $\text{uplo}$ describes the order in which the interchanges were applied. Also, the sign of $\text{ipiv}$ represents the block structure of the symmetric block diagonal matrix $D$ with 1-by-1 or 2-by-2 diagonal blocks, which correspond to 1 or 2 interchanges at each factorization step. If $\text{uplo} = 'U'$ (in factorization order, $k$ decreases from $n$ to 1):

1. A single positive entry $\text{ipiv}(k) > 0$ means that $D(k,k)$ is a 1-by-1 diagonal block. If $\text{ipiv}(k) \neq k$, rows and columns $k$ and $\text{ipiv}(k)$ were interchanged in the matrix $A(1:N,1:N)$. If $\text{ipiv}(k) = k$, no interchange occurred.

2. A pair of consecutive negative entries $\text{ipiv}(k) < 0$ and $\text{ipiv}(k-1).< 0$ means that $D(k-1:k,k-1:k)$ is a 2-by-2 diagonal block. (Note that negative entries in $\text{ipiv}$ appear only in pairs.)
   - If $-\text{ipiv}(k) \neq k$, rows and columns $k$ and $-\text{ipiv}(k)$ were interchanged in the matrix $A(1:N,1:N)$. If $-\text{ipiv}(k) = k$, no interchange occurred.
   - If $-\text{ipiv}(k-1) \neq k-1$, rows and columns $k-1$ and $-\text{ipiv}(k-1)$ were interchanged in the matrix $A(1:N,1:N)$. If $-\text{ipiv}(k-1) = k-1$, no interchange occurred.

3. In both cases 1 and 2, always $\text{ABS}(\text{ipiv}(k)) \leq k$.

NOTE Any entry $\text{ipiv}(k)$ is always nonzero on output.

If $\text{uplo} = 'L'$ (in factorization order, $k$ increases from 1 to $n$):

1. A single positive entry $\text{ipiv}(k) > 0$ means that $D(k,k)$ is a 1-by-1 diagonal block. If $\text{ipiv}(k) \neq k$, rows and columns $k$ and $\text{ipiv}(k)$ were interchanged in the matrix $A(1:N,1:N)$. If $\text{ipiv}(k) = k$, no interchange occurred.

2. A pair of consecutive negative entries $\text{ipiv}(k) < 0$ and $\text{ipiv}(k+1) < 0$ means that $D(k:k+1,k:k+1)$ is a 2-by-2 diagonal block. (Note that negative entries in $\text{ipiv}$ appear only in pairs.)
   - If $-\text{ipiv}(k) \neq k$, rows and columns $k$ and $-\text{ipiv}(k)$ were interchanged in the matrix $A(1:N,1:N)$. If $-\text{ipiv}(k) = k$, no interchange occurred.
   - If $-\text{ipiv}(k+1) \neq k+1$, rows and columns $k-1$ and $-\text{ipiv}(k-1)$ were interchanged in the matrix $A(1:N,1:N)$. If $-\text{ipiv}(k+1) = k+1$, no interchange occurred.

3. In both cases 1 and 2, always $\text{ABS}(\text{ipiv}(k)) \geq k$.

NOTE Any entry $\text{ipiv}(k)$ is always nonzero on output.
Return Values
This function returns a value info.

= 0: Successful exit.
< 0: If info = -k, the kth argument had an illegal value.
> 0: If info = k, the matrix A is singular. If uplo = 'U', column k in the upper triangular part of A contains all zeros. If uplo = 'L', column k in the lower triangular part of A contains all zeros. Therefore, D(k,k) is exactly zero, and superdiagonal elements of column k of U (or subdiagonal elements of column k of L) are all zeros. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

?hetrf
Computes the Bunch-Kaufman factorization of a complex Hermitian matrix.

Syntax
lapack_int LAPACKE_chetrf (int matrix_layout , char uplo , lapack_int n ,
lapack_complex_float * a , lapack_int lda , lapack_int * ipiv );
lapack_int LAPACKE_zhetrf (int matrix_layout , char uplo , lapack_int n ,
lapack_complex_double * a , lapack_int lda , lapack_int * ipiv );

Include Files
 • mkl.h

Description
The routine computes the factorization of a complex Hermitian matrix A using the Bunch-Kaufman diagonal pivoting method:

if uplo='U', A = U*D*UH
if uplo='L', A = L*D*LH,
where A is the input matrix, U and L are products of permutation and triangular matrices with unit diagonal (upper triangular for U and lower triangular for L), and D is a Hermitian block-diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks. U and L have 2-by-2 unit diagonal blocks corresponding to the 2-by-2 blocks of D.

NOTE
This routine supports the Progress Routine feature. See Progress Routines section for details.

Input Parameters

matrix_layout
Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

uplo
Must be 'U' or 'L'.
Indicates whether the upper or lower triangular part of A is stored and how A is factored:
If uplo = 'U', the array a stores the upper triangular part of the matrix A, and A is factored as U*D*UH.
If \( \text{uplo} = 'L' \), the array \( a \) stores the lower triangular part of the matrix \( A \), and \( A \) is factored as \( L \cdot D \cdot L^T \).

\( n \)

The order of matrix \( A \); \( n \geq 0 \).

\( a \)

Array, size \( \max(1, \text{lda} \cdot n) \).

The array \( a \) contains the upper or the lower triangular part of the matrix \( A \) (see \( \text{uplo} \)).

\( \text{lda} \)

The leading dimension of \( a \); at least \( \max(1, n) \).

### Output Parameters

The upper or lower triangular part of \( a \) is overwritten by details of the block-diagonal matrix \( D \) and the multipliers used to obtain the factor \( U \) (or \( L \)).

\( \text{ipiv} \)

Array, size at least \( \max(1, n) \). Contains details of the interchanges and the block structure of \( D \). If \( \text{ipiv}[i-1] = k > 0 \), then \( d_{ii} \) is a 1-by-1 block, and the \( i \)-th row and column of \( A \) was interchanged with the \( k \)-th row and column.

If \( \text{uplo} = 'U' \) and \( \text{ipiv}[i] = \text{ipiv}[i-1] = -m < 0 \), then \( D \) has a 2-by-2 block in rows/columns \( i \) and \( i+1 \), and \( i \)-th row and column of \( A \) was interchanged with the \( m \)-th row and column.

If \( \text{uplo} = 'L' \) and \( \text{ipiv}[i] = \text{ipiv}[i-1] = -m < 0 \), then \( D \) has a 2-by-2 block in rows/columns \( i \) and \( i+1 \), and \((i+1)\)-th row and column of \( A \) was interchanged with the \( m \)-th row and column.

### Return Values

This function returns a value \( \text{info} \).

If \( \text{info} = 0 \), the execution is successful.

If \( \text{info} = -i \), parameter \( i \) had an illegal value.

If \( \text{info} = i \), \( d_{ii} \) is 0. The factorization has been completed, but \( D \) is exactly singular. Division by 0 will occur if you use \( D \) for solving a system of linear equations.

### Application Notes

This routine is suitable for Hermitian matrices that are not known to be positive-definite. If \( A \) is in fact positive-definite, the routine does not perform interchanges, and no 2-by-2 diagonal blocks occur in \( D \).

The 2-by-2 unit diagonal blocks and the unit diagonal elements of \( U \) and \( L \) are not stored. The remaining elements of \( U \) and \( L \) are stored in the corresponding columns of the array \( a \), but additional row interchanges are required to recover \( U \) or \( L \) explicitly (which is seldom necessary).

If \( \text{ipiv}[i-1] = i \) for all \( i = 1 \ldots n \), then all off-diagonal elements of \( U \) (\( L \)) are stored explicitly in the corresponding elements of the array \( a \).

If \( \text{uplo} = 'U' \), the computed factors \( U \) and \( D \) are the exact factors of a perturbed matrix \( A + E \), where

\[
|E| \leq c(n)\varepsilon|U||D||U^T|P^T
\]

\( c(n) \) is a modest linear function of \( n \), and \( \varepsilon \) is the machine precision.

A similar estimate holds for the computed \( L \) and \( D \) when \( \text{uplo} = 'L' \).
The total number of floating-point operations is approximately \((4/3)n^3\).

After calling this routine, you can call the following routines:

- \(?hetrs\) to solve \(A^*X = B\)
- \(?hecon\) to estimate the condition number of \(A\)
- \(?hetri\) to compute the inverse of \(A\).

**Matrix Storage Schemes**

- \(?hetrf_aa\)
  
  **Computes the factorization of a complex hermitian matrix using Aasen's algorithm.**

  ```c
  LAPACK_DECL lapack_int LAPACKE_chetrf_aa (int matrix_layout, char uplo, lapack_int n,
  lapack_complex_float * a, lapack_int lda, lapack_int * ipiv);
  ```

  ```c
  LAPACK_DECL lapack_int LAPACKE_zhetrf_aa (int matrix_layout, char uplo, lapack_int n,
  lapack_complex_double * a, lapack_int lda, lapack_int * ipiv);
  ```

**Description**

\(?hetrf_aa\) computes the factorization of a complex Hermitian matrix \(A\) using Aasen's algorithm. The form of the factorization is \(A = U^*T^*U^H\) or \(A = L^*T^*L^H\) where \(U\) (or \(L\)) is a product of permutation and unit upper (lower) triangular matrices, and \(T\) is a Hermitian tridiagonal matrix. This is the blocked version of the algorithm, calling Level 3 BLAS.

**Input Parameters**

- **matrix_layout**
  
  Specifies whether matrix storage layout is row major (\(LAPACK_ROW_MAJOR\)) or column major (\(LAPACK_COL_MAJOR\)).

- **uplo**
  
  \(= 'U'\): Upper triangle of \(A\) is stored; \(= 'L'\): Lower triangle of \(a\) is stored.

- **n**
  
  The order of the matrix \(A\). \(n \geq 0\).

- **a**
  
  Array of size \(lda*n\). On entry, the Hermitian matrix \(A\).

  If \(uplo = 'U'\), the leading \(n\)-by-\(n\) upper triangular part of \(a\) contains the upper triangular part of the matrix \(A\), and the strictly lower triangular part of \(a\) is not referenced.

  If \(uplo = 'L'\), the leading \(n\)-by-\(n\) lower triangular part of \(a\) contains the lower triangular part of the matrix \(A\), and the strictly upper triangular part of \(a\) is not referenced.

- **lda**
  
  The leading dimension of the array \(a\). \(lda \geq max(1,n)\).

- **lwork**
  
  See **Syntax - Workspace**. The length of \(work\). \(lwork \geq 2*n\). For optimum performance \(lwork \geq n*(1 + nb)\), where \(nb\) is the optimal block size. If \(lwork = -1\), then a workspace query is assumed; the routine only calculates the optimal size of the \(work\) array, returns this value as the first entry of the \(work\) array, and no error message related to \(lwork\) is issued by \(xerbla\).
Output Parameters

\textbf{a} 
On exit, the tridiagonal matrix is stored in the diagonals and the subdiagonals of \(a\) just below (or above) the diagonals, and \(L\) is stored below (or above) the subdiagonals, when \textit{uplo} is 'L' (or 'U').

\textbf{ipiv} 
array, dimension (\(n\)) On exit, it contains the details of the interchanges: the row and column \(k\) of \(a\) were interchanged with the row and column \(\text{ipiv}[k]\).

\textbf{work} 
See Syntax - Workspace. Array of size (max(1, \textit{lwork})). On exit, if \textit{info} = 0, \textit{work}[0] returns the optimal \textit{lwork}.

Return Values

This function returns a value \textit{info}.

If \textit{info} = 0: successful exit < 0: if \textit{info} = -i, the \(i\)-th argument had an illegal value,

If \textit{info} > 0: if \textit{info} = \(i\), \(D_{ii}\) is exactly zero. The factorization has been completed, but the block diagonal matrix \(D\) is exactly singular, and division by zero will occur if it is used to solve a system of equations.

Syntax - Workspace

Use this interface if you want to explicitly provide the workspace array.

\texttt{lapack_int LAPACKE_zhetrf_rook (int \textit{matrix_layout}, char \textit{uplo}, lapack_int \textit{n}, lapack_complex_double * \textit{a}, lapack_int \textit{lda}, lapack_int * \textit{ipiv});}

Include Files

\bullet \texttt{mkl.h}

Description

The routine computes the factorization of a complex Hermitian matrix \(A\) using the bounded Bunch-Kaufman diagonal pivoting method:

\begin{align*}
\text{if } \textit{uplo} = 'U', & A = U \times D \times U^H \\
\text{if } \textit{uplo} = 'L', & A = L \times D \times L^H,
\end{align*}

where \(A\) is the input matrix, \(U\) (or \(L\) ) is a product of permutation and unit upper ( or lower) triangular matrices, and \(D\) is a Hermitian block-diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks.

This is the blocked version of the algorithm, calling Level 3 BLAS.
Input Parameters

matrix_layout

Specifies whether matrix storage layout for array b is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

uplo

Must be 'U' or 'L'.
Indicates whether the upper or lower triangular part of A is stored:
If uplo = 'U', the array a stores the upper triangular part of the matrix A.
If uplo = 'L', the array a stores the lower triangular part of the matrix A.

n

The order of matrix A; n ≥ 0.

a

Array a, size (lda*n)
The array a contains the upper or the lower triangular part of the matrix A (see uplo).
If uplo = 'U', the leading n-by-n upper triangular part of a contains the upper triangular part of the matrix A, and the strictly lower triangular part of a is not referenced. If uplo = 'L', the leading n-by-n lower triangular part of a contains the lower triangular part of the matrix A, and the strictly upper triangular part of a is not referenced.

lda

The leading dimension of a; at least max(1, n).

Output Parameters

a

The block diagonal matrix D and the multipliers used to obtain the factor U or L (see Application Notes for further details).

ipiv

- If uplo = 'U':
  If ipiv(k) > 0, then rows and columns k and ipiv(k) were interchanged and D_{k,k} is a 1-by-1 diagonal block.
  If ipiv(k) < 0 and ipiv(k - 1) < 0, then rows and columns k and -ipiv(k) were interchanged and rows and columns k - 1 and -ipiv(k - 1) were interchanged, D_{k-1:k,k-1:k} is a 2-by-2 diagonal block.
- If uplo = 'L':
  If ipiv(k) > 0, then rows and columns k and ipiv(k) were interchanged and D_{k,k} is a 1-by-1 diagonal block.
  If ipiv(k) < 0 and ipiv(k + 1) < 0, then rows and columns k and -ipiv(k) were interchanged and rows and columns k + 1 and -ipiv(k + 1) were interchanged, D_{k:k+1,k:k+1} is a 2-by-2 diagonal block.

Return Values

This function returns a value info.
If info = 0, the execution is successful.
If \( info = -i \), the \( i \)-th parameter had an illegal value.

If \( info = i \), \( D_{ii} \) is exactly 0. The factorization has been completed, but the block diagonal matrix \( D \) is exactly singular, and division by 0 will occur if you use \( D \) for solving a system of linear equations.

### Application Notes

If \( \text{uplo} = 'U' \), then \( A = U*D*U^H \), where

\[
U = P(n)*U(n)* ... *P(k)U(k)* ..., \]

i.e., \( U \) is a product of terms \( P(k)*U(k) \), where \( k \) decreases from \( n \) to 1 in steps of 1 or 2, and \( D \) is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks \( D(k) \). \( P(k) \) is a permutation matrix as defined by \( \text{ipiv}(k) \), and \( U(k) \) is a unit upper triangular matrix, such that if the diagonal block \( D(k) \) is of order \( s \) (\( s = 1 \) or 2), then

\[
U(k) = \begin{bmatrix}
    I & v & 0 \\
    s & I & 0 \\
    n-k & 0 & I
\end{bmatrix}
\]

If \( s = 1 \), \( D(k) \) overwrites \( A(k,k) \), and \( v \) overwrites \( A(1:k-1,k) \).

If \( s = 2 \), the upper triangle of \( D(k) \) overwrites \( A(k-1,k-1) \), \( A(k-1,k) \), and \( A(k,k) \), and \( v \) overwrites \( A(1:k-2,k-1:k) \).

If \( \text{uplo} = 'L' \), then \( A = L*D*L^H \), where

\[
L = P(1)*L(1)* ... *P(k)*L(k)* ..., \]

i.e., \( L \) is a product of terms \( P(k)*L(k) \), where \( k \) increases from 1 to \( n \) in steps of 1 or 2, and \( D \) is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks \( D(k) \). \( P(k) \) is a permutation matrix as defined by \( \text{ipiv}(k) \), and \( L(k) \) is a unit lower triangular matrix, such that if the diagonal block \( D(k) \) is of order \( s \) (\( s = 1 \) or 2), then

\[
L(k) = \begin{bmatrix}
    I & 0 & 0 \\
    s & I & 0 \\
    n-k-s+1 & 0 & v & I
\end{bmatrix}
\]

If \( s = 1 \), \( D(k) \) overwrites \( A(k,k) \), and \( v \) overwrites \( A(k+1:n,k) \).

If \( s = 2 \), the lower triangle of \( D(k) \) overwrites \( A(k,k) \), \( A(k+1,k) \), and \( A(k+1,k+1) \), and \( v \) overwrites \( A(k+2:n,k+1) \).

### Matrix Storage Schemes

**?hetrf_rk**

Computes the factorization of a complex Hermitian indefinite matrix using the bounded Bunch-Kaufman (rook) diagonal pivoting method (BLAS3 blocked algorithm).

```c
lapack_int LAPACKE_chetrf_rk (int matrix_layout, char uplo, lapack_int n,
  lapack_complex_float * A, lapack_int lda, lapack_complex_float * e, lapack_int * ipiv);

lapack_int LAPACKE_zhetrf_rk (int matrix_layout, char uplo, lapack_int n,
  lapack_complex_double * A, lapack_int lda, lapack_complex_double * e, lapack_int * ipiv);
```
Description

?hetrf_rk computes the factorization of a complex Hermitian matrix A using the bounded Bunch-Kaufman (rook) diagonal pivoting method: A = P*U*D*(U^H)*(P^T) or A = P*L*D*(L^H)*(P^T), where U (or L) is unit upper (or lower) triangular matrix, U^H (or L^H) is the conjugate of U (or L), P is a permutation matrix, P^T is the transpose of P, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the blocked version of the algorithm, calling Level 3 BLAS.

Input Parameters

matrix_layout

Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

uplo

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored:

- = 'U': Upper triangular.
- = 'L': Lower triangular.

n

The order of the matrix A, n ≥ 0.

A

Array of size max(1, lda*n). On entry, the Hermitian matrix A. If uplo = 'U': The leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If uplo = 'L': The leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

lda

The leading dimension of the array A.

Output Parameters

A

On exit, contains:

- Only diagonal elements of the Hermitian block diagonal matrix D on the diagonal of A; that is, D(k,k) = A(k,k). Superdiagonal (or subdiagonal) elements of D are stored on exit in array e.

- and -
- If uplo = 'U', factor U in the superdiagonal part of A. If uplo = 'L', factor L in the subdiagonal part of A.

e

Array of size n. On exit, contains the superdiagonal (or subdiagonal) elements of the Hermitian block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks. If uplo = 'U', e(i) = D(i-1,i), i=2:N, and e(1) is set to 0. If uplo = 'L', e(i) = D(i+1,i), i=1:N-1, and e(n) is set to 0.

NOTE For 1-by-1 diagonal block D(k), where 1 ≤ k ≤ n, the element e[k-1] is set to 0 in both the uplo = 'U' and uplo = 'L' cases.

ipiv

Array of size n. ipiv describes the permutation matrix P in the factorization of matrix A as follows: The absolute value of ipiv[k-1] represents the index of row and column that were interchanged with the kth row and column. The value of uplo describes the order in which the interchanges
were applied. Also, the sign of \( ipiv \) represents the block structure of the Hermitian block diagonal matrix \( D \) with 1-by-1 or 2-by-2 diagonal blocks that correspond to 1 or 2 interchanges at each factorization step. If \( \text{uplo} = 'U' \) (in factorization order, \( k \) decreases from \( n \) to 1):

1. A single positive entry \( ipiv(k) > 0 \) means that \( D(k,k) \) is a 1-by-1 diagonal block. If \( ipiv(k) \neq k \), rows and columns \( k \) and \( ipiv(k) \) were interchanged in the matrix \( A(1:N,1:N) \). If \( ipiv(k) = k \), no interchange occurred.
2. A pair of consecutive negative entries \( ipiv(k) < 0 \) and \( ipiv(k-1) < 0 \) means that \( D(k-1:k-1,k:k) \) is a 2-by-2 diagonal block. (Note that negative entries in \( ipiv \) appear only in pairs.)
   - If \( -ipiv(k) \neq k \), rows and columns \( k \) and \( -ipiv(k) \) were interchanged in the matrix \( A(1:N,1:N) \). If \( -ipiv(k) = k \), no interchange occurred.
   - If \( -ipiv(k-1) \neq k-1 \), rows and columns \( k-1 \) and \( -ipiv(k-1) \) were interchanged in the matrix \( A(1:N,1:N) \). If \( -ipiv(k-1) = k-1 \), no interchange occurred.
3. In both cases 1 and 2, always \( \text{ABS}( ipiv(k) ) \leq k \).

**NOTE** Any entry \( ipiv(k) \) is always nonzero on output.

If \( \text{uplo} = 'L' \) (in factorization order, \( k \) increases from 1 to \( n \)):

1. A single positive entry \( ipiv(k) > 0 \) means that \( D(k,k) \) is a 1-by-1 diagonal block. If \( ipiv(k) \neq k \), rows and columns \( k \) and \( ipiv(k) \) were interchanged in the matrix \( A(1:N,1:N) \). If \( ipiv(k) = k \), no interchange occurred.
2. A pair of consecutive negative entries \( ipiv(k) < 0 \) and \( ipiv(k+1) < 0 \) means that \( D(k:k+1,k:k+1) \) is a 2-by-2 diagonal block. (Note that negative entries in \( ipiv \) appear only in pairs.)
   - If \( -ipiv(k) \neq k \), rows and columns \( k \) and \( -ipiv(k) \) were interchanged in the matrix \( A(1:N,1:N) \). If \( -ipiv(k) = k \), no interchange occurred.
   - If \( -ipiv(k+1) \neq k+1 \), rows and columns \( k-1 \) and \( -ipiv(k-1) \) were interchanged in the matrix \( A(1:N,1:N) \). If \( -ipiv(k+1) = k+1 \), no interchange occurred.
3. In both cases 1 and 2, always \( \text{ABS}( ipiv(k) ) \geq k \).

**NOTE** Any entry \( ipiv(k) \) is always nonzero on output.

**Return Values**
This function returns a value \( info \).

\( = 0 \): Successful exit.

\( < 0 \): If \( info = -k \), the \( k \)th argument had an illegal value.
> 0: If info = k, the matrix A is singular. If uplo = 'U', the column k in the upper triangular part of A contains all zeros. If uplo = 'L', the column k in the lower triangular part of A contains all zeros. Therefore D(k,k) is exactly zero, and superdiagonal elements of column k of U (or subdiagonal elements of column k of L) are all zeros. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

?sptrf
Computes the Bunch-Kaufman factorization of a symmetric matrix using packed storage.

Syntax

```c
lapack_int LAPACKE_ssptrf (int matrix_layout, char uplo, lapack_int n, float * ap, lapack_int * ipiv);

lapack_int LAPACKE_dsptrf (int matrix_layout, char uplo, lapack_int n, double * ap, lapack_int * ipiv);

lapack_int LAPACKE_csptrf (int matrix_layout, char uplo, lapack_int n, lapack_complex_float * ap, lapack_int * ipiv);

lapack_int LAPACKE_zsptrf (int matrix_layout, char uplo, lapack_int n, lapack_complex_double * ap, lapack_int * ipiv);
```

Include Files

- mkl.h

Description

The routine computes the factorization of a real/complex symmetric matrix A stored in the packed format using the Bunch-Kaufman diagonal pivoting method. The form of the factorization is:

- If uplo='U', A = U*D*Uᵀ
- If uplo='L', A = L*D*Lᵀ,

where U and L are products of permutation and triangular matrices with unit diagonal (upper triangular for U and lower triangular for L), and D is a symmetric block-diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks. U and L have 2-by-2 unit diagonal blocks corresponding to the 2-by-2 blocks of D.

**NOTE**
This routine supports the Progress Routine feature. See Progress Function section for details.

Input Parameters

- **matrix_layout**
  Specifies whether matrix storage layout is row major (**LAPACK_ROW_MAJOR**) or column major (**LAPACK_COL_MAJOR**).

- **uplo**
  Must be 'U' or 'L'.
  Indicates whether the upper or lower triangular part of A is packed in the array ap and how A is factored:
  - If uplo = 'U', the array ap stores the upper triangular part of the matrix A, and A is factored as U*D*Uᵀ.
  - If uplo = 'L', the array ap stores the lower triangular part of the matrix A, and A is factored as L*D*Lᵀ.
The order of matrix $A$; $n \geq 0$.

Array, size at least $\max(1, n(n+1)/2)$. The array $ap$ contains the upper or the lower triangular part of the matrix $A$ (as specified by $uplo$) in packed storage (see Matrix Storage Schemes).

Output Parameters

The upper or lower triangle of $A$ (as specified by $uplo$) is overwritten by details of the block-diagonal matrix $D$ and the multipliers used to obtain the factor $U$ (or $L$).

Array, size at least $\max(1, n)$. Contains details of the interchanges and the block structure of $D$. If $ipiv[i-1] = k > 0$, then $d_{ii}$ is a 1-by-1 block, and the $i$-th row and column of $A$ was interchanged with the $k$-th row and column.

If $uplo = 'U'$ and $ipiv[i] = ipiv[i-1] = -m < 0$, then $D$ has a 2-by-2 block in rows/columns $i$ and $i+1$, and $i$-th row and column of $A$ was interchanged with the $m$-th row and column.

If $uplo = 'L'$ and $ipiv[i] = ipiv[i-1] = -m < 0$, then $D$ has a 2-by-2 block in rows/columns $i$ and $i+1$, and $(i+1)$-th row and column of $A$ was interchanged with the $m$-th row and column.

Return Values

This function returns a value $info$.

If $info = 0$, the execution is successful.

If $info = -i$, parameter $i$ had an illegal value.

If $info = i$, $d_{ii}$ is 0. The factorization has been completed, but $D$ is exactly singular. Division by 0 will occur if you use $D$ for solving a system of linear equations.

Application Notes

The 2-by-2 unit diagonal blocks and the unit diagonal elements of $U$ and $L$ are not stored. The remaining elements of $U$ and $L$ overwrite elements of the corresponding columns of the array $ap$, but additional row interchanges are required to recover $U$ or $L$ explicitly (which is seldom necessary).

If $ipiv(i) = i$ for all $i = 1 \ldots n$, then all off-diagonal elements of $U$ ($L$) are stored explicitly in packed form.

If $uplo = 'U'$, the computed factors $U$ and $D$ are the exact factors of a perturbed matrix $A + E$, where

$$|E| \leq c(n)\|P\|\|U\|\|D\|\|U^T\|P^T$$

$c(n)$ is a modest linear function of $n$, and $\varepsilon$ is the machine precision. A similar estimate holds for the computed $L$ and $D$ when $uplo = 'L'$.

The total number of floating-point operations is approximately $(1/3)n^3$ for real flavors or $(4/3)n^3$ for complex flavors.

After calling this routine, you can call the following routines:

- ?sptrs to solve $A^*X = B$
- ?spcon to estimate the condition number of $A$
- ?sptri to compute the inverse of $A$.

Matrix Storage Schemes

?hptrf
Computes the Bunch-Kaufman factorization of a complex Hermitian matrix using packed storage.

Syntax

```c
lapack_int LAPACKE_chptrf (int matrix_layout, char uplo, lapack_int n, 
lapack_complex_float * ap, lapack_int * ipiv);
lapack_int LAPACKE_zhptrf (int matrix_layout, char uplo, lapack_int n, 
lapack_complex_double * ap, lapack_int * ipiv);
```

Include Files

- mkl.h

Description

The routine computes the factorization of a complex Hermitian packed matrix $A$ using the Bunch-Kaufman diagonal pivoting method:

- If $\text{uplo} = 'U'$, $A = U*D*U^H$
- If $\text{uplo} = 'L'$, $A = L*D*L^H$,

where $A$ is the input matrix, $U$ and $L$ are products of permutation and triangular matrices with unit diagonal (upper triangular for $U$ and lower triangular for $L$), and $D$ is a Hermitian block-diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks. $U$ and $L$ have 2-by-2 unit diagonal blocks corresponding to the 2-by-2 blocks of $D$.

**NOTE**
This routine supports the Progress Routine feature. See Progress Function section for details.

Input Parameters

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **uplo**
  Must be 'U' or 'L'.
  Indicates whether the upper or lower triangular part of $A$ is packed and how $A$ is factored:
  - If $\text{uplo} = 'U'$, the array $ap$ stores the upper triangular part of the matrix $A$, and $A$ is factored as $U*D*U^H$.
  - If $\text{uplo} = 'L'$, the array $ap$ stores the lower triangular part of the matrix $A$, and $A$ is factored as $L*D*L^H$.

- **n**
  The order of matrix $A$; $n \geq 0$. 
**Ap**

Array, size at least \( \max(1, n(n+1)/2) \). The array \( \text{ap} \) contains the upper or the lower triangular part of the matrix \( A \) (as specified by \( \text{uplo} \)) in packed storage (see Matrix Storage Schemes).

**Output Parameters**

**Ap**

The upper or lower triangle of \( A \) (as specified by \( \text{uplo} \)) is overwritten by details of the block-diagonal matrix \( D \) and the multipliers used to obtain the factor \( U \) (or \( L \)).

**Ipiv**

Array, size at least \( \max(1, n) \). Contains details of the interchanges and the block structure of \( D \). If \( \text{ipiv}[i-1] = k > 0 \), then \( d_{ii} \) is a 1-by-1 block, and the \( i \)-th row and column of \( A \) was interchanged with the \( k \)-th row and column.

If \( \text{uplo} = 'U' \) and \( \text{ipiv}[i] = \text{ipiv}[i-1] = -m < 0 \), then \( D \) has a 2-by-2 block in rows/columns \( i \) and \( i+1 \), and \( i \)-th row and column of \( A \) was interchanged with the \( m \)-th row and column.

If \( \text{uplo} = 'L' \) and \( \text{ipiv}[i] = \text{ipiv}[i-1] = -m < 0 \), then \( D \) has a 2-by-2 block in rows/columns \( i \) and \( i+1 \), and \((i+1)\)-th row and column of \( A \) was interchanged with the \( m \)-th row and column.

**Return Values**

This function returns a value \( \text{info} \).

If \( \text{info} = 0 \), the execution is successful.

If \( \text{info} = -i \), parameter \( i \) had an illegal value.

If \( \text{info} = i \), \( d_{ii} \) is 0. The factorization has been completed, but \( D \) is exactly singular. Division by 0 will occur if you use \( D \) for solving a system of linear equations.

**Application Notes**

The 2-by-2 unit diagonal blocks and the unit diagonal elements of \( U \) and \( L \) are not stored. The remaining elements of \( U \) and \( L \) are stored in the array \( \text{ap} \), but additional row interchanges are required to recover \( U \) or \( L \) explicitly (which is seldom necessary).

If \( \text{ipiv}[i-1] = i \) for all \( i = 1 \ldots n \), then all off-diagonal elements of \( U \) (\( L \)) are stored explicitly in the corresponding elements of the array \( a \).

If \( \text{uplo} = 'U' \), the computed factors \( U \) and \( D \) are the exact factors of a perturbed matrix \( A + E \), where

\[
|E| \leq c(n)\varepsilon|U||D||U^T||P^T|
\]

\( c(n) \) is a modest linear function of \( n \), and \( \varepsilon \) is the machine precision.

A similar estimate holds for the computed \( L \) and \( D \) when \( \text{uplo} = 'L' \).

The total number of floating-point operations is approximately \((4/3)n^3\).

After calling this routine, you can call the following routines:

- \texttt{?hptrs} to solve \( A^*X = B \)
- \texttt{?hpcon} to estimate the condition number of \( A \)
- \texttt{?hptri} to compute the inverse of \( A \).

Include Files
• mkl.h

Description
The routine computes the partial factorization \( A = LDLᵀ \), where \( L \) is a lower triangular matrix and \( D \) is a diagonal matrix.

Caution
The routine assumes that the matrix \( A \) is factorizable. The routine does not perform pivoting and does not handle diagonal elements which are zero, which cause the routine to produce incorrect results without any indication.

Consider the matrix \( A = \begin{pmatrix} a & b \ T \\ b & C \end{pmatrix} \) where \( a \) is the element in the first row and first column of \( A \), \( b \) is a column vector of size \( n - 1 \) containing the elements from the second through \( n \)-th column of \( A \), \( C \) is the lower-right square submatrix of \( A \), and \( I \) is the identity matrix.

The mkl_?spffrt2 routine performs \( n_{colm} \) successive factorizations of the form

\[
A = \begin{pmatrix} a & b \ T \\ b & C \end{pmatrix} = \begin{pmatrix} a_0 & 0 \\ 0 & I \end{pmatrix} \begin{pmatrix} a_0^{-1} & 0 \\ 0 & C - ba_0^{-1}b_0 \ T \end{pmatrix} \begin{pmatrix} a & b \ T \\ b & I \end{pmatrix}.
\]
The mkl_?spffrtx routine performs ncolm successive factorizations of the form

\[
A = \begin{pmatrix} a & b^T \\ b & C \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ ba^{-1} & I \end{pmatrix} \begin{pmatrix} a & 0 \\ 0 & C - ba^{-1}b^T \end{pmatrix} \begin{pmatrix} 1 & (ba^{-1})^T \\ 0 & I \end{pmatrix}.
\]

The approximate number of floating point operations performed by real flavors of these routines is

\[
(1/6)ncolm(2ncolm^2 - 6ncolm*n + 3ncolm + 6n^2 - 6n + 7).
\]

The approximate number of floating point operations performed by complex flavors of these routines is

\[
(1/3)ncolm(4ncolm^2 - 12ncolm*n + 9ncolm + 12n^2 - 18n + 8).
\]

**Input Parameters**

- **ap**
  - Array, size at least max(1, n(n+1)/2). The array ap contains the lower triangular part of the matrix A in packed storage (see Matrix Storage Schemes for uplo = 'L').

- **n**
  - The order of matrix A; n \geq 0.

- **ncolm**
  - The number of columns to factor, ncolm \leq n.

- **work, work2**
  - Workspace arrays, size of each at least n.

**Output Parameters**

- **ap**
  - Overwritten by the factor L. The first ncolm diagonal elements of the input matrix A are replaced with the diagonal elements of D. The subdiagonal elements of the first ncolm columns are replaced with the corresponding elements of L. The rest of the input array is updated as indicated in the Description section.

**NOTE**

Specifying ncolm = n results in complete factorization \(A = LDL^T\).

Matrix Storage Schemes

**Solving Systems of Linear Equations: LAPACK Computational Routines**

This section describes the LAPACK routines for solving systems of linear equations. Before calling most of these routines, you need to factorize the matrix of your system of equations (see Routines for Matrix Factorization in this chapter). However, the factorization is not necessary if your system of equations has a triangular matrix.

**?getrs**

Solves a system of linear equations with an LU-factored square coefficient matrix, with multiple right-hand sides.

**Syntax**

```c
lapack_int LAPACKE_sgetrs (int matrix_layout , char trans , lapack_int n , lapack_int nrhs , const float * a , lapack_int lda , const lapack_int * ipiv , float * b , lapack_int ldb );
```
lapack_int LAPACKE_dgetrs (int matrix_layout, char trans, lapack_int n, lapack_int nrhs, const double * a, lapack_int lda, const lapack_int * ipiv, double * b, lapack_int ldb);

lapack_int LAPACKE_cgetrs (int matrix_layout, char trans, lapack_int n, lapack_int nrhs, const lapack_complex_float * a, lapack_int lda, const lapack_int * ipiv, lapack_complex_float * b, lapack_int ldb);

lapack_int LAPACKE_zgetrs (int matrix_layout, char trans, lapack_int n, lapack_int nrhs, const lapack_complex_double * a, lapack_int lda, const lapack_int * ipiv, lapack_complex_double * b, lapack_int ldb);

Include Files
• mkl.h

Description
The routine solves for $X$ the following systems of linear equations:

$A*X = B$ if $trans='N'$,

$A^T*X = B$ if $trans='T'$,

$A^H*X = B$ if $trans='C'$ (for complex matrices only).

Before calling this routine, you must call ?getrf to compute the $LU$ factorization of $A$.

Input Parameters

matrix_layout
Specifies whether matrix storage layout is row major
(LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

trans
Must be 'N' or 'T' or 'C'.

Indicates the form of the equations:
If $trans = 'N'$, then $A*X = B$ is solved for $X$.
If $trans = 'T'$, then $A^T*X = B$ is solved for $X$.
If $trans = 'C'$, then $A^H*X = B$ is solved for $X$.

n
The order of $A$; the number of rows in $B$ ($n \geq 0$).

nrhs
The number of right-hand sides; $nrhs \geq 0$.

a
Array of size max(1, lda*n).
The array $a$ contains $LU$ factorization of matrix $A$ resulting from the call of ?getrf.

b
Array of size max(1,ldb*nrhs) for column major layout, and max(1,lda*n) for row major layout.
The array $b$ contains the matrix $B$ whose columns are the right-hand sides for the systems of equations.

lda
The leading dimension of $a$; lda $\geq$ max(1, n).

ldb
The leading dimension of $b$; ldb $\geq$ max(1, n) for column major layout and ldb $\geq$ nrhs for row major layout.
**ipiv**

Array, size at least \( \max(1, n) \). The \( ipiv \) array, as returned by \(?getrf\).

**Output Parameters**

\( b \)

Overwritten by the solution matrix \( X \).

**Return Values**

This function returns a value \( info \).

If \( info = 0 \), the execution is successful.

If \( info = -i \), parameter \( i \) had an illegal value.

**Application Notes**

For each right-hand side \( b \), the computed solution is the exact solution of a perturbed system of equations \( (A + E)x = b \), where

\[
|E| \leq c(n)EPA||U|
\]

\( c(n) \) is a modest linear function of \( n \), and \( \varepsilon \) is the machine precision.

If \( x_0 \) is the true solution, the computed solution \( x \) satisfies this error bound:

\[
\frac{||x - x_0||_\infty}{||x||_\infty} \leq c(n)\text{cond}(A, x)\varepsilon
\]

where \( \text{cond}(A, x) = \frac{||A^{-1}|| \cdot ||A|| \cdot ||x||_\infty}{||x||_\infty \cdot ||A^{-1}||_\infty \cdot ||A||_\infty} = \kappa_\infty(A) \).

Note that \( \text{cond}(A, x) \) can be much smaller than \( \kappa_\infty(A) \); the condition number of \( A^p \) and \( A^H \) might or might not be equal to \( \kappa_\infty(A) \).

The approximate number of floating-point operations for one right-hand side vector \( b \) is \( 2n^2 \) for real flavors and \( 8n^2 \) for complex flavors.

To estimate the condition number \( \kappa_\infty(A) \), call \(?gecon\).

To refine the solution and estimate the error, call \(?gerfs\).

**See Also**

Matrix Storage Schemes

?gbtrs

Solves a system of linear equations with an LU-factored band coefficient matrix, with multiple right-hand sides.

**Syntax**

```c
lapack_int LAPACKE_sgbtrs (int matrix_layout, char trans, lapack_int n, lapack_int kl, lapack_int ku, lapack_int nrhs, const float * ab, lapack_int ldab, const lapack_int * ipiv, float * b, lapack_int ldb);

lapack_int LAPACKE_dgbtrs (int matrix_layout, char trans, lapack_int n, lapack_int kl, lapack_int ku, lapack_int nrhs, const double * ab, lapack_int ldab, const lapack_int * ipiv, double * b, lapack_int ldb);
```
lapack_int LAPACKE_cgbtrs (int matrix_layout, char trans, lapack_int n, lapack_int kl, lapack_int ku, lapack_int nrhs, const lapack_complex_float * ab, lapack_int ldab, const lapack_int * ipiv, lapack_complex_float * b, lapack_int ldb);

lapack_int LAPACKE_zgbtrs (int matrix_layout, char trans, lapack_int n, lapack_int kl, lapack_int ku, lapack_int nrhs, const lapack_complex_double * ab, lapack_int ldab, const lapack_int * ipiv, lapack_complex_double * b, lapack_int ldb);

Include Files
• mkl.h

Description
The routine solves for $X$ the following systems of linear equations:

$$A*X = B \quad \text{if } \text{trans} = 'N',$$
$$A^T*X = B \quad \text{if } \text{trans} = 'T',$$
$$A^H*X = B \quad \text{if } \text{trans} = 'C' \text{ (for complex matrices only).}$$

Here $A$ is an LU-factored general band matrix of order $n$ with $kl$ non-zero subdiagonals and $ku$ nonzero superdiagonals. Before calling this routine, call ?gbtrf to compute the $LU$ factorization of $A$.

Input Parameters
- **matrix_layout**: Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- **trans**: Must be 'N' or 'T' or 'C'.
- **n**: The order of $A$; the number of rows in $B$; $n \geq 0$.
- **kl**: The number of subdiagonals within the band of $A$; $kl \geq 0$.
- **ku**: The number of superdiagonals within the band of $A$; $ku \geq 0$.
- **nrhs**: The number of right-hand sides; $nrhs \geq 0$.
- **ab**: Array $ab$ size max(1, ldab*n)
The array $ab$ contains elements of the LU factors of the matrix $A$ as returned by gbtrf.
- **b**: Array $b$ size max(1, ldb*nrhs) for column major layout and max(1, ldab*n) for row major layout.
The array $b$ contains the matrix $B$ whose columns are the right-hand sides for the systems of equations.
- **ldab**: The leading dimension of the array $ab$; $ldab \geq 2*kl + ku +1$.
- **ldb**: The leading dimension of $b$; $ldb \geq \text{max}(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout.
- **ipiv**: Array, size at least max(1, n). The $ipiv$ array, as returned by ?gbtrf.

Output Parameters
- **b**: Overwritten by the solution matrix $X$. 462
Return Values

This function returns a value info.

If info=0, the execution is successful.

If info = -i, parameter i had an illegal value.

Application Notes

For each right-hand side b, the computed solution is the exact solution of a perturbed system of equations (A + E)x = b, where

\[ |E| \leq c(k_l + k_u + 1)\varepsilon\|L\|\|U\| \]

c(k) is a modest linear function of k, and \( \varepsilon \) is the machine precision.

If \( x_0 \) is the true solution, the computed solution \( x \) satisfies this error bound:

\[ \frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(k_l + k_u + 1)\text{cond}(A, x)\varepsilon \]

where \( \text{cond}(A, x) = \frac{\|A^{-1}\|\|A\|}{\|x\|_\infty / \|Ax\|_\infty \leq \|A^{-1}\|\|A\|_\infty} = \kappa_x(A) \).

Note that \( \text{cond}(A, x) \) can be much smaller than \( \kappa_x(A) \); the condition number of \( A^T \) and \( A^H \) might or might not be equal to \( \kappa_x(A) \).

The approximate number of floating-point operations for one right-hand side vector is 2n(ku + 2kl) for real flavors. The number of operations for complex flavors is 4 times greater. All these estimates assume that kl and ku are much less than \( \min(m, n) \).

To estimate the condition number \( \kappa_x(A) \), call ?gbcon.

To refine the solution and estimate the error, call ?gbrfs.

?gttrs

Solves a system of linear equations with a tridiagonal coefficient matrix using the LU factorization computed by ?gttrf.

Syntax

```c
lapack_int LAPACKE_sgttrs (int matrix_layout , char trans , lapack_int n , lapack_int nrhs , const float * dl , const float * d , const float * du , const float * du2 , const lapack_int * ipiv , float * b , lapack_int ldb );

lapack_int LAPACKE_dgttrs (int matrix_layout , char trans , lapack_int n , lapack_int nrhs , const double * dl , const double * d , const double * du , const double * du2 , const lapack_int * ipiv , double * b , lapack_int ldb );

lapack_int LAPACKE_cgttrs (int matrix_layout , char trans , lapack_int n , lapack_int nrhs , const lapack_complex_float * d1 , const lapack_complex_float * d , const lapack_complex_float * du , const lapack_complex_float * du2 , const lapack_int * ipiv , lapack_complex_float * b , lapack_int ldb );
```
lapack_int LAPACKE_zgttrs (int matrix_layout, char trans, lapack_int n, lapack_int nrhs, const lapack_complex_double * dl, const lapack_complex_double * d, const lapack_complex_double * du, const lapack_complex_double * du2, const lapack_int * ipiv, lapack_complex_double * b, lapack_int LDB);

**Include Files**
- mkl.h

**Description**

The routine solves for $X$ the following systems of linear equations with multiple right hand sides:

- $A*X = B$ if $trans='N'$,
- $A^T*X = B$ if $trans='T'$,
- $A^H*X = B$ if $trans='C'$ (for complex matrices only).

Before calling this routine, you must call **gttrf** to compute the $LU$ factorization of $A$.

**Input Parameters**

- **matrix_layout**
  Specifies whether matrix storage layout for array $b$ is row major (**LAPACK_ROW_MAJOR**) or column major (**LAPACK_COL_MAJOR**).

- **trans**
  Must be 'N' or 'T' or 'C'.
  Indicates the form of the equations:
  - If $trans='N'$, then $A*X = B$ is solved for $X$.
  - If $trans='T'$, then $A^T*X = B$ is solved for $X$.
  - If $trans='C'$, then $A^H*X = B$ is solved for $X$.

- **n**
  The order of $A$; $n \geq 0$.

- **nrhs**
  The number of right-hand sides, that is, the number of columns in $B$; $nrhs \geq 0$.

- **dl, d, du, du2**
  Arrays: $dl(n-1), d(n), du(n-1), du2(n-2)$.
  The array $dl$ contains the $(n - 1)$ multipliers that define the matrix $L$ from the $LU$ factorization of $A$.
  The array $d$ contains the $n$ diagonal elements of the upper triangular matrix $U$ from the $LU$ factorization of $A$.
  The array $du$ contains the $(n - 1)$ elements of the first superdiagonal of $U$.
  The array $du2$ contains the $(n - 2)$ elements of the second superdiagonal of $U$.

- **b**
  Array of size max(1, $LDB*nrhs$) for column major layout and max(1, $n*LDB$) for row major layout. Contains the matrix $B$ whose columns are the right-hand sides for the systems of equations.

- **LDB**
  The leading dimension of $b$: $LDB \geq \max(1, n)$ for column major layout and $LDB \geq nrhs$ for row major layout.
**ipiv**

Array, size \((n)\). The \(ipiv\) array, as returned by \(?gttrf\).

**Output Parameters**

\(b\)  
Overwritten by the solution matrix \(X\).

**Return Values**

This function returns a value \(info\).

If \(info=0\), the execution is successful.

If \(info = -i\), parameter \(i\) had an illegal value.

**Application Notes**

For each right-hand side \(b\), the computed solution is the exact solution of a perturbed system of equations \((A + E)x = b\), where

\[
|E| \leq c(n)\varepsilon|L||U|
\]

\(c(n)\) is a modest linear function of \(n\), and \(\varepsilon\) is the machine precision.

If \(x_0\) is the true solution, the computed solution \(x\) satisfies this error bound:

\[
\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(kL + ku + 1) \text{cond} (A, x)\varepsilon
\]

where \(\text{cond}(A, x) = \|A^{-1}\| |A| |x| / \|x\|_\infty\| |A^{-1}|\|_\infty \|A\|_\infty = \kappa_x(A)\).

Note that \(\text{cond}(A, x)\) can be much smaller than \(\kappa_x(A)\); the condition number of \(A^T\) and \(A^H\) might or might not be equal to \(\kappa_x(A)\).

The approximate number of floating-point operations for one right-hand side vector \(b\) is \(7n\) (including \(n\) divisions) for real flavors and \(34n\) (including \(2n\) divisions) for complex flavors.

To estimate the condition number \(\kappa_x(A)\), call \(?gtcon\).

To refine the solution and estimate the error, call \(?gtrfs\).

\(?dttrsbr\)

Solves a system of linear equations with a diagonally dominant tridiagonal coefficient matrix using the LU factorization computed by \(?dttrfb\).

**Syntax**

```c
void sdttrsb (const char * trans, const MKL_INT * n, const MKL_INT * nrhs, const float * dl, const float * d, const float * du, float * b, const MKL_INT * ldb, MKL_INT * info);
void ddttrsb (const char * trans, const MKL_INT * n, const MKL_INT * nrhs, const double * dl, const double * d, const double * du, double * b, const MKL_INT * ldb, MKL_INT * info);
```
void cdttrsb (const char * trans, const MKL_INT * n, const MKL_INT * nrhs, const MKL_Complex8 * dl, const MKL_Complex8 * d, const MKL_Complex8 * du, MKL_Complex8 * b, const MKL_INT * ldb, MKL_INT * info);
void zdttrsb (const char * trans, const MKL_INT * n, const MKL_INT * nrhs, const MKL_Complex16 * dl, const MKL_Complex16 * d, const MKL_Complex16 * du, MKL_Complex16 * b, const MKL_INT * ldb, MKL_INT * info );

Include Files
• mkl.h

Description
The ?dttrsb routine solves the following systems of linear equations with multiple right hand sides for X:

\[ A \times X = B \quad \text{if } \text{trans} = 'N', \]
\[ A^T \times X = B \quad \text{if } \text{trans} = 'T', \]
\[ A^H \times X = B \quad \text{if } \text{trans} = 'C' \text{ (for complex matrices only)}. \]

Before calling this routine, call ?dttrfb to compute the factorization of A.

Input Parameters

trans
Must be 'N' or 'T' or 'C'.
Indicates the form of the equations solved for X:
If trans = 'N', then \( A \times X = B \).
If trans = 'T', then \( A^T \times X = B \).
If trans = 'C', then \( A^H \times X = B \).

n
The order of A; \( n \geq 0 \).
nrhs
The number of right-hand sides, that is, the number of columns in B; \( nrhs \geq 0 \).

dl, d, du
Arrays: \( dl(n-1), d(n), du(n-1) \).
The array dl contains the \((n-1)\) multipliers that define the matrices \( L_1, L_2 \) from the factorization of A.
The array d contains the \( n \) diagonal elements of the upper triangular matrix \( U \) from the factorization of A.
The array du contains the \((n-1)\) elements of the superdiagonal of \( U \).

b
Array of size max(1, ldb*nrhs). Contains the matrix B whose columns are the right-hand sides for the systems of equations.

ldb
The leading dimension of b; \( ldb \geq \max(1, n) \).

Output Parameters

b
Overwritten by the solution matrix X.
info
If info = 0, the execution is successful.
If \( \text{info} = -i \), the \( i \)-th parameter had an illegal value.

**?potrs**
Solves a system of linear equations with a Cholesky-factored symmetric (Hermitian) positive-definite coefficient matrix.

**Syntax**

```c
lapack_int LAPACKE_spotrs (int matrix_layout, char uplo, lapack_int n, lapack_int nrhs, const float * a, lapack_int lda, float * b, lapack_int ldb );
```

```c
lapack_int LAPACKE_dpotrs (int matrix_layout, char uplo, lapack_int n, lapack_int nrhs, const double * a, lapack_int lda, double * b, lapack_int ldb );
```

```c
lapack_int LAPACKE_cpotrs (int matrix_layout, char uplo, lapack_int n, lapack_int nrhs, const lapack_complex_float * a, lapack_int lda, lapack_complex_float * b, lapack_int ldb );
```

```c
lapack_int LAPACKE_zpotrs (int matrix_layout, char uplo, lapack_int n, lapack_int nrhs, const lapack_complex_double * a, lapack_int lda, lapack_complex_double * b, lapack_int ldb );
```

**Include Files**
- mkl.h

**Description**
The routine solves for \( X \) the system of linear equations \( A \cdot X = B \) with a symmetric positive-definite or, for complex data, Hermitian positive-definite matrix \( A \), given the Cholesky factorization of \( A \):

\[
A = U^T \cdot U \quad \text{for real data,} \quad A = U^H \cdot U \quad \text{for complex data}
\]

\[
A = L \cdot L^T \quad \text{for real data,} \quad A = L \cdot L^H \quad \text{for complex data}
\]

if \( \text{uplo} = \text{'U'} \)

where \( L \) is a lower triangular matrix and \( U \) is upper triangular. The system is solved with multiple right-hand sides stored in the columns of the matrix \( B \).

Before calling this routine, you must call ?potrf to compute the Cholesky factorization of \( A \).

**Input Parameters**

- **matrix_layout**
  Specifies whether matrix storage layout is row major (**LAPACK_ROW_MAJOR**) or column major (**LAPACK_COL_MAJOR**).

- **uplo**
  Must be \( \text{'U'} \) or \( \text{'L'} \).
  Indicates how the input matrix \( A \) has been factored:
  - If \( \text{uplo} = \text{'U'} \), \( U \) is stored, where \( A = U^T \cdot U \) for real data, \( A = U^H \cdot U \) for complex data.
  - If \( \text{uplo} = \text{'L'} \), \( L \) is stored, where \( A = L \cdot L^T \) for real data, \( A = L \cdot L^H \) for complex data.

- **n**
  The order of matrix \( A; n \geq 0 \).

- **nrhs**
  The number of right-hand sides (\( nrhs \geq 0 \)).

- **a**
  Array \( A \) of size at least \( \max(1, lda \cdot n) \)
The array $a$ contains the factor $U$ or $L$ (see uplo) as returned by potrf.

$lda$

The leading dimension of $a$. $lda \geq \max(1, n)$.

$b$

The array $b$ contains the matrix $B$ whose columns are the right-hand sides for the systems of equations. The size of $b$ must be at least $\max(1, ldb \times nrhs)$ for column major layout and $\max(1, ldb \times n)$ for row major layout.

$ldb$

The leading dimension of $b$. $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout.

**Output Parameters**

$b$

Overwritten by the solution matrix $X$.

**Return Values**

This function returns a value $info$.

If $info = 0$, the execution is successful.

If $info = -i$, parameter $i$ had an illegal value.

**Application Notes**

If uplo = 'U', the computed solution for each right-hand side $b$ is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(n)\epsilon |UH||U|$$

$c(n)$ is a modest linear function of $n$, and $\epsilon$ is the machine precision.

A similar estimate holds for uplo = 'L'. If $x_0$ is the true solution, the computed solution $x$ satisfies this error bound:

$$\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(n) cond(A, x)\epsilon$$

where $cond(A, x) = \frac{\|A^{-1}\| |A| |x|}{\| |x| \|_\infty / | \|A^{-1}\|_\infty | |A| \|_\infty = \kappa_\infty(A)$.

Note that $cond(A, x)$ can be much smaller than $\kappa_\infty(A)$. The approximate number of floating-point operations for one right-hand side vector $b$ is $2n^2$ for real flavors and $8n^2$ for complex flavors.

To estimate the condition number $\kappa_\infty(A)$, call ?pocon.

To refine the solution and estimate the error, call ?porfs.

lapack_int LAPACKE_zpftrs (int matrix_layout, char transr, char uplo, lapack_int n,
 lapack_int nrhs, const lapack_complex_double * a, lapack_complex_double * b,
 lapack_int ldb);
```

**Include Files**

- mkl.h

**Description**

The routine solves a system of linear equations $A X = B$ with a symmetric positive-definite or, for complex data, Hermitian positive-definite matrix $A$ using the Cholesky factorization of $A$:

- $A = U^T U$ for real data, $A = U^H U$ for complex data if `uplo='U'`
- $A = L L^T$ for real data, $A = L L^H$ for complex data if `uplo='L'`

Before calling ?pftrs, you must call ?pftrf to compute the Cholesky factorization of $A$. $L$ stands for a lower triangular matrix and $U$ for an upper triangular matrix.

The matrix $A$ is in the Rectangular Full Packed (RFP) format. For the description of the RFP format, see Matrix Storage Schemes.

**Input Parameters**

- `matrix_layout` Specifies whether matrix storage layout is row major (`LAPACK_ROW_MAJOR`) or column major (`LAPACK_COL_MAJOR`).

- `transr` Must be 'N', 'T' (for real data) or 'C' (for complex data).

  - If `transr = 'N'`, the untransposed factor of $A$ is stored in RFP format.
  - If `transr = 'T'`, the transposed factor of $A$ is stored in RFP format.
  - If `transr = 'C'`, the conjugate-transposed factor of $A$ is stored in RFP format.

- `uplo` Must be 'U' or 'L'.

  Indicates how the input matrix $A$ has been factored:

  - If `uplo = 'U'`, $U$ is stored, where $A = U^T U$ for real data, $A = U^H U$ for complex data.
  - If `uplo = 'L'`, $L$ is stored, where $A = L L^T$ for real data, $A = L L^H$ for complex data.

- `n` The order of the matrix $A$; $n \geq 0$. 

nrhs

The number of right-hand sides, that is, the number of columns of the matrix $B$; $nrhs \geq 0$.

$a$

Array $a$ of size $\max(1, n(n + 1)/2)$.
The array $a$ contains, in the RFP format, the factor $U$ or $L$ obtained by factorization of matrix $A$.

$b$

The array $b$ of size $\max(1, ldb*nrhs)$ for column major layout and $\max(1, ldb*n)$ for row major layout contains the matrix $B$ whose columns are the right-hand sides for the systems of equations.

$ldb$

The leading dimension of $b$; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout.

**Output Parameters**

$b$

The solution matrix $X$.

**Return Values**

This function returns a value $info$.

If $info=0$, the execution is successful.

If $info = -i$, parameter $i$ had an illegal value.

```

**Include Files**

- mkl.h

**Description**

The routine solves for $X$ the system of linear equations $A*X = B$ with a packed symmetric positive-definite or, for complex data, Hermitian positive-definite matrix $A$, given the Cholesky factorization of $A$:

$A = U^T*U$ for real data, $A = U^H*U$ for complex data  \hspace{1cm}$\text{if } uplo='U'$

$A = L*L^T$ for real data, $A = L*L^H$ for complex data  \hspace{1cm}$\text{if } uplo='L'$
where $L$ is a lower triangular matrix and $U$ is upper triangular. The system is solved with multiple right-hand sides stored in the columns of the matrix $B$.

Before calling this routine, you must call ?pptrf to compute the Cholesky factorization of $A$.

**Input Parameters**

- **matrix_layout**: Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **uplo**: Must be 'U' or 'L'. Indicates how the input matrix $A$ has been factored:
  - If $uplo = 'U'$, $U$ is stored, where $A = U^T * U$ for real data, $A = U^H * U$ for complex data.
  - If $uplo = 'L'$, $L$ is stored, where $A = L * L^T$ for real data, $A = L * L^H$ for complex data.

- **n**: The order of matrix $A$; $n \geq 0$.

- **nrhs**: The number of right-hand sides ($nrhs \geq 0$).

- **ap, b**: The size of $ap$ must be at least $\max(1, n(n+1)/2)$.
  The array $ap$ contains the factor $U$ or $L$, as specified by $uplo$, in packed storage (see Matrix Storage Schemes).

- **b**: The array $b$ of size $\max(1, ldb*nrhs)$ for column major layout and $\max(1, ldb*n)$ for row major layout contains the matrix $B$ whose columns are the right-hand sides for the systems of equations.

- **ldb**: The leading dimension of $b$; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout.

**Output Parameters**

- **b**: Overwritten by the solution matrix $X$.

**Return Values**

This function returns a value $info$.

- If $info = 0$, the execution is successful.
- If $info = -i$, parameter $i$ had an illegal value.

**Application Notes**

If $uplo = 'U'$, the computed solution for each right-hand side $b$ is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(n)\varepsilon |U^T||U|$$

$c(n)$ is a modest linear function of $n$, and $\varepsilon$ is the machine precision.

A similar estimate holds for $uplo = 'L'$.

If $x_0$ is the true solution, the computed solution $x$ satisfies this error bound:
\[
\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(n) \text{cond} (A, x)\varepsilon
\]

where \(\text{cond} (A, x) = \frac{\|A^{-1}\| \|x\| \|x\| / \|Ax\| \|A\|}{\|A^{-1}\| \|A\|} = \kappa_x(A)\).

Note that \(\text{cond} (A, x)\) can be much smaller than \(\kappa_x(A)\).

The approximate number of floating-point operations for one right-hand side vector \(b\) is \(2n^2\) for real flavors and \(8n^2\) for complex flavors.

To estimate the condition number \(\kappa_x(A)\), call \?ppcon.

To refine the solution and estimate the error, call \?pprfs.

```

Include Files

- mkl.h

Description

The routine solves for real data a system of linear equations \(A^*X = B\) with a symmetric positive-definite or, for complex data, Hermitian positive-definite band matrix \(A\), given the Cholesky factorization of \(A\):

\[
A = U^T \ast U \text{ for real data, } A = U^H \ast U \text{ for complex data}
\]

\[
A = L \ast L^T \text{ for real data, } A = L \ast L^H \text{ for complex data}
\]

where \(L\) is a lower triangular matrix and \(U\) is upper triangular. The system is solved with multiple right-hand sides stored in the columns of the matrix \(B\).

Before calling this routine, you must call \?pbtrf to compute the Cholesky factorization of \(A\) in the band storage form.
Input Parameters

**matrix_layout**
Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

**uplo**
Must be 'U' or 'L'.
Indicates how the input matrix A has been factored:
If uplo = 'U', U is stored in ab, where \( A = U^T \cdot U \) for real matrices and \( A = U^H \cdot U \) for complex matrices.
If uplo = 'L', L is stored in ab, where \( A = L \cdot L^T \) for real matrices and \( A = L \cdot L^H \) for complex matrices.

**n**
The order of matrix A; \( n \geq 0 \).

**kd**
The number of superdiagonals or subdiagonals in the matrix A; \( kd \geq 0 \).

**nrhs**
The number of right-hand sides; \( nrhs \geq 0 \).

**ab**
Array ab is of size max (1, ldab*n).
The array ab contains the Cholesky factor, as returned by the factorization routine, in band storage form.
The array b contains the matrix B whose columns are the right-hand sides for the systems of equations.

**b**
The array b contains the matrix B whose columns are the right-hand sides for the systems of equations.
The size of b is at least max(1, ldb*nrhs) for column major layout and max(1, ldb*n) for row major layout.

**ldab**
The leading dimension of the array ab; \( ldab \geq kd + 1 \).

**ldb**
The leading dimension of b; \( ldb \geq max(1, n) \) for column major layout and \( ldb \geq nrhs \) for row major layout.

Output Parameters

**b**
Overwritten by the solution matrix X.

Return Values

This function returns a value info.
If info=0, the execution is successful.
If info = -i, parameter i had an illegal value.

Application Notes

For each right-hand side b, the computed solution is the exact solution of a perturbed system of equations \((A + E)x = b\), where

\[
|E| \leq c(kd + 1)\varepsilon P|U^H||U| \quad \text{or} \quad |E| \leq c(kd + 1)\varepsilon P|L^T||L|
\]

\(c(k)\) is a modest linear function of \(k\), and \(\varepsilon\) is the machine precision.
If \(x_0\) is the true solution, the computed solution \(x\) satisfies this error bound:
\[ \frac{\| x - x_0 \|_\infty}{\| x \|_\infty} \leq c(kd + 1) \text{cond} (A, x)\varepsilon \]

where \( \text{cond} (A, x) = || A^{-1}|| A \| x \|_\infty / ||x||_\infty \leq || A^{-1}||_\infty \| A \| \_\infty = \kappa_\infty (A) \).

Note that \( \text{cond} (A, x) \) can be much smaller than \( \kappa_\infty (A) \).

The approximate number of floating-point operations for one right-hand side vector is \( 4n*kd \) for real flavors and \( 16n*kd \) for complex flavors.

To estimate the condition number \( \kappa_\infty (A) \), call \?pbcon.

To refine the solution and estimate the error, call \?pbrfs.

\end{align*}
\]

Include Files

- mkl.h

Description

The routine solves for \( X \) a system of linear equations \( A^*X = B \) with a symmetric (Hermitian) positive-definite tridiagonal matrix \( A \). Before calling this routine, call \?pttrf to compute the \( L*D*L^T \) or \( U^*D*U \) for real data and the \( L*D*L^H \) or \( U^*D*U \) factorization of \( A \) for complex data.

Input Parameters

matrix_layout

Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

uplo

Used for cptrs/zptrs only. Must be 'U' or 'L'.

Specifies whether the superdiagonal or the subdiagonal of the tridiagonal matrix \( A \) is stored and how \( A \) is factored:
If uplo = 'U', the array e stores the conjugated values of the superdiagonal of U, and A is factored as $U^H \cdot D \cdot U$.

If uplo = 'L', the array e stores the subdiagonal of L, and A is factored as $L \cdot D \cdot L^H$.

$n$  
The order of A; $n \geq 0$.

$nrhs$  
The number of right-hand sides, that is, the number of columns of the matrix B; $nrhs \geq 0$.

d  
Array, dimension ($n$). Contains the diagonal elements of the diagonal matrix D from the factorization computed by ?pttrf.

e  
Array e is of size ($n - 1$).

The array e contains the $(n - 1)$ sub-diagonal elements of the unit bidiagonal factor L or the conjugated values of the superdiagonal of U from the factorization computed by ?pttrf (see uplo).

e, b  
The array b contains the matrix B whose columns are the right-hand sides for the systems of equations.

The size of b is at least max(1, $ldb \cdot nrhs$) for column major layout and max(1, $ldb \cdot n$) for row major layout.

$ldb$  
The leading dimension of b; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout.

Output Parameters

b  
Overwritten by the solution matrix X.

Return Values

This function returns a value info.

If info=0, the execution is successful.

If info = -i, parameter i had an illegal value.

lapack_int LAPACKE_csytrs (int matrix_layout , char uplo , lapack_int n , lapack_int nrhs , const lapack_complex_float * a , lapack_int lda , const lapack_int * ipiv , lapack_complex_float * b , lapack_int ldb );

LAPACK Routines 3
include mkl.h

Description

The routine solves for X the system of linear equations \( A*X = B \) with a symmetric matrix \( A \), given the Bunch-Kaufman factorization of \( A \):

if \( uplo = 'U' \), \( A = U*D*U^T \)

if \( uplo = 'L' \), \( A = L*D*L^T \)

where \( U \) and \( L \) are upper and lower triangular matrices with unit diagonal and \( D \) is a symmetric block-diagonal matrix. The system is solved with multiple right-hand sides stored in the columns of the matrix \( B \).

You must supply to this routine the factor \( U \) (or \( L \)) and the array \( ipiv \) returned by the factorization routine \?sytrf.

Input Parameters

- \texttt{matrix\_layout}\n  Specifies whether matrix storage layout is row major \( (\text{LAPACK\_ROW\_MAJOR}) \) or column major \( (\text{LAPACK\_COL\_MAJOR}) \).

- \texttt{uplo}\n  Must be \( 'U' \) or \( 'L' \).

- \texttt{n}\n  The order of matrix \( A \); \( n \geq 0 \).

- \texttt{nrhs}\n  The number of right-hand sides; \( nrhs \geq 0 \).

- \texttt{ipiv}\n  Array, size at least \( \max(1, n) \). The \( ipiv \) array, as returned by \?sytrf.

- \texttt{a}\n  The array \( a \) of size \( \max(1, lda*n) \) contains the factor \( U \) or \( L \) (see \texttt{uplo})

- \texttt{b}\n  The array \( b \) contains the matrix \( B \) whose columns are the right-hand sides for the system of equations.

- \texttt{lda}\n  The leading dimension of \( a \); \( lda \geq \max(1, n) \).

- \texttt{ldb}\n  The leading dimension of \( b \); \( ldb \geq \max(1, n) \) for column major layout and \( ldb \geq nrhs \) for row major layout.

Output Parameters

- \texttt{b}\n  Overwritten by the solution matrix \( X \).
**Return Values**

This function returns a value \( \text{info} \).

If \( \text{info}=0 \), the execution is successful.

If \( \text{info} = -i \), parameter \( i \) had an illegal value.

**Application Notes**

For each right-hand side \( b \), the computed solution is the exact solution of a perturbed system of equations \( (A + E)x = b \), where

\[
|E| \leq c(n) \|P\| |U|^T |P^T \text{ or } |E| \leq c(n) \|P\| |L| |D| |U|^T |P^T
\]

\( c(n) \) is a modest linear function of \( n \), and \( \varepsilon \) is the machine precision.

If \( x_0 \) is the true solution, the computed solution \( x \) satisfies this error bound:

\[
\frac{\| x - x_0 \|_\infty}{\| x \|_\infty} \leq c(n) \text{cond} (A, x) \varepsilon
\]

where \( \text{cond}(A, x) = \| A^{-1} \| \|A\| \| x \|_\infty / \| x \|_\infty \leq \| A^{-1} \| \|A\|_\infty = \kappa_\infty (A) \).

Note that \( \text{cond}(A, x) \) can be much smaller than \( \kappa_\infty (A) \).

The total number of floating-point operations for one right-hand side vector is approximately \( 2n^2 \) for real flavors or \( 8n^2 \) for complex flavors.

To estimate the condition number \( \kappa_\infty (A) \), call \(?sycon\).

To refine the solution and estimate the error, call \(?syrfs\).

lapack_int LAPACKE_zsytrs_aa (int matrix_layout, char uplo, lapack_int n, lapack_int nrhs, const lapack_complex_double * A, lapack_int lda, const lapack_int * ipiv, lapack_complex_double * B, lapack_int ldb);
```

**Description**

\( ?\text{sytrs}\_\text{aa} \) solves a system of linear equations \( A * X = B \) with a symmetric matrix \( A \) using the factorization \( A = U^T U^T \) or \( A = L^T L^T \) computed by \(?\text{sytrf}\_\text{aa}\).
Input Parameters

**matrix_layout**
Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

**uplo**
Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
- = 'U': Upper triangular; the form is \( A = U^T \cdot U \).
- = 'L': Lower triangular; the form is \( A = L^T \cdot L \).

**n**
The order of the matrix \( A \). \( n \geq 0 \).

**nrhs**
The number of right-hand sides; that is, the number of columns of the matrix \( B \). \( nrhs \geq 0 \).

**A**
Array of size \( \max(1, lda \cdot n) \). Details of factors computed by ?sytrf_aa.

**lda**
The leading dimension of the array \( A \).

**ipiv**
Array of size \( n \). Details of the interchanges as computed by ?sytrf_aa.

**B**
Array of size \( \max(1, ldb \cdot nrhs) \). On entry, the right-hand side matrix \( B \).

**ldb**
The leading dimension of the array \( B \). \( ldb \geq \max(1, n) \) for column-major layout and \( ldb \geq nrhs \) for row-major layout.

Output Parameters

**B**
On exit, the solution matrix \( X \).

Return Values
This function returns a value \( info \).
- = 0: Successful exit.
- < 0: If \( info = -i \), the \( i \)th argument had an illegal value.

**?sytrs_rook**
Solves a system of linear equations with a UDU- or LDL-factored symmetric coefficient matrix.

Syntax

```c
lapack_int LAPACKE_ssytrs_rook (int matrix_layout, char uplo, lapack_int n, lapack_int nrhs, const float * a, lapack_int lda, const lapack_int * ipiv, float * b, lapack_int ldb);
lapack_int LAPACKE_dsytrs_rook (int matrix_layout, char uplo, lapack_int n, lapack_int nrhs, const double * a, lapack_int lda, const lapack_int * ipiv, double * b, lapack_int ldb);
lapack_int LAPACKE_csytrs_rook (int matrix_layout, char uplo, lapack_int n, lapack_int nrhs, const lapack_complex_float * a, lapack_int lda, const lapack_int * ipiv, lapack_complex_float * b, lapack_int ldb);
lapack_int LAPACKE_zsytrs_rook (int matrix_layout, char uplo, lapack_int n, lapack_int nrhs, const lapack_complex_double * a, lapack_int lda, const lapack_int * ipiv, lapack_complex_double * b, lapack_int ldb);
```
Include Files

- mkl.h

Description

The routine solves a system of linear equations \( A \times X = B \) with a symmetric matrix \( A \), using the factorization \( A = U \times D \times U^T \) or \( A = L \times D \times L^T \) computed by \?sytrf_rook. \n
Input Parameters

- **matrix_layout**
  Specifies whether matrix storage layout for array \( b \) is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **uplo**
  Must be ‘U’ or ‘L’.
  Indicates how the input matrix \( A \) has been factored:
  - If \( uplo = 'U' \), the factorization is of the form \( A = U \times D \times U^T \).
  - If \( uplo = 'L' \), the factorization is of the form \( A = L \times D \times L^T \).

- **n**
  The order of matrix \( A \); \( n \geq 0 \).

- **nrhs**
  The number of right-hand sides; \( nrhs \geq 0 \).

- **ipiv**
  Array, size at least \( \max(1, n) \). The \( ipiv \) array, as returned by \?sytrf_rook.

- **a, b**
  Arrays: \( a \), size \( (lda \times n) \), \( b \) size \( (ldb \times nrhs) \).
  The array \( a \) contains the block diagonal matrix \( D \) and the multipliers used to obtain \( U \) or \( L \) as computed by \?sytrf_rook (see \( uplo \)).
  The array \( b \) contains the matrix \( B \) whose columns are the right-hand sides for the system of equations.

- **lda**
  The leading dimension of \( a \); \( lda \geq \max(1, n) \).

- **ldb**
  The leading dimension of \( b \); \( ldb \geq \max(1, n) \) for column major layout and \( ldb \geq nrhs \) for row major layout.

Output Parameters

- **b**
  Overwritten by the solution matrix \( X \).

Return Values

This function returns a value \( info \).
If \( info=0 \), the execution is successful.
If \( info = -i \), the \( i \)-th parameter had an illegal value.

Application Notes

The total number of floating-point operations for one right-hand side vector is approximately \( 2n^2 \) for real flavors or \( 8n^2 \) for complex flavors.

?hetrs
Solves a system of linear equations with a UDU<sup>T</sup>- or LDL<sup>T</sup>-factored Hermitian coefficient matrix.

**Syntax**

```c
lapack_int LAPACKE_chetrs (int matrix_layout, char uplo, lapack_int n, lapack_int nrhs,
const lapack_complex_float * a, lapack_int lda, const lapack_int * ipiv,
lapack_complex_float * b, lapack_int ldb);

lapack_int LAPACKE_zhetrs (int matrix_layout, char uplo, lapack_int n, lapack_int nrhs,
const lapack_complex_double * a, lapack_int lda, const lapack_int * ipiv,
lapack_complex_double * b, lapack_int ldb);
```

**Include Files**

- mkl.h

**Description**

The routine solves for \( X \) the system of linear equations \( A \cdot X = B \) with a Hermitian matrix \( A \), given the Bunch-Kaufman factorization of \( A \):

\[
\begin{align*}
\text{if } \text{uplo}= 'U', & \quad A = U \cdot D \cdot U^H \\
\text{if } \text{uplo}= 'L', & \quad A = L \cdot D \cdot L^H,
\end{align*}
\]

where \( U \) and \( L \) are upper and lower triangular matrices with unit diagonal and \( D \) is a symmetric block-diagonal matrix. The system is solved with multiple right-hand sides stored in the columns of the matrix \( B \). You must supply to this routine the factor \( U \) (or \( L \)) and the array \( ipiv \) returned by the factorization routine ?hetrf.

**Input Parameters**

- `matrix_layout`: Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- `uplo`: Must be 'U' or 'L'. Indicates how the input matrix \( A \) has been factored:
  - If \( \text{uplo} = 'U' \), the array \( a \) stores the upper triangular factor \( U \) of the factorization \( A = U \cdot D \cdot U^H \).
  - If \( \text{uplo} = 'L' \), the array \( a \) stores the lower triangular factor \( L \) of the factorization \( A = L \cdot D \cdot L^H \).
- `n`: The order of matrix \( A \); \( n \geq 0 \).
- `nrhs`: The number of right-hand sides; \( nrhs \geq 0 \).
- `ipiv`: Array, size at least \( \max(1, n) \). The \( ipiv \) array, as returned by ?hetrf.
- `a`: The array \( a \) of size \( \max(1, \text{lda} \times n) \) contains the factor \( U \) or \( L \) (see \( uplo \)).
- `b`: The array \( b \) contains the matrix \( B \) whose columns are the right-hand sides for the system of equations.
The size of $b$ is at least $\max(1, \text{ldb} \times \text{nrhs})$ for column major layout and $\max(1, \text{ldb} \times n)$ for row major layout.

$\text{lda}$

The leading dimension of $a$; $\text{lda} \geq \max(1, n)$.

$\text{ldb}$

The leading dimension of $b$; $\text{ldb} \geq \max(1, n)$ for column major layout and $\text{ldb} \geq \text{nrhs}$ for row major layout.

**Output Parameters**

$b$

Overwritten by the solution matrix $X$.

**Return Values**

This function returns a value $\text{info}$.

If $\text{info}=0$, the execution is successful.

If $\text{info} = -i$, parameter $i$ had an illegal value.

**Application Notes**

For each right-hand side $b$, the computed solution is the exact solution of a perturbed system of equations $(A + E)x = b$, where

\[ |E| \leq c(n)\varepsilon|U| |D| |P^T| \text{ or } |E| \leq c(n)\varepsilon|L| |D| |L^H| P^T \]

$c(n)$ is a modest linear function of $n$, and $\varepsilon$ is the machine precision.

If $x_0$ is the true solution, the computed solution $x$ satisfies this error bound:

\[
\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(n) \text{cond}(A, x)\varepsilon
\]

where $\text{cond}(A, x) = \| |A^{-1}| |A| |x| \| / \| |x| \| \leq \| |A^{-1}| |A| \| = \kappa_\infty(A)$.

Note that $\text{cond}(A, x)$ can be much smaller than $\kappa_\infty(A)$.

The total number of floating-point operations for one right-hand side vector is approximately $8n^2$.

To estimate the condition number $\kappa_\infty(A)$, call `?hecon`.

To refine the solution and estimate the error, call `?herfs`.

```
Description

?hetrs_aa solves a system of linear equations $A^*X = X$ with a complex Hermitian matrix $A$ using the factorization $A = U * T * U^H$ or $A = L * T * L^H$ computed by ?hetrf_aa.

Input Parameters

matrix_layout

Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

uplo

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.

If $uplo = 'U'$: Upper triangular of the form $A = U * T * U^H$.

If $uplo = 'L'$: Lower triangular of the form $A = L * T * L^H$.

n

The order of the matrix $A$. $n \geq 0$.

nrhs

The number of right hand sides: the number of columns of the matrix $b$. $nrhs \geq 0$.

a

Array of size $lda*n$. Details of factors computed by ?hetrf_aa.

lda

The leading dimension of the array $a$. $lda \geq \max(1, n)$.

ipiv

Array of size $(n)$. Details of the interchanges as computed by ?hetrf_aa.

b

Array of size $ldb*nrhs$. On entry, the right hand side matrix $B$.

ldb

The leading dimension of the array $b$. $ldb \geq \max(1, n)$.

work

See Syntax - Workspace. Array of size $(\max(1, lwork))$.

lwork

See Syntax - Workspace. $lwork \geq \max(1, 3*n-2)$.

Output Parameters

b

On exit, the solution matrix $X$.

Return Values

This function returns a value $info$.

If $info = 0$: successful exit.

If $info < 0$: if $info = -i$, the $i$-th argument had an illegal value.

Syntax - Workspace

Use this interface if you want to explicitly provide the workspace array.

Include Files
- mkl.h

Description
The routine solves a system of linear equations $A*X = B$ with a symmetric matrix $A$ using the factorization of $A$:

if uplo='U', \[ A = U*D*U^T \]
if uplo='L', \[ A = L*D*L^T \]

where
- $U$ and $L$ are upper and lower triangular matrices with unit diagonal
- $D$ is a symmetric block-diagonal matrix.

The factorization is computed by ?sytrf.

Input Parameters

$matrix_layout$
Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

$uplo$
Must be 'U' or 'L'.
Indicates how the input matrix $A$ has been factored:
If uplo = 'U', the array $a$ stores the upper triangular factor $U$ of the factorization $A = U*D*U^T$. 
If \( \text{uplo} = 'L' \), the array \( a \) stores the lower triangular factor \( L \) of the factorization \( A = L*D*L^T \).

\( n \)

The order of matrix \( A \); \( n \geq 0 \).

\( \text{nrhs} \)

The number of right-hand sides; \( \text{nrhs} \geq 0 \).

\( a \)

The array \( a \) of size \( \max(1, \text{lda} \times n) \) contains the block diagonal matrix \( D \) and the multipliers used to obtain the factor \( U \) or \( L \) as computed by \(?sytrf\).

\( b \)

The array \( b \) contains the right-hand side matrix \( B \).

The size of \( b \) is at least \( \max(1, \text{ldb} \times \text{nrhs}) \) for column major layout and \( \max(1, \text{ldb} \times n) \) for row major layout.

\text{lda}

The leading dimension of \( a \); \( \text{lda} \geq \max(1, n) \).

\text{ldb}

The leading dimension of \( b \); \( \text{ldb} \geq \max(1, n) \) for column major layout and \( \text{ldb} \geq \text{nrhs} \) for row major layout.

\text{ipiv}

Array of size \( n \). The \text{ipiv} array contains details of the interchanges and the block structure of \( D \) as determined by \(?sytrf\).

**Output Parameters**

\( b \)

Overwritten by the solution matrix \( X \).

**Return Values**

This function returns a value \( \text{info} \).

If \( \text{info} = 0 \), the execution is successful.

If \( \text{info} = -i \), parameter \( i \) had an illegal value.

Description

The routine solves a system of linear equations \( A \cdot X = B \) with a complex Hermitian matrix \( A \) using the factorization of \( A \):

if \( \text{uplo} = 'U' \), \[ A = U \cdot D \cdot U^H \]
if \( \text{uplo} = 'L' \), \[ A = L \cdot D \cdot L^H \]

where

- \( U \) and \( L \) are upper and lower triangular matrices with unit diagonal
- \( D \) is a Hermitian block-diagonal matrix.

The factorization is computed by \( \text{?hetrf} \).

Input Parameters

- **matrix_layout**
  Specifies whether matrix storage layout is row major (\( \text{LAPACK\_ROW\_MAJOR} \)) or column major (\( \text{LAPACK\_COL\_MAJOR} \)).

- **uplo**
  Must be \( 'U' \) or \( 'L' \).
  Indicates how the input matrix \( A \) has been factored:
  If \( \text{uplo} = 'U' \), the array \( a \) stores the upper triangular factor \( U \) of the factorization \( A = U \cdot D \cdot U^H \).
  If \( \text{uplo} = 'L' \), the array \( a \) stores the lower triangular factor \( L \) of the factorization \( A = L \cdot D \cdot L^H \).

- **n**
  The order of matrix \( A \); \( n \geq 0 \).

- **nrhs**
  The number of right-hand sides; \( nrhs \geq 0 \).

- **a**
  The array \( a \) of size \( \max(1, lda \times n) \) contains the block diagonal matrix \( D \) and the multipliers used to obtain the factor \( U \) or \( L \) as computed by \( \text{?hetrf} \).

- **b**
  The array \( b \) of size \( \max(1, ldb \times nrhs) \) for column major layout and \( \max(1, ldb \times n) \) for row major layout contains the right-hand side matrix \( B \).

- **lda**
  The leading dimension of \( a \); \( lda \geq \max(1, n) \).

- **ldb**
  The leading dimension of \( b \); \( ldb \geq \max(1, n) \) for column major layout and \( ldb \geq nrhs \) for row major layout.

- **ipiv**
  Array of size \( n \). The \( \text{ipiv} \) array contains details of the interchanges and the block structure of \( D \) as determined by \( \text{?hetrf} \).

Output Parameters

- **b**
  Overwritten by the solution matrix \( X \).

Return Values

This function returns a value \( info \).

If \( info = 0 \), the execution is successful.
If $\text{info} = -i$, parameter $i$ had an illegal value.

**?sytrs_3**

Solves a system of linear equations $A \times X = B$ with a real or complex symmetric matrix.

```c
lapack_int LAPACKE_ssytrs_3 (int matrix_layout, char uplo, lapack_int n, lapack_int nrhs, const float * A, lapack_int lda, const float * e, const lapack_int * ipiv, float * B, lapack_int ldb);

lapack_int LAPACKE_dsytrs_3 (int matrix_layout, char uplo, lapack_int n, lapack_int nrhs, const double * A, lapack_int lda, const double * e, const lapack_int * ipiv, double * B, lapack_int ldb);

lapack_int LAPACKE_csytrs_3 (int matrix_layout, char uplo, lapack_int n, lapack_int nrhs, const lapack_complex_float * A, lapack_int lda, const lapack_complex_float * e, const lapack_int * ipiv, lapack_complex_float * B, lapack_int ldb);

lapack_int LAPACKE_zsytrs_3 (int matrix_layout, char uplo, lapack_int n, lapack_int nrhs, const lapack_complex_double * A, lapack_int lda, const lapack_complex_double * e, const lapack_int * ipiv, lapack_complex_double * B, lapack_int ldb);
```

**Description**

?sytrs_3 solves a system of linear equations $A \times X = B$ with a real or complex symmetric matrix $A$ using the factorization computed by ?sytrf_rk: $A = P \times U \times D \times (U^T) \times (P^T)$ or $A = P \times L \times D \times (L^T) \times (P^T)$, where $U$ (or $L$) is unit upper (or lower) triangular matrix, $U^T$ (or $L^T$) is the transpose of $U$ (or $L$), $P$ is a permutation matrix, $P^T$ is the transpose of $P$, and $D$ is a symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This algorithm uses Level 3 BLAS.

**Input Parameters**

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **uplo**
  Specifies whether the details of the factorization are stored as an upper or lower triangular matrix:
  - $'U'$: Upper triangular; the form is $A = P \times U \times D \times (U^T) \times (P^T)$.
  - $'L'$: Lower triangular; the form is $A = P \times L \times D \times (L^T) \times (P^T)$.

- **n**
  The order of the matrix $A$. $n \geq 0$.

- **nrhs**
  The number of right-hand sides; that is, the number of columns of the matrix $B$. $nrhs \geq 0$.

- **A**
  Array of size max$(1, \text{lda} \times n)$. Diagonal of the block diagonal matrix $D$ and factors $U$ or $L$ as computed by ?sytrf_rk:
  - Only diagonal elements of the symmetric block diagonal matrix $D$ on the diagonal of $A$; that is, $D(k,k) = A(k,k)$. Superdiagonal (or subdiagonal) elements of $D$ should be provided on entry in array $e$. —and—
• If $\text{uplo} = 'U'$, factor U in the superdiagonal part of A. If $\text{uplo} = 'L'$, factor L in the subdiagonal part of A.

$\text{lda}$

The leading dimension of the array $A$.

$\text{e}$

Array of size $n$. On entry, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix $D$ with 1-by-1 or 2-by-2 diagonal blocks. If $\text{uplo} = 'U'$, $e(i) = D(i-1,i), i=2:N$, and $e(1)$ is not referenced. If $\text{uplo} = 'L'$, $e(i) = D(i+1,i), i=1:N-1$, and $e(n)$ is not referenced.

**NOTE** For 1-by-1 diagonal block $D(k)$, where $1 \leq k \leq n$, the element $e[k-1]$ is not referenced in both the $\text{uplo} = 'U'$ and $\text{uplo} = 'L'$ cases.

$\text{ipiv}$

Array of size $n$. Details of the interchanges and the block structure of $D$ as determined by ?sytrf_rk.

$B$

On entry, the right-hand side matrix $B$.

The size of $B$ is at least $\max(1, \text{ldb} \times \text{nrhs})$ for column-major layout and $\max(1, \text{ldb} \times n)$ for row-major layout.

$\text{ldb}$

The leading dimension of the array $B$. $\text{ldb} \geq \max(1, n)$ for column-major layout and $\text{ldb} \geq \text{nrhs}$ for row-major layout.

**Output Parameters**

$B$

On exit, the solution matrix $X$.

**Return Values**

This function returns a value $\text{info}$.

$= 0$: Successful exit.

$< 0$: If $\text{info} = -i$, the $i$th argument had an illegal value.

**?hetrs_3**

Solves a system of linear equations $A \times X = B$ with a complex Hermitian matrix using the factorization computed by ?hetrf_rk.

```c
lapack_int LAPACKE_chetrs_3 (int matrix_layout, char uplo, lapack_int n, lapack_int nrhs, const lapack_complex_float * A, lapack_int lda, const lapack_complex_float * e, const lapack_int * ipiv, lapack_complex_float * B, lapack_int ldb);

lapack_int LAPACKE_zhetrs_3 (int matrix_layout, char uplo, lapack_int n, lapack_int nrhs, const lapack_complex_double * A, lapack_int lda, const lapack_complex_double * e, const lapack_int * ipiv, lapack_complex_double * B, lapack_int ldb);
```

**Description**

?hetrs_3 solves a system of linear equations $A \times X = B$ with a complex Hermitian matrix $A$ using the factorization computed by ?hetrf_rk: $A = P^T U^* D(\text{U}^*)^* (P^T)$ or $A = P^T L^* D(\text{L}^*)^* (P^T)$, where $U$ (or $L$) is unit upper (or lower) triangular matrix, $U^*$ (or $L^*$) is the conjugate of $U$ (or $L$), $P$ is a permutation matrix, $P^T$ is the transpose of $P$, and $D$ is a Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This algorithm uses Level 3 BLAS.
**Input Parameters**

`matrix_layout` Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

`uplo` Specifies whether the details of the factorization are stored as an upper or lower triangular matrix:
- `'U'`: Upper triangular; form is \( A = P \times U \times D \times (U^H) \times (P^T) \).
- `'L'`: Lower triangular; form is \( A = P \times L \times D \times (L^H) \times (P^T) \).

`n` The order of the matrix \( A \). \( n \geq 0 \).

`nrhs` The number of right-hand sides; that is, the number of columns in the matrix \( B \). \( nrhs \geq 0 \).

`A` Array of size \( \max(1, \text{lda} \times n) \). Diagonal of the block diagonal matrix \( D \) and factor \( U \) or \( L \) as computed by \(?hetrf_rk\):
- Only diagonal elements of the Hermitian block diagonal matrix \( D \) on the diagonal of \( A \); that is, \( D(k,k) = A(k,k) \). Superdiagonal (or subdiagonal) elements of \( D \) should be provided on entry in array \( e \).
- If `uplo` = `'U'`, factor \( U \) in the superdiagonal part of \( A \). If `uplo` = `'L'`, factor \( L \) in the subdiagonal part of \( A \).

`lda` The leading dimension of the array \( A \).

`e` Array of size \( n \). On entry, contains the superdiagonal (or subdiagonal) elements of the Hermitian block diagonal matrix \( D \) with 1-by-1 or 2-by-2 diagonal blocks. If `uplo` = `'U'`, \( e(i) = D(i-1,i), i=2:N \), and \( e(1) \) is not referenced. If `uplo` = `'L'`, \( e(i) = D(i+1,i), i=1:N-1 \), and \( e(n) \) is not referenced.

**NOTE** For 1-by-1 diagonal block \( D(k) \), where \( 1 \leq k \leq n \), the element \( e[k-1] \) is not referenced in both the `uplo` = `'U'` and `uplo` = `'L'` cases.

`ipiv` Array of size \( n \). Details of the interchanges and the block structure of \( D \) as determined by \(?hetrf_rk\).

`B` On entry, the right-hand side matrix \( B \).

The size of \( B \) is at least \( \max(1, \text{ldb} \times nrhs) \) for column-major layout and \( \max(1, \text{ldb} \times n) \) for row-major layout.

`ldb` The leading dimension of the array \( B \). \( ldb \geq \max(1, n) \) for column-major layout and \( ldb \geq nrhs \) for row-major layout.

**Output Parameters**

`B` On exit, the solution matrix \( X \).

**Return Values**

This function returns a value \( info \).

\( = 0 \): Successful exit.
< 0: If info = -i, the i-th argument had an illegal value.

`?sptrs`
Solves a system of linear equations with a UDU- or LDL-factored symmetric coefficient matrix using packed storage.

**Syntax**

```c
lapack_int LAPACKE_ssptrs (int matrix_layout, char uplo, lapack_int n, lapack_int nrhs, const float * ap, const lapack_int * ipiv, float * b, lapack_int ldb);
```

```c
lapack_int LAPACKE_dsptrs (int matrix_layout, char uplo, lapack_int n, lapack_int nrhs, const double * ap, const lapack_int * ipiv, double * b, lapack_int ldb);
```

```c
lapack_int LAPACKE_csptrs (int matrix_layout, char uplo, lapack_int n, lapack_int nrhs, const lapack_complex_float * ap, const lapack_int * ipiv, lapack_complex_float * b, lapack_int ldb);
```

```c
lapack_int LAPACKE_zsptrs (int matrix_layout, char uplo, lapack_int n, lapack_int nrhs, const lapack_complex_double * ap, const lapack_int * ipiv, lapack_complex_double * b, lapack_int ldb);
```

**Include Files**

- mkl.h

**Description**

The routine solves for X the system of linear equations $A*X = B$ with a symmetric matrix $A$, given the Bunch-Kaufman factorization of $A$:

$$
\begin{align*}
\text{if } \text{uplo} &= \text{`U'}, & A &= U*Diag*D*U^T \\
\text{if } \text{uplo} &= \text{`L'}, & A &= L*Diag*D*L^T,
\end{align*}
$$

where $U$ and $L$ are upper and lower packed triangular matrices with unit diagonal and $D$ is a symmetric block-diagonal matrix. The system is solved with multiple right-hand sides stored in the columns of the matrix $B$. You must supply the factor $U$ (or $L$) and the array `ipiv` returned by the factorization routine `?sptrf`.

**Input Parameters**

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **uplo**
  Must be `U` or `L`.

  Indicates how the input matrix $A$ has been factored:

  If uplo = `U`, the array `ap` stores the packed factor $U$ of the factorization $A = U*Diag*D*U^T$. If uplo = `L`, the array `ap` stores the packed factor $L$ of the factorization $A = L*Diag*D*L^T$.

- **n**
  The order of matrix $A$; $n \geq 0$.

- **nrhs**
  The number of right-hand sides; $nrhs \geq 0$.

- **ipiv**
  Array, size at least max(1, n). The `ipiv` array, as returned by `?sptrf`. 

The dimension of array \( ap \) must be at least \( \max(1, n(n+1)/2) \). The array \( ap \) contains the factor \( U \) or \( L \), as specified by \textit{uplo}, in packed storage (see Matrix Storage Schemes).

The array \( b \) contains the matrix \( B \) whose columns are the right-hand sides for the system of equations. The size of \( b \) is \( \max(1, \text{ldb} \times \text{nrhs}) \) for column major layout and \( \max(1, ldb \times n) \) for row major layout.

The leading dimension of \( b \); \( ldb \geq \max(1, n) \) for column major layout and \( ldb \geq \text{nrhs} \) for row major layout.

**Output Parameters**

\( b \) Overwritten by the solution matrix \( X \).

**Return Values**

This function returns a value \( info \).

If \( info=0 \), the execution is successful.

If \( info = -i \), parameter \( i \) had an illegal value.

**Application Notes**

For each right-hand side \( b \), the computed solution is the exact solution of a perturbed system of equations \( (A + E)x = b \), where

\[
|E| \leq c(n)\varepsilon \|U\| \|D\| \|U^T\| F^2 \quad \text{or} \quad |E| \leq c(n)\varepsilon \|L\| \|D\| \|L^T\| F^2
\]

\( c(n) \) is a modest linear function of \( n \), and \( \varepsilon \) is the machine precision.

If \( x_0 \) is the true solution, the computed solution \( x \) satisfies this error bound:

\[
\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(n) \text{cond}_\infty (A, x) \varepsilon
\]

where \( \text{cond}_\infty (A, x) = \frac{\| A^{-1} \| \| A \| \| x \|_\infty}{\| x \|_\infty} \leq \frac{\| A^{-1} \| \| x \|_\infty}{\| A \|_\infty} = \kappa_\infty (A) \).

Note that \( \text{cond}_\infty (A, x) \) can be much smaller than \( \kappa_\infty (A) \).

The total number of floating-point operations for one right-hand side vector is approximately \( 2n^2 \) for real flavors or \( 8n^2 \) for complex flavors.

To estimate the condition number \( \kappa_\infty (A) \), call \textit{?spcon}.

To refine the solution and estimate the error, call \textit{?sprfs}.

Description

The routine solves for $X$ the system of linear equations $AX = B$ with a Hermitian matrix $A$, given the Bunch-Kaufman factorization of $A$:

- If `uplo='U'`, $A = U*D*U^H$
- If `uplo='L'`, $A = L*D*L^H$

where $U$ and $L$ are upper and lower packed triangular matrices with unit diagonal and $D$ is a symmetric block-diagonal matrix. The system is solved with multiple right-hand sides stored in the columns of the matrix $B$.

You must supply to this routine the arrays `ap` (containing $U$ or $L$) and `ipiv` in the form returned by the factorization routine `?hptrf`.

Input Parameters

- `matrix_layout` Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- `uplo` Must be 'U' or 'L'.
- `n` The order of matrix $A$; $n \geq 0$.
- `nrhs` The number of right-hand sides; $nrhs \geq 0$.
- `ipiv` Array, size at least max(1, $n$). The `ipiv` array, as returned by `?hptrf`.
- `ap` The dimension of array `ap` must be at least max(1, $n(n+1)/2$). The array `ap` contains the factor $U$ or $L$, as specified by `uplo`, in packed storage (see Matrix Storage Schemes).
- `b` The array $b$ contains the matrix $B$ whose columns are the right-hand sides for the system of equations. The size of $b$ is max(1, $ldb*nrhs$) for column major layout and max(1, $ldb*n$) for row major layout.
- `ldb` The leading dimension of $b$; $ldb \geq max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout.
Output Parameters

- \( b \)
  Overwritten by the solution matrix \( X \).

Return Values

This function returns a value \( info \).

If \( info = 0 \), the execution is successful.

If \( info = -i \), parameter \( i \) had an illegal value.

Application Notes

For each right-hand side \( b \), the computed solution is the exact solution of a perturbed system of equations \((A + E)x = b\), where

\[
|E| \leq c(n)\varepsilon|U||D||L| \leq c(n)\varepsilon|P||U||D||L|
\]

\( c(n) \) is a modest linear function of \( n \), and \( \varepsilon \) is the machine precision.

If \( x_0 \) is the true solution, the computed solution \( x \) satisfies this error bound:

\[
\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(n)\text{cond}(A, x)\varepsilon
\]

where \( \text{cond}(A, x) = \frac{||A^{-1}||A||x||_\infty}{||x||_\infty} \leq ||A^{-1}||_\infty ||A||_\infty = \kappa_\infty(A) \).

Note that \( \text{cond}(A, x) \) can be much smaller than \( \kappa_\infty(A) \).

The total number of floating-point operations for one right-hand side vector is approximately \( 8n^2 \) for complex flavors.

To estimate the condition number \( \kappa_\infty(A) \), call \( \text{hpcon} \).

To refine the solution and estimate the error, call \( \text{hprfs} \).

Include Files
• mkl.h

Description
The routine solves for \( X \) the following systems of linear equations with a triangular matrix \( A \), with multiple right-hand sides stored in \( B \):

\[
A*X = B \quad \text{if } trans='N',
\]

\[
A^T*X = B \quad \text{if } trans='T',
\]

\[
A^H*X = B \quad \text{if } trans='C' \text{ (for complex matrices only)}.
\]

Input Parameters

\textit{matrix\_layout} \quad \text{Specifies whether matrix storage layout is row major (LAPACK\_ROW\_MAJOR) or column major (LAPACK\_COL\_MAJOR).}

\textit{uplo} \quad \text{Must be 'U' or 'L'.}

Indicates whether \( A \) is upper or lower triangular:

If \( \text{uplo} = 'U' \), then \( A \) is upper triangular.

If \( \text{uplo} = 'L' \), then \( A \) is lower triangular.

\textit{trans} \quad \text{Must be 'N' or 'T' or 'C'.}

If \( \text{trans} = 'N' \), then \( A*X = B \) is solved for \( X \).

If \( \text{trans} = 'T' \), then \( A^T*X = B \) is solved for \( X \).

If \( \text{trans} = 'C' \), then \( A^H*X = B \) is solved for \( X \).

\textit{diag} \quad \text{Must be 'N' or 'U'.}

If \( \text{diag} = 'N' \), then \( A \) is not a unit triangular matrix.

If \( \text{diag} = 'U' \), then \( A \) is unit triangular: diagonal elements of \( A \) are assumed to be 1 and not referenced in the array \( a \).

\textit{n} \quad \text{The order of \( A \); the number of rows in \( B \); } n \geq 0.

\textit{nrhs} \quad \text{The number of right-hand sides; } nrhs \geq 0.

\textit{a} \quad \text{The array } a \text{ contains the matrix } A.

The size of \( a \) is \text{max}(1, lda*n).

\textit{b} \quad \text{The array } b \text{ contains the matrix } B \text{ whose columns are the right-hand sides for the systems of equations.}

The size of \( b \) is \text{max}(1, ldb*nrhs) \text{ for column major layout and } \text{max}(1, ldb*n) \text{ for row major layout.}

\textit{lda} \quad \text{The leading dimension of } a; \quad \text{lda} \geq \text{max}(1, n).

\textit{ldb} \quad \text{The leading dimension of } b; \quad \text{ldb} \geq \text{max}(1, n) \text{ for column major layout and } \text{ldb} \geq nrhs \text{ for row major layout.}
Output Parameters

\( b \) 
Overwritten by the solution matrix \( X \).

Return Values

This function returns a value \( info \).

If \( info = 0 \), the execution is successful.

If \( info = -i \), parameter \( i \) had an illegal value.

Application Notes

For each right-hand side \( b \), the computed solution is the exact solution of a perturbed system of equations \( (A + E) x = b \), where

\[
|E| \leq c(n) \varepsilon |A|
\]

\( c(n) \) is a modest linear function of \( n \), and \( \varepsilon \) is the machine precision. If \( x_0 \) is the true solution, the computed solution \( x \) satisfies this error bound:

\[
\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(n) \text{cond}(A, x) \varepsilon \text{ provided } c(n) \text{cond}(A, x) \varepsilon < 1
\]

where \( \text{cond}(A, x) = \| |A^{-1}|A| |x| |x|_\infty / |x|_\infty \leq \|A^{-1}|A|_\infty = \kappa_\infty(A) \).

Note that \( \text{cond}(A, x) \) can be much smaller than \( \kappa_\infty(A) \); the condition number of \( A^T \) and \( A^H \) might or might not be equal to \( \kappa_\infty(A) \).

The approximate number of floating-point operations for one right-hand side vector \( b \) is \( n^2 \) for real flavors and \( 4n^2 \) for complex flavors.

To estimate the condition number \( \kappa_\infty(A) \), call \( ?\text{trcon} \).

To estimate the error in the solution, call \( ?\text{trrfs} \).

Description
The routine solves for $X$ the following systems of linear equations with a packed triangular matrix $A$, with multiple right-hand sides stored in $B$:

- $A*X = B$ if $trans='N'$,
- $A^T*X = B$ if $trans='T'$,
- $A^H*X = B$ if $trans='C'$ (for complex matrices only).

Input Parameters

- $matrix\_layout$: Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- $uplo$: Must be 'U' or 'L'. Indicates whether $A$ is upper or lower triangular:
  - If $uplo = 'U'$, then $A$ is upper triangular.
  - If $uplo = 'L'$, then $A$ is lower triangular.
- $trans$: Must be 'N' or 'T' or 'C'.
  - If $trans = 'N'$, then $A*X = B$ is solved for $X$.
  - If $trans = 'T'$, then $A^T*X = B$ is solved for $X$.
  - If $trans = 'C'$, then $A^H*X = B$ is solved for $X$.
- $diag$: Must be 'N' or 'U'.
  - If $diag = 'N'$, then $A$ is not a unit triangular matrix.
  - If $diag = 'U'$, then $A$ is unit triangular: diagonal elements are assumed to be 1 and not referenced in the array $ap$.
- $n$: The order of $A$; the number of rows in $B$; $n \geq 0$.
- $nrhs$: The number of right-hand sides; $nrhs \geq 0$.
- $ap$: The dimension of array $ap$ must be at least max(1,$n(n+1)/2$). The array $ap$ contains the matrix $A$ in packed storage (see Matrix Storage Schemes).
- $b$: The array $b$ contains the matrix $B$ whose columns are the right-hand sides for the system of equations.
  - The size of $b$ is max(1, $ldb*nrhs$) for column major layout and max(1, $ldb*n$) for row major layout.
- $ldb$: The leading dimension of $b$; $ldb \geq \text{max}(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout.
Output Parameters

\[ b \]

Overwritten by the solution matrix \( X \).

Return Values

This function returns a value \( info \).

If \( info=0 \), the execution is successful.

If \( info = -i \), parameter \( i \) had an illegal value.

Application Notes

For each right-hand side \( b \), the computed solution is the exact solution of a perturbed system of equations \((A + E)x = b\), where

\[ |E| \leq c(n)\varepsilon |A| \]

\( c(n) \) is a modest linear function of \( n \), and \( \varepsilon \) is the machine precision.

If \( x_0 \) is the true solution, the computed solution \( x \) satisfies this error bound:

\[ \frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(n) \text{cond} (A, x)\varepsilon \text{ provided } c(n) \text{cond} (A, x)\varepsilon < 1 \]

where \( \text{cond} (A, x) = \| |A^{-1}| |A| |x| \| / \| |x|\| \leq | |A^{-1}| |A| \| \|n = \kappa_n (A) \).

Note that \( \text{cond} (A, x) \) can be much smaller than \( \kappa_n (A) \); the condition number of \( A^T \) and \( A^H \) might or might not be equal to \( \kappa_n (A) \).

The approximate number of floating-point operations for one right-hand side vector \( b \) is \( n^2 \) for real flavors and \( 4n^2 \) for complex flavors.

To estimate the condition number \( \kappa_n (A) \), call \(?tpcon\).

To estimate the error in the solution, call \(?tprfs\).

Include Files
• mkl.h

Description
The routine solves for $X$ the following systems of linear equations with a band triangular matrix $A$, with 
multiple right-hand sides stored in $B$:

\[
\begin{align*}
A \cdot X &= B & \text{if } \text{trans='N'}, \\
A^T \cdot X &= B & \text{if } \text{trans='T'}, \\
A^H \cdot X &= B & \text{if } \text{trans='C'} \text{ (for complex matrices only)}. 
\end{align*}
\]

Input Parameters

matrix_layout Specifies whether matrix storage layout is row major 
(LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

uplo Must be 'U' or 'L'. 
Indicates whether $A$ is upper or lower triangular: 
If uplo = 'U', then $A$ is upper triangular. 
If uplo = 'L', then $A$ is lower triangular.

trans Must be 'N' or 'T' or 'C'. 
If trans = 'N', then $A \cdot X = B$ is solved for $X$. 
If trans = 'T', then $A^T \cdot X = B$ is solved for $X$. 
If trans = 'C', then $A^H \cdot X = B$ is solved for $X$.

diag Must be 'N' or 'U'. 
If diag = 'N', then $A$ is not a unit triangular matrix. 
If diag = 'U', then $A$ is unit triangular: diagonal elements are 
assumed to be 1 and not referenced in the array ab.

n The order of $A$; the number of rows in $B$; $n \geq 0$.

kd The number of superdiagonals or subdiagonals in the matrix $A$; $kd \geq 0$.

nrhs The number of right-hand sides; $nrhs \geq 0$.

ab The array $ab$ contains the matrix $A$ in band storage form.
The size of $ab$ must be $\max(1, \text{ldab} \cdot n)$

b The array $b$ contains the matrix $B$ whose columns are the right-hand 
sides for the systems of equations. 
The size of $b$ is $\max(1, \text{ldb} \cdot nrhs)$ for column major layout and 
$\max(1, \text{ldb} \cdot n)$ for row major layout.
ldab  The leading dimension of ab; \( ldab \geq kd + 1 \).

ldb  The leading dimension of b; \( ldb \geq \max(1, n) \) for column major layout and \( ldb \geq nrhs \) for row major layout.

Output Parameters

b  Overwritten by the solution matrix X.

Return Values

This function returns a value info.

If info=0, the execution is successful.

If info = -i, parameter i had an illegal value.

Application Notes

For each right-hand side b, the computed solution is the exact solution of a perturbed system of equations \((A + E)x = b\), where

\[ \|E\| \leq c(n)\epsilon\|A\| \]

\( c(n) \) is a modest linear function of \( n \), and \( \epsilon \) is the machine precision. If \( x_0 \) is the true solution, the computed solution \( x \) satisfies this error bound:

\[
\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(n) \text{cond} (A, x) \epsilon \quad \text{provided} \quad c(n) \text{cond} (A, x) \epsilon < 1
\]

where \( \text{cond} (A, x) = \frac{||A^{-1}||A||x||_\infty}{||x||_\infty} \leq ||A^{-1}||_\infty \frac{||A||_\infty}{||A||_\infty} = \kappa_\infty (A) \).

Note that \( \text{cond} (A, x) \) can be much smaller than \( \kappa_\infty (A) \); the condition number of \( A^T \) and \( A^H \) might or might not be equal to \( \kappa_\infty (A) \).

The approximate number of floating-point operations for one right-hand side vector \( b \) is \( 2n^*kd \) for real flavors and \( 8n^*kd \) for complex flavors.

To estimate the condition number \( \kappa_\infty (A) \), call \texttt{?tbcon}.

To estimate the error in the solution, call \texttt{?tbrfs}.

Matrix Storage Schemes

Estimating the Condition Number: LAPACK Computational Routines

This section describes the LAPACK routines for estimating the condition number of a matrix. The condition number is used for analyzing the errors in the solution of a system of linear equations (see Error Analysis). Since the condition number may be arbitrarily large when the matrix is nearly singular, the routines actually compute the reciprocal condition number.

?gecon

Estimates the reciprocal of the condition number of a general matrix in the 1-norm or the infinity-norm.
**Syntax**

```c
lapack_int LAPACKE_sgecon( int matrix_layout, char norm, lapack_int n, const float* a, lapack_int lda, float anorm, float* rcond );

lapack_int LAPACKE_dgecon( int matrix_layout, char norm, lapack_int n, const double* a, lapack_int lda, double anorm, double* rcond );

lapack_int LAPACKE_cgecon( int matrix_layout, char norm, lapack_int n, const lapack_complex_float* a, lapack_int lda, float anorm, float* rcond );

lapack_int LAPACKE_zgecon( int matrix_layout, char norm, lapack_int n, const lapack_complex_double* a, lapack_int lda, double anorm, double* rcond );
```

**Include Files**
- mkl.h

**Description**

The routine estimates the reciprocal of the condition number of a general matrix $A$ in the 1-norm or infinity-norm:

- $\kappa_1(A) = \|A\|_1\|A^{-1}\|_1 = \kappa_1(A^T) = \kappa_1(A^H)$
- $\kappa_\infty(A) = \|A\|_\infty\|A^{-1}\|_\infty = \kappa_\infty(A^T) = \kappa_1(A^H)$.

An estimate is obtained for $\|A^{-1}\|$, and the reciprocal of the condition number is computed as $rcond = 1 / (\|A\|_1 \|A^{-1}\|_1)$.

Before calling this routine:
- compute $anorm$ (either $\|A\|_1 = \max_i \sum_j |a_{ij}|$ or $\|A\|_\infty = \max_j \sum_i |a_{ij}|$)
- call `?getrf` to compute the $LU$ factorization of $A$.

**Input Parameters**

- `matrix_layout` Specifies whether matrix storage layout is row major (`LAPACK_ROW_MAJOR`) or column major (`LAPACK_COL_MAJOR`).
- `norm` Must be '1' or 'O' or 'I'.
  - If `norm` = '1' or 'O', then the routine estimates the condition number of matrix $A$ in 1-norm.
  - If `norm` = 'I', then the routine estimates the condition number of matrix $A$ in infinity-norm.
- `n` The order of the matrix $A$; $n \geq 0$.
- `a` The array $a$ contains the $LU$-factored matrix $A$, as returned by `?getrf`.
- `anorm` The norm of the original matrix $A$ (see `Description`).
- `lda` The leading dimension of $a$; $lda \geq \max(1, n)$. 
Output Parameters

\( rcond \)

An estimate of the reciprocal of the condition number. The routine sets \( rcond = 0 \) if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime \( rcond \) is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.

Return Values

This function returns a value \( info \).

If \( info=0 \), the execution is successful.

If \( info = -i \), parameter \( i \) had an illegal value.

Application Notes

The computed \( rcond \) is never less than \( r \) (the reciprocal of the true condition number) and in practice is nearly always less than 10\( r \). A call to this routine involves solving a number of systems of linear equations \( A^* x = b \) or \( A^H x = b \); the number is usually 4 or 5 and never more than 11. Each solution requires approximately \( 2n^2 \) floating-point operations for real flavors and \( 8n^2 \) for complex flavors.

lapack_int LAPACKE_zgbcon( int matrix_layout, char norm, lapack_int n, lapack_int kl, lapack_int ku, const lapack_complex_double* ab, lapack_int ldab, const lapack_int* ipiv, double anorm, double* rcond );

Include Files

- mkl.h

Description

The routine estimates the reciprocal of the condition number of a general band matrix \( A \) in the 1-norm or infinity-norm:

\[ \kappa_1(A) = ||A||_1 ||A^{-1}||_1 = \kappa_1(A^T) = \kappa_1(A^H) \]

\[ \kappa_\infty(A) = ||A||_\infty ||A^{-1}||_\infty = \kappa_1(A^T) = \kappa_1(A^H). \]
An estimate is obtained for \(||A^{-1}|||\), and the reciprocal of the condition number is computed as \(rcond = 1 / (||A|| ||A^{-1}||)\).

Before calling this routine:
- compute \(anorm\) (either \(||A||_1 = \max \sum |a_{ij}|\) or \(||A||_\infty = \max \sum |a_{ij}|\))
- call \(?gbtrf\) to compute the \(LU\) factorization of \(A\).

**Input Parameters**

- \(matrix\_layout\)  
  Specifies whether matrix storage layout is row major (\(\text{LAPACK\_ROW\_MAJOR}\)) or column major (\(\text{LAPACK\_COL\_MAJOR}\)).

- \(norm\)
  Must be ‘1’ or ‘0’ or ‘I’.
  - If \(norm = '1'\) or ‘0’, then the routine estimates the condition number of matrix \(A\) in 1-norm.
  - If \(norm = 'I'\), then the routine estimates the condition number of matrix \(A\) in infinity-norm.

- \(n\)
  The order of the matrix \(A\); \(n \geq 0\).

- \(kl\)
  The number of subdiagonals within the band of \(A\); \(kl \geq 0\).

- \(ku\)
  The number of superdiagonals within the band of \(A\); \(ku \geq 0\).

- \(ldab\)
  The leading dimension of the array \(ab\). \((ldab \geq 2*kl + ku + 1)\).

- \(ipiv\)
  Array, size at least \(\max(1, n)\). The \(ipiv\) array, as returned by \(?gbtrf\).

- \(ab\)
  The array \(ab\) of size \(\max(1, ldab*n)\) contains the factored band matrix \(A\), as returned by \(?gbtrf\).

- \(anorm\)
  The norm of the original matrix \(A\)(see Description).

**Output Parameters**

- \(rcond\)
  An estimate of the reciprocal of the condition number. The routine sets \(rcond = 0\) if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime \(rcond\) is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.

**Return Values**

This function returns a value \(info\).

- If \(info = 0\), the execution is successful.
- If \(info = -i\), parameter \(i\) had an illegal value.

**Application Notes**

The computed \(rcond\) is never less than \(r\) (the reciprocal of the true condition number) and in practice is nearly always less than \(10r\). A call to this routine involves solving a number of systems of linear equations \(A^*x = b\) or \(A^Hx = b\); the number is usually 4 or 5 and never more than 11. Each solution requires approximately \(2n(ku + 2kl)\) floating-point operations for real flavors and \(8n(ku + 2kl)\) for complex flavors.

```

Include Files
- mkl.h

Description

The routine estimates the reciprocal of the condition number of a real or complex tridiagonal matrix A in the 1-norm or infinity-norm:

- \( \kappa_1(A) = \frac{||A|| \cdot ||A^{-1}||}{1} \)
- \( \kappa_\infty(A) = \frac{||A|| \cdot ||A^{-1}||}{\infty} \)

An estimate is obtained for \( ||A^{-1}|| \), and the reciprocal of the condition number is computed as \( rcond = \frac{1}{||A|| \cdot ||A^{-1}||} \).

Before calling this routine:
- compute \( \text{anorm} \) (either \( ||A||_1 = \max_j \sum_i |a_{ij}| \) or \( ||A||_\infty = \max_i \sum_j |a_{ij}| \))
- call ?gttrf to compute the LU factorization of A.

Input Parameters

- **norm**
  - Must be '1' or 'O' or 'I'.
  - If \( \text{norm} = '1' \) or '0', then the routine estimates the condition number of matrix A in 1-norm.
  - If \( \text{norm} = 'I' \), then the routine estimates the condition number of matrix A in infinity-norm.

- **n**
  - The order of the matrix A; \( n \geq 0 \).

- **dl, d, du, du2**
  - Arrays: \( dl(n-1), d(n), du(n-1), du2(n-2) \).
  - The array \( dl \) contains the \((n - 1)\) multipliers that define the matrix L from the LU factorization of A as computed by ?gttrf.
The array \( d \) contains the \( n \) diagonal elements of the upper triangular matrix \( U \) from the LU factorization of \( A \).

The array \( du \) contains the \((n - 1)\) elements of the first superdiagonal of \( U \).

The array \( du2 \) contains the \((n - 2)\) elements of the second superdiagonal of \( U \).

\( ipiv \)

Array, size \( (n) \). The array of pivot indices, as returned by \?gttrf.

\( anorm \)

The norm of the original matrix \( A \)(see Description).

Output Parameters

\( rcond \)

An estimate of the reciprocal of the condition number. The routine sets \( rcond=0 \) if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime \( rcond \) is small compared to \( 1.0 \), for the working precision, the matrix may be poorly conditioned or even singular.

Return Values

This function returns a value \( info \).

If \( info = 0 \), the execution is successful.

If \( info = -i \), parameter \( i \) had an illegal value.

Application Notes

The computed \( rcond \) is never less than \( r \) (the reciprocal of the true condition number) and in practice is nearly always less than \( 10r \). A call to this routine involves solving a number of systems of linear equations \( A^*x = b \); the number is usually 4 or 5 and never more than 11. ### Description

The routine estimates the reciprocal of the condition number of a symmetric (Hermitian) positive-definite matrix $A$:

$$\kappa_1(A) = ||A||_1 ||A^{-1}||_1$$  
(since $A$ is symmetric or Hermitian, $\kappa_\infty(A) = \kappa_1(A)$).

An estimate is obtained for $||A^{-1}||$, and the reciprocal of the condition number is computed as $rcond = 1 / (||A|| ||A^{-1}||)$.

Before calling this routine:
- compute $anorm$ (either $||A||_1 = \max_j \Sigma_i |a_{ij}|$ or $||A||_\infty = \max_i \Sigma_j |a_{ij}|$)
- call $?potrf$ to compute the Cholesky factorization of $A$.

### Input Parameters

- **matrix_layout**: Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- **uplo**: Must be 'U' or 'L'. Indicates how the input matrix $A$ has been factored:
  - If $\text{uplo} = 'U'$, $A$ is factored as $A = U^T U$ for real flavors or $A = UH^* U$ for complex flavors, and $U$ is stored.
  - If $\text{uplo} = 'L'$, $A$ is factored as $A = LL^T$ for real flavors or $A = L^* LH$ for complex flavors, and $L$ is stored.
- **n**: The order of the matrix $A$; $n \geq 0$.
- **a**: The array $a$ of size $\max(1, lda*n)$ contains the factored matrix $A$, as returned by $?potrf$.
- **lda**: The leading dimension of $a$; $lda \geq \max(1, n)$.
- **anorm**: The norm of the original matrix $A$ (see Description).

### Output Parameters

- **rcond**: An estimate of the reciprocal of the condition number. The routine sets $rcond = 0$ if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime $rcond$ is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.

### Return Values

This function returns a value $\text{info}$.

- If $\text{info} = 0$, the execution is successful.
- If $\text{info} = -i$, parameter $i$ had an illegal value.

### Application Notes

The computed $rcond$ is never less than $r$ (the reciprocal of the true condition number) and in practice is nearly always less than 10$r$. A call to this routine involves solving a number of systems of linear equations $A^* x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2n^2$ floating-point operations for real flavors and $8n^2$ for complex flavors.

Description

The routine estimates the reciprocal of the condition number of a packed symmetric (Hermitian) positive-
definite matrix $A$:

$$ \kappa_1(A) = \frac{||A||_1}{||A^{-1}||_1} $$

(since $A$ is symmetric or Hermitian, $\kappa_\infty(A) = \kappa_1(A)$).

An estimate is obtained for $||A^{-1}||$, and the reciprocal of the condition number is computed as $rcond = 
1 / (||A|| \cdot ||A^{-1}||)$.

Before calling this routine:

- compute $anorm$ (either $||A||_1 = \max_i \sum_j |a_{ij}|$ or $||A||_\infty = \max_j \sum_i |a_{ij}|$)
- call ?pptrf to compute the Cholesky factorization of $A$.

Input Parameters

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **uplo**
  Must be 'U' or 'L'.
  Indicates how the input matrix $A$ has been factored:
  If uplo = 'U', $A$ is factored as $A = U^*U$ for real flavors or $A = U^H*U$ for complex flavors, and $U$ is stored.
  If uplo = 'L', $A$ is factored as $A = L*L^*$ for real flavors or $A = L^*L^H$ for complex flavors, and $L$ is stored.

- **n**
  The order of the matrix $A$; $n \geq 0$.

- **ap**
  The array $ap$ contains the packed factored matrix $A$, as returned by ?pptrf. The dimension of $ap$ must be at least $\max(1,n(n+1)/2)$.
  The norm of the original matrix $A$ (see Description).
Output Parameters

\( rcond \)

An estimate of the reciprocal of the condition number. The routine sets \( rcond = 0 \) if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime \( rcond \) is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.

Return Values

This function returns a value \( info \).

If \( info = 0 \), the execution is successful.

If \( info = -i \), parameter \( i \) had an illegal value.

Application Notes

The computed \( rcond \) is never less than \( r \) (the reciprocal of the true condition number) and in practice is nearly always less than 10\( r \). A call to this routine involves solving a number of systems of linear equations \( A^T x = b \); the number is usually 4 or 5 and never more than 11. Each solution requires approximately \( 2n^2 \) floating-point operations for real flavors and \( 8n^2 \) for complex flavors.

• mkl.h

Description

The routine estimates the reciprocal of the condition number of a symmetric (Hermitian) positive-definite band matrix \( A \):

\[ \kappa_1(A) = \| A \|_1 / \| A^{-1} \|_1 \]  
(since \( A \) is symmetric or Hermitian, \( \kappa_\infty(A) = \kappa_1(A) \)).

An estimate is obtained for \( \| A^{-1} \|, \) and the reciprocal of the condition number is computed as \( rcond = 1 / (\| A \| / \| A^{-1} \|) \).

Before calling this routine:

• compute \( anorm \) (either \( \| A \|_1 = \max_j \sum_i |a_{ij}| \) or \( \| A \|_\infty = \max_i \sum_j |a_{ij}| \))
• call ?pbtrf to compute the Cholesky factorization of A.

**Input Parameters**

*matrix_layout* Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

*uplo* Must be 'U' or 'L'.

Indicates how the input matrix A has been factored:

If *uplo* = 'U', A is factored as $A = U^T \cdot U$ for real flavors or $A = U^H \cdot U$ for complex flavors, and $U$ is stored.

If *uplo* = 'L', A is factored as $A = L \cdot L^T$ for real flavors or $A = L \cdot L^H$ for complex flavors, and $L$ is stored.

*n* The order of the matrix $A$; $n \geq 0$.

*kd* The number of superdiagonals or subdiagonals in the matrix $A$; $kd \geq 0$.

*ldab* The leading dimension of the array $ab$. ($ldab \geq kd + 1$).

*ab* The array $ab$ of size max(1, $ldab \cdot n$) contains the factored matrix $A$ in band form, as returned by ?pbtrf.

*anorm* The norm of the original matrix $A$ (see Description).

**Output Parameters**

*rcond* An estimate of the reciprocal of the condition number. The routine sets $rcond = 0$ if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime $rcond$ is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.

**Return Values**

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -i, parameter i had an illegal value.

**Application Notes**

The computed $rcond$ is never less than $r$ (the reciprocal of the true condition number) and in practice is nearly always less than 10$r$. A call to this routine involves solving a number of systems of linear equations $A^* \cdot x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $4 \cdot n (kd + 1)$ floating-point operations for real flavors and $16 \cdot n (kd + 1)$ for complex flavors.

Description

The routine computes the reciprocal of the condition number (in the 1-norm) of a real symmetric or complex Hermitian positive-definite tridiagonal matrix using the factorization $A = L \cdot D \cdot L^T$ for real flavors and $A = L \cdot D \cdot L^H$ for complex flavors or $A = U^T \cdot D \cdot U$ for real flavors and $A = U^H \cdot D \cdot U$ for complex flavors computed by `$pttrf$`: 

$$\kappa_1(A) = ||A||_1 \cdot ||A^{-1}||_1$$

(since $A$ is symmetric or Hermitian, $\kappa_1(A) = \kappa_1(A)$).

The norm $||A^{-1}||$ is computed by a direct method, and the reciprocal of the condition number is computed as $rcond = 1 / (||A|| \cdot ||A^{-1}||)$.

Before calling this routine:

- compute $anorm$ as $||A||_1 = \max_i \sum_j |a_{ij}|$
- call `$pttrf$` to compute the factorization of $A$.

Input Parameters

- $n$ The order of the matrix $A$; $n \geq 0$.
- $d$ Arrays, dimension $(n)$. The array $d$ contains the $n$ diagonal elements of the diagonal matrix $D$ from the factorization of $A$, as computed by `$pttrf$`.
- $e$ Array, size $(n - 1)$. Contains off-diagonal elements of the unit bidiagonal factor $U$ or $L$ from the factorization computed by `$pttrf$`.
- $anorm$ The 1-norm of the original matrix $A$ (see Description).

Output Parameters

- $rcond$ An estimate of the reciprocal of the condition number. The routine sets $rcond = 0$ if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime $rcond$ is small compared to $1.0$, for the working precision, the matrix may be poorly conditioned or even singular.
Return Values
This function returns a value info.

If info = 0, the execution is successful.
If info = -i, parameter i had an illegal value.

Application Notes
The computed rcond is never less than r (the reciprocal of the true condition number) and in practice is nearly always less than 10r. A call to this routine involves solving a number of systems of linear equations \( A^T x = b \); the number is usually 4 or 5 and never more than 11. Each solution requires approximately 4*n*(kd + 1) floating-point operations for real flavors and 16*n*(kd + 1) for complex flavors.

?sycon
Estimates the reciprocal of the condition number of a symmetric matrix.

Syntax

```c
lapack_int LAPACKE_ssycon( int matrix_layout, char uplo, lapack_int n, const float* a, lapack_int lda, const lapack_int* ipiv, float anorm, float* rcond );
```
```c
lapack_int LAPACKE_dsycon( int matrix_layout, char uplo, lapack_int n, const double* a, lapack_int lda, const lapack_int* ipiv, double anorm, double* rcond );
```
```c
lapack_int LAPACKE_csycon( int matrix_layout, char uplo, lapack_int n, const lapack_complex_float* a, lapack_int lda, const lapack_int* ipiv, float anorm, float* rcond );
```
```c
lapack_int LAPACKE_zsycon( int matrix_layout, char uplo, lapack_int n, const lapack_complex_double* a, lapack_int lda, const lapack_int* ipiv, double anorm, double* rcond );
```

Include Files

Description
The routine estimates the reciprocal of the condition number of a symmetric matrix \( A \):

\[
\kappa_1(A) = ||A||_1 ||A^{-1}||_1 \text{ (since } A \text{ is symmetric, } \kappa_\infty(A) = \kappa_1(A)\).
\]

An estimate is obtained for ||\( A^{-1} ||_1 \), and the reciprocal of the condition number is computed as \( rcond = 1 / (||A||_1 ||A^{-1}||_1) \).

Before calling this routine:
- compute anorm (either ||A||_1 = max_i |a_i| or ||A||_\infty = max_j |a_j|)
- call ?sytrf to compute the factorization of A.

Input Parameters

- matrix_layout Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- uplo Must be 'U' or 'L'.

Indicates how the input matrix \( A \) has been factored:

If \( \text{uplo} = 'U' \), the array \( a \) stores the upper triangular factor \( U \) of the factorization \( A = U*D*U^T \).

If \( \text{uplo} = 'L' \), the array \( a \) stores the lower triangular factor \( L \) of the factorization \( A = L*D*L^T \).

\( n \)

The order of matrix \( A \); \( n \geq 0 \).

\( a \)

The array \( a \) of size \( \max(1, \text{lda} \times n) \) contains the factored matrix \( A \), as returned by \(?sytrf\).

\( \text{lda} \)

The leading dimension of \( a \); \( \text{lda} \geq \max(1, n) \).

\( \text{ipiv} \)

Array, size at least \( \max(1, n) \).

The array \( \text{ipiv} \), as returned by \(?sytrf\).

\( \text{anorm} \)

The norm of the original matrix \( A \) (see Description).

**Output Parameters**

\( \text{rcond} \)

An estimate of the reciprocal of the condition number. The routine sets \( \text{rcond} = 0 \) if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime \( \text{rcond} \) is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.

**Return Values**

This function returns a value \( \text{info} \).

If \( \text{info} = 0 \), the execution is successful.

If \( \text{info} = -i \), parameter \( i \) had an illegal value.

**Application Notes**

The computed \( \text{rcond} \) is never less than \( r \) (the reciprocal of the true condition number) and in practice is nearly always less than 10\( r \). A call to this routine involves solving a number of systems of linear equations \( A^*x = b \); the number is usually 4 or 5 and never more than 11. Each solution requires approximately \( 2n^2 \) floating-point operations for real flavors and \( 8n^2 \) for complex flavors.

\(?sycon_3\)

Estimates the reciprocal of the condition number (in the 1-norm) of a real or complex symmetric matrix \( A \) using the factorization computed by \(?sytrf_rk\).

```c
lapack_int LAPACK_ssycon_3 (int matrix_layout, char uplo, lapack_int n, const float * A, lapack_int lda, const float * e, const lapack_int * ipiv, float anorm, float * rcond);

lapack_int LAPACK_dsycon_3 (int matrix_layout, char uplo, lapack_int n, const double * A, lapack_int lda, const double * e, const lapack_int * ipiv, double anorm, double * rcond);
```
lapack_int LAPACKE_csycon_3 (int matrix_layout, char uplo, lapack_int n, const lapack_complex_float * A, lapack_int lda, const lapack_complex_float * e, const lapack_int * ipiv, float anorm, float * rcond);

lapack_int LAPACKE_zsycon_3 (int matrix_layout, char uplo, lapack_int n, const lapack_complex_double * A, lapack_int lda, const lapack_complex_double * e, const lapack_int * ipiv, double anorm, double * rcond);

Description

`?sycon_3` estimates the reciprocal of the condition number (in the 1-norm) of a real or complex symmetric matrix A using the factorization computed by `?sytrf_rk`. A = P*U*D*(Uᵀ)*(Pᵀ) or A = P*L*D*(Lᵀ)*(Pᵀ), where U (or L) is unit upper (or lower) triangular matrix, Uᵀ (or Lᵀ) is the transpose of U (or L), P is a permutation matrix, Pᵀ is the transpose of P, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as rcond = 1 / (anorm * norm(inv(A))).

This routine uses BLAS3 solver `?sytrs_3`.

Input Parameters

* **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

* **uplo**
  Specifies whether the details of the factorization are stored as an upper or lower triangular matrix:
  - 'U': Upper triangular. The form is A = P*U*D*(Uᵀ)*(Pᵀ).
  - 'L': Lower triangular. The form is A = P*L*D*(Lᵀ)*(Pᵀ).

* **n**
  The order of the matrix A. n ≥ 0.

* **A**
  Array of size max(1, lda*n). Diagonal of the block diagonal matrix D and factors U or L as computed by `?sytrf_rk`:
  - Only diagonal elements of the symmetric block diagonal matrix D on the diagonal of A; that is, D(k,k) = A(k,k). Superdiagonal (or subdiagonal) elements of D should be provided on entry in array e).
  - If uplo = 'U', factor U in the superdiagonal part of A. If uplo = 'L', factor L in the subdiagonal part of A.

* **lda**
  The leading dimension of the array A.

* **e**
  Array of size n. On entry, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks. If uplo = 'U', e(i) = D(i-1,i), i = 2:N, and e(1) is not referenced. If uplo = 'L', e(i) = D(i+1,i), i = 1:N-1, and e(n) is not referenced.

**NOTE** For 1-by-1 diagonal block D(k), where 1 ≤ k ≤ n, the element e[k-1] is not referenced in both the uplo = 'U' and uplo = 'L' cases.
**ipiv**

Array of size \( n \). Details of the interchanges and the block structure of \( D \) as determined by \(?sytrf_rk\).

**anorm**

The 1-norm of the original matrix \( A \).

**Output Parameters**

**rcond**

The reciprocal of the condition number of the matrix \( A \), computed as \( rcond = 1/(anorm \times AINVNM) \), where \( AINVNM \) is an estimate of the 1-norm of \( \text{inv}(A) \) computed in this routine.

**Return Values**

This function returns a value \( info \).

- \( = 0 \): Successful exit.
- \(< 0\): If \( info = -i \), the \( i \)th argument had an illegal value.

**?hecon**

Estimates the reciprocal of the condition number of a Hermitian matrix.

**Syntax**

```c
lapack_int LAPACKE_checon( int matrix_layout, char uplo, lapack_int n, const lapack_complex_float* a, lapack_int lda, const lapack_int* ipiv, float anorm, float* rcond );
```

```c
lapack_int LAPACKE_zhecon( int matrix_layout, char uplo, lapack_int n, const lapack_complex_double* a, lapack_int lda, const lapack_int* ipiv, double anorm, double* rcond );
```

**Include Files**

- mkl.h

**Description**

The routine estimates the reciprocal of the condition number of a Hermitian matrix \( A \):

\[
\kappa_1(A) = \| \|A|\|_1 / \| \|A^{-1}|\|_1 \quad (\text{since } A \text{ is Hermitian, } \kappa_\infty(A) = \kappa_1(A))
\]

Before calling this routine:

- compute \( anorm \) (either \( \| |A| \|_1 = \max_j \sum_i |a_{ij}| \) or \( \| |A| \|_\infty = \max_i \sum_j |a_{ij}| \))
- call \(?hetrf\) to compute the factorization of \( A \).

**Input Parameters**

- **matrix_layout**: Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- **uplo**: Must be 'U' or 'L'.

Indicates how the input matrix \( A \) has been factored:

- If \( uplo = 'U' \), the array \( a \) stores the upper triangular factor \( U \) of the factorization \( A = U*D*U^H \).
If `uplo = 'L'`, the array `a` stores the lower triangular factor `L` of the factorization `A = L*D*L^H`.

`n`

The order of matrix `A`; `n ≥ 0`.

`a`

The array `a` of size `max(1, lda*n)` contains the factored matrix `A`, as returned by `?hetrf`.

`lda`

The leading dimension of `a`; `lda ≥ max(1, n)`.

`ipiv`

Array, size at least `max(1, n)`.

The array `ipiv`, as returned by `?hetrf`.

`anorm`

The norm of the original matrix `A` (see Description).

### Output Parameters

`rcond`

An estimate of the reciprocal of the condition number. The routine sets `rcond = 0` if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime `rcond` is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.

### Return Values

This function returns a value `info`.

- If `info = 0`, the execution is successful.
- If `info = -i`, parameter `i` had an illegal value.

### Application Notes

The computed `rcond` is never less than `r` (the reciprocal of the true condition number) and in practice is nearly always less than `10r`. A call to this routine involves solving a number of systems of linear equations `A*x = b`; the number is usually 5 and never more than 11. Each solution requires approximately `8n^2` floating-point operations.

### See Also

`?hecon_3`

Estimates the reciprocal of the condition number (in the 1-norm) of a complex Hermitian matrix `A`.

```c
lapack_int LAPACK_checon_3 (int matrix_layout, char uplo, lapack_int n, const
lapack_complex_float * A, lapack_int lda, const lapack_complex_float * e, const
lapack_int * ipiv, float anorm, float * rcond);
```

```c
lapack_int LAPACK_zhecon_3 (int matrix_layout, char uplo, lapack_int n, const
lapack_complex_double * A, lapack_int lda, const lapack_complex_double * e, const
lapack_int * ipiv, double anorm, double * rcond);
```

### Description

`?hecon_3` estimates the reciprocal of the condition number (in the 1-norm) of a complex Hermitian matrix `A` using the factorization computed by `?hetrf_rk`: `A = P*U*D*(U^H)*(P^T)` or `A = P*L*D*(L^H)*(P^T)`, where `U` (or `L`) is unit upper (or lower) triangular matrix, `U^H` (or `L^H`) is the conjugate of `U` (or `L`), `P` is a permutation...
matrix, $P^T$ is the transpose of $P$, and $D$ is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks. An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $rcond = 1 / (\text{anorm} \times \text{norm}(\text{inv}(A)))$.

This routine uses BLAS3 solver `?hetrs_3`.

**Input Parameters**

- **matrix_layout**: Specifies whether matrix storage layout is row major (`LAPACK_ROW_MAJOR`) or column major (`LAPACK_COL_MAJOR`).
- **uplo**: Specifies whether the details of the factorization are stored as an upper or lower triangular matrix: `$'U'$`: Upper triangular, form is $A = P*U*D*(U^H)*(P^T)$; `$'L'$`: Lower triangular, form is $A = P*L*D*(L^H)*(P^T)$.
- **n**: The order of the matrix $A$. $n \geq 0$.
- **A**: Array of size $\max(1, lda*n)$. Diagonal of the block diagonal matrix $D$ and factor $U$ or $L$ as computed by `?hetrf_rk`:
  - *Only* diagonal elements of the Hermitian block diagonal matrix $D$ on the diagonal of $A$—that is, $D(k,k) = A(k,k)$. Superdiagonal (or subdiagonal) elements of $D$ must be provided on entry in array $e$.
  - and—
  - If $uplo = 'U'$, factor $U$ in the superdiagonal part of $A$. If $uplo = 'L'$, factor $L$ in the subdiagonal part of $A$.
- **lda**: The leading dimension of the array $A$.
- **e**: Array of size $n$. On entry, contains the superdiagonal (or subdiagonal) elements of the Hermitian block diagonal matrix $D$ with 1-by-1 or 2-by-2 diagonal blocks. If $uplo = 'U'$, $e(i) = D(i-1,i), i=2:N$, and $e(1)$ is not referenced. If $uplo = 'L'$, $e(i) = D(i+1,i), i=1:N-1$, and $e(n)$ is not referenced.

**NOTE** For 1-by-1 diagonal block $D(k)$, where $1 \leq k \leq n$, the element $e[k-1]$ is not referenced in both the $uplo = 'U'$ and $uplo = 'L'$ cases.

- **ipiv**: Array of size $n$. Details of the interchanges and the block structure of $D$ as determined by `?hetrf_rk`.
- **anorm**: The 1-norm of the original matrix $A$.

**Output Parameters**

- **rcond**: The reciprocal of the condition number of the matrix $A$, computed as $rcond = 1 / (\text{anorm} \times AINVNM)$, where $AINVNM$ is an estimate of the 1-norm of inv($A$) computed in this routine.

**Return Values**

This function returns a value $info$.

- $= 0$: Successful exit.
< 0: If info = -i, the i-th argument had an illegal value.

**?spcon**
Estimates the reciprocal of the condition number of a packed symmetric matrix.

**Syntax**
lapack_int LAPACKE_sspcon( int matrix_layout, char uplo, lapack_int n, const float* ap, const lapack_int* ipiv, float anorm, float* rcond );
lapack_int LAPACKE_dspcon( int matrix_layout, char uplo, lapack_int n, const double* ap, const lapack_int* ipiv, double anorm, double* rcond );
lapack_int LAPACKE_cspcon( int matrix_layout, char uplo, lapack_int n, const lapack_complex_float* ap, const lapack_int* ipiv, float anorm, float* rcond );
lapack_int LAPACKE_zspcon( int matrix_layout, char uplo, lapack_int n, const lapack_complex_double* ap, const lapack_int* ipiv, double anorm, double* rcond );

**Include Files**
- mkl.h

**Description**
The routine estimates the reciprocal of the condition number of a packed symmetric matrix $A$:

$$
\kappa_1(A) = \frac{||A||_1 ||A^{-1}||_1}{(||A||_1 ||A^{-1}||_1)} \quad \text{(since A is symmetric, } \kappa_\infty(A) = \kappa_1(A)).
$$

An estimate is obtained for $||A^{-1}||$, and the reciprocal of the condition number is computed as $rcond = 1 / (||A|| \cdot ||A^{-1}||)$.

Before calling this routine:
- compute $anorm$ (either $||A||_1 = \max_{i} \sum_{j} |a_{ij}|$ or $||A||_\infty = \max_{j} \sum_{i} |a_{ij}|$)
- call ?sptrf to compute the factorization of $A$.

**Input Parameters**
- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- **uplo**
  Must be 'U' or 'L'.
  Indicates how the input matrix $A$ has been factored:
  - If $uplo = 'U'$, the array $ap$ stores the packed upper triangular factor $U$ of the factorization $A = U^*D*U^T$.
  - If $uplo = 'L'$, the array $ap$ stores the packed lower triangular factor $L$ of the factorization $A = L^*D*L^T$.
- **n**
  The order of matrix $A$; $n \geq 0$.
- **ap**
  The array $ap$ contains the packed factored matrix $A$, as returned by ?sptrf. The dimension of $ap$ must be at least $max(1,n(n+1)/2)$.
- **ipiv**
  Array, size at least $max(1, n)$.
  The array $ipiv$, as returned by ?sptrf.
- **anorm**
  The norm of the original matrix $A$ (see Description).
Output Parameters

\( rcond \)
An estimate of the reciprocal of the condition number. The routine sets \( rcond = 0 \) if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime \( rcond \) is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.

Return Values

This function returns a value \( info \).

Include Files

- mkl.h

Description

The routine estimates the reciprocal of the condition number of a Hermitian matrix \( A \):

\[
\kappa_1(A) = \| A \|_1 / \| A^{-1} \|_1 \quad (\text{since } A \text{ is Hermitian}, \quad \kappa_\infty(A) = \kappa_1(A)).
\]

An estimate is obtained for \( \| A^{-1} \|_1 \), and the reciprocal of the condition number is computed as \( rcond = 1 / (\| A \|_1 \| A^{-1} \|) \).

Before calling this routine:

- compute \( \text{anorm} \) (either \( \| A \|_1 = \max_i \sum_j | a_{ij} | \) or \( \| A \|_\infty = \max_j \sum_i | a_{ij} | \))
- call ?hptrf to compute the factorization of \( A \).

Input Parameters

\( matrix_layout \)
Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
uplo

Must be 'U' or 'L'.

Indicates how the input matrix $A$ has been factored:
If $\text{uplo} = 'U'$, the array $ap$ stores the packed upper triangular factor $U$ of the factorization $A = UDU^T$.
If $\text{uplo} = 'L'$, the array $ap$ stores the packed lower triangular factor $L$ of the factorization $A = LDL^T$.

$n$

The order of matrix $A$; $n \geq 0$.

$ap$

The array $ap$ contains the packed factored matrix $A$, as returned by $\text{?hptrf}$. The dimension of $ap$ must be at least $\max(1, n(n+1)/2)$.

$ipiv$

Array, size at least $\max(1, n)$. The array $ipiv$, as returned by $\text{?hptrf}$.

$anorm$

The norm of the original matrix $A$ (see Description).

Output Parameters

$rcond$

An estimate of the reciprocal of the condition number. The routine sets $rcond = 0$ if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime $rcond$ is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.

Return Values

This function returns a value $info$.

If $info = 0$, the execution is successful.

If $info = -i$, parameter $i$ had an illegal value.

Application Notes

The computed $rcond$ is never less than $r$ (the reciprocal of the true condition number) and in practice is nearly always less than $10r$. A call to this routine involves solving a number of systems of linear equations $A^*x = b$; the number is usually 5 and never more than 11. Each solution requires approximately $8n^2$ floating-point operations.

$\text{?trcon}$

Estimates the reciprocal of the condition number of a triangular matrix.

Syntax

```
lapack_int LAPACKE_strcon ( int matrix_layout, char norm, char uplo, char diag,
    lapack_int n, const float* a, lapack_int lda, float* rcond );
lapack_int LAPACKE_dtrcon ( int matrix_layout, char norm, char uplo, char diag,
    lapack_int n, const double* a, lapack_int lda, double* rcond );
lapack_int LAPACKE_ctrcon ( int matrix_layout, char norm, char uplo, char diag,
    lapack_int n, const lapack_complex_float* a, lapack_int lda, float* rcond );
```
lapack_int LAPACKE_ztrcon( int matrix_layout, char norm, char uplo, char diag,
lapack_int n, const lapack_complex_double* a, lapack_int lda, double* rcond );

Include Files
• mkl.h

Description
The routine estimates the reciprocal of the condition number of a triangular matrix A in either the 1-norm or infinity-norm:
k_1(A) = ||A||_1 ||A^{-1}||_1 = \kappa_1(A^T) = \kappa_1(A^H)
k_\infty(A) = ||A||_\infty ||A^{-1}||_\infty = \kappa_1(A^T) = \kappa_1(A^H).

Input Parameters

matrix_layout
Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

norm
Must be '1' or 'O' or 'I'.
If norm = '1' or 'O', then the routine estimates the condition number of matrix A in 1-norm.
If norm = 'I', then the routine estimates the condition number of matrix A in infinity-norm.

uplo
Must be 'U' or 'L'.
Indicates whether A is upper or lower triangular:
If uplo = 'U', the array a stores the upper triangle of A, other array elements are not referenced.
If uplo = 'L', the array a stores the lower triangle of A, other array elements are not referenced.

diag
Must be 'N' or 'U'.
If diag = 'N', then A is not a unit triangular matrix.
If diag = 'U', then A is unit triangular: diagonal elements are assumed to be 1 and not referenced in the array a.

n
The order of the matrix A; n \geq 0.

a
The array a of size max(1, lda*n) contains the matrix A.

lda
The leading dimension of a; lda \geq max(1, n).

Output Parameters

rcond
An estimate of the reciprocal of the condition number. The routine sets rcond =0 if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime rcond is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.
Return Values

This function returns a value `info`.

If `info = 0`, the execution is successful.

If `info = -i`, parameter `i` had an illegal value.

Application Notes

The computed `rcond` is never less than `r` (the reciprocal of the true condition number) and in practice is nearly always less than `10r`. A call to this routine involves solving a number of systems of linear equations `A*x = b`; the number is usually 4 or 5 and never more than 11. Each solution requires approximately `n^2` floating-point operations for real flavors and `4n^2` operations for complex flavors.

Matrix Storage Schemes

`?tpcon`
Estimates the reciprocal of the condition number of a packed triangular matrix.

Syntax

```c
lapack_int LAPACKE_stpcon( int matrix_layout, char norm, char uplo, char diag,
                         lapack_int n, const float* ap, float* rcond );

lapack_int LAPACKE_dtpcon( int matrix_layout, char norm, char uplo, char diag,
                         lapack_int n, const double* ap, double* rcond );

lapack_int LAPACKE_ctpcon( int matrix_layout, char norm, char uplo, char diag,
                         lapack_int n, const lapack_complex_float* ap, float* rcond );

lapack_int LAPACKE_ztpcon( int matrix_layout, char norm, char uplo, char diag,
                         lapack_int n, const lapack_complex_double* ap, double* rcond );
```

Include Files

- `mkl.h`

Description

The routine estimates the reciprocal of the condition number of a packed triangular matrix `A` in either the 1-norm or infinity-norm:

\[
\kappa_1(A) = \|A\|_1 \|A^{-1}\|_1 = \kappa_e(A^T) = \kappa_e(A^H)
\]

\[
\kappa_\infty(A) = \|A\|_\infty \|A^{-1}\|_\infty = \kappa_1(A^T) = \kappa_1(A^H).
\]

Input Parameters

- `matrix_layout`
  Specifies whether matrix storage layout is row major (`LAPACK_ROW_MAJOR`) or column major (`LAPACK_COL_MAJOR`).

- `norm`
  Must be '1' or 'O' or 'I'.
  - If `norm = '1'` or 'O', then the routine estimates the condition number of matrix `A` in 1-norm.
  - If `norm = 'I'`, then the routine estimates the condition number of matrix `A` in infinity-norm.
uplo

Must be 'U' or 'L'. Indicates whether A is upper or lower triangular:
If uplo = 'U', the array ap stores the upper triangle of A in packed form.
If uplo = 'L', the array ap stores the lower triangle of A in packed form.

diag

Must be 'N' or 'U'.
If diag = 'N', then A is not a unit triangular matrix.
If diag = 'U', then A is unit triangular: diagonal elements are assumed to be 1 and not referenced in the array ap.

n

The order of the matrix A; n ≥ 0.

ap

The array ap contains the packed matrix A. The dimension of ap must be at least max(1, n(n+1)/2).

Output Parameters

rcond

An estimate of the reciprocal of the condition number. The routine sets rcond = 0 if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime rcond is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.

Return Values

This function returns a value info.
If info = 0, the execution is successful.
If info = -i, parameter i had an illegal value.

Application Notes

The computed rcond is never less than r (the reciprocal of the true condition number) and in practice is nearly always less than 10r. A call to this routine involves solving a number of systems of linear equations A*x = b; the number is usually 4 or 5 and never more than 11. Each solution requires approximately n^2 floating-point operations for real flavors and 4n^2 operations for complex flavors.

Matrix Storage Schemes

?tbcon
Estimates the reciprocal of the condition number of a triangular band matrix.

Syntax

lapack_int LAPACKE_stbcon( int matrix_layout, char norm, char uplo, char diag, lapack_int n, lapack_int kd, const float* ab, lapack_int ldab, float* rcond );

lapack_int LAPACKE_dtbcon( int matrix_layout, char norm, char uplo, char diag, lapack_int n, lapack_int kd, const double* ab, lapack_int ldab, double* rcond );

lapack_int LAPACKE_ctbcon( int matrix_layout, char norm, char uplo, char diag, lapack_int n, lapack_int kd, const lapack_complex_float* ab, lapack_int ldab, float* rcond );
lapack_int LAPACKE_ztbcon( int matrix_layout, char norm, char uplo, char diag,
lapack_int n, lapack_int kd, const lapack_complex_double* ab, lapack_int ldab, double* rcond );

Include Files
• mkl.h

Description
The routine estimates the reciprocal of the condition number of a triangular band matrix \( A \) in either the 1-norm or infinity-norm:

\[
\kappa_1(A) = \|A\|_1 \|A^{-1}\|_1 = \kappa_\infty(A^T) = \kappa_\infty(A^H)
\]

\[
\kappa_\infty(A) = \|A\|_\infty \|A^{-1}\|_\infty = \kappa_1(A^T) = \kappa_1(A^H).
\]

Input Parameters

\textit{matrix_layout}  
Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

\textit{norm}  
Must be '1' or 'O' or 'I'.

If \textit{norm} = '1' or 'O', then the routine estimates the condition number of matrix \( A \) in 1-norm.

If \textit{norm} = 'I', then the routine estimates the condition number of matrix \( A \) in infinity-norm.

\textit{uplo}  
Must be 'U' or 'L'. Indicates whether \( A \) is upper or lower triangular:

If \textit{uplo} = 'U', the array \textit{ap} stores the upper triangle of \( A \) in packed form.

If \textit{uplo} = 'L', the array \textit{ap} stores the lower triangle of \( A \) in packed form.

\textit{diag}  
Must be 'N' or 'U'.

If \textit{diag} = 'N', then \( A \) is not a unit triangular matrix.

If \textit{diag} = 'U', then \( A \) is unit triangular: diagonal elements are assumed to be 1 and not referenced in the array \textit{ab}.

\textit{n}  
The order of the matrix \( A \); \( n \geq 0 \).

\textit{kd}  
The number of superdiagonals or subdiagonals in the matrix \( A \); \( kd \geq 0 \).

\textit{ab}  
The array \textit{ab} of size \( \max(1, ldab*\textit{n}) \) contains the band matrix \( A \).

\textit{ldab}  
The leading dimension of the array \textit{ab}. (\( ldab \geq kd +1 \)).

Output Parameters

\textit{rcond}  
An estimate of the reciprocal of the condition number. The routine sets \textit{rcond} =0 if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime \textit{rcond} is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.
Return Values
This function returns a value info.
If info = 0, the execution is successful.
If info = -i, parameter i had an illegal value.

Application Notes
The computed rcond is never less than r (the reciprocal of the true condition number) and in practice is nearly always less than 10r. A call to this routine involves solving a number of systems of linear equations $A^*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2n(kd + 1)$ floating-point operations for real flavors and $8n(kd + 1)$ operations for complex flavors.

Refracting the Solution and Estimating Its Error: LAPACK Computational Routines
This section describes the LAPACK routines for refining the computed solution of a system of linear equations and estimating the solution error. You can call these routines after factorizing the matrix of the system of equations and computing the solution (see Routines for Matrix Factorization and Routines for Solving Systems of Linear Equations).

?gerfs
Refrains the solution of a system of linear equations with a general coefficient matrix and estimates its error.

Syntax

```
lapack_int LAPACKE_sgerfs( int matrix_layout, char trans, lapack_int n, lapack_int nrhs, const float* a, lapack_int lda, const float* af, lapack_int ldaf, const lapack_int* ipiv, const float* b, lapack_int ldb, float* x, lapack_int ldx, float* ferr, float* berr );

lapack_int LAPACKE_dgerfs( int matrix_layout, char trans, lapack_int n, lapack_int nrhs, const double* a, lapack_int lda, const double* af, lapack_int ldaf, const lapack_int* ipiv, const double* b, lapack_int ldb, double* x, lapack_int ldx, double* ferr, double* berr );

lapack_int LAPACKE_cgerfs( int matrix_layout, char trans, lapack_int n, lapack_int nrhs, const lapack_complex_float* a, lapack_int lda, const lapack_complex_float* af, lapack_int ldaf, const lapack_int* ipiv, const lapack_complex_float* b, lapack_int ldb, lapack_complex_float* x, lapack_int ldx, float* ferr, float* berr );

lapack_int LAPACKE_zgerfs( int matrix_layout, char trans, lapack_int n, lapack_int nrhs, const lapack_complex_double* a, lapack_int lda, const lapack_complex_double* af, lapack_int ldaf, const lapack_int* ipiv, const lapack_complex_double* b, lapack_int ldb, lapack_complex_double* x, lapack_int ldx, double* ferr, double* berr );
```
The routine performs an iterative refinement of the solution to a system of linear equations $A*X = B$ or $A^T*X = B$ or $A^H*X = B$ with a general matrix $A$, with multiple right-hand sides. For each computed solution vector $x$, the routine computes the component-wise backward error $\beta$. This error is the smallest relative perturbation in elements of $A$ and $b$ such that $x$ is the exact solution of the perturbed system:

$$|\delta a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| \leq \beta |b_i| \quad \text{such that} \quad (A + \delta A)x = (b + \delta b).$$

Finally, the routine estimates the component-wise forward error in the computed solution $||x - x_e||_\infty/||x||_\infty$ (here $x_e$ is the exact solution).

Before calling this routine:
- call the factorization routine ?getrf
- call the solver routine ?getrs.

### Input Parameters

- **matrix_layout**
  - Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **trans**
  - Must be 'N' or 'T' or 'C'.
  - Indicates the form of the equations:
    - If $trans = 'N'$, the system has the form $A*X = B$.
    - If $trans = 'T'$, the system has the form $A^T*X = B$.
    - If $trans = 'C'$, the system has the form $A^H*X = B$.

- **n**
  - The order of the matrix $A$; $n \geq 0$.

- **nrhs**
  - The number of right-hand sides; $nrhs \geq 0$.

- **a, af, b, x**
  - Arrays:
    - $a(\text{size max}(1, \text{lda} * n))$ contains the original matrix $A$, as supplied to ?getrf.
    - $af(\text{size max}(1, \text{ldaf} * n))$ contains the factored matrix $A$, as returned by ?getrf.
    - $b(\text{size max}(1, \text{ldb} * nrhs))$ for column major layout and max$(1, \text{ldb} * n)$ for row major layout contains the right-hand side matrix $B$.
    - $x(\text{size max}(1, \text{ldx} * nrhs))$ for column major layout and max$(1, \text{ldx} * n)$ for row major layout contains the solution matrix $X$.

- **lda**
  - The leading dimension of $a$; $lda \geq \text{max}(1, n)$.

- **ldaf**
  - The leading dimension of $af$; $ldaf \geq \text{max}(1, n)$.

- **ldb**
  - The leading dimension of $b$; $ldb \geq \text{max}(1, n)$ for column major layout and $ldb \geq \text{nrhs}$ for row major layout.

- **ldx**
  - The leading dimension of $x$; $ldx \geq \text{max}(1, n)$ for column major layout and $ldx \geq \text{nrhs}$ for row major layout.

- **ipiv**
  - Array, size at least $\text{max}(1, n)$.
  - The ipiv array, as returned by ?getrf.
Output Parameters

- x: The refined solution matrix X.
- ferr, berr: Arrays, size at least \( \max(1, nrhs) \). Contain the component-wise forward and backward errors, respectively, for each solution vector.

Return Values

This function returns a value info.

If info = 0, the execution is successful.

If info = -i, parameter i had an illegal value.

Application Notes

The bounds returned in ferr are not rigorous, but in practice they almost always overestimate the actual error.

For each right-hand side, computation of the backward error involves a minimum of \( 4n^2 \) floating-point operations (for real flavors) or \( 16n^2 \) operations (for complex flavors). In addition, each step of iterative refinement involves \( 6n^2 \) operations (for real flavors) or \( 24n^2 \) operations (for complex flavors); the number of iterations may range from 1 to 5. Estimating the forward error involves solving a number of systems of linear equations \( Ax = b \) with the same coefficient matrix \( A \) and different right hand sides \( b \); the number is usually 4 or 5 and never more than 11. Each solution requires approximately \( 2n^2 \) floating-point operations for real flavors or \( 8n^2 \) for complex flavors.

lapack_complex_double* af, lapack_int ldaf, const lapack_int* ipiv, const double* r,
const double* c, const lapack_complex_double* b, lapack_int ldb, lapack_complex_double*
x, lapack_int ldx, double* rcond, double* berr, lapack_int n_err_bnds, double*
err_bnds_norm, double* err_bnds_comp, lapack_int nparams, double* params );
```

### Include Files
- mkl.h

### Description

The routine improves the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution. In addition to a normwise error bound, the code provides a maximum componentwise error bound, if possible. See comments for `err_bnds_norm` and `err_bnds_comp` for details of the error bounds.

The original system of linear equations may have been equilibrated before calling this routine, as described by the parameters `equed`, `r`, and `c` below. In this case, the solution and error bounds returned are for the original unequilibrated system.

### Input Parameters

- **matrix_layout**
  Specifies whether two-dimensional array storage is row major (`LAPACK_ROW_MAJOR`) or column major (`LAPACK_COL_MAJOR`).

- **trans**
  Must be 'N', 'T', or 'C'.

  Specifies the form of the system of equations:
  - If `trans` = 'N', the system has the form $A * X = B$ (No transpose).
  - If `trans` = 'T', the system has the form $A^T * X = B$ (Transpose).
  - If `trans` = 'C', the system has the form $A^H * X = B$ (Conjugate transpose for complex flavors, Transpose for real flavors).

- **equed**
  Must be 'N', 'R', 'C', or 'B'.

  Specifies the form of equilibration that was done to $A$ before calling this routine.
  - If `equed` = 'N', no equilibration was done.
  - If `equed` = 'R', row equilibration was done, that is, $A$ has been premultiplied by $\text{diag}(r)$.
  - If `equed` = 'C', column equilibration was done, that is, $A$ has been postmultiplied by $\text{diag}(c)$.
  - If `equed` = 'B', both row and column equilibration was done, that is, $A$ has been replaced by $\text{diag}(r) * A * \text{diag}(c)$. The right-hand side $B$ has been changed accordingly.

- **n**
  The number of linear equations; the order of the matrix $A$; $n \geq 0$.

- **nrhs**
  The number of right-hand sides; the number of columns of the matrices $B$ and $X$; $nrhs \geq 0$. 

Arrays: $a$ (size max(1, \(lda\times n\))), $af$ (size max(1, \(ldaf\times n\))), $b$ (size max(1, \(ldb\times nrhs\))) for column major layout and max(1, \(ldb\times n\)) for row major layout).

The array $a$ contains the original $n$-by-$n$ matrix $A$.

The array $af$ contains the factored form of the matrix $A$, that is, the factors $L$ and $U$ from the factorization $A = P*L*U$ as computed by \texttt{getrf}.

The array $b$ contains the matrix $B$ whose columns are the right-hand sides for the systems of equations.

The leading dimension of $a$; \(lda\geq\max(1, n)\).

The leading dimension of $af$; \(ldaf\geq\max(1, n)\).

Array, size at least max(1, \(n\)). Contains the pivot indices as computed by \texttt{getrf}; for row \(1 \leq i \leq n\), row $i$ of the matrix was interchanged with row $ipiv(i)$.

Arrays: $r$ (size $n$), $c$ (size $n$). The array $r$ contains the row scale factors for $A$, and the array $c$ contains the column scale factors for $A$.

If $equed = 'R'$ or 'B', $A$ is multiplied on the left by $\text{diag}(r)$; if $equed = 'N'$ or 'C', $r$ is not accessed.

If $equed = 'R'$ or 'B', each element of $r$ must be positive.

If $equed = 'C'$ or 'B', $A$ is multiplied on the right by $\text{diag}(c)$; if $equed = 'N'$ or 'R', $c$ is not accessed.

If $equed = 'C'$ or 'B', each element of $c$ must be positive.

Each element of $r$ or $c$ should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

The leading dimension of the array $b$; \(ldb\geq\max(1, n)\) for column major layout and \(ldb\geq\text{nrhs}\) for row major layout.

Array, of size max(1, \(ldx\times nrhs\))) for column major layout and max(1, \(ldx\times n\)) for row major layout.

The solution matrix $X$ as computed by \texttt{getrs}.

The leading dimension of the output array $x$; \(ldx\geq\max(1, n)\) for column major layout and \(ldx\geq\text{nrhs}\) for row major layout.

Number of error bounds to return for each right hand side and each type (normwise or componentwise). See \texttt{err_bnds_norm} and \texttt{err_bnds_comp} descriptions in Output Arguments section below.

Specifies the number of parameters set in \texttt{params}. If \(\leq 0\), the \texttt{params} array is never referenced and default values are used.
Array, size nparams. Specifies algorithm parameters. If an entry is less than 0.0, that entry is filled with the default value used for that parameter. Only positions up to nparams are accessed; defaults are used for higher-numbered parameters. If defaults are acceptable, you can pass nparams = 0, which prevents the source code from accessing the params argument.

params[0] : Whether to perform iterative refinement or not. Default: 1.0

=0.0  No refinement is performed and no error bounds are computed.

=1.0  Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support double precision.

(Other values are reserved for future use.)

params[1] : Maximum number of residual computations allowed for refinement.

Default  10.0

Aggressive  Set to 100.0 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in err_bnds_norm and err_bnds_comp may no longer be trustworthy.

params[2] : Flag determining if the code will attempt to find a solution with a small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence).

Output Parameters

x  The improved solution matrix X.

rcond  Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If rcond is less than the machine precision, in particular, if rcond = 0, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned.

berr  Array, size at least max(1, nrhs). Contains the componentwise relative backward error for each solution vector x_j, that is, the smallest relative change in any element of A or B that makes x_j an exact solution.
Array of size \( nrhs * n_{\text{err_bnds}} \). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the \( i \)-th solution vector

\[
\frac{\max_j |X_{true,j} - X_{j,i}|}{\max_j |X_{j,i}|}
\]

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned.

**err=1**  "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold \( \sqrt{n} * \text{slamch}(\varepsilon) \) for single precision flavors and \( \sqrt{n} * \text{dlamch}(\varepsilon) \) for double precision flavors.

**err=2**  "Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold \( \sqrt{n} * \text{slamch}(\varepsilon) \) for single precision flavors and \( \sqrt{n} * \text{dlamch}(\varepsilon) \) for double precision flavors. This error bound should only be trusted if the previous boolean is true.

**err=3**  Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold \( \sqrt{n} * \text{slamch}(\varepsilon) \) for single precision flavors and \( \sqrt{n} * \text{dlamch}(\varepsilon) \) for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers for some appropriately scaled matrix \( Z \) are:

\[
\|Z\|_\infty \cdot \|Z^{-1}\|_\infty
\]

Let \( z=s*a \), where \( s \) scales each row by a power of the radix so all absolute row sums of \( z \) are approximately 1.

The information for right-hand side \( i \), where \( 1 \leq i \leq nrhs \), and type of error \( err \) is stored in:

- **Column major layout:** \( \text{err_bnds_norm}[(err - 1)*nrhs + i - 1] \).
- **Row major layout:** \( \text{err_bnds_norm}[err - 1 + (i - 1)*n_{\text{err_bnds}}] \)
err_bnds_comp

Array of size nrhs\times n_{\text{err\_bnds}}. For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the \(i\)-th solution vector:

\[
\max_j \frac{|X_{\text{true},ji} - X_{ji}|}{|X_{ji}|}
\]

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (\(\text{params}[2] = 0.0\)), then \(\text{err\_bnds\_comp}\) is not accessed. If \(n_{\text{err\_bnds}} < 3\), then at most the first \(n_{\text{err\_bnds}}\) columns of the \(\text{err\_bnds\_comp}\) array are returned.

**err=1**

"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold \(\sqrt{n} \cdot \text{slamch(\varepsilon)}\) for single precision flavors and \(\sqrt{n} \cdot \text{dlamch(\varepsilon)}\) for double precision flavors.

**err=2**

"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold \(\sqrt{n} \cdot \text{slamch(\varepsilon)}\) for single precision flavors and \(\sqrt{n} \cdot \text{dlamch(\varepsilon)}\) for double precision flavors. This error bound should only be trusted if the previous boolean is true.

**err=3**

Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold \(\sqrt{n} \cdot \text{slamch(\varepsilon)}\) for single precision flavors and \(\sqrt{n} \cdot \text{dlamch(\varepsilon)}\) for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers for some appropriately scaled matrix \(Z\) are:

\[
\|Z\|_\infty \cdot \|Z^{-1}\|_\infty
\]

Let \(z = s \cdot (a \cdot \text{diag}(x))\), where \(x\) is the solution for the current right-hand side and \(s\) scales each row of \(a \cdot \text{diag}(x)\) by a power of the radix so all absolute row sums of \(z\) are approximately 1.

The information for right-hand side \(i\), where \(1 \leq i \leq \text{nrhs}\), and type of error \(\text{err}\) is stored in:
• Column major layout: \( \text{err}_\text{bnds}_\text{comp}[(\text{err} - 1) \times \text{nrhs} + i - 1] \).
• Row major layout: \( \text{err}_\text{bnds}_\text{comp}[\text{err} - 1 + (i - 1) \times \text{n}_\text{err}_\text{bnds}] \)

params

Output parameter only if the input contains erroneous values, namely, in \( \text{params}[0], \text{params}[1], \text{params}[2] \). In such a case, the corresponding elements of params are filled with default values on output.

Return Values

This function returns a value info.

If \( \text{info} = 0 \), the execution is successful. The solution to every right-hand side is guaranteed.

If \( \text{info} = -i \), parameter \( i \) had an illegal value.

If \( 0 < \text{info} < \text{n} \): \( \text{U}_\text{info} \) is exactly zero. The factorization has been completed, but the factor \( U \) is exactly singular, so the solution and error bounds could not be computed; \( r\text{cond} = 0 \) is returned.

If \( \text{info} = \text{n} + j \): The solution corresponding to the \( j \)-th right-hand side is not guaranteed. The solutions corresponding to other right-hand sides \( k \) with \( k > j \) may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested \( \text{params}[2] = 0.0 \), then the \( j \)-th right-hand side is the first with a normwise error bound that is not guaranteed (the smallest \( j \) such that for column major layout \( \text{err}_\text{bnds}_\text{norm}[j - 1] = 0.0 \) or \( \text{err}_\text{bnds}_\text{comp}[j - 1] = 0.0 \); or for row major layout \( \text{err}_\text{bnds}_\text{norm}[(j - 1) \times \text{n}_\text{err}_\text{bnds}] = 0.0 \) or \( \text{err}_\text{bnds}_\text{comp}[(j - 1) \times \text{n}_\text{err}_\text{bnds}] = 0.0 \)). See the definition of \( \text{err}_\text{bnds}_\text{norm} \) and \( \text{err}_\text{bnds}_\text{comp} \) for \( \text{err} = 1 \). To get information about all of the right-hand sides, check \( \text{err}_\text{bnds}_\text{norm} \) or \( \text{err}_\text{bnds}_\text{comp} \).

Include Files

• mkl.h

Description

The routine performs an iterative refinement of the solution to a system of linear equations $A \cdot X = B$ or $A^T \cdot X = B$ with a band matrix $A$, with multiple right-hand sides. For each computed solution vector $x$, the routine computes the component-wise backward error $\beta$. This error is the smallest relative perturbation in elements of $A$ and $b$ such that $x$ is the exact solution of the perturbed system:

$$|\delta a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| \leq \beta |b_i| \quad \text{such that} \quad (A + \delta A)x = (b + \delta b).$$

Finally, the routine estimates the component-wise forward error in the computed solution $\|x - x_\|\|_\|_\infty / \|x_\|_\|_\infty$ (here $x_\|$ is the exact solution).

Before calling this routine:

• call the factorization routine ?gbtrf
• call the solver routine ?gbtrs.

Input Parameters

matrix_layout

Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

trans

Must be 'N' or 'T' or 'C'.

Indicates the form of the equations:

If trans = 'N', the system has the form $A \cdot X = B$.

If trans = 'T', the system has the form $A^T \cdot X = B$.

If trans = 'C', the system has the form $A^H \cdot X = B$.

n

The order of the matrix $A$; $n \geq 0$.

kl

The number of sub-diagonals within the band of $A$; $kl \geq 0$.

ku

The number of super-diagonals within the band of $A$; $ku \geq 0$.

nrhs

The number of right-hand sides; $nrhs \geq 0$.

ab, afb, b, x

Arrays:

$ab$(size max(1, ldab*n)) contains the original band matrix $A$, as supplied to ?gbtrf, but stored in rows from 1 to $kl + ku + 1$ for column major layout, and columns from 1 to $kl + ku + 1$ for row major layout.

$afb$(size max(1, ldafb*n)) contains the factored band matrix $A$, as returned by ?gbtrf.

$b$(size max(1, ldb*nrhs) for column major layout and max(1, ldx*n) for row major layout) contains the right-hand side matrix $B$. 
The leading dimension of $ab$, $ldab \geq kl + ku + 1$.

The leading dimension of $afb$, $ldafb \geq 2*kl + ku + 1$.

The leading dimension of $b$; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout.

The leading dimension of $x$; $ldx \geq \max(1, n)$.

Array, size at least $\max(1, n)$. The $ipiv$ array, as returned by $?gbtrf$.

### Output Parameters

- $x$:
The refined solution matrix $X$.

- $ferr, berr$:
Arrays, size at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.

### Return Values

This function returns a value $info$.

If $info = 0$, the execution is successful.

If $info = -i$, parameter $i$ had an illegal value.

### Application Notes

The bounds returned in $ferr$ are not rigorous, but in practice they almost always overestimate the actual error.

For each right-hand side, computation of the backward error involves a minimum of $4n(kl + ku)$ floating-point operations (for real flavors) or $16n(kl + ku)$ operations (for complex flavors). In addition, each step of iterative refinement involves $2n(4kl + 3ku)$ operations (for real flavors) or $8n(4kl + 3ku)$ operations (for complex flavors); the number of iterations may range from 1 to 5. Estimating the forward error involves solving a number of systems of linear equations $A^*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2n^2$ floating-point operations for real flavors or $8n^2$ for complex flavors.

Include Files

- mkl.h

Description

The routine improves the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution. In addition to a normwise error bound, the code provides a maximum componentwise error bound, if possible. See comments for err_bnds_norm and err_bnds_comp for details of the error bounds.

The original system of linear equations may have been equilibrated before calling this routine, as described by the parameters equed, r, and c below. In this case, the solution and error bounds returned are for the original unequilibrated system.

Input Parameters

matrix_layout

Specifies whether two-dimensional array storage is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

trans

Must be 'N', 'T', or 'C'.

Specifies the form of the system of equations:

- If trans = 'N', the system has the form A*X = B (No transpose).
- If trans = 'T', the system has the form A^T*X = B (Transpose).
- If trans = 'C', the system has the form A^H*X = B (Conjugate transpose for complex flavors, Transpose for real flavors).

equed

Must be 'N', 'R', 'C', or 'B'.

Specifies the form of equilibration that was done to A before calling this routine.

- If equed = 'N', no equilibration was done.
If `equed = 'R'`, row equilibration was done, that is, \( A \) has been premultiplied by \( \text{diag}(r) \).

If `equed = 'C'`, column equilibration was done, that is, \( A \) has been postmultiplied by \( \text{diag}(c) \).

If `equed = 'B'`, both row and column equilibration was done, that is, \( A \) has been replaced by \( \text{diag}(r) \cdot A \cdot \text{diag}(c) \). The right-hand side \( B \) has been changed accordingly.

The number of linear equations; the order of the matrix \( A \); \( n \geq 0 \).

The number of subdiagonals within the band of \( A \); \( kl \geq 0 \).

The number of superdiagonals within the band of \( A \); \( ku \geq 0 \).

The number of right-hand sides; the number of columns of the matrices \( B \) and \( X \); \( nrhs \geq 0 \).

The array \( ab \) of size \( \max(1, \text{ldab} \cdot n) \) contains the original matrix \( A \) in band storage, in rows from 1 to \( kl + ku + 1 \) for column major layout, and in columns from 1 to \( kl + ku + 1 \) for row major layout.

The array \( afb \) of size \( \max(1, \text{ldafb} \cdot n) \) contains details of the LU factorization of the banded matrix \( A \) as computed by \( ?\text{gbtrf} \).

The array \( b \) of size \( \max(1, \text{ldb} \cdot nrhs) \) for column major layout and \( \max(1, \text{ldb} \cdot n) \) for row major layout contains the matrix \( B \) whose columns are the right-hand sides for the systems of equations.

The leading dimension of the array \( ab \); \( \text{ldab} \geq kl + ku + 1 \).

The leading dimension of the array \( afb \); \( \text{ldafb} \geq 2 \cdot kl + ku + 1 \).

Array, size at least \( \max(1, n) \). Contains the pivot indices as computed by \( ?\text{gbtrf} \); for row \( 1 \leq i \leq n \), row \( i \) of the matrix was interchanged with row \( \text{ipiv}[i-1] \).

Arrays: \( r(n) \), \( c(n) \). The array \( r \) contains the row scale factors for \( A \), and the array \( c \) contains the column scale factors for \( A \).

If `equed = 'R'` or `'B'`, \( A \) is multiplied on the left by \( \text{diag}(r) \); if `equed = 'N'` or `'C'`, \( r \) is not accessed.

If `equed = 'R'` or `'B'`, each element of \( r \) must be positive.

If `equed = 'C'` or `'B'`, \( A \) is multiplied on the right by \( \text{diag}(c) \); if `equed = 'N'` or `'R'`, \( c \) is not accessed.

If `equed = 'C'` or `'B'`, each element of \( c \) must be positive.

Each element of \( r \) or \( c \) should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

The leading dimension of the array \( b \); \( \text{ldb} \geq \max(1, n) \) for column major layout and \( \text{ldb} \geq nrhs \) for row major layout.
x

Array, size max(1, ldx*nrhs) for column major layout and max(1, ldx*n) for row major layout.
The solution matrix $X$ as computed by `sbgtrs/dgbtrs` for real flavors or `cgbtrs/zgbtrs` for complex flavors.

ldx

The leading dimension of the output array $x$; $ldx \geq \max(1, n)$ for column major layout and $ldx \geq nrhs$ for row major layout.

n_err_bnds

Number of error bounds to return for each right-hand side and each type (normwise or componentwise). See `err_bnds_norm` and `err_bnds_comp` descriptions in **Output Arguments** section below.

nparams

Specifies the number of parameters set in `params`. If $\leq 0$, the `params` array is never referenced and default values are used.

params

Array, size `nparams`. Specifies algorithm parameters. If an entry is less than 0.0, that entry will be filled with the default value used for that parameter. Only positions up to `nparams` are accessed; defaults are used for higher-numbered parameters. If defaults are acceptable, you can pass `nparams = 0`, which prevents the source code from accessing the `params` argument.

`params[0]`: Whether to perform iterative refinement or not. Default: 1.0 (for single precision flavors), 1.0D+0 (for double precision flavors).

- **=0.0**: No refinement is performed and no error bounds are computed.
- **=1.0**: Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support double precision.

(Other values are reserved for future use.)

`params[1]`: Maximum number of residual computations allowed for refinement.

Default 10.0

Aggressive

Set to 100.0 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in `err_bnds_norm` and `err_bnds_comp` may no longer be trustworthy.

`params[2]`: Flag determining if the code will attempt to find a solution with a small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence).

**Output Parameters**

x

The improved solution matrix $X$. 

---

536
Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix $A$ after equilibration (if done). If $rcond$ is less than the machine precision, in particular, if $rcond = 0$, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned.

Array, size at least max(1, nrhs). Contains the componentwise relative backward error for each solution vector $x_j$, that is, the smallest relative change in any element of $A$ or $B$ that makes $x_j$ an exact solution.

Array of size $nrhs \times n\_err\_bnds$. For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

$$\frac{\max_j |X_{true,j} - X_{j,i}|}{\max_j |X_{j,i}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned.

$err=1$  
"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} \times \text{slamch}(\varepsilon)$ for single precision flavors and $\sqrt{n} \times \text{dlamch}(\varepsilon)$ for double precision flavors.

$err=2$  
"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} \times \text{slamch}(\varepsilon)$ for single precision flavors and $\sqrt{n} \times \text{dlamch}(\varepsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.

$err=3$  
Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold $\sqrt{n} \times \text{slamch}(\varepsilon)$ for single precision flavors and $\sqrt{n} \times \text{dlamch}(\varepsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers for some appropriately scaled matrix $Z$ are

$$\|Z\|_\infty \cdot \|Z^{-1}\|_\infty$$

Let $z = s \times a$, where $s$ scales each row by a power of the radix so all absolute row sums of $z$ are approximately 1.

The information for right-hand side $i$, where $1 \leq irhs$, and type of error $err$ is stored in:
- Column major layout: $\text{err\_bnds\_norm}[(\text{err} - 1)\cdot \text{nrhs} + i - 1]$.
- Row major layout: $\text{err\_bnds\_norm}[	ext{err} - 1 + (i - 1)\cdot n\_err\_bnds]$

Array of size $\text{nrhs}\cdot n\_err\_bnds$. For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the $i$-th solution vector:

$$\max \frac{|X_{true_{ij}} - X_{ii}|}{|X_{ii}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested ($\text{params}[2] = 0.0$), then $\text{err\_bnds\_comp}$ is not accessed.

$\text{err}=1$  
"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n}\cdot \text{slamch}(\varepsilon)$ for single precision flavors and $\sqrt{n}\cdot \text{dlamch}(\varepsilon)$ for double precision flavors.

$\text{err}=2$  
"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n}\cdot \text{slamch}(\varepsilon)$ for single precision flavors and $\sqrt{n}\cdot \text{dlamch}(\varepsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.

$\text{err}=3$  
Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold $\sqrt{n}\cdot \text{slamch}(\varepsilon)$ for single precision flavors and $\sqrt{n}\cdot \text{dlamch}(\varepsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers for some appropriately scaled matrix $Z$ are

$$\|Z\|\cdot \|Z^{-1}\|$$

Let $z = s\cdot(a\cdot\text{diag}(x))$, where $x$ is the solution for the current right-hand side and $s$ scales each row of $a\cdot\text{diag}(x)$ by a power of the radix so all absolute row sums of $z$ are approximately 1.

The information for right-hand side $i$, where $1 \leq i \leq \text{nrhs}$, and type of error $\text{err}$ is stored in:

- Column major layout: $\text{err\_bnds\_comp}[(\text{err} - 1)\cdot \text{nrhs} + i - 1]$.
Row major layout: \( \text{err\_bnds\_comp}[\text{err} - 1 + (i - 1)\times\text{n\_err\_bnds}] \)

Output parameter only if the input contains erroneous values, namely, in \( \text{params}[0], \text{params}[1], \) and \( \text{params}[2] \). In such a case, the corresponding elements of \( \text{params} \) are filled with default values on output.

**Return Values**

This function returns a value \( \text{info} \).

If \( \text{info} = 0 \), the execution is successful. The solution to every right-hand side is guaranteed.

If \( \text{info} = -i \), parameter \( i \) had an illegal value.

If \( 0 < \text{info} \leq n \): \( \text{U}^{\text{info}} \), \( \text{info} \) is exactly zero. The factorization has been completed, but the factor \( \text{U} \) is exactly singular, so the solution and error bounds could not be computed; \( \text{rcond} = 0 \) is returned.

If \( \text{info} = n + j \): The solution corresponding to the \( j \)-th right-hand side is not guaranteed. The solutions corresponding to other right-hand sides \( k \) with \( k > j \) may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested \( \text{params}[2] = 0.0 \), then the \( j \)-th right-hand side is the first with a normwise error bound that is not guaranteed (the smallest \( j \) such that for column major layout \( \text{err\_bnds\_norm}[j - 1] = 0.0 \) or \( \text{err\_bnds\_comp}[j - 1] = 0.0 \); or for row major layout \( \text{err\_bnds\_norm}[(j - 1)\times\text{n\_err\_bnds}] = 0.0 \) or \( \text{err\_bnds\_comp}[(j - 1)\times\text{n\_err\_bnds}] = 0.0 \). See the definition of \( \text{err\_bnds\_norm} \) and \( \text{err\_bnds\_comp} \) for \( \text{err} = 1 \). To get information about all of the right-hand sides, check \( \text{err\_bnds\_norm} \) or \( \text{err\_bnds\_comp} \).

• mkl.h

Description
The routine performs an iterative refinement of the solution to a system of linear equations \( A \mathbf{x} = \mathbf{b} \) or \( A^\top \mathbf{x} = \mathbf{b} \) or \( A^H \mathbf{x} = \mathbf{b} \) with a tridiagonal matrix \( A \), with multiple right-hand sides. For each computed solution vector \( \mathbf{x} \), the routine computes the component-wise backward error \( \beta \). This error is the smallest relative perturbation in elements of \( A \) and \( b \) such that \( \mathbf{x} \) is the exact solution of the perturbed system:

\[
\frac{|\delta a_{ij}|}{|a_{ij}|} \leq \beta, \quad \frac{|\delta b_i|}{|b_i|} \leq \beta \quad \text{such that} \quad (A + \delta A) \mathbf{x} = (b + \delta b).
\]

Finally, the routine estimates the component-wise forward error in the computed solution \( \| \mathbf{x} - \mathbf{x}_e \|_\infty / \| \mathbf{x} \|_\infty \) (here \( \mathbf{x}_e \) is the exact solution).

Before calling this routine:
• call the factorization routine ?gttrf
• call the solver routine ?gttrs.

Input Parameters

- **matrix_layout**: Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **trans**: Must be 'N' or 'T' or 'C'.

- **n**: The order of the matrix \( A \); \( n \geq 0 \).

- **nrhs**: The number of right-hand sides, that is, the number of columns of the matrix \( B \); \( nrhs \geq 0 \).

- **dl**: Array \( d_l \) of size \( n - 1 \) contains the subdiagonal elements of \( A \).

- **d**: Array \( d \) of size \( n \) contains the diagonal elements of \( A \).

- **du**: Array \( d_u \) of size \( n - 1 \) contains the superdiagonal elements of \( A \).

- **dlf**: Array \( d_{lf} \) of size \( n - 1 \) contains the \((n - 1)\) multipliers that define the matrix \( L \) from the LU factorization of \( A \) as computed by ?gttrf.

- **df**: Array \( df \) of size \( n \) contains the \( n \) diagonal elements of the upper triangular matrix \( U \) from the LU factorization of \( A \).

- **duf**: Array \( d_{uf} \) of size \( n - 1 \) contains the \((n - 1)\) elements of the first superdiagonal of \( U \).

- **du2**: Array \( d_{u2} \) of size \( n - 2 \) contains the \((n - 2)\) elements of the second superdiagonal of \( U \).
$b$ (size max(1, $ldb \times nrhs$) for column major layout and max(1, $ldb \times n$) for row major layout) contains the right-hand side matrix $B$.

$x$ (size max(1, $ldx \times nrhs$) for column major layout and max(1, $ldx \times n$) contains the solution matrix $X$, as computed by $\texttt{?gttrs}$.

$ldb$ The leading dimension of $b$; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq \max(1, nrhs)$ for row major layout.

$ldx$ The leading dimension of $x$; $ldx \geq \max(1, n)$ for column major layout and $ldx \geq \max(1, nrhs)$ for row major layout.

$ipiv$ Array, size at least $\max(1, n)$. The $ipiv$ array, as returned by $\texttt{?gttrf}$.

**Output Parameters**

$x$ The refined solution matrix $X$.

$ferr, berr$ Arrays, size at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.

**Return Values**

This function returns a value $info$.

If $info = 0$, the execution is successful.

If $info = -i$, parameter $i$ had an illegal value.

Description
The routine performs an iterative refinement of the solution to a system of linear equations \( A \cdot X = B \) with a symmetric (Hermitian) positive definite matrix \( A \), with multiple right-hand sides. For each computed solution vector \( x \), the routine computes the component-wise backward error. This error is the smallest relative perturbation in elements of \( A \) and \( b \) such that \( x \) is the exact solution of the perturbed system:

\[
|\delta a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| \leq \beta |b_i| \quad \text{such that} \quad (A + \delta A) \cdot x = (b + \delta b).
\]

Finally, the routine estimates the component-wise forward error in the computed solution \( \|x - x_e\|_\infty / \|x\|_\infty \) (here \( x_e \) is the exact solution).

Before calling this routine:
• call the factorization routine \( ?potrf \)
• call the solver routine \( ?potrs \).

Input Parameters

- **matrix_layout**: Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- **uplo**: Must be 'U' or 'L'.
  - If \( \text{uplo} = 'U' \), the upper triangle of \( A \) is stored.
  - If \( \text{uplo} = 'L' \), the lower triangle of \( A \) is stored.
- **n**: The order of the matrix \( A ; n \geq 0 \).
- **nrhs**: The number of right-hand sides; \( nrhs \geq 0 \).
- **a**: Array (size max(1, lda*n)) contains the original matrix \( A \), as supplied to \( ?potrf \).
- **af**: Array (size max(1, ldaf*n)) contains the factored matrix \( A \), as returned by \( ?potrf \).
- **b**: Array (size max(1, ldb*nrhs)) for column major layout and max(1, ldb*n) for row major layout contains the right-hand side matrix \( B \).
  - The second dimension of \( B \) must be at least max(1, nrhs).
- **x**: Array (size max(1, ldx*nrhs)) for column major layout and max(1, ldx*n) for row major layout contains the solution matrix \( X \).
- **lda**: The leading dimension of \( a ; lda \geq \text{max}(1, n) \).
- **ldaf**: The leading dimension of \( af ; ldaf \geq \text{max}(1, n) \).
- **ldb**: The leading dimension of \( b ; ldb \geq \text{max}(1, n) \) for column major layout and \( ldb \geq nrhs \) for row major layout.
- **ldx**: The leading dimension of \( x ; ldx \geq \text{max}(1, n) \) for column major layout and \( ldx \geq nrhs \) for row major layout.
Output Parameters

\[ x \]

The refined solution matrix \( X \).

\[ ferr, berr \]

Arrays, size at least \( \max(1, nrhs) \). Contain the component-wise forward and backward errors, respectively, for each solution vector.

Return Values

This function returns a value \( info \).

If \( info = 0 \), the execution is successful.

If \( info = -i \), parameter \( i \) had an illegal value.

Application Notes

The bounds returned in \( ferr \) are not rigorous, but in practice they almost always overestimate the actual error.

For each right-hand side, computation of the backward error involves a minimum of \( 4n^2 \) floating-point operations (for real flavors) or \( 16n^2 \) operations (for complex flavors). In addition, each step of iterative refinement involves \( 6n^2 \) operations (for real flavors) or \( 24n^2 \) operations (for complex flavors); the number of iterations may range from 1 to 5. Estimating the forward error involves solving a number of systems of linear equations \( A^*x = b \); the number is usually 4 or 5 and never more than 11. Each solution requires approximately \( 2n^2 \) floating-point operations for real flavors or \( 8n^2 \) for complex flavors.

Include Files
• mkl.h

Description
The routine improves the computed solution to a system of linear equations and provides error bounds and
backward error estimates for the solution. In addition to a normwise error bound, the code provides a
maximum componentwise error bound, if possible. See comments for err_bnds_norm and err_bnds_comp
for details of the error bounds.

The original system of linear equations may have been equilibrated before calling this routine, as described
by the parameters equed and s below. In this case, the solution and error bounds returned are for the
original unequilibrated system.

Input Parameters

**matrix_layout**
- Specifies whether two-dimensional array storage is row major
  (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

**uplo**
- Must be 'U' or 'L'.
- Indicates whether the upper or lower triangular part of A is stored:
  - If uplo = 'U', the upper triangle of A is stored.
  - If uplo = 'L', the lower triangle of A is stored.

**equed**
- Must be 'N' or 'Y'.
- Specifies the form of equilibration that was done to A before calling this
  routine.
  - If equed = 'N', no equilibration was done.
  - If equed = 'Y', both row and column equilibration was done, that is, A has
    been replaced by diag(s)*A*diag(s). The right-hand side B has been
    changed accordingly.

**n**
- The number of linear equations; the order of the matrix A; n ≥ 0.

**nrhs**
- The number of right-hand sides; the number of columns of the matrices B
  and X; nrhs ≥ 0.

**a**
- The array a (size max(1, lda*n)) contains the symmetric/Hermitian matrix
  A as specified by uplo. If uplo = 'U', the leading n-by-n upper triangular
  part of a contains the upper triangular part of the matrix A and the strictly
  lower triangular part of a is not referenced. If uplo = 'L', the leading n-
  by-n lower triangular part of a contains the lower triangular part of the
  matrix A and the strictly upper triangular part of a is not referenced.
The array \( af \) (size max(1, \( ldaf \times n \))) contains the triangular factor \( L \) or \( U \) from the Cholesky factorization \( A = U^T U \) or \( A = L^T L \) as computed by \texttt{spotrf} for real flavors or \texttt{dpotrf} for complex flavors.

The array \( b \) (size max(1, \( ldb \times nrhs \)) for column major layout and max(1, \( ldb \times n \)) for row major layout) contains the matrix \( B \) whose columns are the right-hand sides for the systems of equations.

The leading dimension of \( a \); \( lda \geq \max(1, n) \).

The leading dimension of \( af \); \( ldaf \geq \max(1, n) \).

Array of size \( n \). The array \( s \) contains the scale factors for \( A \).

If \( \texttt{equed} = 'N' \), \( s \) is not accessed.

If \( \texttt{equed} = 'Y' \), each element of \( s \) must be positive.

Each element of \( s \) should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

The leading dimension of the array \( b \); \( ldb \geq \max(1, n) \) for column major layout and \( ldb \geq nrhs \) for row major layout.

Array, size max(1, \( ldx \times nrhs \)) for column major layout and max(1, \( ldx \times n \)) for row major layout.

The solution matrix \( X \) as computed by \texttt{?potrs}

The leading dimension of the output array \( x \); \( ldx \geq \max(1, n) \) for column major layout and \( ldx \geq nrhs \) for row major layout.

Number of error bounds to return for each right hand side and each type (normwise or componentwise). See \texttt{err_bnds_norm} and \texttt{err_bnds_comp} descriptions in \texttt{Output Arguments} section below.

Specifies the number of parameters set in \( \texttt{params} \). If \( \leq 0 \), the \( \texttt{params} \) array is never referenced and default values are used.

Array, size \( nparams \). Specifies algorithm parameters. If an entry is less than 0.0, that entry will be filled with the default value used for that parameter. Only positions up to \( nparams \) are accessed; defaults are used for higher-numbered parameters. If defaults are acceptable, you can pass \( nparams = 0 \), which prevents the source code from accessing the \( \texttt{params} \) argument.

\( \texttt{params}[0] \): Whether to perform iterative refinement or not. Default: 1.0 (for single precision flavors), 1.0D0 (for double precision flavors).

\( =0.0 \) No refinement is performed and no error bounds are computed.

\( =1.0 \) Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support double precision.

(Other values are reserved for future use.)
**params[1]**: Maximum number of residual computations allowed for refinement.

- **Default**: 10.0
- **Aggressive**: Set to 100.0 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in **err_bnds_norm** and **err_bnds_comp** may no longer be trustworthy.

**params[2]**: Flag determining if the code will attempt to find a solution with a small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence).

### Output Parameters

- **x**: The improved solution matrix $X$.
- **rcond**: Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix $A$ after equilibration (if done). If $rcond$ is less than the machine precision, in particular, if $rcond = 0$, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned.
- **berr**: Array, size at least $\max(1, nrhs)$. Contains the componentwise relative backward error for each solution vector $x_j$, that is, the smallest relative change in any element of $A$ or $B$ that makes $x_j$ an exact solution.
- **err_bnds_norm**: Array of size $nrhs*\text{n_err_bnds}$. For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

\[
\frac{\max_j |x_j^{\text{true}} - x_j^i|}{\max_j |x_j^i|}
\]

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned.

- **err=1**: "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors.

- **err=2**: "Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and
Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold \( \sqrt{n} \cdot \text{slamch}(\varepsilon) \) for single precision flavors and \( \sqrt{n} \cdot \text{dlamch}(\varepsilon) \) for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers for some appropriately scaled matrix \( Z \) are

\[
\|Z\|_\infty \cdot \|Z^{-1}\|_\infty
\]

Let \( z = s \cdot a \), where \( s \) scales each row by a power of the radix so all absolute row sums of \( z \) are approximately 1.

The information for right-hand side \( i \), where \( 1 \leq i \leq \text{nrhs} \), and type of error \( err \) is stored in:

- Column major layout: \( \text{err_bnds_norm}[\text{(err - 1)} \cdot \text{nrhs} + i - 1] \).
- Row major layout: \( \text{err_bnds_norm}[(\text{err} - 1) + (i - 1) \cdot \text{n_err_bnds}] \)

Array of size \( \text{nrhs} \cdot \text{n_err_bnds} \). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the \( i \)-th solution vector:

\[
\max_j \left\| \frac{X_{\text{true},ij} - X_{ij}}{|X_{ij}|} \right\|
\]

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (\( \text{params}[2] = 0.0 \)), then \( \text{err_bnds_comp} \) is not accessed.

\( err = 1 \)

"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold \( \sqrt{n} \cdot \text{slamch}(\varepsilon) \) for single precision flavors and \( \sqrt{n} \cdot \text{dlamch}(\varepsilon) \) for double precision flavors.

\( err = 2 \)

"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold \( \sqrt{n} \cdot \text{slamch}(\varepsilon) \) for single precision flavors and
sqrt(n)*dlamch(e) for double precision flavors. This error bound should only be trusted if the previous boolean is true.

Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold
sqrt(n)*slamch(e) for single precision flavors and sqrt(n)*dlamch(e) for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers for some appropriately scaled matrix Z are

\[ \|Z\|_\infty \cdot \|Z^{-1}\|_\infty \]

Let \( z = s \cdot (a \cdot \text{diag}(x)) \), where \( x \) is the solution for the current right-hand side and \( s \) scales each row of \( a \cdot \text{diag}(x) \) by a power of the radix so all absolute row sums of \( z \) are approximately 1.

The information for right-hand side \( i \), where \( 1 \leq i \leq \text{nrhs} \), and type of error \( \text{err} \) is stored in:

- Column major layout: \( \text{err_bnds_comp}[(\text{err} - 1)\cdot\text{nrhs} + i - 1] \).
- Row major layout: \( \text{err_bnds_comp}[\text{err} - 1 + (i - 1)\cdot\text{n_err_bnds}] \).

Output parameter only if the input contains erroneous values, namely in \( \text{params}[0], \text{params}[1], \) or \( \text{params}[2] \). In such a case, the corresponding elements of \( \text{params} \) are filled with default values on output.

Return Values
This function returns a value \( \text{info} \).

If \( \text{info} = 0 \), the execution is successful. The solution to every right-hand side is guaranteed.

If \( \text{info} = -i \), parameter \( i \) had an illegal value.

If \( 0 < \text{info} < n \): \( U^{\text{info},\text{info}} \) is exactly zero. The factorization has been completed, but the factor \( U \) is exactly singular, so the solution and error bounds could not be computed; \( rcond = 0 \) is returned.

If \( \text{info} = n+j \): The solution corresponding to the \( j \)-th right-hand side is not guaranteed. The solutions corresponding to other right-hand sides \( k \) with \( k > j \) may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested \( \text{params}[2] = 0.0 \), then the \( j \)-th right-hand side is the first with a normwise error bound that is not guaranteed (the smallest \( j \) such that for column major layout \( \text{err_bnds_norm}[j - 1] = 0.0 \) or \( \text{err_bnds_comp}[j - 1] = 0.0 \); or for row major layout \( \text{err_bnds_norm}[(j - 1)\cdot\text{n_err_bnds}] = 0.0 \) or \( \text{err_bnds_comp}[(j - 1)\cdot\text{n_err_bnds}] = 0.0 \)). See the definition of \( \text{err_bnds_norm} \) and \( \text{err_bnds_comp} \) for \( \text{err} = 1 \). To get information about all of the right-hand sides, check \( \text{err_bnds_norm} \) or \( \text{err_bnds_comp} \).

Include Files

- mkl.h

Description

The routine performs an iterative refinement of the solution to a system of linear equations \( A \times X = B \) with a symmetric (Hermitian) positive definite matrix \( A \), with multiple right-hand sides. For each computed solution vector \( x \), the routine computes the component-wise backward error. This error is the smallest relative perturbation in elements of \( A \) and \( b \) such that \( x \) is the exact solution of the perturbed system:

\[
|\delta a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| \leq \beta |b_i| \quad \text{such that} \quad (A + \delta A) x = (b + \delta b).
\]

Finally, the routine estimates the component-wise forward error in the computed solution

\[
\|x - x_e\|_\infty / \|x\|_\infty
\]

where \( x_e \) is the exact solution.

Before calling this routine:

- call the factorization routine ?pptrf
- call the solver routine ?pptrs.

Input Parameters

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **uplo**
  Must be 'U' or 'L'.

  Indicates how the input matrix \( A \) has been factored:
  - If \( \text{uplo} = 'U' \), the upper triangle of \( A \) is stored.
  - If \( \text{uplo} = 'L' \), the lower triangle of \( A \) is stored.
The order of the matrix \( A \); \( n \geq 0 \).

The number of right-hand sides; \( nrhs \geq 0 \).

\( ap \) contains the original matrix \( A \) in a packed format, as supplied to \(?pptrf\). The dimension of \( ap \) must be at least \( \max(1, n(n+1)/2) \).

\( afp \) contains the factored matrix \( A \) in a packed format, as returned by \(?pptrf\). The dimension of \( afp \) must be at least \( \max(1, n(n+1)/2) \).

Array \( b \) of size \( \max(1, ldb*nrhs) \) for column major layout and \( \max(1, ldb*n) \) for row major layout contains the right-hand side matrix \( B \).

Array \( x \) of size \( \max(1, ldx*nrhs) \) for column major layout and \( \max(1, ldx*n) \) for row major layout contains the solution matrix \( X \).

The leading dimension of \( b \); \( ldb \geq \max(1, n) \) for column major layout and \( ldb \geq nrhs \) for row major layout.

The leading dimension of \( x \); \( ldx \geq \max(1, n) \) for column major layout and \( ldx \geq nrhs \) for row major layout.

**Output Parameters**

\( x \) The refined solution matrix \( X \).

\( ferr, berr \) Arrays, size at least \( \max(1, nrhs) \). Contain the component-wise forward and backward errors, respectively, for each solution vector.

**Return Values**

This function returns a value \( info \).

If \( info=0 \), the execution is successful.

If \( info = -i \), parameter \( i \) had an illegal value.

**Application Notes**

The bounds returned in \( ferr \) are not rigorous, but in practice they almost always overestimate the actual error.

For each right-hand side, computation of the backward error involves a minimum of \( 4n^2 \) floating-point operations (for real flavors) or \( 16n^2 \) operations (for complex flavors). In addition, each step of iterative refinement involves \( 6n^2 \) operations (for real flavors) or \( 24n^2 \) operations (for complex flavors); the number of iterations may range from 1 to 5.

Estimating the forward error involves solving a number of systems of linear equations \( A^*x = b \); the number of systems is usually 4 or 5 and never more than 11. Each solution requires approximately \( 2n^2 \) floating-point operations for real flavors or \( 8n^2 \) for complex flavors.

Description

The routine performs an iterative refinement of the solution to a system of linear equations \( A X = B \) with a symmetric (Hermitian) positive definite band matrix \( A \), with multiple right-hand sides. For each computed solution vector \( x \), the routine computes the component-wise backward error. This error is the smallest relative perturbation in elements of \( A \) and \( b \) such that \( x \) is the exact solution of the perturbed system:

\[
|\delta a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| \leq \beta |b_i| \quad \text{such that} \quad (A + \delta A)x = (b + \delta b).
\]

Finally, the routine estimates the component-wise forward error in the computed solution \( ||x - x_e||_\infty / ||x||_\infty \) (here \( x_e \) is the exact solution).

Before calling this routine:
- call the factorization routine \(?pbtrf\)
- call the solver routine \(?pbtrs\).

Input Parameters

- `matrix_layout`: Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- `uplo`: Must be 'U' or 'L'. Indicates how the input matrix \( A \) has been factored:
  - If `uplo` = 'U', the upper triangle of \( A \) is stored.
  - If `uplo` = 'L', the lower triangle of \( A \) is stored.
- `n`: The order of the matrix \( A \); \( n \geq 0 \).
- `kd`: The number of superdiagonals or subdiagonals in the matrix \( A \); \( kd \geq 0 \).
- `nrhs`: The number of right-hand sides; \( nrhs \geq 0 \).
$ab$

Array $ab$ (size max($ldab\times n$)) contains the original band matrix $A$, as supplied to ?pbtrf.

$afb$

Array $afb$ (size max($ldafb\times n$)) contains the factored band matrix $A$, as returned by ?pbtrf.

$b$

Array $b$ of size max($1, ldb\times nrhs$) for column major layout and max($1, ldb\times n$) for row major layout contains the right-hand side matrix $B$.

$x$

Array $x$ of size max($1, ldx\times nrhs$) for column major layout and max($1, ldx\times n$) for row major layout contains the solution matrix $X$.

$ldab$

The leading dimension of $ab$; $ldab\geq kd + 1$.

$ldafb$

The leading dimension of $afb$; $ldafb\geq kd + 1$.

$ldb$

The leading dimension of $b$; $ldb\geq\text{max}(1, n)$ for column major layout and $ldb\geq\text{nrhs}$ for row major layout.

$ldx$

The leading dimension of $x$; $ldx\geq\text{max}(1, n)$ for column major layout and $ldx\geq\text{nrhs}$ for row major layout.

Output Parameters

$x$

The refined solution matrix $X$.

$ferr, berr$

Arrays, size at least max($1, nrhs$). Contain the component-wise forward and backward errors, respectively, for each solution vector.

Return Values

This function returns a value $info$. If $info = 0$, the execution is successful. If $info = -i$, parameter $i$ had an illegal value.

Application Notes

The bounds returned in $ferr$ are not rigorous, but in practice they almost always overestimate the actual error.

For each right-hand side, computation of the backward error involves a minimum of $8n\times kd$ floating-point operations (for real flavors) or $32n\times kd$ operations (for complex flavors). In addition, each step of iterative refinement involves $12n\times kd$ operations (for real flavors) or $48n\times kd$ operations (for complex flavors); the number of iterations may range from 1 to 5.

Estimating the forward error involves solving a number of systems of linear equations $A^*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $4n\times kd$ floating-point operations for real flavors or $16n\times kd$ for complex flavors.

Description

The routine performs an iterative refinement of the solution to a system of linear equations $A \cdot X = B$ with a symmetric (Hermitian) positive definite tridiagonal matrix $A$, with multiple right-hand sides. For each computed solution vector $x$, the routine computes the component-wise backward error $\beta$. This error is the smallest relative perturbation in elements of $A$ and $b$ such that $x$ is the exact solution of the perturbed system:

$$|\delta a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| \leq \beta |b_i|$$

such that $(A + \delta A) \cdot x = (b + \delta b)$.

Finally, the routine estimates the component-wise forward error in the computed solution $\|x - x_e\|/\|x\|$ (here $x_e$ is the exact solution).

Before calling this routine:

- call the factorization routine $\texttt{?pttrf}$
- call the solver routine $\texttt{?pttrs}$.

Input Parameters

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **uplo**
  Used for complex flavors only. Must be 'U' or 'L'.
  Specifies whether the superdiagonal or the subdiagonal of the tridiagonal matrix $A$ is stored and how $A$ is factored:
  - If $\text{uplo} = 'U'$, the array $e$ stores the superdiagonal of $A$, and $A$ is factored as $U^H \cdot D \cdot U$.
  - If $\text{uplo} = 'L'$, the array $e$ stores the subdiagonal of $A$, and $A$ is factored as $L \cdot D \cdot L^H$.

- **n**
  The order of the matrix $A; n \geq 0$.

- **nrhs**
  The number of right-hand sides; $nrhs \geq 0$. 

553
The array \( d \) (size \( n \)) contains the \( n \) diagonal elements of the tridiagonal matrix \( A \).

The array \( df \) (size \( n \)) contains the \( n \) diagonal elements of the diagonal matrix \( D \) from the factorization of \( A \) as computed by \(?pttrf\).

The array \( e \) (size \( n - 1 \)) contains the \((n - 1)\) off-diagonal elements of the tridiagonal matrix \( A \) (see \( uplo \)).

The array \( ef \) (size \( n - 1 \)) contains the \((n - 1)\) off-diagonal elements of the unit bidiagonal factor \( U \) or \( L \) from the factorization computed by \(?pttrf\) (see \( uplo \)).

The array \( b \) of size \( \max(1, ldb*nrhs) \) for column major layout and \( \max(1, ldx*n) \) for row major layout contains the matrix \( B \) whose columns are the right-hand sides for the systems of equations.

The array \( x \) of size \( \max(1, ldx*nrhs) \) for column major layout and \( \max(1, ldx*n) \) for row major layout contains the solution matrix \( X \) as computed by \(?pttrs\).

The leading dimension of \( b \); \( ldb \geq \max(1, n) \) for column major layout and \( ldb \geq nrhs \) for row major layout.

The leading dimension of \( x \); \( ldx \geq \max(1, n) \) for column major layout and \( ldx \geq nrhs \) for row major layout.

Output Parameters

- \( x \): The refined solution matrix \( X \).
- \( ferr, berr \): Arrays, size at least \( \max(1, nrhs) \). Contain the component-wise forward and backward errors, respectively, for each solution vector.

Return Values

This function returns a value \( info \).

If \( info = 0 \), the execution is successful.

If \( info = -i \), parameter \( i \) had an illegal value.

Matrix Storage Schemes

\(?syrs\)

Refines the solution of a system of linear equations with a symmetric coefficient matrix and estimates its error.

Syntax

```c
lapack_int LAPACKE_ssyrs( int matrix_layout, char uplo, lapack_int n, lapack_int nrhs, const float* a, lapack_int lda, const float* af, lapack_int ldaf, const lapack_int* ipiv, const float* b, lapack_int ldb, float* x, lapack_int ldx, float* ferr, float* berr );
```
The routine performs an iterative refinement of the solution to a system of linear equations \( A^*X = B \) with a symmetric full-storage matrix \( A \), with multiple right-hand sides. For each computed solution vector \( x \), the routine computes the component-wise backward error. This error is the smallest relative perturbation in elements of \( A \) and \( b \) such that \( x \) is the exact solution of the perturbed system:

\[
|\delta a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| \leq \beta |b_i| \quad \text{such that} \quad (A + \delta A)x = (b + \delta b).
\]

Finally, the routine estimates the component-wise forward error in the computed solution \( || x - x_e ||_\infty / || x ||_\infty \) (here \( x_e \) is the exact solution).

Before calling this routine:
- call the factorization routine \(?sytrf\)
- call the solver routine \(?sytrs\).

### Input Parameters

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **uplo**
  Must be 'U' or 'L'.

  - If \( uplo = 'U' \), the upper triangle of \( A \) is stored.
  - If \( uplo = 'L' \), the lower triangle of \( A \) is stored.

- **n**
  The order of the matrix \( A \); \( n \geq 0 \).

- **nrhs**
  The number of right-hand sides; \( nrhs \geq 0 \).

- **a**
  Array of size \( \text{max}(1, lda*n) \) contains the original matrix \( A \), as supplied to \(?sytrf\).

- **af**
  Array \( af \) of size \( \text{max}(1, ldaf*n) \) contains the factored matrix \( A \), as returned by \(?sytrf\).

- **b**
  Array \( b \) of size \( \text{max}(1, ldb*nrhs) \) for column major layout and \( \text{max}(1, ldb*n) \) for row major layout contains the right-hand side matrix \( B \).
Array $x$ of size $\max(1, ldx\times nrhs)$ for column major layout and $\max(1, ldx\times n)$ for row major layout contains the solution matrix $X$.

The leading dimension of $a$; $lda \geq \max(1, n)$.

The leading dimension of $af$; $ldaf \geq \max(1, n)$.

The leading dimension of $b$; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout.

The leading dimension of $x$; $ldx \geq \max(1, n)$ for column major layout and $ldx \geq nrhs$ for row major layout.

Array, size at least $\max(1, n)$. The $ipiv$ array, as returned by $\text{?sytrf}$.

Output Parameters

$x$ The refined solution matrix $X$.

$ferr, berr$ Arrays, size at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.

Return Values

This function returns a value $info$.

If $info = 0$, the execution is successful.

If $info = -i$, parameter $i$ had an illegal value.

Application Notes

The bounds returned in $ferr$ are not rigorous, but in practice they almost always overestimate the actual error.

For each right-hand side, computation of the backward error involves a minimum of $4n^2$ floating-point operations (for real flavors) or $16n^2$ operations (for complex flavors). In addition, each step of iterative refinement involves $6n^2$ operations (for real flavors) or $24n^2$ operations (for complex flavors); the number of iterations may range from 1 to 5. Estimating the forward error involves solving a number of systems of linear equations $A^*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2n^2$ floating-point operations for real flavors or $8n^2$ for complex flavors.

Include Files

• mkl.h

Description

The routine improves the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite, and provides error bounds and backward error estimates for the solution. In addition to a normwise error bound, the code provides a maximum componentwise error bound, if possible. See comments for err_bnds_norm and err_bnds_comp for details of the error bounds.

The original system of linear equations may have been equilibrated before calling this routine, as described by the parameters equed and s below. In this case, the solution and error bounds returned are for the original unequilibrated system.

Input Parameters

matrix_layout

Specifies whether two-dimensional array storage is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

uplo

Must be 'U' or 'L'.

Indicates whether the upper or lower triangular part of A is stored:

If uplo = 'U', the upper triangle of A is stored.

If uplo = 'L', the lower triangle of A is stored.

equed

Must be 'N' or 'Y'.

Specifies the form of equilibration that was done to A before calling this routine.

If equed = 'N', no equilibration was done.

If equed = 'Y', both row and column equilibration was done, that is, A has been replaced by diag(s)*A*diag(s). The right-hand side B has been changed accordingly.

n

The number of linear equations; the order of the matrix A; \( n \geq 0 \).
The number of right-hand sides; the number of columns of the matrices \( B \) and \( X \); \( nrhs \geq 0 \).

The array \( a \) (size \( \max(1, lda*n) \)) contains the symmetric/Hermitian matrix \( A \) as specified by \( uplo \). If \( uplo = 'U' \), the leading \( n \)-by-\( n \) upper triangular part of \( a \) contains the upper triangular part of the matrix \( A \) and the strictly lower triangular part of \( a \) is not referenced. If \( uplo = 'L' \), the leading \( n \)-by-\( n \) lower triangular part of \( a \) contains the lower triangular part of the matrix \( A \) and the strictly upper triangular part of \( a \) is not referenced.

The array \( af \) (size \( \max(1, ldaf*n) \)) contains the triangular factor \( L \) or \( U \) from the Cholesky factorization \( A = U^T U \) or \( A = L L^T \) as computed by \texttt{ssytrf} for real flavors or \texttt{dsytrf} for complex flavors.

The array \( b \) (size \( \max(1, ldb*nrhs) \) for column major layout and \( \max(1, ldb*n) \) for row major layout) contains the matrix \( B \) whose columns are the right-hand sides for the systems of equations.

The leading dimension of \( a \); \( lda \geq \max(1, n) \).

The leading dimension of \( af \); \( ldaf \geq \max(1, n) \).

Array, size at least \( \max(1, n) \). Contains details of the interchanges and the block structure of \( D \) as determined by \texttt{ssytrf} for real flavors or \texttt{dsytrf} for complex flavors.

Array, size \( (n) \). The array \( s \) contains the scale factors for \( A \).

If \( equed = 'N' \), \( s \) is not accessed.

If \( equed = 'Y' \), each element of \( s \) must be positive.

Each element of \( s \) should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

The leading dimension of the array \( b \); \( ldb \geq \max(1, n) \) for column major layout and \( ldb \geq nrhs \) for row major layout.

Array, of size \( \max(1, ldx*nrhs) \) for column major layout and \( \max(1, ldx*n) \) for row major layout.

The solution matrix \( X \) as computed by \texttt{?sytrs}

The leading dimension of the output array \( x \); \( ldx \geq \max(1, n) \) for column major layout and \( ldx \geq nrhs \) for row major layout.

Number of error bounds to return for each right hand side and each type (normwise or componentwise). See \texttt{err_bnds_norm} and \texttt{err_bnds_comp} descriptions in \texttt{Output Arguments} section below.

Specifies the number of parameters set in \( \texttt{params} \). If \( \leq 0 \), the \( \texttt{params} \) array is never referenced and default values are used.
Array, size \texttt{np}arams. Specifies algorithm parameters. If an entry is less than 0.0, that entry will be filled with the default value used for that parameter. Only positions up to \texttt{np}arams are accessed; defaults are used for higher-numbered parameters. If defaults are acceptable, you can pass \texttt{np}arams = 0, which prevents the source code from accessing the \texttt{params} argument.

\texttt{params}[0] : Whether to perform iterative refinement or not. Default: 1.0 (for single precision flavors), 1.0D+0 (for double precision flavors).

=0.0
No refinement is performed and no error bounds are computed.

=1.0
Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support double precision.

(Other values are reserved for future use.)

\texttt{params}[1] : Maximum number of residual computations allowed for refinement.

Default 10.0
Aggressive Set to 100.0 to permit convergence using approximate factorizations or factorizations other than \textit{LU}. If the factorization uses a technique other than Gaussian elimination, the guarantees in \texttt{err_bnds_norm} and \texttt{err_bnds_comp} may no longer be trustworthy.

\texttt{params}[2] : Flag determining if the code will attempt to find a solution with a small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence).

\textbf{Output Parameters}

\textit{x}
The improved solution matrix \( X \).

\textit{rcond}
Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix \( A \) after equilibration (if done). If \texttt{rcond} is less than the machine precision, in particular, if \texttt{rcond} = 0, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned.

\textit{berr}
Array, size at least \( \max(1, \texttt{nrhs}) \). Contains the componentwise relative backward error for each solution vector \( x_j \), that is, the smallest relative change in any element of \( A \) or \( B \) that makes  \( x_j \) an exact solution.

\textit{err_bnds_norm}
Array of size \( \texttt{nrhs} \times \texttt{n_{err_bnds}} \). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the \( i \)-th solution vector
The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned.

**err=1**  
"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} \times \text{slamch}(\varepsilon)$ for single precision flavors and $\sqrt{n} \times \text{dlamch}(\varepsilon)$ for double precision flavors.

**err=2**  
"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} \times \text{slamch}(\varepsilon)$ for single precision flavors and $\sqrt{n} \times \text{dlamch}(\varepsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.

**err=3**  
Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold $\sqrt{n} \times \text{slamch}(\varepsilon)$ for single precision flavors and $\sqrt{n} \times \text{dlamch}(\varepsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers for some appropriately scaled matrix $Z$ are:

$$\|Z\|_\infty \cdot \|Z^{-1}\|_\infty$$

The information for right-hand side $i$, where $1 \leq i \leq \text{nrhs}$, and type of error $\text{err}$ is stored in:

- Column major layout: $\text{err}_\text{bnds}_\text{norm}[(\text{err} - 1) \times \text{nrhs} + i - 1]$.
- Row major layout: $\text{err}_\text{bnds}_\text{norm}[	ext{err} - 1 + (i - 1) \times n_{\text{err}_\text{bnds}}]$.

Array of size $\text{nrhs} \times n_{\text{err}_\text{bnds}}$. For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the $i$-th solution vector:

$$\max_j \frac{|X_{\text{true}_{ji}} - X_{\text{ji}}|}{\max_j |X_{\text{ji}}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested ($\text{params}[2] = 0.0$), then $\text{err}_\text{bnds}_\text{comp}$ is not accessed.
err=1

"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold \( \sqrt{n} \times \text{slamch}(\varepsilon) \) for single precision flavors and \( \sqrt{n} \times \text{dlamch}(\varepsilon) \) for double precision flavors.

err=2

"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold \( \sqrt{n} \times \text{slamch}(\varepsilon) \) for single precision flavors and \( \sqrt{n} \times \text{dlamch}(\varepsilon) \) for double precision flavors. This error bound should only be trusted if the previous boolean is true.

err=3

Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold \( \sqrt{n} \times \text{slamch}(\varepsilon) \) for single precision flavors and \( \sqrt{n} \times \text{dlamch}(\varepsilon) \) for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers for some appropriately scaled matrix \( Z \) are:

\[
\frac{\|Z\|_\infty}{\|Z^{-1}\|_\infty}
\]

Let \( z = s \cdot (a \cdot \text{diag}(x)) \), where \( x \) is the solution for the current right-hand side and \( s \) scales each row of \( a \cdot \text{diag}(x) \) by a power of the radix so all absolute row sums of \( z \) are approximately 1.

The information for right-hand side \( i \), where \( 1 \leq i \leq \text{nrhs} \), and type of error \( \text{err} \) is stored in:

- Column major layout: \( \text{err_bnds_comp}[(\text{err} - 1) \times \text{nrhs} + i - 1] \).
- Row major layout: \( \text{err_bnds_comp}[(\text{err} - 1) + (i - 1) \times \text{n_err_bnds}] \)

\( \text{params} \)

Output parameter only if the input contains erroneous values, namely, in \( \text{params}[0], \text{params}[1], \text{params}[2] \). In such a case, the corresponding elements of \( \text{params} \) are filled with default values on output.

**Return Values**

This function returns a value \( \text{info} \).

If \( \text{info} = 0 \), the execution is successful. The solution to every right-hand side is guaranteed.

If \( \text{info} = -i \), parameter \( i \) had an illegal value.

If \( 0 < \text{info} < n \): \( U_{i\text{\text{info}},i\text{\text{info}}} \) is exactly zero. The factorization has been completed, but the factor \( U \) is exactly singular, so the solution and error bounds could not be computed; \( rcond = 0 \) is returned.

If \( \text{info} = n+j \): The solution corresponding to the \( j \)-th right-hand side is not guaranteed. The solutions corresponding to other right-hand sides \( k \) with \( k > j \) may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested \( \text{params}[2] = 0.0 \), then the \( j \)-th
right-hand side is the first with a normwise error bound that is not guaranteed (the smallest $j$ such that for column major layout $err_bnds_norm[j-1] = 0.0$ or $err_bnds_comp[j-1] = 0.0$; or for row major layout $err_bnds_norm[(j-1)*n + err_bnds] = 0.0$ or $err_bnds_comp[(j-1)*n + err_bnds] = 0.0$). See the definition of $err_bnds_norm$ and $err_bnds_comp$ for $err = 1$. To get information about all of the right-hand sides, check $err_bnds_norm$ or $err_bnds_comp$.

Matrix Storage Schemes

?herfs
Refines the solution of a system of linear equations with a complex Hermitian coefficient matrix and estimates its error.

Syntax

```c
lapack_int LAPACKE_cherfs( int matrix_layout, char uplo, lapack_int n, lapack_int nrhs,
 const lapack_complex_float* a, lapack_int lda, const lapack_complex_float* af,
 lapack_int ldaf, const lapack_int* ipiv, const lapack_complex_float* b, lapack_int ldb,
 lapack_complex_float* x, lapack_int ldx, float* ferr, float* berr );
```

Include Files
- mkl.h

Description
The routine performs an iterative refinement of the solution to a system of linear equations $A^*X = B$ with a complex Hermitian full-storage matrix $A$, with multiple right-hand sides. For each computed solution vector $x$, the routine computes the component-wise backward error $\beta$. This error is the smallest relative perturbation in elements of $A$ and $b$ such that $x$ is the exact solution of the perturbed system:

$$
|\delta a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| \leq \beta |b_i| \quad \text{such that} \quad (A + \delta A)x = (b + \delta b).
$$

Finally, the routine estimates the component-wise forward error in the computed solution $||x - x_e||_\infty/||x||_\infty$ (here $x_e$ is the exact solution).

Before calling this routine:
- call the factorization routine ?hetrf
- call the solver routine ?hetrs.

Input Parameters

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **uplo**
  Must be 'U' or 'L'.
  If uplo = 'U', the upper triangle of $A$ is stored.
  If uplo = 'L', the lower triangle of $A$ is stored.

- **n**
  The order of the matrix $A$; $n \geq 0$. 
nrhs

The number of right-hand sides; \( nrhs \geq 0 \).

Arrays:

\( a \) (size max(1, \( lda * n \))) contains the original matrix \( A \), as supplied to \( ?hetrf \).

\( af \) (size max(1, \( ldaf * n \))) contains the factored matrix \( A \), as returned by \( ?hetrf \).

\( b \) of size max(1, \( ldb * nrhs \)) for column major layout and max(1, \( ldb * n \)) for row major layout contains the right-hand side matrix \( B \).

\( x \) of size max(1, \( ldx * nrhs \)) for column major layout and max(1, \( ldx * n \)) for row major layout contains the solution matrix \( X \).

\( lda \)

The leading dimension of \( a \); \( lda \geq \) max(1, \( n \)).

\( ldaf \)

The leading dimension of \( af \); \( ldaf \geq \) max(1, \( n \)).

\( ldb \)

The leading dimension of \( b \); \( ldb \geq \) max(1, \( n \)) for column major layout and \( \geq \) \( nrhs \) for row major layout.

\( ldx \)

The leading dimension of \( x \); \( ldx \geq \) max(1, \( n \)) for column major layout and \( \geq \) \( nrhs \) for row major layout.

\( ipiv \)

Array, size at least \( \max(1, n) \). The \( ipiv \) array, as returned by \( ?hetrf \).

Output Parameters

\( x \)

The refined solution matrix \( X \).

\( ferr, berr \)

Arrays, size at least \( \max(1, nrhs) \). Contain the component-wise forward and backward errors, respectively, for each solution vector.

Return Values

This function returns a value \( info \).

If \( info = 0 \), the execution is successful.

If \( info = -i \), parameter \( i \) had an illegal value.

Application Notes

The bounds returned in \( ferr \) are not rigorous, but in practice they almost always overestimate the actual error.

For each right-hand side, computation of the backward error involves a minimum of \( 16n^2 \) operations. In addition, each step of iterative refinement involves \( 24n^2 \) operations; the number of iterations may range from 1 to 5.

Estimating the forward error involves solving a number of systems of linear equations \( A^*x = b \); the number is usually 4 or 5 and never more than 11. Each solution requires approximately \( 8n^2 \) floating-point operations.

The real counterpart of this routine is \( ?ssyrsf/\?dsyrsf \)

```

Include Files

- mkl.h

Description

The routine improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian indefinite, and provides error bounds and backward error estimates for the solution. In addition to a normwise error bound, the code provides a maximum componentwise error bound, if possible. See comments for `err_bnds_norm` and `err_bnds_comp` for details of the error bounds.

The original system of linear equations may have been equilibrated before calling this routine, as described by the parameters `equed` and `s` below. In this case, the solution and error bounds returned are for the original unequilibrated system.

Input Parameters

- **matrix_layout**
  Specifies whether two-dimensional array storage is row major (`LAPACK_ROW_MAJOR`) or column major (`LAPACK_COL_MAJOR`).

- **uplo**
  Must be `'U'` or `'L'`.
  Indicates whether the upper or lower triangular part of A is stored:
  - If `uplo` = `'U'`, the upper triangle of A is stored.
  - If `uplo` = `'L'`, the lower triangle of A is stored.

- **equed**
  Must be `'N'` or `'Y'`.
  Specifies the form of equilibration that was done to A before calling this routine:
  - If `equed` = `'N'`, no equilibration was done.
  - If `equed` = `'Y'`, both row and column equilibration was done, that is, A has been replaced by `diag(s)*A*diag(s)`. The right-hand side B has been changed accordingly.
The number of linear equations; the order of the matrix $A$; \( n \geq 0 \).

The number of right-hand sides; the number of columns of the matrices $B$ and $X$; \( nrhs \geq 0 \).

The array $a$ of size $\max(1, \text{lda} \times n)$ contains the Hermitian matrix $A$ as specified by $\text{uplo}$. If $\text{uplo} = 'U'$, the leading $n$-by-$n$ upper triangular part of $a$ contains the upper triangular part of the matrix $A$ and the strictly lower triangular part of $a$ is not referenced. If $\text{uplo} = 'L'$, the leading $n$-by-$n$ lower triangular part of $a$ contains the lower triangular part of the matrix $A$ and the strictly upper triangular part of $a$ is not referenced.

The array $af$ of size $\max(1, \text{ldaf} \times n)$ contains the block diagonal matrix $D$ and the multipliers used to obtain the factor $U$ or $L$ from the factorization $A = U^*D*U^T$ or $A = L^*D*L^T$ as computed by $\text{ssytrf}$ for $\text{cherfsx}$ or $\text{dsytrf}$ for $\text{zherfsx}$.

The array $b$ of size $\max(1, \text{ldb} \times nrhs)$ for row major layout and $\max(1, \text{ldb} \times n)$ for column major layout contains the matrix $B$ whose columns are the right-hand sides for the systems of equations.

The leading dimension of $a$; \( \text{lda} \geq \max(1, n) \).

The leading dimension of $af$; \( \text{ldaf} \geq \max(1, n) \).

Array, size at least $\max(1, n)$. Contains details of the interchanges and the block structure of $D$ as determined by $\text{ssytrf}$ for real flavors or $\text{dsytrf}$ for complex flavors.

Array, size $(n)$. The array $s$ contains the scale factors for $A$.

If $\text{equed} = 'N'$, $s$ is not accessed.

If $\text{equed} = 'Y'$, each element of $s$ must be positive.

Each element of $s$ should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

The leading dimension of the array $b$; \( \text{ldb} \geq \max(1, n) \) for column major layout and $\text{ldb} \geq nrhs$ for row major layout.

Array, size $\max(1, \text{ldx} \times nrhs)$ for column major layout and $\max(1, \text{ldx} \times n)$ for row major layout.

The solution matrix $X$ as computed by $\text{?hetrs}$.

The leading dimension of the output array $x$; \( \text{ldx} \geq \max(1, n) \) for column major layout and $\text{ldx} \geq nrhs$ for row major layout.

Number of error bounds to return for each right hand side and each type (normwise or componentwise). See $\text{err_bnds_norm}$ and $\text{err_bnds_comp}$ descriptions in $\text{Output Arguments}$ section below.

Specifies the number of parameters set in $\text{params}$. If \( \leq 0 \), the $\text{params}$ array is never referenced and default values are used.
**params**

Array, size nparams. Specifies algorithm parameters. If an entry is less than 0.0, that entry will be filled with the default value used for that parameter. Only positions up to nparams are accessed; defaults are used for higher-numbered parameters. If defaults are acceptable, you can pass nparams = 0, which prevents the source code from accessing the params argument.

**params[0]**: Whether to perform iterative refinement or not. Default: 1.0 (for cherfsx), 1.0D+0 (for zherfsx).

- **0.0**: No refinement is performed and no error bounds are computed.
- **1.0**: Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support double precision.

(Other values are reserved for future use.)

**params[1]**: Maximum number of residual computations allowed for refinement.

- **Default**: 10
- **Aggressive**: Set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in err_bnds_norm and err_bnds_comp may no longer be trustworthy.

**params[2]**: Flag determining if the code will attempt to find a solution with a small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence).

**Output Parameters**

- **x**: The improved solution matrix X.
- **rcond**: Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If rcond is less than the machine precision, in particular, if rcond = 0, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned.

- **berr**: Array, size at least max(1, nrhs). Contains the componentwise relative backward error for each solution vector xj, that is, the smallest relative change in any element of A or B that makes xj an exact solution.

- **err_bnds_norm**: Array of size nrhs*n_err_bnds. For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

  Normwise relative error in the i-th solution vector
The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned.

\[ \text{err} = 1 \]

"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold \( \sqrt{n} \cdot \text{slamch}(\varepsilon) \) for \texttt{cherfsx} and \( \sqrt{n} \cdot \text{dlamch}(\varepsilon) \) for \texttt{zherfsx}.

\[ \text{err} = 2 \]

"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold \( \sqrt{n} \cdot \text{slamch}(\varepsilon) \) for \texttt{cherfsx} and \( \sqrt{n} \cdot \text{dlamch}(\varepsilon) \) for \texttt{zherfsx}. This error bound should only be trusted if the previous boolean is true.

\[ \text{err} = 3 \]

Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold \( \sqrt{n} \cdot \text{slamch}(\varepsilon) \) for single precision flavors and \( \sqrt{n} \cdot \text{dlamch}(\varepsilon) \) for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers for some appropriately scaled matrix \( Z \) are:

\[ \|Z\|_\infty \cdot \|Z^{-1}\|_\infty \]

Let \( z = s \cdot a \), where \( s \) scales each row by a power of the radix so all absolute row sums of \( z \) are approximately 1.

The information for right-hand side \( i \), where \( 1 \leq i \leq \text{nrhs} \), and type of error \( \text{err} \) is stored in:

- **Column major layout**: \( \text{err}_{\text{bnds}}_{\text{norm}}[(\text{err} - 1) \times \text{nrhs} + i - 1] \).
- **Row major layout**: \( \text{err}_{\text{bnds}}_{\text{norm}}[\text{err} - 1 + (i - 1) \times \text{n_err_bnds}] \)

\( \text{err}_{\text{bnds}}_{\text{comp}} \)

Array of size \( \text{nrhs} \times \text{n_err_bnds} \). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the \( i \)-th solution vector:

\[ \max_j \frac{|X_{\text{true}_{ji}} - X_{ji}|}{|X_{ji}|} \]
The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (\texttt{params[2]} = 0.0), then \texttt{err_bnds_comp} is not accessed.

\texttt{err=1} "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold \(\sqrt{n} \times \text{slamch}(\varepsilon)\) for \texttt{cherfsx} and \(\sqrt{n} \times \text{dlamch}(\varepsilon)\) for \texttt{zherfsx}.

\texttt{err=2} "Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold \(\sqrt{n} \times \text{slamch}(\varepsilon)\) for \texttt{cherfsx} and \(\sqrt{n} \times \text{dlamch}(\varepsilon)\) for \texttt{zherfsx}. This error bound should only be trusted if the previous boolean is true.

\texttt{err=3} Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold \(\sqrt{n} \times \text{slamch}(\varepsilon)\) for single precision flavors and \(\sqrt{n} \times \text{dlamch}(\varepsilon)\) for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers for some appropriately scaled matrix \(Z\) are:

\[
\begin{align*}
\|Z\|_\infty & \cdot \|Z^{-1}\|_\infty
\end{align*}
\]

Let \(z=s \times (a \times \text{diag}(x))\), where \(x\) is the solution for the current right-hand side and \(s\) scales each row of \(a \times \text{diag}(x)\) by a power of the radix so all absolute row sums of \(z\) are approximately 1.

The information for right-hand side \(i\), where \(1 \leq i \leq \texttt{nrhs}\), and type of error \texttt{err} is stored in:

- Column major layout: \texttt{err_bnds_comp[(err - 1) \times \texttt{nrhs} + i - 1]}.
- Row major layout: \texttt{err_bnds_comp[err - 1 + (i - 1) \times \texttt{n_err_bnds}]}.

\texttt{params}

Output parameter only if the input contains erroneous values, namely, in \texttt{params[0]}, \texttt{params[1]}, \texttt{params[2]}. In such a case, the corresponding elements of \texttt{params} are filled with default values on output.

Return Values

This function returns a value \texttt{info}.

If \(\texttt{info} = 0\), the execution is successful. The solution to every right-hand side is guaranteed.

If \(\texttt{info} = -i\), parameter \(i\) had an illegal value.

If \(0 < \texttt{info}\): \(\texttt{info}\) is exactly zero. The factorization has been completed, but the factor \(D\) is exactly singular, so the solution and error bounds could not be computed; \(\texttt{rcond} = 0\) is returned.
If $info = n+j$: The solution corresponding to the $j$-th right-hand side is not guaranteed. The solutions corresponding to other right-hand sides $k$ with $k > j$ may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested $params[2] = 0.0$, then the $j$-th right-hand side is the first with a normwise error bound that is not guaranteed (the smallest $j$ such that for column major layout $err\_bnds\_norm[j-1] = 0.0$ or $err\_bnds\_comp[j-1] = 0.0$; or for row major layout $err\_bnds\_norm[(j-1)*n\_err\_bnds] = 0.0$ or $err\_bnds\_comp[(j-1)*n\_err\_bnds] = 0.0$). See the definition of $err\_bnds\_norm$ and $err\_bnds\_comp$ for $err = 1$. To get information about all of the right-hand sides, check $err\_bnds\_norm$ or $err\_bnds\_comp$.

Description
The routine performs an iterative refinement of the solution to a system of linear equations $A*X = B$ with a packed symmetric matrix $A$, with multiple right-hand sides. For each computed solution vector $x$, the routine computes the component-wise backward error $β$. This error is the smallest relative perturbation in elements of $A$ and $b$ such that $x$ is the exact solution of the perturbed system:

$$|\delta a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| \leq \beta |b_i| \quad \text{such that} \quad (A + \delta A)x = (b + \delta b).$$

Finally, the routine estimates the component-wise forward error in the computed solution $||x - x_e||_\infty / ||x||_\infty$ (here $x_e$ is the exact solution).

Before calling this routine:
- call the factorization routine ?sptrfs
- call the solver routine ?sprtrs.
**Input Parameters**

*matrix_layout*  
Specifies whether matrix storage layout is row major (*LAPACK_ROW_MAJOR*) or column major (*LAPACK_COL_MAJOR*).

*uplo*  
Must be 'U' or 'L'.  
If *uplo* = 'U', the upper triangle of *A* is stored.  
If *uplo* = 'L', the lower triangle of *A* is stored.

*n*  
The order of the matrix *A*; *n* ≥ 0.

*nrhs*  
The number of right-hand sides; *nrhs* ≥ 0.

*ap, afp, b, x*  
Arrays:  
*ap* of size max(1, *n*(n+1)/2) contains the original packed matrix *A*, as supplied to ?sptrf.  
*afp* of size max(1, *n*(n+1)/2) contains the factored packed matrix *A*, as returned by ?sptrf.  
*b* of size max(1, ldb*nrhs) for column major layout and max(1, ldx*n) for row major layout contains the right-hand side matrix *B*.  
*x* of size max(1, ldx*nrhs) for column major layout and max(1, ldx*n) for row major layout contains the solution matrix *X*.

*ldb*  
The leading dimension of *b*; *ldb* ≥ max(1, *n*) for column major layout and *ldb* ≥ *nrhs* for row major layout.

*ldx*  
The leading dimension of *x*; *ldx* ≥ max(1, *n*) for column major layout and *ldx* ≥ max(1, *nrhs*) for row major layout.

*ipiv*  
Array, size at least max(1, *n*). The *ipiv* array, as returned by ?sptrf.

**Output Parameters**

*x*  
The refined solution matrix *X*.

*ferr, berr*  
Arrays, size at least max(1, *nrhs*). Contain the component-wise forward and backward errors, respectively, for each solution vector.

**Return Values**

This function returns a value *info*.  
If *info* = 0, the execution is successful.  
If *info* = -i, parameter *i* had an illegal value.

**Application Notes**

The bounds returned in *ferr* are not rigorous, but in practice they almost always overestimate the actual error.  
For each right-hand side, computation of the backward error involves a minimum of $4n^2$ floating-point operations (for real flavors) or $16n^2$ operations (for complex flavors). In addition, each step of iterative refinement involves $6n^2$ operations (for real flavors) or $24n^2$ operations (for complex flavors); the number of iterations may range from 1 to 5.
Estimating the forward error involves solving a number of systems of linear equations $A^*x = b$; the number of systems is usually 4 or 5 and never more than 11. Each solution requires approximately $2n^2$ floating-point operations for real flavors or $8n^2$ for complex flavors.

- mkl.h

Description

The routine performs an iterative refinement of the solution to a system of linear equations $A^*X = B$ with a packed complex Hermitian matrix $A$, with multiple right-hand sides. For each computed solution vector $x$, the routine computes the component-wise backward error. This error is the smallest relative perturbation in elements of $A$ and $b$ such that $x$ is the exact solution of the perturbed system:

$$
|\delta a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| \leq \beta |b_i| \quad \text{such that} \quad (A + \delta A)x = (b + \delta b).
$$

Finally, the routine estimates the component-wise forward error in the computed solution $||x - x_e||_{\infty}/||x||_{\infty}$ (here $x_e$ is the exact solution).

Before calling this routine:
- call the factorization routine ?hptrf
- call the solver routine ?hptrs.

Input Parameters

- **matrix_layout**: Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- **uplo**: Must be 'U' or 'L'.
  - If uplo = 'U', the upper triangle of $A$ is stored.
  - If uplo = 'L', the lower triangle of $A$ is stored.
- **n**: The order of the matrix $A$; $n \geq 0$.
- **nrhs**: The number of right-hand sides; $nrhs \geq 0$. 
Arrays:
ap\text{max}(1, n(n + 1)/2) contains the original packed matrix \( A \), as supplied to \( \text{?hptrf} \).
afp\text{max}(1, n(n + 1)/2) contains the factored packed matrix \( A \), as returned by \( \text{?hptrf} \).

b of size \text{max}(1, ldb*nrhs) for column major layout and \text{max}(1, ldx*n) for row major layout contains the right-hand side matrix \( B \).
x of size \text{max}(1, ldx*nrhs) for column major layout and \text{max}(1, ldb*n) for row major layout contains the solution matrix \( X \).

\text{ldb}
The leading dimension of \( b \); \( ldb \geq \text{max}(1, n) \) for column major layout and \( ldb \geq \text{nrhs} \) for row major layout.

\text{ldx}
The leading dimension of \( x \); \( ldx \geq \text{max}(1, n) \) for column major layout and \( ldx \geq \text{nrhs} \) for row major layout.

ipiv
Array, size at least \text{max}(1, n). The \( ipiv \) array, as returned by \( \text{?hptrf} \).

Output Parameters
x
The refined solution matrix \( X \).

ferr, berr
Arrays, size at least \text{max}(1, nrhs). Contain the component-wise forward and backward errors, respectively, for each solution vector.

Return Values
This function returns a value \( info \).
If \( info = 0 \), the execution is successful.
If \( info = -i \), parameter \( i \) had an illegal value.

Application Notes
The bounds returned in \( ferr \) are not rigorous, but in practice they almost always overestimate the actual error.

For each right-hand side, computation of the backward error involves a minimum of \( 16n^2 \) operations. In addition, each step of iterative refinement involves \( 24n^2 \) operations; the number of iterations may range from 1 to 5.

Estimating the forward error involves solving a number of systems of linear equations \( A^*x = b \); the number is usually 4 or 5 and never more than 11. Each solution requires approximately \( 8n^2 \) floating-point operations.

The real counterpart of this routine is \( \text{?ssprfs} / \text{?dsprfs} \).

**Description**

The routine estimates the errors in the solution to a system of linear equations \( A \times X = B \) or \( A^T \times X = B \) or \( A^H \times X = B \) with a triangular matrix \( A \), with multiple right-hand sides. For each computed solution vector \( x \), the routine computes the *component-wise backward error*. This error is the smallest relative perturbation in elements of \( A \) and \( b \) such that \( x \) is the exact solution of the perturbed system:

\[
|\delta a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| \leq \beta |b_i| \quad \text{such that} \quad (A + \delta A) x = (b + \delta b).
\]

The routine also estimates the *component-wise forward error* in the computed solution \( ||x - x_e||_\infty/||x||_\infty \) (here \( x_e \) is the exact solution).

Before calling this routine, call the solver routine ?trtrs.

**Input Parameters**

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **uplo**
  Must be 'U' or 'L'. Indicates whether \( A \) is upper or lower triangular:
  - If `uplo` = 'U', then \( A \) is upper triangular.
  - If `uplo` = 'L', then \( A \) is lower triangular.

- **trans**
  Must be 'N' or 'T' or 'C'. Indicates the form of the equations:
  - If `trans` = 'N', the system has the form \( A \times X = B \).
  - If `trans` = 'T', the system has the form \( A^T \times X = B \).
  - If `trans` = 'C', the system has the form \( A^H \times X = B \).

- **diag**
  Must be 'N' or 'U'.
If \( \text{diag} = 'N' \), then \( A \) is not a unit triangular matrix.

If \( \text{diag} = 'U' \), then \( A \) is unit triangular: diagonal elements of \( A \) are assumed to be 1 and not referenced in the array \( a \).

\( n \)

The order of the matrix \( A \); \( n \geq 0 \).

\( \text{nrhs} \)

The number of right-hand sides; \( \text{nrhs} \geq 0 \).

\( a, b, x \)

Arrays:

\( a(\text{size } \max(1, \text{lda} \times n)) \) contains the upper or lower triangular matrix \( A \), as specified by \( \text{uplo} \).

\( b \) of size \( \max(1, \text{ldb} \times \text{nrhs}) \) for column major layout and \( \max(1, \text{ldb} \times n) \) for row major layout contains the right-hand side matrix \( B \).

\( x \) of size \( \max(1, \text{ldx} \times \text{nrhs}) \) for column major layout and \( \max(1, \text{ldx} \times n) \) for row major layout contains the solution matrix \( X \).

\( \text{lda} \)

The leading dimension of \( a \); \( \text{lda} \geq \max(1, n) \).

\( \text{ldb} \)

The leading dimension of \( b \); \( \text{ldb} \geq \max(1, n) \) for column major layout and \( \text{ldb} \geq \text{nrhs} \) for row major layout.

\( \text{ldx} \)

The leading dimension of \( x \); \( \text{ldx} \geq \max(1, n) \) for column major layout and \( \text{ldx} \geq \text{nrhs} \) for row major layout.

**Output Parameters**

\( \text{ferr}, \text{berr} \)

Arrays, size at least \( \max(1, \text{nrhs}) \). Contain the component-wise forward and backward errors, respectively, for each solution vector.

**Return Values**

This function returns a value \( \text{info} \).

If \( \text{info} = 0 \), the execution is successful.

If \( \text{info} = -i \), parameter \( i \) had an illegal value.

**Application Notes**

The bounds returned in \( \text{ferr} \) are not rigorous, but in practice they almost always overestimate the actual error.

A call to this routine involves, for each right-hand side, solving a number of systems of linear equations \( A^*x = b \); the number of systems is usually 4 or 5 and never more than 11. Each solution requires approximately \( n^2 \) floating-point operations for real flavors or \( 4n^2 \) for complex flavors.

Description

The routine estimates the errors in the solution to a system of linear equations \( AX = B \) or \( A^T X = B \) or \( A^H X = B \) with a packed triangular matrix \( A \), with multiple right-hand sides. For each computed solution vector \( x \), the routine computes the **component-wise backward error**. This error is the smallest relative perturbation in elements of \( A \) and \( b \) such that \((A + \delta A)x = (b + \delta b)\).

The routine also estimates the **component-wise forward error** in the computed solution \( \| x - x_e \|_\infty / \| x \|_\infty \) (here \( x_e \) is the exact solution).

Before calling this routine, call the solver routine `?tptrs`.

Input Parameters

- **matrix_layout**
  - Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **uplo**
  - Must be 'U' or 'L'.
  - Indicates whether \( A \) is upper or lower triangular:
    - If `uplo` is 'U', then \( A \) is upper triangular.
    - If `uplo` is 'L', then \( A \) is lower triangular.

- **trans**
  - Must be 'N' or 'T' or 'C'.
  - Indicates the form of the equations:
    - If `trans` is 'N', the system has the form \( AX = B \).
    - If `trans` is 'T', the system has the form \( A^T X = B \).
    - If `trans` is 'C', the system has the form \( A^H X = B \).

- **diag**
  - Must be 'N' or 'U'.

If \( \text{diag} = 'N' \), \( A \) is not a unit triangular matrix.

If \( \text{diag} = 'U' \), \( A \) is unit triangular: diagonal elements of \( A \) are assumed to be 1 and not referenced in the array \( \text{ap} \).

\( n \)

The order of the matrix \( A; n \geq 0 \).

\( \text{nrhs} \)

The number of right-hand sides; \( \text{nrhs} \geq 0 \).

\( \text{ap}, \text{b}, \text{x} \)

Arrays:

- \( \text{ap} \) of size \( \text{apmax}(1, n(n + 1)/2) \) contains the upper or lower triangular matrix \( A \), as specified by \( \text{uplo} \).
- \( \text{b} \) of size \( \text{max}(1, \text{ldb} \times \text{nrhs}) \) for column major layout and \( \text{max}(1, \text{ldb} \times n) \) for row major layout contains the right-hand side matrix \( B \).
- \( \text{x} \) of size \( \text{max}(1, \text{ldx} \times \text{nrhs}) \) for column major layout and \( \text{max}(1, \text{ldx} \times n) \) for row major layout contains the solution matrix \( X \).

\( \text{ldb} \)

The leading dimension of \( \text{b} \); \( \text{ldb} \geq \text{max}(1, n) \) for column major layout and \( \text{ldb} \geq \text{nrhs} \) for row major layout.

\( \text{ldx} \)

The leading dimension of \( \text{x} \); \( \text{ldx} \geq \text{max}(1, n) \) for column major layout and \( \text{ldx} \geq \text{nrhs} \) for row major layout.

Output Parameters

\( \text{ferr}, \text{berr} \)

Arrays, size at least \( \text{max}(1, \text{nrhs}) \). Contain the component-wise forward and backward errors, respectively, for each solution vector.

Return Values

This function returns a value \( \text{info} \).

If \( \text{info} = 0 \), the execution is successful.

If \( \text{info} = -i \), parameter \( i \) had an illegal value.

Application Notes

The bounds returned in \( \text{ferr} \) are not rigorous, but in practice they almost always overestimate the actual error.

A call to this routine involves, for each right-hand side, solving a number of systems of linear equations \( A^*x = b \); the number of systems is usually 4 or 5 and never more than 11. Each solution requires approximately \( n^2 \) floating-point operations for real flavors or \( 4n^2 \) for complex flavors.

Description

The routine estimates the errors in the solution to a system of linear equations $A\cdot X = B$ or $A^T\cdot X = B$ or $A^H\cdot X = B$ with a triangular band matrix $A$, with multiple right-hand sides. For each computed solution vector $x$, the routine computes the component-wise backward error. This error is the smallest relative perturbation in elements of $A$ and $b$ such that $x$ is the exact solution of the perturbed system:

$$
|\delta a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| \leq \beta |b_i| \quad \text{such that} \quad (A + \delta A) \cdot x = (b + \delta b).
$$

The routine also estimates the component-wise forward error in the computed solution $||x - x_e||_\infty / ||x||_\infty$ (here $x_e$ is the exact solution).

Before calling this routine, call the solver routine ?tbtrs.

Input Parameters

**matrix_layout**

Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

**uplo**

Must be 'U' or 'L'.

Indicates whether $A$ is upper or lower triangular:

- If uplo = 'U', then $A$ is upper triangular.
- If uplo = 'L', then $A$ is lower triangular.

**trans**

Must be 'N' or 'T' or 'C'.

Indicates the form of the equations:

- If trans = 'N', the system has the form $A\cdot X = B$.
- If trans = 'T', the system has the form $A^T\cdot X = B$.
- If trans = 'C', the system has the form $A^H\cdot X = B$.

**diag**

Must be 'N' or 'U'.

If diag = 'N', $A$ is not a unit triangular matrix.

If diag = 'U', $A$ is unit triangular: diagonal elements of $A$ are assumed to be 1 and not referenced in the array ab.
The order of the matrix $A$; $n \geq 0$.

The number of super-diagonals or sub-diagonals in the matrix $A$; $kd \geq 0$.

The number of right-hand sides; $nrhs \geq 0$.

Arrays:

$ab$ (size max(1, $ldab*\ n$)) contains the upper or lower triangular matrix $A$, as specified by $uplo$, in band storage format.

$b$ of size max(1, $ldb*nrhs$) for column major layout and max(1, $ldb*n$) for row major layout contains the right-hand side matrix $B$.

$x$ of size max(1, $ldx*nrhs$) for column major layout and max(1, $ldx*n$) for row major layout contains the solution matrix $X$.

The leading dimension of the array $ab$; $ldab \geq kd + 1$.

The leading dimension of $b$; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout.

The leading dimension of $x$; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout.

Arrays, size at least max(1, $nrhs$). Contain the component-wise forward and backward errors, respectively, for each solution vector.

This function returns a value $info$.

If $info = 0$, the execution is successful.

If $info = -i$, parameter $i$ had an illegal value.

The bounds returned in $ferr$ are not rigorous, but in practice they almost always overestimate the actual error.

A call to this routine involves, for each right-hand side, solving a number of systems of linear equations $A^*x = b$; the number of systems is usually 4 or 5 and never more than 11. Each solution requires approximately $2n*kd$ floating-point operations for real flavors or $8n*kd$ operations for complex flavors.

Matrix Inversion: LAPACK Computational Routines

It is seldom necessary to compute an explicit inverse of a matrix. In particular, do not attempt to solve a system of equations $Ax = b$ by first computing $A^{-1}$ and then forming the matrix-vector product $x = A^{-1}b$. Call a solver routine instead (see Routines for Solving Systems of Linear Equations); this is more efficient and more accurate.

However, matrix inversion routines are provided for the rare occasions when an explicit inverse matrix is needed.
Computes the inverse of an LU-factored general matrix.

Syntax

```c
lapack_int LAPACKE_sgetri (int matrix_layout, lapack_int n, float * a, lapack_int lda, const lapack_int * ipiv);
```

```c
lapack_int LAPACKE_dgetri (int matrix_layout, lapack_int n, double * a, lapack_int lda, const lapack_int * ipiv);
```

```c
lapack_int LAPACKE_cgetri (int matrix_layout, lapack_int n, lapack_complex_float * a, lapack_int lda, const lapack_int * ipiv);
```

```c
lapack_int LAPACKE_zgetri (int matrix_layout, lapack_int n, lapack_complex_double * a, lapack_int lda, const lapack_int * ipiv);
```

Include Files

- `mkl.h`

Description

The routine computes the inverse \( \text{inv}(A) \) of a general matrix \( A \). Before calling this routine, call \(?getrf\) to factorize \( A \).

Input Parameters

- `matrix_layout` Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- `n` The order of the matrix \( A \); \( n \geq 0 \).
- `a` Array \( a(\text{size max}(1, \text{lda}*n)) \) contains the factorization of the matrix \( A \), as returned by \(?getrf\): \( A = P*L*U \). The second dimension of \( a \) must be at least \( \text{max}(1, n) \).
- `lda` The leading dimension of \( a \); \( lda \geq \text{max}(1, n) \).
- `ipiv` Array, size at least \( \text{max}(1, n) \). The \( ipiv \) array, as returned by \(?getrf\).

Output Parameters

- `a` Overwritten by the \( n \)-by-\( n \) matrix \( \text{inv}(A) \).

Return Values

This function returns a value \( info \).

If \( info = 0 \), the execution is successful.

If \( info = -i \), parameter \( i \) had an illegal value.

If \( info = i \), the \( i \)-th diagonal element of the factor \( U \) is zero, \( U \) is singular, and the inversion could not be completed.
Application Notes

The computed inverse $X$ satisfies the following error bound:

$$|XA - I| \leq c(n)\varepsilon|X|P|L||U|,$$

where $c(n)$ is a modest linear function of $n$; $\varepsilon$ is the machine precision; $I$ denotes the identity matrix; $P$, $L$, and $U$ are the factors of the matrix factorization $A = P*L*U$.

The total number of floating-point operations is approximately $(4/3)n^3$ for real flavors and $(16/3)n^3$ for complex flavors.

lapack_complex_float * a, lapack_int lda);

lapack_int LAPACKE_mkl_zgetrinp (int matrix_layout, lapack_int n, 
lapack_complex_double * a, lapack_int lda);
```

Include Files

- mkl.h

Description

The routine computes the inverse $\text{inv}(A)$ of a general matrix $A$. Before calling this routine, call **mkl_?getrfnp** to factorize $A$.

Input Parameters

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **n**
  The order of the matrix $A$; $n \geq 0$.

- **a**
  Array(size max(1, lda*n)) contains the factorization of the matrix $A$, as returned by **mkl_?getrfnp**: $A = L*U$. The second dimension of $a$ must be at least max(1, n).

- **lda**
  The leading dimension of $a$; $lda \geq \text{max}(1, n)$.

Output Parameters

- **a**
  Overwritten by the $n$-by-$n$ matrix $\text{inv}(A)$.
Return Values
This function returns a value info.
If info = 0, the execution is successful.
If info = -i, parameter i had an illegal value.
If info = i, the i-th diagonal element of the factor U is zero, U is singular, and the inversion could not be completed.

Application Notes
The total number of floating-point operations is approximately \((4/3)n^3\) for real flavors and \((16/3)n^3\) for complex flavors.

Matrix Storage Schemes

?potri
Computes the inverse of a symmetric (Hermitian) positive-definite matrix using the Cholesky factorization.

Syntax
lapack_int LAPACKE_spotri (int matrix_layout, char uplo, lapack_int n, float * a, lapack_int lda);
lapack_int LAPACKE_dpotri (int matrix_layout, char uplo, lapack_int n, double * a, lapack_int lda);
lapack_int LAPACKE_cpotri (int matrix_layout, char uplo, lapack_int n, lapack_complex_float * a, lapack_int lda);
lapack_int LAPACKE_zpotri (int matrix_layout, char uplo, lapack_int n, lapack_complex_double * a, lapack_int lda);

Include Files
• mkl.h

Description
The routine computes the inverse \(\text{inv}(A)\) of a symmetric positive definite or, for complex flavors, Hermitian positive-definite matrix \(A\). Before calling this routine, call ?potrf to factorize \(A\).

Input Parameters

matrix_layout
规定的矩阵存储布局是行优先（LAPACK_ROW_MAJOR）还是列优先（LAPACK_COL_MAJOR）。

uplo

Must be 'U' or 'L'.

Indicates how the input matrix \(A\) has been factored:
If uplo = 'U', the upper triangle of \(A\) is stored.
If uplo = 'L', the lower triangle of \(A\) is stored.

The order of the matrix \(A\); \(n \geq 0\).
Array \( a(\text{size max}(1, \text{lda}*n)) \). Contains the factorization of the matrix \( A \), as returned by \( \text{?potrf} \).

\( \text{lda} \)

The leading dimension of \( a \). \( \text{lda} \geq \text{max}(1, n) \).

Output Parameters

\( a \)

Overwritten by the upper or lower triangle of the inverse of \( A \).

Return Values

This function returns a value \( \text{info} \).

If \( \text{info} = 0 \), the execution is successful.

If \( \text{info} = -i \), parameter \( i \) had an illegal value.

If \( \text{info} = i \), the \( i \)-th diagonal element of the Cholesky factor (and therefore the factor itself) is zero, and the inversion could not be completed.

Application Notes

The computed inverse \( X \) satisfies the following error bounds:

\[
||X - I||_2 \leq c(n) \kappa_2(A),
||AX - I||_2 \leq c(n) \kappa_2(A),
\]

where \( c(n) \) is a modest linear function of \( n \), and \( \varepsilon \) is the machine precision; \( I \) denotes the identity matrix.

The 2-norm \( ||A||_2 \) of a matrix \( A \) is defined by \( ||A||_2 = \max_{x \neq 0} (Ax \cdot Ax)^{1/2} \), and the condition number \( \kappa_2(A) \) is defined by \( \kappa_2(A) = ||A||_2 ||A^{-1}||_2 \).

The total number of floating-point operations is approximately \((2/3) n^3\) for real flavors and \((8/3) n^3\) for complex flavors.

\( \text{?pftri} \)

Computes the inverse of a symmetric (Hermitian) positive-definite matrix in RFP format using the Cholesky factorization.

Syntax

```c
lapack_int LAPACK_spftri (int \text{matrix_layout} , char \text{transr} , char \text{uplo} , lapack_int \text{n} , float * a );

lapack_int LAPACK_dpftri (int \text{matrix_layout} , char \text{transr} , char \text{uplo} , lapack_int \text{n} , double * a );

lapack_int LAPACK_cpftri (int \text{matrix_layout} , char \text{transr} , char \text{uplo} , lapack_int \text{n} , lapack_complex_float * a );

lapack_int LAPACK_zpftri (int \text{matrix_layout} , char \text{transr} , char \text{uplo} , lapack_int \text{n} , lapack_complex_double * a );
```

Include Files

- mkl.h

Description
The routine computes the inverse \( \text{inv}(A) \) of a symmetric positive definite or, for complex data, Hermitian positive-definite matrix \( A \) using the Cholesky factorization:

\[
A = U^T U \text{ for real data, } A = U^H U \text{ for complex data} \quad \text{if } \text{uplo} = 'U'
\]
\[
A = L L^T \text{ for real data, } A = L L^H \text{ for complex data} \quad \text{if } \text{uplo} = 'L'
\]

Before calling this routine, call \( \text{?pftrf} \) to factorize \( A \).

The matrix \( A \) is in the Rectangular Full Packed (RFP) format. For the description of the RFP format, see Matrix Storage Schemes.

**Input Parameters**

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **transr**
  Must be 'N', 'T' (for real data) or 'C' (for complex data).

  If \( \text{transr} = 'N' \), the Normal \( \text{transr} \) of RFP \( U \) (if \( \text{uplo} = 'U' \)) or \( L \) (if \( \text{uplo} = 'L' \)) is stored.

  If \( \text{transr} = 'T' \), the Transpose \( \text{transr} \) of RFP \( U \) (if \( \text{uplo} = 'U' \)) or \( L \) (if \( \text{uplo} = 'L' \)) is stored.

  If \( \text{transr} = 'C' \), the Conjugate-Transpose \( \text{transr} \) of RFP \( U \) (if \( \text{uplo} = 'U' \)) or \( L \) (if \( \text{uplo} = 'L' \)) is stored.

- **uplo**
  Must be 'U' or 'L'.

  Indicates how the input matrix \( A \) has been factored:

  If \( \text{uplo} = 'U' \), \( A = U^T U \) for real data or \( A = U^H U \) for complex data, and \( U \) is stored.

  If \( \text{uplo} = 'L' \), \( A = L L^T \) for real data or \( A = L L^H \) for complex data, and \( L \) is stored.

- **n**
  The order of the matrix \( A \); \( n \geq 0 \).

- **a**
  Array, size \( (n \times (n+1)/2) \). The array \( a \) contains the factor \( U \) or \( L \) matrix \( A \) in the RFP format.

**Output Parameters**

- **a**
  The symmetric/Hermitian inverse of the original matrix in the same storage format.

**Return Values**

This function returns a value \( \text{info} \).

If \( \text{info}=0 \), the execution is successful.

If \( \text{info} = -i \), parameter \( i \) had an illegal value.

If \( \text{info} = i \), the \( (i,i) \) element of the factor \( U \) or \( L \) is zero, and the inverse could not be computed.

?pptri
Computes the inverse of a packed symmetric (Hermitian) positive-definite matrix using Cholesky factorization.

Syntax

```c
lapack_int LAPACKE_spptri (int matrix_layout, char uplo, lapack_int n, float * ap);

lapack_int LAPACKE_dpptri (int matrix_layout, char uplo, lapack_int n, double * ap);

lapack_int LAPACKE_cpptri (int matrix_layout, char uplo, lapack_int n, lapack_complex_float * ap);

lapack_int LAPACKE_zpptri (int matrix_layout, char uplo, lapack_int n, lapack_complex_double * ap);
```

Include Files

- mkl.h

Description

The routine computes the inverse \( \text{inv}(A) \) of a symmetric positive definite or, for complex flavors, Hermitian positive-definite matrix \( A \) in packed form. Before calling this routine, call ?pptrf to factorize \( A \).

Input Parameters

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **uplo**
  Must be 'U' or 'L'.

  Indicates whether the upper or lower triangular factor is stored in \( ap \):
  - If \( \text{uplo} = 'U' \), then the upper triangular factor is stored.
  - If \( \text{uplo} = 'L' \), then the lower triangular factor is stored.

- **n**
  The order of the matrix \( A \); \( n \geq 0 \).

- **ap**
  Array, size at least \( \text{max}(1, n(n+1)/2) \).

  Contains the factorization of the packed matrix \( A \), as returned by ?pptrf.

  The dimension \( ap \) must be at least \( \text{max}(1,n(n+1)/2) \).

Output Parameters

- **ap**
  Overwritten by the packed \( n \)-by-\( n \) matrix \( \text{inv}(A) \).

Return Values

This function returns a value \( \text{info} \).

- If \( \text{info} = 0 \), the execution is successful.
- If \( \text{info} = -i \), parameter \( i \) had an illegal value.
- If \( \text{info} = i \), the \( i \)-th diagonal element of the Cholesky factor (and therefore the factor itself) is zero, and the inversion could not be completed.
Application Notes
The computed inverse $X$ satisfies the following error bounds:

\[ ||X - I||_2 \leq c(n) \kappa_2(A), \quad ||AX - I||_2 \leq c(n) \kappa(A), \]

where $c(n)$ is a modest linear function of $n$, and $\varepsilon$ is the machine precision; $I$ denotes the identity matrix.

The 2-norm $||A||_2$ of a matrix $A$ is defined by $||A||_2 = \max_{\|x\|=1} (Ax \cdot Ax)^{1/2}$, and the condition number $\kappa_2(A)$ is defined by $\kappa_2(A) = ||A||_2 \cdot ||A^{-1}||_2$.

The total number of floating-point operations is approximately $\frac{2}{3} n^3$ for real flavors and $\frac{8}{3} n^3$ for complex flavors.

lapack_int LAPACKE_zsytri (int matrix_layout, char uplo, lapack_int n, lapack_complex_double * a, lapack_int lda, const lapack_int * ipiv);
```

Include Files

- mkl.h

Description
The routine computes the inverse $\text{inv}(A)$ of a symmetric matrix $A$. Before calling this routine, call sytrf to factorize $A$.

Input Parameters

- **matrix_layout**: Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- **uplo**: Must be ‘U’ or ‘L’.
- **n**: The order of the matrix $A$; $n \geq 0$. 

$a$

$a$ contains the factorization of the matrix $A$, as returned by _?sytrf_.

$lda$

The leading dimension of $a$; $lda \geq \max(1, n)$.

$ipiv$

Array, size at least $\max(1, n)$.

The $ipiv$ array, as returned by _?sytrf_.

**Output Parameters**

$a$

Overwritten by the $n$-by-$n$ matrix $\text{inv}(A)$.

**Return Values**

This function returns a value $info$.

If $info = 0$, the execution is successful.

If $info = -i$, parameter $i$ had an illegal value.

If $info = i$, the $i$-th diagonal element of $D$ is zero, $D$ is singular, and the inversion could not be completed.

**Application Notes**

The computed inverse $X$ satisfies the following error bounds:

$$ |D^*U^T P^T X^* P^T U - I| \leq c(n) \varepsilon (|D| |U^T| P^T |X| P |U| + |D| |D^{-1}|) $$

for $uplo = 'U'$, and

$$ |D^*L^T P^T X^* P^T L - I| \leq c(n) \varepsilon (|D| |L^T| P^T |X| P |L| + |D| |D^{-1}|) $$

for $uplo = 'L$'. Here $c(n)$ is a modest linear function of $n$, and $\varepsilon$ is the machine precision; $I$ denotes the identity matrix.

The total number of floating-point operations is approximately $\frac{2}{3} n^3$ for real flavors and $\frac{8}{3} n^3$ for complex flavors.

```

**Include Files**

- mkl.h

**Description**
The routine computes the inverse \( \text{inv} (A) \) of a complex Hermitian matrix \( A \). Before calling this routine, call \(?\text{hetrf}\) to factorize \( A \).

**Input Parameters**

- **matrix_layout**
  Specifies whether matrix storage layout is row major \((\text{LAPACK\_ROW\_MAJOR})\) or column major \((\text{LAPACK\_COL\_MAJOR})\).

- **uplo**
  Must be 'U' or 'L'.
  Indicates how the input matrix \( A \) has been factored:
  - If \( \text{uplo} = 'U' \), the array \( a \) stores the Bunch-Kaufman factorization \( A = U*D*U^H \).
  - If \( \text{uplo} = 'L' \), the array \( a \) stores the Bunch-Kaufman factorization \( A = L*D*L^H \).

- **n**
  The order of the matrix \( A \); \( n \geq 0 \).

- **a**, array \( a(\text{size max}(1, \text{lda}*n)) \)
  Contains the factorization of the matrix \( A \), as returned by \(?\text{hetrf}\). The second dimension of \( a \) must be at least \( \text{max}(1, n) \).

- **lda**
  The leading dimension of \( a \); \( \text{lda} \geq \text{max}(1, n) \).

- **ipiv**
  Array, size at least \( \text{max}(1, n) \). The \( \text{ipiv} \) array, as returned by \(?\text{hetrf}\).

**Output Parameters**

- **a**
  Overwritten by the \( n \)-by-\( n \) matrix \( \text{inv}(A) \).

**Return Values**

This function returns a value \( \text{info} \).

- If \( \text{info} = 0 \), the execution is successful.
- If \( \text{info} = -i \), parameter \( i \) had an illegal value.
- If \( \text{info} = i \), the \( i \)-th diagonal element of \( D \) is zero, \( D \) is singular, and the inversion could not be completed.

**Application Notes**

The computed inverse \( X \) satisfies the following error bounds:

\[
|D*U^H*P^T*X*P*U - I| \leq c(n)\varepsilon(\|D\|\|U^H\|^2\|P\|\|X\|\|P\|\|U\| + |D||D^{-1}|)
\]

for \( \text{uplo} = 'U' \), and

\[
|D*L^H*P^T*X*P*L - I| \leq c(n)\varepsilon(\|D\|\|L^H\|^2\|P\|\|X\|\|P\|\|L\| + |D||D^{-1}|)
\]

for \( \text{uplo} = 'L' \). Here \( c(n) \) is a modest linear function of \( n \), and \( \varepsilon \) is the machine precision; \( I \) denotes the identity matrix.

The total number of floating-point operations is approximately \( (8/3)n^3 \) for complex flavors.

The real counterpart of this routine is \(?\text{sytri}\).

```

Include Files

- mkl.h

Description

The routine computes the inverse \( \text{inv}(A) \) of a symmetric indefinite matrix \( A \) using the factorization \( A = U^*D*U \) or \( A = L*D*L^T \) computed by ?sytrf.

The ?sytri2 routine allocates a temporary buffer before calling ?sytri2x that actually computes the inverse.

Input Parameters

- `matrix_layout` Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- `uplo` Must be 'U' or 'L'. Indicates how the input matrix \( A \) has been factored:
  - If `uplo` = 'U', the array \( a \) stores the factorization \( A = U^*D*U \).
  - If `uplo` = 'L', the array \( a \) stores the factorization \( A = L*D*L^T \).
- `n` The order of the matrix \( A \); \( n \geq 0 \).
- `a` Array \( a(\text{size max}(1, lda*n)) \) contains the block diagonal matrix \( D \) and the multipliers used to obtain the factor \( U \) or \( L \) as returned by ?sytrf.
- `lda` The leading dimension of \( a \); \( lda \geq \text{max}(1, n) \).
- `ipiv` Array, size at least \( \text{max}(1, n) \). Details of the interchanges and the block structure of \( D \) as returned by ?sytrf.

Output Parameters

- `a` If `info = 0`, the symmetric inverse of the original matrix.
  - If `uplo` = 'U', the upper triangular part of the inverse is formed and the part of \( A \) below the diagonal is not referenced.
If uplo = 'L', the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

**Return Values**

This function returns a value info.

- If info = 0, the execution is successful.
- If info = -i, the i-th parameter had an illegal value.
- If info = i, D(i,i) = 0; D is singular and its inversion could not be computed.

lapack_complex_double * A, lapack_int lda, const lapack_complex_double * e, const
lapack_int * ipiv);
```

Description

?sytri_3 computes the inverse of a real or complex symmetric matrix $A$ using the factorization computed by ?sytrf_rk: $A = P*U*D*(U^T)*(P^T)$ or $A = P*L*D*(L^T)*(P^T)$, where $U$ (or $L$) is a unit upper (or lower) triangular matrix, $U^T$ (or $L^T$) is the transpose of $U$ (or $L$), $P$ is a permutation matrix, $P^T$ is the transpose of $P$, and $D$ is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

?sytri_3 sets the leading dimension of the workspace before calling ?sytri_3x, which actually computes the inverse. This is the blocked version of the algorithm, calling Level-3 BLAS.

Input Parameters

- **matrix_layout**: Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- **uplo**: Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
  - = 'U': The upper triangle of $A$ is stored.
  - = 'L': The lower triangle of $A$ is stored.
- **n**: The order of the matrix $A$. $n \geq 0$.
- **A**: Array of size max(1, $\text{lda} \times n$). On entry, diagonal of the block diagonal matrix $D$ and factors $U$ or $L$ as computed by ?sytrf_rk:
  - Only diagonal elements of the symmetric block diagonal matrix $D$ on the diagonal of $A$; that is, $D(k,k) = A(k,k)$. Superdiagonal (or subdiagonal) elements of $D$ should be provided on entry in array $e$. —and—
• If uplo = 'U', factor U in the superdiagonal part of A. If uplo = 'L', factor L in the subdiagonal part of A.

lda
The leading dimension of the array A.

e
Array of size n. On entry, contains the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks. If uplo = 'U', e(i) = D(i-1:i), i=2:N, and e(1) is not referenced. If uplo = 'L', e(i) = D(i:i+1), i=1:N-1, and e(n) is not referenced.

NOTE For 1-by-1 diagonal block D(k), where 1 ≤ k ≤ n, the element e[k-1] is not referenced in both the uplo = 'U' and uplo = 'L' cases.

ipiv
Array of size n. Details of the interchanges and the block structure of D as determined by ?sytrf_rk.

Output Parameters

A
On exit, if info = 0, the symmetric inverse of the original matrix. If uplo = 'U', the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced. If uplo = 'L', the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

Return Values

This function returns a value info.

= 0: Successful exit.
< 0: If info = -i, the i-th argument had an illegal value.
> 0: If info = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

?hetri_3
Computes the inverse of a complex Hermitian matrix using the factorization computed by ?hetrf_rk.

?hetri_3 computes the inverse of a complex Hermitian matrix A using the factorization computed by ?hetrf_rk: A = P*U*D*(U^H)*(P^T) or A = P*L*D*(L^H)*(P^T), where U (or L) is a unit upper (or lower) triangular matrix, U^H (or L^H) is the conjugate of U (or L), P is a permutation matrix, P^T is the transpose of P, and D is a Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

?hetri_3 sets the leading dimension of the workspace before calling ?hetri_3x, which actually computes the inverse.
This is the blocked version of the algorithm, calling Level-3 BLAS.

**Input Parameters**

- **matrix_layout**: Specifies whether matrix storage layout is row major (**LAPACK_ROW_MAJOR**) or column major (**LAPACK_COL_MAJOR**).

- **uplo**: Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
  - = 'U': The upper triangle of A is stored.
  - = 'L': The lower triangle of A is stored.

- **n**: The order of the matrix A. \( n \geq 0 \).

- **A**: Array of size \( \max(1, lda*n) \). On entry, diagonal of the block diagonal matrix D and factor U or L as computed by \(?hetrf_rk\):
  - Only diagonal elements of the Hermitian block diagonal matrix D on the diagonal of A; that is, \( D(k,k) = A(k,k) \). Superdiagonal (or subdiagonal) elements of D should be provided on entry in array \( e \).
  - If \( uplo = 'U' \), factor U in the superdiagonal part of A. If \( uplo = 'L' \), factor L is the subdiagonal part of A.

- **lda**: The leading dimension of the array A.

- **e**: Array of size \( n \). On entry, contains the superdiagonal (or subdiagonal) elements of the Hermitian block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks. If \( uplo = 'U' \), \( e(i) = D(i-1,i) \), \( i=2:N \), and \( e(1) \) is not referenced. If \( uplo = 'L' \), \( e(i) = D(i+1,i) \), \( i=1:N-1 \), and \( e(n) \) is not referenced.

  **NOTE**: For 1-by-1 diagonal block \( D(k) \), where \( 1 \leq k \leq n \), the element \( e[k-1] \) is not referenced in both the \( uplo = 'U' \) and \( uplo = 'L' \) cases.

- **ipiv**: Array of size \( n \). Details of the interchanges and the block structure of D as determined by \(?hetrf_rk\).

**Output Parameters**

- **A**: On exit, if \( info = 0 \), the Hermitian inverse of the original matrix. If \( uplo = 'U' \), the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced. If \( uplo = 'L' \), the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

**Return Values**

This function returns a value \( info \).

- \( = 0 \): Successful exit.
- \( < 0 \): If \( info = -i \), the \( i^{th} \) argument had an illegal value.
- \( > 0 \): If \( info = i \), \( D(i,i) = 0 \); the matrix is singular and its inverse could not be computed.
Computes the inverse of a symmetric matrix using \(U^\star D \star U^T\) or \(L^\star D \star L^T\) Bunch-Kaufman factorization of matrix in packed storage.

**Syntax**

```c
lapack_int LAPACKE_ssptri (int matrix_layout, char uplo, lapack_int n, float * ap, const lapack_int * ipiv);
lapack_int LAPACKE_dsptri (int matrix_layout, char uplo, lapack_int n, double * ap, const lapack_int * ipiv);
lapack_int LAPACKE_csptri (int matrix_layout, char uplo, lapack_int n, lapack_complex_float * ap, const lapack_int * ipiv);
lapack_int LAPACKE_zsptri (int matrix_layout, char uplo, lapack_int n, lapack_complex_double * ap, const lapack_int * ipiv);
```

**Include Files**

- mkl.h

**Description**

The routine computes the inverse \(\text{inv}(A)\) of a packed symmetric matrix \(A\). Before calling this routine, call \(?\text{sptrf}\) to factorize \(A\).

**Input Parameters**

- `matrix_layout`
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- `uplo`
  Must be 'U' or 'L'.
  Indicates how the input matrix \(A\) has been factored:
  - If `uplo` = 'U', the array `ap` stores the Bunch-Kaufman factorization \(A = U^\star D \star U^T\).
  - If `uplo` = 'L', the array `ap` stores the Bunch-Kaufman factorization \(A = L^\star D \star L^T\).

- `n`
  The order of the matrix \(A\); \(n \geq 0\).

- `ap`
  Arrays `ap` (size \(\max(1, n(n+1)/2)\)) contains the factorization of the matrix \(A\), as returned by \(?\text{sptrf}\).

- `ipiv`
  Array, size at least \(\max(1, n)\). The `ipiv` array, as returned by \(?\text{sptrf}\).

**Output Parameters**

- `ap`
  Overwritten by the matrix \(\text{inv}(A)\) in packed form.

**Return Values**

This function returns a value `info`.

- If `info` = 0, the execution is successful.
- If `info` = \(-i\), parameter \(i\) had an illegal value.
If \( info = i \), the \( i \)-th diagonal element of \( D \) is zero, \( D \) is singular, and the inversion could not be completed.

**Application Notes**

The computed inverse \( X \) satisfies the following error bounds:

\[
|D^*U^*P^*X*P*U - I| \leq c(n)\varepsilon(|D| |U^*P^*X| |P|U| + |D| |D^{-1}|)
\]

for \( uplo = 'U' \), and

\[
|D^*L^*P^*X*P*L - I| \leq c(n)\varepsilon(|D| |L^*P^*X| |P|L| + |D| |D^{-1}|)
\]

for \( uplo = 'L' \). Here \( c(n) \) is a modest linear function of \( n \), and \( \varepsilon \) is the machine precision; \( I \) denotes the identity matrix.

The total number of floating-point operations is approximately \((2/3)n^3\) for real flavors and \((8/3)n^3\) for complex flavors.

**Description**

The routine computes the inverse \( \text{inv}(A) \) of a complex Hermitian matrix \( A \) using packed storage. Before calling this routine, call ?hptrf to factorize \( A \).

**Input Parameters**

- \( matrix\_layout \): Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- \( uplo \): Must be \('U'\) or \('L'\).
  Indicates how the input matrix \( A \) has been factored:
  - If \( uplo = 'U' \), the array \( ap \) stores the packed Bunch-Kaufman factorization \( A = U^*D^*U^T \).
  - If \( uplo = 'L' \), the array \( ap \) stores the packed Bunch-Kaufman factorization \( A = L^*D^*L^T \).
- \( n \): The order of the matrix \( A \); \( n \geq 0 \).
Array \( ap \) (size \( \max(1,n(n+1)/2) \)) contains the factorization of the matrix \( A \), as returned by \(?hptrf\).

Array, size at least \( \max(1, n) \).

The \( ipiv \) array, as returned by \(?hptrf\).

**Output Parameters**

\( ap \) Overwritten by the matrix \( \text{inv}(A) \).

**Return Values**

This function returns a value \( info \).

If \( info = 0 \), the execution is successful.

If \( info = -i \), parameter \( i \) had an illegal value.

If \( info = i \), the \( i \)-th diagonal element of \( D \) is zero, \( D \) is singular, and the inversion could not be completed.

**Application Notes**

The computed inverse \( X \) satisfies the following error bounds:

\[
| D^*U^*P^*X^*P^*U - I | \leq c(n)\varepsilon \left( |D| |U^*P^*X|P|U| + |D| |D^{-1}| \right)
\]

for \( \text{uplo} = 'U' \), and

\[
| D^*L^*P^*X^*PL - I | \leq c(n)\varepsilon \left( |D^*L^*P^*X|P|L| + |D| |D^{-1}| \right)
\]

for \( \text{uplo} = 'L' \). Here \( c(n) \) is a modest linear function of \( n \), and \( \varepsilon \) is the machine precision; \( I \) denotes the identity matrix.

The total number of floating-point operations is approximately \( (8/3)n^3 \).

The real counterpart of this routine is \(?sptri\).

lapack_int LAPACKE_ztftri (int matrix_layout , char transr , char uplo , char diag ,
lapack_int n , lapack_complex_double * a );
```

**Include Files**
- mkl.h

**Description**

Computes the inverse of a triangular matrix stored in the Rectangular Full Packed (RFP) format. For the description of the RFP format, see Matrix Storage Schemes.

This is the block version of the algorithm, calling Level 3 BLAS.

**Input Parameters**

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **transr**
  Must be 'N', 'T' (for real data) or 'C' (for complex data).
  If `transr` = 'N', the Normal `transr` of RFP A is stored.
  If `transr` = 'T', the Transpose `transr` of RFP A is stored.
  If `transr` = 'C', the Conjugate-Transpose `transr` of RFP A is stored.

- **uplo**
  Must be 'U' or 'L'.
  Indicates whether the upper or lower triangular part of RFP A is stored:
  If `uplo` = 'U', the array `a` stores the upper triangular part of the matrix A.
  If `uplo` = 'L', the array `a` stores the lower triangular part of the matrix A.

- **diag**
  Must be 'N' or 'U'.
  If `diag` = 'N', then A is not a unit triangular matrix.
  If `diag` = 'U', A is unit triangular: diagonal elements of A are assumed to be 1 and not referenced in the array `a`.

- **n**
  The order of the matrix A; \( n \geq 0 \).
Array, size max(1, n*(n + 1)/2). The array \( a \) contains the matrix \( A \) in the RFP format.

**Output Parameters**

\( a \)  
The (triangular) inverse of the original matrix in the same storage format.

**Return Values**

This function returns a value \( info \).
- If \( info=0 \), the execution is successful.
- If \( info = -i \), parameter \( i \) had an illegal value.
- If \( info = i, A_{i, i} \) is exactly zero. The triangular matrix is singular and its inverse cannot be computed.

\[ n \]

The order of the matrix \( A \); \( n \geq 0 \).

\[ ap \]

Array, size at least \( \max(1, n(n+1)/2) \).

Contains the packed triangular matrix \( A \).

Output Parameters

\[ ap \]

Overwritten by the packed \( n \)-by-\( n \) matrix \( \text{inv}(A) \).

Return Values

This function returns a value \( \text{info} \).

If \( \text{info} = 0 \), the execution is successful.

If \( \text{info} = -i \), parameter \( i \) had an illegal value.

If \( \text{info} = i \), the \( i \)-th diagonal element of \( A \) is zero, \( A \) is singular, and the inversion could not be completed.

Application Notes

The computed inverse \( X \) satisfies the following error bounds:

\[ |XA - I| \leq c(n)\varepsilon |X||A| \]

\[ |X - A^{-1}| \leq c(n)\varepsilon |A^{-1}||A||X| \]

where \( c(n) \) is a modest linear function of \( n \); \( \varepsilon \) is the machine precision; \( I \) denotes the identity matrix.

The total number of floating-point operations is approximately \( (1/3)n^3 \) for real flavors and \( (4/3)n^3 \) for complex flavors.

Matrix Equilibration: LAPACK Computational Routines

Routines described in this section are used to compute scaling factors needed to equilibrate a matrix. Note that these routines do not actually scale the matrices.

?geequ

Computes row and column scaling factors intended to equilibrate a general matrix and reduce its condition number.

Syntax

```c
lapack_int LAPACKE_sgeequ( int matrix_layout, lapack_int m, lapack_int n, const float* a, lapack_int lda, float* r, float* c, float* rowcnd, float* colcnd, float* amax );
```

```c
lapack_int LAPACKE_dgeequ( int matrix_layout, lapack_int m, lapack_int n, const double* a, lapack_int lda, double* r, double* c, double* rowcnd, double* colcnd, double* amax );
```

```c
lapack_int LAPACKE_cgeequ( int matrix_layout, lapack_int m, lapack_int n, const lapack_complex_float* a, lapack_int lda, float* r, float* c, float* rowcnd, float* colcnd, float* amax );
```

```c
lapack_int LAPACKE_zgeequ( int matrix_layout, lapack_int m, lapack_int n, const lapack_complex_double* a, lapack_int lda, double* r, double* c, double* rowcnd, double* colcnd, double* amax );
```
lapack_int LAPACKE_zgeequ( int matrix_layout, lapack_int m, lapack_int n, const
lapack_complex_double* a, lapack_int lda, double* r, double* c, double* rowcnd, double* colcnd, double* amax );

**Include Files**

- mkl.h

**Description**

The routine computes row and column scalings intended to equilibrate an $m$-by-$n$ matrix $A$ and reduce its condition number. The output array $r$ returns the row scale factors and the array $c$ the column scale factors. These factors are chosen to try to make the largest element in each row and column of the matrix $B$ with elements $b_{ij} = r_{i-1} \cdot a_{ij} \cdot c_{j-1}$ have absolute value 1.

**Input Parameters**

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- **m**
  The number of rows of the matrix $A$; $m \geq 0$.
- **n**
  The number of columns of the matrix $A$; $n \geq 0$.
- **a**
  Array: size max(1, $lda \cdot n$) for column major layout and max(1, $lda \cdot m$) for row major layout.
  Contains the $m$-by-$n$ matrix $A$ whose equilibration factors are to be computed.
- **lda**
  The leading dimension of $a$; $lda \geq \max(1, m)$.

**Output Parameters**

- **r**, **c**
  Arrays: $r$ (size $m$), $c$ (size $n$).
  If $info = 0$, or $info > m$, the array $r$ contains the row scale factors of the matrix $A$.
  If $info = 0$, the array $c$ contains the column scale factors of the matrix $A$.
- **rowcnd**
  If $info = 0$ or $info > m$, $rowcnd$ contains the ratio of the smallest $r[i]$ to the largest $r[i]$.
- **colcnd**
  If $info = 0$, $colcnd$ contains the ratio of the smallest $c[i]$ to the largest $c[i]$.
- **amax**
  Absolute value of the largest element of the matrix $A$.

**Return Values**

This function returns a value $info$.
If $info = 0$, the execution is successful.
If $info = -i$, parameter $i$ had an illegal value.
If $info = i$, $i > 0$, and $i \leq m$, the $i$-th row of $A$ is exactly zero;
If \( i > m \), the \((i-m)\)th column of \( A \) is exactly zero.

**Application Notes**

All the components of \( r \) and \( c \) are restricted to be between \( \text{SMLNUM} = \text{smallest safe number} \) and \( \text{BIGNUM} = \text{largest safe number} \). Use of these scaling factors is not guaranteed to reduce the condition number of \( A \) but works well in practice.

\( \text{SMLNUM} \) and \( \text{BIGNUM} \) are parameters representing machine precision. You can use the \texttt{?lamch} routines to compute them. For example, compute single precision values of \( \text{SMLNUM} \) and \( \text{BIGNUM} \) as follows:

\[
\text{SMLNUM} = \text{slamch ('s')}
\text{BIGNUM} = \frac{1}{\text{SMLNUM}}
\]

If \( \text{rowcnd} \geq 0.1 \) and \( \text{amax} \) is neither too large nor too small, it is not worth scaling by \( r \).

If \( \text{colcnd} \geq 0.1 \), it is not worth scaling by \( c \).

If \( \text{amax} \) is very close to \( \text{SMLNUM} \) or very close to \( \text{BIGNUM} \), the matrix \( A \) should be scaled.

**See Also**

Error Analysis
Matrix Storage Schemes

\texttt{?geequb}

*Computes row and column scaling factors restricted to a power of radix to equilibrate a general matrix and reduce its condition number.*

**Syntax**

```c
lapack_int LAPACK_sgeequb( int matrix_layout, lapack_int m, lapack_int n, const float* a, lapack_int lda, float* r, float* c, float* rowcnd, float* colcnd, float* amax );
```

```c
lapack_int LAPACK_dgeequb( int matrix_layout, lapack_int m, lapack_int n, const double* a, lapack_int lda, double* r, double* c, double* rowcnd, double* colcnd, double* amax );
```

```c
lapack_int LAPACK_cgeequb( int matrix_layout, lapack_int m, lapack_int n, const lapack_complex_float* a, lapack_int lda, float* r, float* c, float* rowcnd, float* colcnd, float* amax );
```

```c
lapack_int LAPACK_zgeequb( int matrix_layout, lapack_int m, lapack_int n, const lapack_complex_double* a, lapack_int lda, double* r, double* c, double* rowcnd, double* colcnd, double* amax );
```

**Include Files**

- \texttt{mkl.h}

**Description**

The routine computes row and column scalings intended to equilibrate an \( m \)-by-\( n \) general matrix \( A \) and reduce its condition number. The output array \( r \) returns the row scale factors and the array \( c \) - the column scale factors. These factors are chosen to try to make the largest element in each row and column of the matrix \( B \) with elements \( b_{i,j} = r_{[i-1]}a_{i,j}c_{[j-1]} \) have an absolute value of at most the radix.

\( r_{[i-1]} \) and \( c_{[j-1]} \) are restricted to be a power of the radix between \( \text{SMLNUM} = \text{smallest safe number} \) and \( \text{BIGNUM} = \text{largest safe number} \). Use of these scaling factors is not guaranteed to reduce the condition number of \( A \) but works well in practice.
**SMLNUM** and **BIGNUM** are parameters representing machine precision. You can use the ?lamch routines to compute them. For example, compute single precision values of **SMLNUM** and **BIGNUM** as follows:

```
SMLNUM = slamch ('s')
BIGNUM = 1 / SMLNUM
```

This routine differs from ?geequ by restricting the scaling factors to a power of the radix. Except for over- and underflow, scaling by these factors introduces no additional rounding errors. However, the scaled entries' magnitudes are no longer equal to approximately 1 but lie between \(\sqrt{\text{radix}}\) and \(1/\sqrt{\text{radix}}\).

**Input Parameters**

```

Include Files

```
• mkl.h
```

Description

The routine computes row and column scalings intended to equilibrate an m-by-n band matrix A and reduce its condition number. The output array r returns the row scale factors and the array c the column scale factors. These factors are chosen to try to make the largest element in each row and column of the matrix B with elements \( b_{ij} = r[i - 1] \cdot a_{ij} \cdot c[j - 1] \) have absolute value 1.

Input Parameters

```
matrix_layout
   Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

m
   The number of rows of the matrix A; n ≥ 0.

n
   The number of columns of the matrix A; n ≥ 0.

kl
   The number of subdiagonals within the band of A; kl ≥ 0.

ku
   The number of superdiagonals within the band of A; ku ≥ 0.

ab
   Array, size max(1, ldab*n) for column major layout and max(1, ldab*m) for row major layout. Contains the original band matrix A.

ldab
   The leading dimension of ab; ldab ≥ kl+ku+1.
```
Output Parameters

$r, c$

Arrays: $r$ (size $m$), $c$ (size $n$).

If $info = 0$, or $info > m$, the array $r$ contains the row scale factors of the matrix $A$.

If $info = 0$, the array $c$ contains the column scale factors of the matrix $A$.

$\text{rowcnd}$

If $info = 0$ or $info > m$, $\text{rowcnd}$ contains the ratio of the smallest $r[i]$ to the largest $r[i]$.

$\text{colcnd}$

If $info = 0$, $\text{colcnd}$ contains the ratio of the smallest $c[i]$ to the largest $c[i]$.

$\text{amax}$

Absolute value of the largest element of the matrix $A$.

Return Values

This function returns a value $info$.

If $info = 0$, the execution is successful.

If $info = -i$, parameter $i$ had an illegal value.

If $info = i$ and

- $i \leq m$, the $i$-th row of $A$ is exactly zero;
- $i > m$, the $(i-m)$th column of $A$ is exactly zero.

Application Notes

All the components of $r$ and $c$ are restricted to be between $SMLNUM = \text{smallest safe number}$ and $BIGNUM = \text{largest safe number}$.

Use of these scaling factors is not guaranteed to reduce the condition number of $A$ but works well in practice.

$SMLNUM$ and $BIGNUM$ are parameters representing machine precision. You can use the $?\text{lamch}$ routines to compute them. For example, compute single precision values of $SMLNUM$ and $BIGNUM$ as follows:

```plaintext
SMLNUM = slamch('s')
BIGNUM = 1 / SMLNUM
```

If $\text{rowcnd} \geq 0.1$ and $\text{amax}$ is neither too large nor too small, it is not worth scaling by $r$.

If $\text{colcnd} \geq 0.1$, it is not worth scaling by $c$.

If $\text{amax}$ is very close to $SMLNUM$ or very close to $BIGNUM$, the matrix $A$ should be scaled.

Description

The routine computes row and column scalings intended to equilibrate an \( m \)-by-\( n \) banded matrix \( A \) and reduce its condition number. The output array \( r \) returns the row scale factors and the array \( c \) - the column scale factors. These factors are chosen to try to make the largest element in each row and column of the matrix \( B \) with elements \( b_{i,j} = r_{[i-1]} \times a_{i,j} \times c_{[j-1]} \) have an absolute value of at most the radix. \( r_{[i]} \) and \( c_{[j]} \) are restricted to be a power of the radix between \( \text{SMLNUM} = \text{smallest safe number} \) and \( \text{BIGNUM} = \text{largest safe number} \). Use of these scaling factors is not guaranteed to reduce the condition number of \( A \) but works well in practice.

\( \text{SMLNUM} \) and \( \text{BIGNUM} \) are parameters representing machine precision. You can use the \(?\text{lamch}\) routines to compute them. For example, compute single precision values of \( \text{SMLNUM} \) and \( \text{BIGNUM} \) as follows:

```c
SMLNUM = slamch('s')
BIGNUM = 1 / SMLNUM
```

This routine differs from \(?\text{gbequ}\) by restricting the scaling factors to a power of the radix. Except for over- and underflow, scaling by these factors introduces no additional rounding errors. However, the scaled entries' magnitudes are no longer equal to approximately 1 but lie between \( \sqrt{\text{radix}} \) and \( 1/\sqrt{\text{radix}} \).

Input Parameters

- `matrix_layout` Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- `m` The number of rows of the matrix \( A \); \( m \geq 0 \).
- `n` The number of columns of the matrix \( A \); \( n \geq 0 \).
- `kl` The number of subdiagonals within the band of \( A \); \( kl \geq 0 \).
- `ku` The number of superdiagonals within the band of \( A \); \( ku \geq 0 \).
- `ab` Array: size max(1, \( \text{ldab} \times n \)) for column major layout and max(1, \( \text{ldab} \times m \)) for row major layout.
- `ldab` The leading dimension of \( A \); \( \text{ldab} \geq \max(1, m) \).
Output Parameters

$r, c$
Arrays: $r$ (size $m$), $c$ (size $n$).
If $info = 0$, or $info > m$, the array $r$ contains the row scale factors for the matrix $A$.
If $info = 0$, the array $c$ contains the column scale factors for the matrix $A$.

$\text{rowcnd}$
If $info = 0$ or $info > m$, $\text{rowcnd}$ contains the ratio of the smallest $r(i)$ to the largest $r(i)$. If $\text{rowcnd} \geq 0.1$, and $amax$ is neither too large nor too small, it is not worth scaling by $r$.

$\text{colcnd}$
If $info = 0$, $\text{colcnd}$ contains the ratio of the smallest $c[i]$ to the largest $c[i]$. If $\text{colcnd} \geq 0.1$, it is not worth scaling by $c$.

$\text{amax}$
Absolute value of the largest element of the matrix $A$. If $\text{amax}$ is very close to SMLNUM or BIGNUM, the matrix should be scaled.

Return Values
This function returns a value $info$.
If $info = 0$, the execution is successful.
If $info = -i$, parameter $i$ had an illegal value.
If $info = i$, the $i$-th diagonal element of $A$ is nonpositive.
$i \leq m$, the $i$-th row of $A$ is exactly zero;
$i > m$, the $(i-m)$-th column of $A$ is exactly zero.

Description

The routine computes row and column scalings intended to equilibrate a symmetric (Hermitian) positive-definite matrix $A$ and reduce its condition number (with respect to the two-norm). The output array $s$ returns scale factors such that contains

$$1 / \sqrt{a_{i,i}}$$

These factors are chosen so that the scaled matrix $B$ with elements $B_{i,j} = s[i-1] * A_{i,j} * s[j-1]$ has diagonal elements equal to 1.

This choice of $s$ puts the condition number of $B$ within a factor $n$ of the smallest possible condition number over all possible diagonal scalings.

Input Parameters

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **n**
  The order of the matrix $A$; $n \geq 0$.

- **a**
  Array: size max(1, $lda * n$).
  Contains the $n$-by-$n$ symmetric or Hermitian positive definite matrix $A$ whose scaling factors are to be computed. Only the diagonal elements of $A$ are referenced.

- **lda**
  The leading dimension of $a$; $lda \geq max(1, n)$.

Output Parameters

- **s**
  Array, size $n$.
  If $info = 0$, the array $s$ contains the scale factors for $A$.

- **scond**
  If $info = 0$, $scond$ contains the ratio of the smallest $s[i]$ to the largest $s[i]$.

- **amax**
  Absolute value of the largest element of the matrix $A$.

Return Values

This function returns a value $info$.

If $info = 0$, the execution is successful.

If $info = -i$, parameter $i$ had an illegal value.

If $info = i$, the $i$-th diagonal element of $A$ is nonpositive.

Application Notes

If $scond \geq 0.1$ and $amax$ is neither too large nor too small, it is not worth scaling by $s$.

If $amax$ is very close to SMLNUM or very close to BIGNUM, the matrix $A$ should be scaled.

Description

The routine computes row and column scalings intended to equilibrate a symmetric (Hermitian) positive-definite matrix \( A \) and reduce its condition number (with respect to the two-norm).

These factors are chosen so that the scaled matrix \( B \) with elements \( B_{ij} = s_{i-1}A_{ij}s_{j-1} \) has diagonal elements equal to 1. \( s[i - 1] \) is a power of two nearest to, but not exceeding \( 1/sqrt(A_{ii}) \).

This choice of \( s \) puts the condition number of \( B \) within a factor \( n \) of the smallest possible condition number over all possible diagonal scalings.

Input Parameters

- `matrix_layout`
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- `n`
  The order of the matrix \( A \); \( n \geq 0 \).

- `a`
  Array: size max(1, lda*n).
  Contains the \( n \)-by-\( n \) symmetric or Hermitian positive definite matrix \( A \) whose scaling factors are to be computed. Only the diagonal elements of \( A \) are referenced.

- `lda`
  The leading dimension of \( a \); \( lda \geq max(1, m) \).

Output Parameters

- `s`
  Array, size \((n)\).
  If `info = 0`, the array \( s \) contains the scale factors for \( A \).
If info = 0, scond contains the ratio of the smallest $s[i]$ to the largest $s[i]$. If $scond \geq 0.1$, and $amax$ is neither too large nor too small, it is not worth scaling by $s$.

$amax$

Absolute value of the largest element of the matrix $A$. If $amax$ is very close to SMLNUM or BIGNUM, the matrix should be scaled.

Return Values

This function returns a value info.

If info = 0, the execution is successful.

If info = -i, parameter i had an illegal value.

If info = i, the $i$-th diagonal element of $A$ is nonpositive.

Description

The routine computes row and column scalings intended to equilibrate a symmetric (Hermitian) positive definite matrix $A$ in packed storage and reduce its condition number (with respect to the two-norm). The output array $s$ returns scale factors such that contains

$$s(i) = \frac{1}{\sqrt{a_{ii}}}$$

These factors are chosen so that the scaled matrix $B$ with elements $b_{ij}=s[i-1]*a_{ij}*s[j-1]$ has diagonal elements equal to 1.

This choice of $s$ puts the condition number of $B$ within a factor $n$ of the smallest possible condition number over all possible diagonal scalings.
Input Parameters

matrix_layout
Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

uplo
Must be 'U' or 'L'.
Indicates whether the upper or lower triangular part of A is packed in the array ap:
If uplo = 'U', the array ap stores the upper triangular part of the matrix A.
If uplo = 'L', the array ap stores the lower triangular part of the matrix A.

n
The order of matrix A; n ≥ 0.

ap
Array, size at least max(1, n(n+1)/2). The array ap contains the upper or the lower triangular part of the matrix A (as specified by uplo) in packed storage (see Matrix Storage Schemes).

Output Parameters

s
Array, size (n).
If info = 0, the array s contains the scale factors for A.

scond
If info = 0, scond contains the ratio of the smallest s[i] to the largest s[i].

amax
Absolute value of the largest element of the matrix A.

Return Values

This function returns a value info.
If info = 0, the execution is successful.
If info = -i, parameter i had an illegal value.
If info = i, the i-th diagonal element of A is nonpositive.

Application Notes

If scond ≥ 0.1 and amax is neither too large nor too small, it is not worth scaling by s.
If amax is very close to SMLNUM or very close to BIGNUM, the matrix A should be scaled.

Description

The routine computes row and column scalings intended to equilibrate a symmetric (Hermitian) positive definite band matrix \( A \) and reduce its condition number (with respect to the two-norm). The output array \( s \) returns scale factors such that contains

\[
S(i) = \frac{1}{\sqrt{a_{i,i}}}
\]

These factors are chosen so that the scaled matrix \( B \) with elements \( b_{ij} = s_{i-1} \cdot a_{ij} \cdot s_{j-1} \) has diagonal elements equal to 1. This choice of \( s \) puts the condition number of \( B \) within a factor \( n \) of the smallest possible condition number over all possible diagonal scalings.

Input Parameters

- **matrix_layout**: Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- **uplo**: Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of \( A \) is stored in the array \( ab \):
  - If \( uplo = \text{'U'} \), the array \( ab \) stores the upper triangular part of the matrix \( A \).
  - If \( uplo = \text{'L'} \), the array \( ab \) stores the lower triangular part of the matrix \( A \).
- **n**: The order of matrix \( A \); \( n \geq 0 \).
- **kd**: The number of superdiagonals or subdiagonals in the matrix \( A \); \( kd \geq 0 \).
- **ab**: Array, size \( \max(1, ldab \cdot n) \).
  - The array \( ab \) contains either the upper or the lower triangular part of the matrix \( A \) (as specified by \( uplo \)) in band storage (see Matrix Storage Schemes).
- **ldab**: The leading dimension of the array \( ab \); \( ldab \geq kd + 1 \).
Output Parameters

$s$  
Array, size ($n$).  
If $info = 0$, the array $s$ contains the scale factors for $A$.

$scond$  
If $info = 0$, $scond$ contains the ratio of the smallest $s[i]$ to the largest $s[i]$.

$amax$  
Absolute value of the largest element of the matrix $A$.

Return Values

This function returns a value $info$.

If $info = 0$, the execution is successful.

If $info = -i$, parameter $i$ had an illegal value.

If $info = i$, the $i$-th diagonal element of $A$ is nonpositive.

Application Notes

If $scond < 0.1$ and $amax$ is neither too large nor too small, it is not worth scaling by $s$.

If $amax$ is very close to $SMLNUM$ or very close to $BIGNUM$, the matrix $A$ should be scaled.

lapack_int LAPACKE_zheequb( int matrix_layout, char uplo, lapack_int n, const 
lapack_complex_double* a, lapack_int lda, double* s, double* scond, double* amax );
```

Include Files

- mkl.h

Description

The routine computes row and column scalings intended to equilibrate a Hermitian indefinite matrix $A$ and reduce its condition number (with respect to the two-norm).

The array $s$ contains the scale factors, $s[i-1] = 1/\sqrt{a_{i,i}}$. These factors are chosen so that the scaled matrix $B$ with elements $b_{i,j} = s[i-1]a_{i,j}s[j-1]$ has ones on the diagonal.

This choice of $s$ puts the condition number of $B$ within a factor $n$ of the smallest possible condition number over all possible diagonal scalings.

Input Parameters

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **uplo**
  Must be 'U' or 'L'.
  Indicates whether the upper or lower triangular part of $A$ is stored:
  - If uplo = 'U', the array $a$ stores the upper triangular part of the matrix $A$.
  - If uplo = 'L', the array $a$ stores the lower triangular part of the matrix $A$.

- **n**
  The order of the matrix $A$; $n \geq 0$.

- **a**
  Array $a$: size max(1, lda*n).
  Contains the $n$-by-$n$ symmetric indefinite matrix $A$ whose scaling factors are to be computed. Only the diagonal elements of $A$ are referenced.

- **lda**
  The leading dimension of $a$; lda $\geq$ max(1, $m$).

Output Parameters

- **s**
  Array, size ($n$).
  If info = 0, the array $s$ contains the scale factors for $A$.

- **scond**
  If info = 0, scond contains the ratio of the smallest $s[i]$ to the largest $s[i]$. If scond $\geq$ 0.1, and amax is neither too large nor too small, it is not worth scaling by s.

- **amax**
  Absolute value of the largest element of the matrix $A$. If amax is very close to SMLNUM or BIGNUM, the matrix should be scaled.
Return Values
This function returns a value info.
If info = 0, the execution is successful.
If info = -i, parameter i had an illegal value.
If info = i, the i-th diagonal element of A is nonpositive.

lapack_int LAPACKE_cgesv (int matrix_layout, lapack_int n, lapack_int nrhs, lapack_complex_float *a, lapack_int lda, lapack_int *ipiv, lapack_complex_float *b, lapack_int ldb);

lapack_int LAPACKE_zgesv (int matrix_layout, lapack_int n, lapack_int nrhs, lapack_complex_double *a, lapack_int lda, lapack_int *ipiv, lapack_complex_double *b, lapack_int ldb);

lapack_int LAPACKE_dsgesv (int matrix_layout, lapack_int n, lapack_int nrhs, double *a, lapack_int lda, lapack_int *ipiv, double *b, lapack_int ldb, double *x, lapack_int ldx, lapack_int *iter);

lapack_int LAPACKE_zcgesv (int matrix_layout, lapack_int n, lapack_int nrhs, lapack_complex_double *a, lapack_int lda, lapack_int *ipiv, lapack_complex_double *b, lapack_int ldb, lapack_complex_double *x, lapack_int ldx, lapack_int *iter);
```

**Include Files**

- mkl.h

**Description**

The routine solves for X the system of linear equations $A^*X = B$, where $A$ is an $n$-by-$n$ matrix, the columns of matrix $B$ are individual right-hand sides, and the columns of $X$ are the corresponding solutions. The LU decomposition with partial pivoting and row interchanges is used to factor $A$ as $A = P*L*U$, where $P$ is a permutation matrix, $L$ is unit lower triangular, and $U$ is upper triangular. The factored form of $A$ is then used to solve the system of equations $A^*X = B$.

The dsgesv and zcgessv are mixed precision iterative refinement subroutines for exploiting fast single precision hardware. They first attempt to factorize the matrix in single precision (dsgesv) or single complex precision (zcgesv) and use this factorization within an iterative refinement procedure to produce a solution with double precision (dsgesv) / double complex precision (zcgesv) normwise backward error quality (see below). If the approach fails, the method switches to a double precision or double complex precision factorization respectively and computes the solution.
The iterative refinement is not going to be a winning strategy if the ratio single precision performance over double precision performance is too small. A reasonable strategy should take the number of right-hand sides and the size of the matrix into account. This might be done with a call to ilaenv in the future. At present, iterative refinement is implemented.

The iterative refinement process is stopped if

\[ \text{iter} > \text{itermax} \]

or for all the right-hand sides:

\[ \text{rnmr} < \sqrt{n} \times \text{xnrm} \times \text{anrm} \times \text{eps} \times \text{bwmax} \]

where

- \text{iter} is the number of the current iteration in the iterative refinement process
- \text{rnmr} is the infinity-norm of the residual
- \text{xnrm} is the infinity-norm of the solution
- \text{anrm} is the infinity-operator-norm of the matrix \( A \)
- \text{eps} is the machine epsilon returned by \text{dlamch} (‘Epsilon’).

The values \text{itermax} and \text{bwmax} are fixed to 30 and 1.0d+00 respectively.

**Input Parameters**

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- **n**
  The number of linear equations, that is, the order of the matrix \( A \); \( n \geq 0 \).
- **nrhs**
  The number of right-hand sides, that is, the number of columns of the matrix \( B \); \( nrhs \geq 0 \).
- **a**
  The array \( a \) of size \( \max(1, lda \times n) \) contains the \( n \)-by-\( n \) coefficient matrix \( A \).
- **b**
  The array \( b \) of size \( \max(1, ldb \times nrhs) \) for column major layout and \( \max(1, ldb \times n) \) for row major layout contains the \( n \)-by-\( nrhs \) matrix of right hand side matrix \( B \).
- **lda**
  The leading dimension of the array \( a \); \( lda \geq \max(1, n) \).
- **ldb**
  The leading dimension of the array \( b \); \( ldb \geq \max(1, n) \) for column major layout and \( ldb \geq nrhs \) for row major layout.
- **ldx**
  The leading dimension of the array \( x \); \( ldx \geq \max(1, n) \) for column major layout and \( ldx \geq nrhs \) for row major layout.

**Output Parameters**

- **a**
  Overwritten by the factors \( L \) and \( U \) from the factorization of \( A = P*L*U \); the unit diagonal elements of \( L \) are not stored.

  If iterative refinement has been successfully used (\text{info} = 0 and \text{iter} \geq 0), then \( A \) is unchanged.
If double precision factorization has been used (\( \text{info} = 0 \) and \( \text{iter} < 0 \)), then the array \( A \) contains the factors \( L \) and \( U \) from the factorization \( A = P*L*U \); the unit diagonal elements of \( L \) are not stored.

\[ b \]
Overwritten by the solution matrix \( X \) for \( \text{dgesv} \), \( \text{sgevs} \), \( \text{zgesv} \), \( \text{zgesv} \). Unchanged for \( \text{dsgevs} \) and \( \text{zcgesv} \).

\[ \text{ipiv} \]
Array, size at least \( \max(1, n) \). The pivot indices that define the permutation matrix \( P \); row \( i \) of the matrix was interchanged with row \( \text{ipiv}[i-1] \). Corresponds to the single precision factorization (if \( \text{info} = 0 \) and \( \text{iter} \geq 0 \)) or the double precision factorization (if \( \text{info} = 0 \) and \( \text{iter} < 0 \)).

\[ x \]
Array, size \( \max(1, ldx*nrhs) \) for column major layout and \( \max(1, ldx*n) \) for row major layout. If \( \text{info} = 0 \), contains the \( n \)-by-\( nrhs \) solution matrix \( X \).

\[ \text{iter} \]
If \( \text{iter} < 0 \): iterative refinement has failed. Iterative refinement has been performed

- If \( \text{iter} = -1 \): the routine fell back to full precision for implementation- or machine-specific reason
- If \( \text{iter} = -2 \): narrowing the precision induced an overflow, the routine fell back to full precision
- If \( \text{iter} = -3 \): failure of \( \text{sgetrf} \) for \( \text{dgesv} \), or \( \text{cgetrf} \) for \( \text{zcgesv} \)
- If \( \text{iter} = -31 \): stop the iterative refinement after the 30th iteration.

If \( \text{iter} > 0 \): iterative refinement has been successfully used. Returns the number of iterations.

**Return Values**

This function returns a value \( \text{info} \).

If \( \text{info}=0 \), the execution is successful.

If \( \text{info} = -i \), parameter \( i \) had an illegal value.

If \( \text{info} = i, U_{ii} \) (computed in double precision for mixed precision subroutines) is exactly zero. The factorization has been completed, but the factor \( U \) is exactly singular, so the solution could not be computed.

```

Include Files

- mkl.h

Description

The routine uses the LU factorization to compute the solution to a real or complex system of linear equations

$$AX = B,$$

where $A$ is an $n$-by-$n$ matrix, the columns of matrix $B$ are individual right-hand sides, and the
columns of $X$ are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine ?gesvx performs the following steps:

1. If `fact = 'E'`, real scaling factors $r$ and $c$ are computed to equilibrate the system:
   
   - $\text{trans} = 'N'$: $\text{diag}(r)^*A^{\text{trans}}\text{diag}(c)^{-1}X = \text{diag}(r)^*B$
   - $\text{trans} = 'T'$: $(\text{diag}(r)^*A^{\text{trans}}\text{diag}(c)^{-1})X = \text{diag}(r)^*B$
   - $\text{trans} = 'C'$: $(\text{diag}(r)^*A^{\text{trans}}\text{diag}(c)^{-1})X = \text{diag}(c)^*B$

   Whether or not the system will be equilibrated depends on the scaling of the matrix $A$, but if
   equilibration is used, $A$ is overwritten by $\text{diag}(r)^*A^{\text{trans}}\text{diag}(c)$ and $B$
   by $\text{diag}(r)^*B$ (if $\text{trans} = 'N'$) or $\text{diag}(c)^*B$ (if $\text{trans} = 'T'$ or 'C').

2. If `fact = 'N'` or 'E', the LU decomposition is used to factor the matrix $A$ (after equilibration if `fact`
   = 'E') as $A = P \cdot L \cdot U$, where $P$ is a permutation matrix, $L$ is a unit lower triangular matrix, and $U$
is upper triangular.

3. If some $U_{ii} = 0$, so that $U$ is exactly singular, then the routine returns with `info = i`. Otherwise, the
   factored form of $A$ is used to estimate the condition number of the matrix $A$. If the reciprocal of the
   condition number is less than machine precision, `info = n + 1` is returned as a warning, but the
   routine still goes on to solve for $X$ and compute error bounds as described below.

4. The system of equations is solved for $X$ using the factored form of $A$.

5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and
   backward error estimates for it.
6. If equilibration was used, the matrix $X$ is premultiplied by $\text{diag}(c)$ (if $\text{trans} = 'N'$) or $\text{diag}(r)$ (if $\text{trans} = 'T'$ or 'C') so that it solves the original system before equilibration.

**Input Parameters**

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **fact**
  Must be 'F', 'N', or 'E'.
  Specifies whether or not the factored form of the matrix $A$ is supplied on entry, and if not, whether the matrix $A$ should be equilibrated before it is factored.
  
  If $\text{fact} = 'F'$: on entry, $af$ and $ipiv$ contain the factored form of $A$. If $\text{equed}$ is not 'N', the matrix $A$ has been equilibrated with scaling factors given by $r$ and $c$. $a$, $af$, and $ipiv$ are not modified.
  
  If $\text{fact} = 'N'$, the matrix $A$ will be copied to $af$ and factored.
  
  If $\text{fact} = 'E'$, the matrix $A$ will be equilibrated if necessary, then copied to $af$ and factored.

- **trans**
  Must be 'N', 'T', or 'C'.
  Specifies the form of the system of equations:
  
  If $\text{trans} = 'N'$, the system has the form $A*X = B$ (No transpose).
  
  If $\text{trans} = 'T'$, the system has the form $A^T*X = B$ (Transpose).
  
  If $\text{trans} = 'C'$, the system has the form $A^H*X = B$ (Transpose for real flavors, conjugate transpose for complex flavors).

- **n**
  The number of linear equations; the order of the matrix $A$; $n \geq 0$.

- **nrhs**
  The number of right hand sides; the number of columns of the matrices $B$ and $X$; $nrhs \geq 0$.

- **a**
  The array $a$ of size $\text{max}(1, lda*n)$ contains the matrix $A$. If $\text{fact} = 'F'$ and $\text{equed}$ is not 'N', then $A$ must have been equilibrated by the scaling factors in $r$ and/or $c$.

- **af**
  The array $af$ of size $\text{max}(1, ldaf*n)$ is an input argument if $\text{fact} = 'F'$. It contains the factored form of the matrix $A$, that is, the factors $L$ and $U$ from the factorization $A = P*L*U$ as computed by ?getrf. If $\text{equed}$ is not 'N', then $af$ is the factored form of the equilibrated matrix $A$.

- **b**
  The array $b$ of size $\text{max}(1, ldb*nrhs)$ for column major layout and $\text{max}(1, ldb*n)$ for row major layout contains the matrix $B$ whose columns are the right-hand sides for the systems of equations.

- **lda**
  The leading dimension of $a$; $lda \geq \text{max}(1, n)$.

- **ldaf**
  The leading dimension of $af$; $ldaf \geq \text{max}(1, n)$.

- **ldb**
  The leading dimension of $b$; $ldb \geq \text{max}(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout.
ipiv

Array, size at least \( \max(1, n) \). The array \( \text{ipiv} \) is an input argument if \( \text{fact} = 'F' \). It contains the pivot indices from the factorization \( A = PLU \) as computed by \texttt{?getrf}; row \( i \) of the matrix was interchanged with row \( \text{ipiv}[i-1] \).

equed

Must be 'N', 'R', 'C', or 'B'.

equed is an input argument if \( \text{fact} = 'F' \). It specifies the form of equilibration that was done:

If \( \text{equed} = 'N' \), no equilibration was done (always true if \( \text{fact} = 'N' \)).

If \( \text{equed} = 'R' \), row equilibration was done, that is, \( A \) has been premultiplied by \( \text{diag}(r) \).

If \( \text{equed} = 'C' \), column equilibration was done, that is, \( A \) has been postmultiplied by \( \text{diag}(c) \).

If \( \text{equed} = 'B' \), both row and column equilibration was done, that is, \( A \) has been replaced by \( \text{diag}(r)^*A*\text{diag}(c) \).

\( r, c \)

Arrays: \( r \) (size \( n \)), \( c \) (size \( n \)). The array \( r \) contains the row scale factors for \( A \), and the array \( c \) contains the column scale factors for \( A \). These arrays are input arguments if \( \text{fact} = 'F' \) only; otherwise they are output arguments.

If \( \text{equed} = 'R' \) or 'B', \( A \) is multiplied on the left by \( \text{diag}(r) \); if \( \text{equed} = 'N' \) or 'C', \( r \) is not accessed.

If \( \text{fact} = 'F' \) and \( \text{equed} = 'R' \) or 'B', each element of \( r \) must be positive.

If \( \text{equed} = 'C' \) or 'B', \( A \) is multiplied on the right by \( \text{diag}(c) \); if \( \text{equed} = 'N' \) or 'R', \( c \) is not accessed.

If \( \text{fact} = 'F' \) and \( \text{equed} = 'C' \) or 'B', each element of \( c \) must be positive.

\( ldx \)

The leading dimension of the output array \( x \); \( ldx \geq \max(1, n) \) for column major layout and \( ldx \geq \text{nrhs} \) for row major layout.

Output Parameters

\( x \)

Array, size \( \max(1, ldx*\text{nrhs}) \) for column major layout and \( \max(1, ldx*n) \) for row major layout.

If \( \text{info} = 0 \) or \( \text{info} = n+1 \), the array \( x \) contains the solution matrix \( X \) to the original system of equations. Note that \( A \) and \( B \) are modified on exit if \( \text{equed} = 'N' \), and the solution to the equilibrated system is:

\[
\text{diag}(C)^{-1}*X, \text{ if } \text{trans} = 'N' \text{ and } \text{equed} = 'C' \text{ or 'B'};
\]

\[
\text{diag}(R)^{-1}*X, \text{ if } \text{trans} = 'T' \text{ or 'C'} \text{ and } \text{equed} = 'R' \text{ or 'B'}.\]

The second dimension of \( x \) must be at least \( \max(1, \text{nrhs}) \).

\( a \)

Array \( a \) is not modified on exit if \( \text{fact} = 'F' \) or 'N', or if \( \text{fact} = 'E' \) and \( \text{equed} = 'N' \). If \( \text{equed} = 'N' \), \( A \) is scaled on exit as follows:

\( \text{equed} = 'R': \ A = \text{diag}(R)^*A \)
equed = 'C': $A = A*\text{diag}(c)$
equed = 'B': $A = \text{diag}(R)*A*\text{diag}(c)$.

If $\text{fact} = 'N$' or 'E', then $af$ is an output argument and on exit returns the factors $L$ and $U$ from the factorization $A = PLU$ of the original matrix $A$ (if $\text{fact} = 'N$') or of the equilibrated matrix $A$ (if $\text{fact} = 'E$'). See the description of $a$ for the form of the equilibrated matrix.

*b*

Overwritten by $\text{diag}(r)*B$ if $\text{trans} = 'N$' and equed = 'R' or 'B';
overwritten by $\text{diag}(c)*B$ if $\text{trans} = 'T$' or 'C' and equed = 'C' or 'B';
not changed if equed = 'N'.

*r, c*

These arrays are output arguments if $\text{fact}$='F'. See the description of $r, c$ in Input Arguments section.

*rcond*

An estimate of the reciprocal condition number of the matrix $A$ after equilibration (if done). If $rcond$ is less than the machine precision, in particular, if $rcond = 0$, the matrix is singular to working precision. This condition is indicated by a return code of $\text{info} > 0$.

*ferr*

Array, size at least max(1, nrhs). Contains the estimated forward error bound for each solution vector $x_j$ (the $j$-th column of the solution matrix $X$). If $\text{xtrue}$ is the true solution corresponding to $x_j$, $\text{ferr}[j-1]$ is an estimated upper bound for the magnitude of the largest element in $(x_j - \text{xtrue})$ divided by the magnitude of the largest element in $x_j$. The estimate is as reliable as the estimate for $\text{rcond}$, and is almost always a slight overestimate of the true error.

*berr*

Array, size at least max(1, nrhs). Contains the component-wise relative backward error for each solution vector $x_j$, that is, the smallest relative change in any element of $A$ or $B$ that makes $x_j$ an exact solution.

*ipiv*

If $\text{fact} = 'N$' or 'E', then $ipiv$ is an output argument and on exit contains the pivot indices from the factorization $A = P*L*U$ of the original matrix $A$ (if $\text{fact} = 'N$') or of the equilibrated matrix $A$ (if $\text{fact} = 'E$').

*equed*

If $\text{fact}='F$', then $\text{equed}$ is an output argument. It specifies the form of equilibration that was done (see the description of $\text{equed}$ in Input Arguments section).

*rpivot*

On exit, $\text{rpivot}$ contains the reciprocal pivot growth factor:

$$\frac{||A||}{||U||}$$

If $\text{rpivot}$ is much less than 1, then the stability of the $LU$ factorization of the (equilibrated) matrix $A$ could be poor. This also means that the solution $x$, condition estimator $\text{rcond}$, and forward
error bound \( \text{ferr} \) could be unreliable. If factorization fails with \( 0 < \text{info} \leq n \), then \( \text{rpivot} \) contains the reciprocal pivot growth factor for the leading \( \text{info} \) columns of \( A \).

Return Values

This function returns a value \( \text{info} \).

If \( \text{info} = 0 \), the execution is successful.

If \( \text{info} = -i \), parameter \( i \) had an illegal value.

If \( \text{info} = i \), and \( i \leq n \), then \( U(i, i) \) is exactly zero. The factorization has been completed, but the factor \( U \) is exactly singular, so the solution and error bounds could not be computed; \( \text{rcond} = 0 \) is returned.

If \( \text{info} = n + 1 \), then \( U \) is nonsingular, but \( \text{rcond} \) is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of \( \text{rcond} \) would suggest.

\]
Description

The routine uses the LU factorization to compute the solution to a real or complex system of linear equations
\( A \times X = B \), where \( A \) is an \( n \times n \) matrix, the columns of the matrix \( B \) are individual right-hand sides, and the
columns of \( X \) are the corresponding solutions.

Both normwise and maximum componentwise error bounds are also provided on request. The routine returns
a solution with a small guaranteed error (\( O(\varepsilon) \), where \( \varepsilon \) is the working machine precision) unless the
matrix is very ill-conditioned, in which case a warning is returned. Relevant condition numbers are also
calculated and returned.

The routine accepts user-provided factorizations and equilibration factors; see definitions of the fact and
equed options. Solving with refinement and using a factorization from a previous call of the routine also
produces a solution with \( O(\varepsilon) \) errors or warnings but that may not be true for general user-provided
factorizations and equilibration factors if they differ from what the routine would itself produce.

The routine \?gesvxx performs the following steps:

1. If \( \text{fact} = 'E' \), scaling factors \( r \) and \( c \) are computed to equilibrate the system:
   \[
   \begin{align*}
   \text{trans} = 'N': & \quad \text{diag}(r) \times A \times \text{diag}(c) \times \text{inv}(\text{diag}(c)) \times X = \text{diag}(r) \times B \\
   \text{trans} = 'T': & \quad (\text{diag}(r) \times A \times \text{diag}(c))^T \times \text{inv}(\text{diag}(r)) \times X = \text{diag}(c) \times B \\
   \text{trans} = 'C': & \quad (\text{diag}(r) \times A \times \text{diag}(c))^H \times \text{inv}(\text{diag}(r)) \times X = \text{inv}(\text{diag}(r)) \times B
   \end{align*}
   \]
   Whether or not the system will be equilibrated depends on the scaling of the matrix \( A \), but if
   equilibration is used, \( A \) is overwritten by \( \text{diag}(r) \times A \times \text{diag}(c) \) and \( B \) by \( \text{diag}(r) \times B \) (if \( \text{trans} = 'N' \) ) or
   \( \text{diag}(c) \times B \) (if \( \text{trans} = 'T' \) or 'C').
2. If \( \text{fact} = 'N' \) or 'E', the LU decomposition is used to factor the matrix \( A \) (after equilibration if \( \text{fact} = 'E' \) ) as \( A = P \times L \times U \), where \( P \) is a permutation matrix, \( L \) is a unit lower triangular matrix, and \( U \) is
   upper triangular.
3. If some \( U_{ii} = 0 \), so that \( U \) is exactly singular, then the routine returns with \( \text{info} = i \). Otherwise, the
   factored form of \( A \) is used to estimate the condition number of the matrix \( A \) (see the rcond parameter).
   If the reciprocal of the condition number is less than machine precision, the routine still goes on to
   solve for \( X \) and compute error bounds.
4. The system of equations is solved for \( X \) using the factored form of \( A \).
5. By default, unless is set to zero, the routine applies iterative refinement to improve the computed
   solution matrix and calculate error bounds. Refinement calculates the residual to at least twice the
   working precision.
6. If equilibration was used, the matrix \( X \) is premultiplied by \( \text{diag}(c) \) (if \( \text{trans} = 'N' \) ) or \( \text{diag}(r) \) (if
   \( \text{trans} = 'T' \) or 'C') so that it solves the original system before equilibration.

Input Parameters

\textit{matrix\_layout} \hspace{1cm} Specifies whether matrix storage layout is row major
\hspace{1cm} \text{(LAPACK\_ROW\_MAJOR)} or column major \text{(LAPACK\_COL\_MAJOR)}.

\textit{fact} \hspace{1cm} Must be 'F', 'N', or 'E'.

\hspace{1cm} Specifies whether or not the factored form of the matrix \( A \) is supplied
\hspace{1cm} on entry, and if not, whether the matrix \( A \) should be equilibrated
\hspace{1cm} before it is factored.
If fact = 'F', on entry, af and ipiv contain the factored form of A. If equed is not 'N', the matrix A has been equilibrated with scaling factors given by r and c. Parameters a, af, and ipiv are not modified.

If fact = 'N', the matrix A will be copied to af and factored. If fact = 'E', the matrix A will be equilibrated, if necessary, copied to af and factored.

trans
Must be 'N', 'T', or 'C'.

Specifies the form of the system of equations:
If trans = 'N', the system has the form A*X = B (No transpose).
If trans = 'T', the system has the form A^T*X = B (Transpose).
If trans = 'C', the system has the form A^H*X = B (Conjugate Transpose = Transpose for real flavors, Conjugate Transpose for complex flavors).

n
The number of linear equations; the order of the matrix A; n ≥ 0.
nrhs
The number of right hand sides; the number of columns of the matrices B and X; nrhs ≥ 0.

a, af, b
Arrays: a(size max(lda*n)), af(size max(ldaf*n)), b(size max(1, ldb*nrhs) for column major layout and max(1, ldb*n) for row major layout).

The array a contains the matrix A. If fact = 'F' and equed is not 'N', then A must have been equilibrated by the scaling factors in r and/or c.

The array af is an input argument if fact = 'F'. It contains the factored form of the matrix A, that is, the factors L and U from the factorization A = P*L*U as computed by ?getrf. If equed is not 'N', then af is the factored form of the equilibrated matrix A.

The array b contains the matrix B whose columns are the right-hand sides for the systems of equations.

lda
The leading dimension of a; lda ≥ max(1, n).

ldaf
The leading dimension of af; ldaf ≥ max(1, n).

ipiv
Array, size at least max(1, n). The array ipiv is an input argument if fact = 'F'. It contains the pivot indices from the factorization A = P*L*U as computed by ?getrf; row i of the matrix was interchanged with row ipiv[i-1].

equed
Must be 'N', 'R', 'C', or 'B'.
equed is an input argument if fact = 'F'. It specifies the form of equilibration that was done:
If equed = 'N', no equilibration was done (always true if fact = 'N').
If $\text{equed} = 'R'$, row equilibration was done, that is, $A$ has been premultiplied by $\text{diag}(r)$.

If $\text{equed} = 'C'$, column equilibration was done, that is, $A$ has been postmultiplied by $\text{diag}(c)$.

If $\text{equed} = 'B'$, both row and column equilibration was done, that is, $A$ has been replaced by $\text{diag}(r) \cdot A \cdot \text{diag}(c)$.

Arrays: $r$ (size $n$), $c$ (size $n$). The array $r$ contains the row scale factors for $A$, and the array $c$ contains the column scale factors for $A$. These arrays are input arguments if $\text{fact} = 'F'$ only; otherwise they are output arguments.

If $\text{equed} = 'R'$ or $'B'$, $A$ is multiplied on the left by $\text{diag}(r)$; if $\text{equed} = 'N'$ or $'C'$, $r$ is not accessed.

If $\text{fact} = 'F'$ and $\text{equed} = 'R'$ or $'B'$, each element of $r$ must be positive.

If $\text{equed} = 'C'$ or $'B'$, $A$ is multiplied on the right by $\text{diag}(c)$; if $\text{equed} = 'N'$ or $'R'$, $c$ is not accessed.

If $\text{fact} = 'F'$ and $\text{equed} = 'C'$ or $'B'$, each element of $c$ must be positive.

Each element of $r$ or $c$ should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

`ldb` The leading dimension of the array $b$; $\text{ldb} \geq \max(1, n)$ for column major layout and $\text{ldb} \geq \text{nrhs}$ for row major layout.

`ldx` The leading dimension of the output array $x$; $\text{ldx} \geq \max(1, n)$ for column major layout and $\text{ldx} \geq \text{nrhs}$ for row major layout.

`n_err_bnds` Number of error bounds to return for each right hand side and each type (normwise or componentwise). See $\text{err_bnds_norm}$ and $\text{err_bnds_comp}$ descriptions in *Output Arguments* section below.

`nparams` Specifies the number of parameters set in `params`. If $\leq 0$, the `params` array is never referenced and default values are used.

`params` Array, size $\max(1, nparams)$. Specifies algorithm parameters. If an entry is less than 0.0, that entry is filled with the default value used for that parameter. Only positions up to $\text{nparams}$ are accessed; defaults are used for higher-numbered parameters. If defaults are acceptable, you can pass $\text{nparams} = 0$, which prevents the source code from accessing the `params` argument.

`params[0]`: Whether to perform iterative refinement or not. Default: 1.0

=0.0 No refinement is performed and no error bounds are computed.
Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support double precision.

(Other values are reserved for future use.)

`params[1]`: Maximum number of residual computations allowed for refinement.

**Default**

10.0

**Aggressive**

Set to 100.0 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in `err_bnds_norm` and `err_bnds_comp` may no longer be trustworthy.

`params[2]`: Flag determining if the code will attempt to find a solution with a small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence).

**Output Parameters**

*x*

Array, size `max(1, idx*nrhs)` for column major layout and `max(1, ldx*n)` for row major layout.

If `info = 0`, the array `x` contains the solution `n-by-nrhs` matrix `X` to the original system of equations. Note that `A` and `B` are modified on exit if `equed` is 'N', and the solution to the equilibrated system is:

- `inv(diag(c))*X`, if `trans = 'N'` and `equed = 'C'` or 'B'; or
- `inv(diag(r))*X`, if `trans = 'T'` or 'C' and `equed = 'R'` or 'B'.

*a*

Array `a` is not modified on exit if `fact = 'F'` or 'N', or if `fact = 'E'` and `equed = 'N'`.

If `equed` is 'N', `A` is scaled on exit as follows:

- `equed = 'R'`: `A = diag(r)*A`
- `equed = 'C'`: `A = A*diag(c)`
- `equed = 'B'`: `A = diag(r)*A*diag(c)`.

*af*

If `fact = 'N'` or 'E', then *af* is an output argument and on exit returns the factors `L` and `U` from the factorization `A = PLU` of the original matrix `A` (if `fact = 'N'`) or of the equilibrated matrix `A` (if `fact = 'E'`). See the description of `a` for the form of the equilibrated matrix.

*b*

Overwritten by `diag(r)*B` if `trans = 'N'` and `equed = 'R'` or 'B';
overwritten by `trans = 'T'` or 'C' and `equed = 'C'` or 'B';
not changed if `equed = 'N'`. 
These arrays are output arguments if `fact` ≠ `'F'`. Each element of these arrays is a power of the radix. See the description of `r, c` in `Input Arguments` section.

Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix `A` after equilibration (if done). If `rcond` is less than the machine precision, in particular, if `rcond = 0`, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned.

Contains the reciprocal pivot growth factor:

\[ \|A\|/\|C\| \]

If this is much less than 1, the stability of the `LU` factorization of the (equilibrated) matrix `A` could be poor. This also means that the solution `X`, estimated condition numbers, and error bounds could be unreliable. If factorization fails with `0 < info ≤ n`, this parameter contains the reciprocal pivot growth factor for the leading `info` columns of `A`. In `gesvx`, this quantity is returned in `rpivot`.

Array, size at least \( \max(1, nrhs) \). Contains the componentwise relative backward error for each solution vector \( x_j \), that is, the smallest relative change in any element of `A` or `B` that makes \( x_j \) an exact solution.

Array of size `nrhs*n_err_bnds`. For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the \( i \)-th solution vector

\[ \max_j \left| \frac{X_{true,j} - X_{j,i}}{\max_j |X_{true,j}|} \right| \]

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned.

- **err=1**
  "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold `sqrt(n)*slamch(ε)` for single precision flavors and `sqrt(n)*dlamch(ε)` for double precision flavors.

- **err=2**
  "Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold `sqrt(n)*slamch(ε)` for single precision flavors and `sqrt(n)*dlamch(ε)` for double precision flavors. This error bound should only be trusted if the previous boolean is true.

- **err=3**
  Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold
Let \( z = s \cdot a \), where \( s \) scales each row by a power of the radix so all absolute row sums of \( z \) are approximately 1.

The information for right-hand side \( i \), where \( 1 \leq i \leq \text{nrhs} \), and type of error \( \text{err} \) is stored in \( \text{err}_bnds\_comp[ (\text{err}-1) \cdot \text{nrhs} + i - 1 ] \).

Array of size \( \text{nrhs} \cdot \text{n_err_bnds} \). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the \( i \)-th solution vector:

\[
\max_j \frac{|X^{true}_{ji} - X_{ji}|}{|X_{ji}|}
\]

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (\( \text{params}[2] = 0.0 \)), then \( \text{err}_bnds\_comp \) is not accessed.

\( \text{err}=1 \)

"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold \( \sqrt{n} \cdot \text{slamch}(\varepsilon) \) for single precision flavors and \( \sqrt{n} \cdot \text{dlamch}(\varepsilon) \) for double precision flavors.

\( \text{err}=2 \)

"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold \( \sqrt{n} \cdot \text{slamch}(\varepsilon) \) for single precision flavors and \( \sqrt{n} \cdot \text{dlamch}(\varepsilon) \) for double precision flavors. This error bound should only be trusted if the previous boolean is true.

\( \text{err}=3 \)

Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold \( \sqrt{n} \cdot \text{slamch}(\varepsilon) \) for single precision flavors and \( \sqrt{n} \cdot \text{dlamch}(\varepsilon) \) for double precision flavors to determine if the error estimate is...
"guaranteed". These reciprocal condition numbers for some appropriately scaled matrix Z are:

\[ ||Z||_\infty \cdot ||Z^{-1}||_\infty \]

Let \( z = s \cdot (a \cdot \text{diag}(x)) \), where \( x \) is the solution for the current right-hand side and \( s \) scales each row of \( a \cdot \text{diag}(x) \) by a power of the radix so all absolute row sums of \( z \) are approximately 1.

The information for right-hand side \( i \), where \( 1 \leq i \leq \text{nrhs} \), and type of error \( \text{err} \) is stored in \( \text{err\_bnds\_comp}\left[(\text{err}-1)\times\text{nrhs} + i - 1\right] \).

- **ipiv**
  - If \( \text{fact} = 'N' \) or \( 'E' \), then \( \text{ipiv} \) is an output argument and on exit contains the pivot indices from the factorization \( A = P \cdot L \cdot U \) of the original matrix \( A \) (if \( \text{fact} = 'N' \)) or of the equilibrated matrix \( A \) (if \( \text{fact} = 'E' \)).

- **equed**
  - If \( \text{fact} \neq 'F' \), then \( \text{equed} \) is an output argument. It specifies the form of equilibration that was done (see the description of \( \text{equed} \) in Input Arguments section).

- **params**
  - If an entry is less than 0.0, that entry is filled with the default value used for that parameter, otherwise the entry is not modified.

**Return Values**

This function returns a value \( \text{info} \).

- If \( \text{info} = 0 \), the execution is successful. The solution to every right-hand side is guaranteed.
- If \( \text{info} = -i \), parameter \( i \) had an illegal value.
- If \( 0 < \text{info} < \text{nrhs} \) \( \text{info} \) is exactly zero. The factorization has been completed, but the factor \( U \) is exactly singular, so the solution and error bounds could not be computed; \( \text{rcond} = 0 \) is returned.
- If \( \text{info} = n + j \): The solution corresponding to the \( j \)-th right-hand side is not guaranteed. The solutions corresponding to other right-hand sides \( k \) with \( k > j \) may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested \( \text{params}[2] = 0.0 \), then the \( j \)-th right-hand side is the first with a normwise error bound that is not guaranteed (the smallest \( j \) such that for column major layout \( \text{err\_bnds\_norm}(j - 1) = 0.0 \) or \( \text{err\_bnds\_comp}(j - 1) = 0.0 \); or for row major layout \( \text{err\_bnds\_norm}[(j - 1) \times n_{\text{err\_bnds}}] = 0.0 \) or \( \text{err\_bnds\_comp}[(j - 1) \times n_{\text{err\_bnds}}] = 0.0 \)). See the definition of \( \text{err\_bnds\_norm} \) and \( \text{err\_bnds\_comp} \) for \( \text{err} = 1 \). To get information about all of the right-hand sides, check \( \text{err\_bnds\_norm} \) or \( \text{err\_bnds\_comp} \).

Matrix Storage Schemes

**?gbsv**

*Computes the solution to the system of linear equations with a band coefficient matrix A and multiple right-hand sides.*

**Syntax**

```c
lapack_int LAPACKE_sgbsv (int matrix_layout , lapack_int n , lapack_int kl , lapack_int ku , lapack_int nrhs , float * ab , lapack_int ldab , lapack_int * ipiv , float * b , lapack_int ldb );
```
The routine solves for $X$ the real or complex system of linear equations $A*X = B$, where $A$ is an $n$-by-$n$ band matrix with $kl$ subdiagonals and $ku$ superdiagonals, the columns of matrix $B$ are individual right-hand sides, and the columns of $X$ are the corresponding solutions.

The $LU$ decomposition with partial pivoting and row interchanges is used to factor $A$ as $A = L*U$, where $L$ is a product of permutation and unit lower triangular matrices with $kl$ subdiagonals, and $U$ is upper triangular with $kl+ku$ superdiagonals. The factored form of $A$ is then used to solve the system of equations $A*X = B$.

**Input Parameters**

- **matrix_layout**
  Specifies whether matrix storage layout is row major (**LAPACK_ROW_MAJOR**) or column major (**LAPACK_COL_MAJOR**).

- **$n$**
  The order of $A$. The number of rows in $B$; $n \geq 0$.

- **$kl$**
  The number of subdiagonals within the band of $A$; $kl \geq 0$.

- **$ku$**
  The number of superdiagonals within the band of $A$; $ku \geq 0$.

- **$nrhs$**
  The number of right-hand sides. The number of columns in $B$; $nrhs \geq 0$.

- **$ab$, $b$**
  Arrays: $ab$ (size max(1, $ldab*n$)), $b$ (size max(1, $ldb*nrhs$)) for column major layout and max(1, $ldb*n$) for row major layout.

  The array $ab$ contains the matrix $A$ in band storage (see Matrix Storage Schemes).

  The array $b$ contains the matrix $B$ whose columns are the right-hand sides for the systems of equations.

- **$ldab$**
  The leading dimension of the array $ab$. ($ldab \geq 2kl + ku +1$)

- **$ldb$**
  The leading dimension of $b$; $ldb \geq max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout.

**Output Parameters**

- **$ab$**
  Overwritten by $L$ and $U$. $U$ is stored as an upper triangular band matrix with $kl + ku$ superdiagonals and $L$ is stored as a lower triangular band matrix with $kl$ subdiagonals. See Matrix Storage Schemes.
Overwritten by the solution matrix $X$.

Array, size at least \( \max(1, n) \). The pivot indices: row $i$ was interchanged with row $ipiv[i-1]$.

**Return Values**

This function returns a value $info$.

If $info = 0$, the execution is successful.

If $info = -i$, parameter $i$ had an illegal value.

If $info = i$, $U_{ii}$ is exactly zero. The factorization has been completed, but the factor $U$ is exactly singular, so the solution could not be computed.

Description

The routine uses the $LU$ factorization to compute the solution to a real or complex system of linear equations $A*X = B$, $A^TX = B$, or $A^H*X = B$, where $A$ is a band matrix of order $n$ with $kl$ subdiagonals and $ku$ superdiagonals, the columns of matrix $B$ are individual right-hand sides, and the columns of $X$ are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine `?gbsvx` performs the following steps:

1. If `fact = 'E'`, real scaling factors $r$ and $c$ are computed to equilibrate the system:
   
   $\text{trans} = 'N'$: $\text{diag}(r)*A\text{diag}(c) *\text{inv}(\text{diag}(c))*X = \text{diag}(r)*B$
   
   $\text{trans} = 'T'$: $(\text{diag}(r)*A\text{diag}(c))^T *\text{inv}(\text{diag}(r))*X = \text{diag}(c)*B$
   
   $\text{trans} = 'C'$: $(\text{diag}(r)*A\text{diag}(c))^H *\text{inv}(\text{diag}(r))*X = \text{diag}(c)*B$

   Whether the system will be equilibrated depends on the scaling of the matrix $A$, but if equilibration is used, $A$ is overwritten by $\text{diag}(r)*A\text{diag}(c)$ and $B$ by $\text{diag}(r)*B$ (if $\text{trans} = 'N'$) or $\text{diag}(c)*B$ (if $\text{trans} = 'T'$ or 'C').

2. If `fact = 'N'` or 'E', the $LU$ decomposition is used to factor the matrix $A$ (after equilibration if `fact = 'E'`) as $A = L*U$, where $L$ is a product of permutation and unit lower triangular matrices with $kl$ subdiagonals, and $U$ is upper triangular with $kl+ku$ superdiagonals.

3. If some $U_{i,j} = 0$, so that $U$ is exactly singular, then the routine returns with $\text{info} = i$. Otherwise, the factored form of $A$ is used to estimate the condition number of the matrix $A$. If the reciprocal of the condition number is less than machine precision, $\text{info} = n + 1$ is returned as a warning, but the routine still goes on to solve for $X$ and compute error bounds as described below.

4. The system of equations is solved for $X$ using the factored form of $A$.

5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

6. If equilibration was used, the matrix $X$ is premultiplied by $\text{diag}(c)$ (if $\text{trans} = 'N'$) or $\text{diag}(r)$ (if $\text{trans} = 'T'$ or 'C') so that it solves the original system before equilibration.

Input Parameters

`matrix_layout`  
Specifies whether matrix storage layout is row major (`LAPACK_ROW_MAJOR`) or column major (`LAPACK_COL_MAJOR`).

`fact`  
Must be 'F', 'N', or 'E'.  

Specifies whether the factored form of the matrix $A$ is supplied on entry, and if not, whether the matrix $A$ should be equilibrated before it is factored.  

If `fact = 'F'`: on entry, $ab$ and $ipiv$ contain the factored form of $A$.  

If `equed` is not 'N', the matrix $A$ is equilibrated with scaling factors given by $r$ and $c$.  

$ab$, $afb$, and $ipiv$ are not modified.  

If `fact = 'N'`, the matrix $A$ will be copied to $ab$ and factored.  

If `fact = 'E'`, the matrix $A$ will be equilibrated if necessary, then copied to $ab$ and factored.

`trans`  
Must be 'N', 'T', or 'C'.  

Specifies the form of the system of equations:  

If `trans = 'N'`, the system has the form $A*X = B$ (No transpose).
If \( \text{trans} = 'T' \), the system has the form \( A^T X = B \) (Transpose).

If \( \text{trans} = 'C' \), the system has the form \( A^\dagger X = B \) (Transpose for real flavors, conjugate transpose for complex flavors).

\( n \)

The number of linear equations, the order of the matrix \( A \); \( n \geq 0 \).

\( kl \)

The number of subdiagonals within the band of \( A \); \( kl \geq 0 \).

\( ku \)

The number of superdiagonals within the band of \( A \); \( ku \geq 0 \).

\( nrhs \)

The number of right hand sides, the number of columns of the matrices \( B \) and \( X \); \( nrhs \geq 0 \).

\( ab, afb, b \)

Arrays: \( ab \) (max(\( ldab \)*\( n \))), \( afb \) (max(\( ldafb \)*\( n \))), \( b \) (max(1, \( ldb \)*\( nrhs \)) for column major layout and max(1, \( ldb \)*\( n \)) for row major layout).

The array \( ab \) contains the matrix \( A \) in band storage (see Matrix Storage Schemes). If \( \text{fact} = 'F' \) and \( \text{equed} \) is not 'N', then \( A \) must have been equilibrated by the scaling factors in \( r \) and/or \( c \).

The array \( afb \) is an input argument if \( \text{fact} = 'F' \). It contains the factored form of the matrix \( A \), that is, the factors \( L \) and \( U \) from the factorization \( A = P*L*U \) as computed by \(?gbtrf\). \( U \) is stored as an upper triangular band matrix with \( kl + ku \) superdiagonals. \( L \) is stored as lower triangular band matrix with \( kl \) subdiagonals. If \( \text{equed} \) is not 'N', then \( afb \) is the factored form of the equilibrated matrix \( A \).

The array \( b \) contains the matrix \( B \) whose columns are the right-hand sides for the systems of equations.

\( ldab \)

The leading dimension of \( ab \); \( ldab \geq kl + ku + 1 \).

\( ldafb \)

The leading dimension of \( afb \); \( ldafb \geq 2*kl + ku + 1 \).

\( ldb \)

The leading dimension of \( b \); \( ldb \geq \max(1, \ n) \) for column major layout and \( ldb \geq nrhs \) for row major layout.

\( ipiv \)

Array, size at least \( \max(1, \ n) \). The array \( ipiv \) is an input argument if \( \text{fact} = 'F' \). It contains the pivot indices from the factorization \( A = P*L*U \) as computed by \(?gbtrf\); row \( i \) of the matrix was interchanged with row \( ipiv[i-1] \).

\( equed \)

Must be 'N', 'R', 'C', or 'B'.

\( equed \) is an input argument if \( \text{fact} = 'F' \). It specifies the form of equilibration that was done:

If \( \text{equed} = 'N' \), no equilibration was done (always true if \( \text{fact} = 'N' \)).

If \( \text{equed} = 'R' \), row equilibration was done, that is, \( A \) has been premultiplied by \( \text{diag}(r) \).

If \( \text{equed} = 'C' \), column equilibration was done, that is, \( A \) has been postmultiplied by \( \text{diag}(c) \).

If \( \text{equed} = 'B' \), both row and column equilibration was done, that is, \( A \) has been replaced by \( \text{diag}(r)*A*\text{diag}(c) \).
Arrays: \( r \) (size \( n \)), \( c \) (size \( n \)).

The array \( r \) contains the row scale factors for \( A \), and the array \( c \) contains the column scale factors for \( A \). These arrays are input arguments if \( \text{fact} = 'F' \) only; otherwise they are output arguments.

If \( \text{equed} = 'R' \) or 'B', \( A \) is multiplied on the left by \( \text{diag}(r) \); if \( \text{equed} = 'N' \) or 'C', \( r \) is not accessed.

If \( \text{fact} = 'F' \) and \( \text{equed} = 'R' \) or 'B', each element of \( r \) must be positive.

If \( \text{equed} = 'C' \) or 'B', \( A \) is multiplied on the right by \( \text{diag}(c) \); if \( \text{equed} = 'N' \) or 'R', \( c \) is not accessed.

If \( \text{fact} = 'F' \) and \( \text{equed} = 'C' \) or 'B', each element of \( c \) must be positive.

\( ldx \)

The leading dimension of the output array \( x \); \( ldx \geq \max(1, n) \) for column major layout and \( ldx \geq \text{nrhs} \) for row major layout.

Output Parameters

\( x \)

Array, size \( \max(1, ldx*\text{nrhs}) \) for column major layout and \( \max(1, ldx*n) \) for row major layout.

If \( \text{info} = 0 \) or \( \text{info} = n+1 \), the array \( x \) contains the solution matrix \( X \) to the original system of equations. Note that \( A \) and \( B \) are modified on exit if \( \text{equed} \neq 'N' \), and the solution to the equilibrated system is:

\[
\text{inv(\text{diag}(c))}*X, \text{if trans} = 'N' \text{ and } \text{equed} = 'C' \text{ or 'B'}; \\
\text{inv(\text{diag}(r))}*X, \text{if trans} = 'T' \text{ or 'C' and equed} = 'R' \text{ or 'B'.}
\]

\( ab \)

Array \( ab \) is not modified on exit if \( \text{fact} = 'F' \) or 'N', or if \( \text{fact} = 'E' \) and \( \text{equed} = 'N' \).

If \( \text{equed} \neq 'N' \), \( A \) is scaled on exit as follows:

\[
\text{equed} = 'R': A = \text{diag}(r) * A \\
\text{equed} = 'C': A = A * \text{diag}(c) \\
\text{equed} = 'B': A = \text{diag}(r) * A * \text{diag}(c).
\]

\( afb \)

If \( \text{fact} = 'N' \) or 'E', then \( afb \) is an output argument and on exit returns details of the \( LU \) factorization of the original matrix \( A \) (if \( \text{fact} = 'N' \)) or of the equilibrated matrix \( A \) (if \( \text{fact} = 'E' \)). See the description of \( ab \) for the form of the equilibrated matrix.

\( b \)

Overwritten by \( \text{diag}(r)*b \) if \( \text{trans} = 'N' \) and \( \text{equed} = 'R' \) or 'B';

overwritten by \( \text{diag}(c)*b \) if \( \text{trans} = 'T' \) or 'C' and \( \text{equed} = 'C' \) or 'B';

not changed if \( \text{equed} = 'N' \).

\( r, c \)

These arrays are output arguments if \( \text{fact} \neq 'F' \). See the description of \( r, c \) in Input Arguments section.

\( rcond \)

An estimate of the reciprocal condition number of the matrix \( A \) after equilibration (if done).
If \( rcond \) is less than the machine precision (in particular, if \( rcond = 0 \)), the matrix is singular to working precision. This condition is indicated by a return code of \( info > 0 \).

\textbf{ferr}

Array, size at least \( \max(1, nrhs) \). Contains the estimated forward error bound for each solution vector \( x_j \) (the \( j \)-th column of the solution matrix \( X \)). If \( xtrue \) is the true solution corresponding to \( x_j \), \( ferr[j-1] \) is an estimated upper bound for the magnitude of the largest element in \( (x_j - xtrue) \) divided by the magnitude of the largest element in \( x_j \). The estimate is as reliable as the estimate for \( rcond \), and is almost always a slight overestimate of the true error.

\textbf{berr}

Array, size at least \( \max(1, nrhs) \). Contains the component-wise relative backward error for each solution vector \( x_j \), that is, the smallest relative change in any element of \( A \) or \( B \) that makes \( x_j \) an exact solution.

\textbf{ipiv}

If \( fact = 'N' \) or \( 'E' \), then \( ipiv \) is an output argument and on exit contains the pivot indices from the factorization \( A = L*U \) of the original matrix \( A \) (if \( fact = 'N' \)) or of the equilibrated matrix \( A \) (if \( fact = 'E' \)).

\textbf{equed}

If \( fact \\# 'F' \), then \( equed \) is an output argument. It specifies the form of equilibration that was done (see the description of \( equed \) in Input Arguments section).

\textbf{rpivot}

On exit, \( rpivot \) contains the reciprocal pivot growth factor:

\[
\frac{\|A\|}{\|U\|}
\]

If \( rpivot \) is much less than 1, then the stability of the \( LU \) factorization of the (equilibrated) matrix \( A \) could be poor. This also means that the solution \( x \), condition estimator \( rcond \), and forward error bound \( ferr \) could be unreliable. If factorization fails with \( 0 < info \leq n \), then \( rpivot \) contains the reciprocal pivot growth factor for the leading \( info \) columns of \( A \).

\textbf{Return Values}

This function returns a value \( info \).

If \( info = 0 \), the execution is successful.

If \( info = -i \), parameter \( i \) had an illegal value.

If \( info = i \), and \( i \leq n \), then \( U_{i,i} \) is exactly zero. The factorization has been completed, but the factor \( U \) is exactly singular, so the solution and error bounds could not be computed; \( rcond = 0 \) is returned. If \( info = i \), and \( i = n+1 \), then \( U \) is nonsingular, but \( rcond \) is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of \( rcond \) would suggest.

\textbf{See Also}

Matrix Storage Schemes
?gbsvxx

Uses extra precise iterative refinement to compute the solution to the system of linear equations with a banded coefficient matrix $A$ and multiple right-hand sides.

**Syntax**

**Include Files**

- mkl.h

**Description**

The routine uses the LU factorization to compute the solution to a real or complex system of linear equations $A^T X = B$, $A^H X = B$, or $A^H X = B$, where $A$ is an $n$-by-$n$ banded matrix, the columns of the matrix $B$ are individual right-hand sides, and the columns of $X$ are the corresponding solutions.

Both normwise and maximum componentwise error bounds are also provided on request. The routine returns a solution with a small guaranteed error ($O(\varepsilon)$), where $\varepsilon$ is the working machine precision) unless the matrix is very ill-conditioned, in which case a warning is returned. Relevant condition numbers are also calculated and returned.

The routine accepts user-provided factorizations and equilibration factors; see definitions of the `fact` and `equed` options. Solving with refinement and using a factorization from a previous call of the routine also produces a solution with $O(\varepsilon)$ errors or warnings but that may not be true for general user-provided factorizations and equilibration factors if they differ from what the routine would itself produce.
The routine \( ?gbsvxx \) performs the following steps:

1. If \( \text{fact} = 'E' \), scaling factors \( r \) and \( c \) are computed to equilibrate the system:
   \[
   \begin{align*}
   \text{trans} = 'N': & \quad \text{diag}(r)A\text{diag}(c)\text{inv}(\text{diag}(c))X = \text{diag}(r)B \\
   \text{trans} = 'T': & \quad (\text{diag}(r)A\text{diag}(c))^2\text{inv}(\text{diag}(r))X = \text{diag}(c)B \\
   \text{trans} = 'C': & \quad (\text{diag}(r)A\text{diag}(c))^H\text{inv}(\text{diag}(r))X = \text{diag}(c)B
   \end{align*}
   \]
   Whether or not the system will be equilibrated depends on the scaling of the matrix \( A \), but if equilibration is used, \( A \) is overwritten by \( \text{diag}(r)A\text{diag}(c) \) and \( B \) by \( \text{diag}(r)B \) (if \( \text{trans} = 'N' \)) or \( \text{diag}(c)B \) (if \( \text{trans} = 'T' \) or \( 'C' \)).

2. If \( \text{fact} = 'N' \) or \( 'E' \), the \( LU \) decomposition is used to factor the matrix \( A \) (after equilibration if \( \text{fact} = 'E' \)) as \( A = PLU \), where \( P \) is a permutation matrix, \( L \) is a unit lower triangular matrix, and \( U \) is upper triangular.

3. If some \( U_{i,i} = 0 \), so that \( U \) is exactly singular, then the routine returns with \( \text{info} = i \). Otherwise, the factored form of \( A \) is used to estimate the condition number of the matrix \( A \) (see the \( \text{rcond} \) parameter). If the reciprocal of the condition number is less than machine precision, the routine still goes on to solve for \( X \) and compute error bounds.

4. The system of equations is solved for \( X \) using the factored form of \( A \).

5. By default, unless \( \text{params}[0] \) is set to zero, the routine applies iterative refinement to improve the computed solution matrix and calculate error bounds. Refinement calculates the residual to at least twice the working precision.

6. If equilibration was used, the matrix \( X \) is premultiplied by \( \text{diag}(c) \) (if \( \text{trans} = 'N' \)) or \( \text{diag}(r) \) (if \( \text{trans} = 'T' \) or \( 'C' \)) so that it solves the original system before equilibration.

**Input Parameters**

- **matrix_layout**
  
  Specifies whether two-dimensional array storage is row major (\text{LAPACK\_ROW\_MAJOR}) or column major (\text{LAPACK\_COL\_MAJOR}).

- **fact**
  
  Must be \( 'F' \), \( 'N' \), or \( 'E' \).

  Specifies whether or not the factored form of the matrix \( A \) is supplied on entry, and if not, whether the matrix \( A \) should be equilibrated before it is factored.

  If \( \text{fact} = 'F' \), on entry, \( \text{afb} \) and \( \text{ipiv} \) contain the factored form of \( A \). If \( \text{equed} \) is not \( 'N' \), the matrix \( A \) has been equilibrated with scaling factors given by \( r \) and \( c \). Parameters \( \text{ab} \), \( \text{afb} \), and \( \text{ipiv} \) are not modified.

  If \( \text{fact} = 'N' \), the matrix \( A \) will be copied to \( \text{afb} \) and factored.

  If \( \text{fact} = 'E' \), the matrix \( A \) will be equilibrated, if necessary, copied to \( \text{afb} \) and factored.

- **trans**
  
  Must be \( 'N' \), \( 'T' \), or \( 'C' \).

  Specifies the form of the system of equations:

  If \( \text{trans} = 'N' \), the system has the form \( AX = B \) (No transpose).

  If \( \text{trans} = 'T' \), the system has the form \( A^T X = B \) (Transpose).

  If \( \text{trans} = 'C' \), the system has the form \( A^H X = B \) (Conjugate Transpose = Transpose for real flavors, Conjugate Transpose for complex flavors).

- **n**
  
  The number of linear equations; the order of the matrix \( A \); \( n \geq 0 \).
The number of subdiagonals within the band of $A$; $kl \geq 0$.

The number of superdiagonals within the band of $A$; $ku \geq 0$.

The number of right-hand sides; the number of columns of the matrices $B$ and $X$; $nrhs \geq 0$.

Arrays: $ab$ (max($ldab*ln$)), $afb$ (max($ldafb*ln$)), $b$ (max(1, $ldb*nrhs$) for column major layout and max(1, $ldb*n$) for row major layout).

The array $ab$ contains the matrix $A$ in band storage.

If $fact = 'F'$ and $equed$ is not 'N', then $AB$ must have been equilibrated by the scaling factors in $r$ and/or $c$.

The array $afb$ is an input argument if $fact = 'F'$. It contains the factored form of the banded matrix $A$, that is, the factors $L$ and $U$ from the factorization $A = P*L*U$ as computed by $?gbtrf$. $U$ is stored as an upper triangular banded matrix with $kl + ku$ superdiagonals. $L$ is stored as lower triangular band matrix with $kl$ subdiagonals. If $equed$ is not 'N', then $afb$ is the factored form of the equilibrated matrix $A$.

The array $b$ contains the matrix $B$ whose columns are the right-hand sides for the systems of equations.

The leading dimension of the array $ab$; $ldab \geq kl + ku + 1$.

The leading dimension of the array $afb$; $ldafb \geq 2*kl + ku + 1$.

Array, size at least max(1, $n$). The array $ipiv$ is an input argument if $fact = 'F'$. It contains the pivot indices from the factorization $A = P*L*U$ as computed by $?gbtrf$; row $i$ of the matrix was interchanged with row $ipiv[i-1]$.

Must be 'N', 'R', 'C', or 'B'.

equed is an input argument if $fact = 'F'$. It specifies the form of equilibration that was done:

If $equed$ = 'N', no equilibration was done (always true if $fact$ = 'N').

If $equed$ = 'R', row equilibration was done, that is, $A$ has been premultiplied by $diag(r)$.

If $equed$ = 'C', column equilibration was done, that is, $A$ has been postmultiplied by $diag(c)$.

If $equed$ = 'B', both row and column equilibration was done, that is, $A$ has been replaced by $diag(r)*A*diag(c)$.

Arrays: $r$ (size $n$), $c$ (size $n$). The array $r$ contains the row scale factors for $A$, and the array $c$ contains the column scale factors for $A$. These arrays are input arguments if $fact = 'F'$ only; otherwise they are output arguments.

If $equed$ = 'R' or 'B', $A$ is multiplied on the left by $diag(r)$; if $equed$ = 'N' or 'C', $r$ is not accessed.
If \( fact = 'F' \) and \( equed = 'R' \) or \( 'B' \), each element of \( r \) must be positive.

If \( equed = 'C' \) or \( 'B' \), \( A \) is multiplied on the right by \( \text{diag}(c) \); if \( equed = 'N' \) or \( 'R' \), \( c \) is not accessed.

If \( fact = 'F' \) and \( equed = 'C' \) or \( 'B' \), each element of \( c \) must be positive.

Each element of \( r \) or \( c \) should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

\( \text{ldb} \)

The leading dimension of the array \( b \); \( \text{ldb} \geq \max(1, n) \) for column major layout and \( \text{ldb} \geq \text{nrhs} \) for row major layout.

\( \text{ldx} \)

The leading dimension of the output array \( x \); \( \text{ldx} \geq \max(1, n) \) for column major layout and \( \text{ldx} \geq \text{nrhs} \) for row major layout.

\( n_{\text{err\_bnds}} \)

Number of error bounds to return for each right hand side and each type (normwise or componentwise). See \( \text{err\_bnds\_norm} \) and \( \text{err\_bnds\_comp} \) descriptions in \textit{Output Arguments} section below.

\( n_{\text{params}} \)

Specifies the number of parameters set in \( \text{params} \). If \( \leq 0 \), the \( \text{params} \) array is never referenced and default values are used.

\( \text{params} \)

Array, size \( \max(1, n_{\text{params}}) \). Specifies algorithm parameters. If an entry is less than 0.0, that entry is filled with the default value used for that parameter. Only positions up to \( n_{\text{params}} \) are accessed; defaults are used for higher-numbered parameters. If defaults are acceptable, you can pass \( n_{\text{params}} = 0 \), which prevents the source code from accessing the \( \text{params} \) argument.

\( \text{params}[0] \) : Whether to perform iterative refinement or not. Default: 1.0 (for single precision flavors), 1.0D+0 (for double precision flavors).

\( =0.0 \)

No refinement is performed and no error bounds are computed.

\( =1.0 \)

Use the extra-precise refinement algorithm.

(Other values are reserved for future use.)

\( \text{params}[1] \) : Maximum number of residual computations allowed for refinement.

Default 10.0

Aggressive

Set to 100.0 to permit convergence using approximate factorizations or factorizations other than \( LU \). If the factorization uses a technique other than Gaussian elimination,
the guarantees in `err_bnds_norm` and `err_bnds_comp` may no longer be trustworthy.

`params[2]` : Flag determining if the code will attempt to find a solution with a small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence).

**Output Parameters**

`x`  
Array, size max(1, `ldx*nrhs`) for column major layout and max(1, `ldx*n`) for row major layout.

If `info = 0`, the array `x` contains the solution `n`-by-`nrhs` matrix `X` to the original system of equations. Note that `A` and `B` are modified on exit if `equed≠'N'`, and the solution to the equilibrated system is:

\[
\text{inv}(\text{diag}(c)) \times X, \text{ if } \text{trans} = 'N' \text{ and equed = 'C' or 'B'}; \text{ or}
\]

\[
\text{inv}(\text{diag}(r)) \times X, \text{ if } \text{trans} = 'T' \text{ or 'C'} \text{ and equed = 'R' or 'B'}.
\]

`ab`  
Array `ab` is not modified on exit if `fact = 'F'` or 'N', or if `fact = 'E'` and `equed = 'N'`.

If `equed≠'N'`, `A` is scaled on exit as follows:

- `equed = 'R'`: \( A = \text{diag}(r) \times A \)
- `equed = 'C'`: \( A = A \times \text{diag}(c) \)
- `equed = 'B'`: \( A = \text{diag}(r) \times A \times \text{diag}(c) \).

`afb`  
If `fact = 'N'` or 'E', then `afb` is an output argument and on exit returns the factors `L` and `U` from the factorization \( A = PLU \) of the original matrix `A` (if `fact = 'N'`) or of the equilibrated matrix `A` (if `fact = 'E'`).

`b`  
Overwritten by `\text{diag}(r) \times B` if `trans = 'N'` and `equed = 'R'` or 'B';

overwritten by `\text{trans} = 'T'` or 'C' and `equed = 'C' or 'B';`

not changed if `equed = 'N'`.

`r, c`  
These arrays are output arguments if `fact≠'F'`. Each element of these arrays is a power of the radix. See the description of `r, c` in Input Arguments section.

`rcond`  
Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix `A` after equilibration (if done). If `rcond` is less than the machine precision, in particular, if `rcond = 0`, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned.

`rpvgrw`  
Contains the reciprocal pivot growth factor:

\[ \frac{\|A\|}{\|L\|\|U\|} \]

If this is much less than 1, the stability of the `LU` factorization of the (equilibrated) matrix `A` could be poor. This also means that the solution `X`, estimated condition numbers, and error bounds could be unreliable. If
factorization fails with $0 < \text{info} \leq n$, this parameter contains the reciprocal pivot growth factor for the leading info columns of A. In gbsvx, this quantity is returned in rpivot.

*berr*

Array, size at least $\max(1, \text{nrhs})$. Contains the componentwise relative backward error for each solution vector $x_j$, that is, the smallest relative change in any element of $A$ or $B$ that makes $x_j$ an exact solution.

*err_bnds_norm*

Array of size $\text{nrhs} \times n\_err\_bnds$. For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the $i$-th solution vector

$$\frac{\max_j |X_{true,j} - X_{j}|}{\max_j |X_{j}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned.

*err=1*  
"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} \times \text{slamch}(\varepsilon)$ for single precision flavors and $\sqrt{n} \times \text{dlamch}(\varepsilon)$ for double precision flavors.

*err=2*  
"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} \times \text{slamch}(\varepsilon)$ for single precision flavors and $\sqrt{n} \times \text{dlamch}(\varepsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.

*err=3*  
Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold $\sqrt{n} \times \text{slamch}(\varepsilon)$ for single precision flavors and $\sqrt{n} \times \text{dlamch}(\varepsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers for some appropriately scaled matrix $Z$ are:

$$\|Z\| \cdot \|Z^{-1}\|_\infty$$

Let $z=s\times a$, where $s$ scales each row by a power of the radix so all absolute row sums of $z$ are approximately 1.

The information for right-hand side $i$, where $1 \leq i \leq \text{nrhs}$, and type of error err is stored in err_bnds_norm[(err-1)*nrhs + i - 1].
**err_bnds_comp**

Array of size $nrhs \times n_{\text{err\_bnds}}$. For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the $i$-th solution vector:

$$\max_j \frac{|X_{true}_{ij} - X_{i,j}|}{|X_{i,j}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested ($params[2] = 0.0$), then `err_bnds_comp` is not accessed.

**err=1**

"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} \times \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} \times \text{dlamch}(\epsilon)$ for double precision flavors.

**err=2**

"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} \times \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} \times \text{dlamch}(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.

**err=3**

Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold $\sqrt{n} \times \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} \times \text{dlamch}(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers for some appropriately scaled matrix $Z$ are:

$$\|Z\|_\infty \cdot \|Z^{-1}\|_\infty$$

Let $z=s \times (a \times \text{diag}(x))$, where $x$ is the solution for the current right-hand side and $s$ scales each row of $a \times \text{diag}(x)$ by a power of the radix so all absolute row sums of $z$ are approximately 1.

The information for right-hand side $i$, where $1 \leq i \leq nrhs$, and type of error $err$ is stored in `err_bnds_comp[(err-1) \times nrhs + i - 1]`.

**ipiv**

If `fact = 'N'` or `'E'`, then `ipiv` is an output argument and on exit contains the pivot indices from the factorization $A = P \times L \times U$ of the original matrix $A$ (if `fact = 'N'`) or of the equilibrated matrix $A$ (if `fact = 'E'`).
equed

If fact ≠ 'F', then equed is an output argument. It specifies the form of equilibration that was done (see the description of equed in Input Arguments section).

params

If an entry is less than 0.0, that entry is filled with the default value used for that parameter, otherwise the entry is not modified.

info

If info = 0, the execution is successful. The solution to every right-hand side is guaranteed.

If info = -i, the i-th parameter had an illegal value.

If 0 < info ≤ n: Uinfo,info is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed; rcond = 0 is returned.

If info = n+j: The solution corresponding to the j-th right-hand side is not guaranteed. The solutions corresponding to other right-hand sides k with k > j may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested params[2] = 0.0, then the j-th right-hand side is the first with a normwise error bound that is not guaranteed (the smallest j such that err_bnds_norm[j - 1] = 0.0 or err_bnds_comp[j - 1] = 0.0. See the definition of err_bnds_norm and err_bnds_comp for err = 1. To get information about all of the right-hand sides, check err_bnds_norm or err_bnds_comp.

Return Values

This function returns a value info.

If info = 0, the execution is successful. The solution to every right-hand side is guaranteed.

If info = -i, parameter i had an illegal value.

If 0 < info ≤ n: Uinfo,info is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed; rcond = 0 is returned.

If info = n+j: The solution corresponding to the j-th right-hand side is not guaranteed. The solutions corresponding to other right-hand sides k with k > j may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested params[2] = 0.0, then the j-th right-hand side is the first with a normwise error bound that is not guaranteed (the smallest j such that for column major layout err_bnds_norm[j - 1] = 0.0 or err_bnds_comp[j - 1] = 0.0; or for row major layout err_bnds_norm[(j - 1)*n_err_bnds] = 0.0 or err_bnds_comp[(j - 1)*n_err_bnds] = 0.0). See the definition of err_bnds_norm and err_bnds_comp for err = 1. To get information about all of the right-hand sides, check err_bnds_norm or err_bnds_comp.

Include Files
• mkl.h

Description
The routine solves for $X$ the system of linear equations $AX = B$, where $A$ is an $n$-by-$n$ tridiagonal matrix, the columns of matrix $B$ are individual right-hand sides, and the columns of $X$ are the corresponding solutions. The routine uses Gaussian elimination with partial pivoting.

Note that the equation $A^T X = B$ may be solved by interchanging the order of the arguments $du$ and $dl$.

Input Parameters

matrix_layout  
Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

n  
The order of $A$, the number of rows in $B$; $n \geq 0$.

nrhs  
The number of right-hand sides, the number of columns in $B$; $nrhs \geq 0$.

dl  
The array $dl$ (size $n - 1$) contains the $(n - 1)$ subdiagonal elements of $A$.

d  
The array $d$ (size $n$) contains the diagonal elements of $A$.

du  
The array $du$ (size $n - 1$) contains the $(n - 1)$ superdiagonal elements of $A$.

b  
The array $b$ of size $\max(1, ldb*nrhs)$ for column major layout and $\max(1, ldb*n)$ for row major layout contains the matrix $B$ whose columns are the right-hand sides for the systems of equations.

ldb  
The leading dimension of $b$; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout.

Output Parameters

dl  
Overwritten by the $(n-2)$ elements of the second superdiagonal of the upper triangular matrix $U$ from the $LU$ factorization of $A$. These elements are stored in $dl[0]$, $\ldots$, $dl[n - 3]$.

d  
Overwritten by the $n$ diagonal elements of $U$.

du  
Overwritten by the $(n-1)$ elements of the first superdiagonal of $U$.

b  
Overwritten by the solution matrix $X$. 
Return Values

This function returns a value info.

If info = 0, the execution is successful.

If info = -i, parameter i had an illegal value.

If info = i, $U_{ii}$ is exactly zero, and the solution has not been computed. The factorization has not been completed unless i = n.

- mkl.h

Description

The routine uses the LU factorization to compute the solution to a real or complex system of linear equations $A \times X = B$, $A^T \times X = B$, or $A^H \times X = B$, where $A$ is a tridiagonal matrix of order $n$, the columns of matrix $B$ are individual right-hand sides, and the columns of $X$ are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine ?gtsvx performs the following steps:
1. If \texttt{fact = 'N'}, the \textit{LU} decomposition is used to factor the matrix \( A \) as \( A = LU \), where \( L \) is a product of permutation and unit lower bidiagonal matrices and \( U \) is an upper triangular matrix with nonzeros in only the main diagonal and first two superdiagonals.

2. If some \( U_{i,i} = 0 \), so that \( U \) is exactly singular, then the routine returns with \texttt{info = i}. Otherwise, the factored form of \( A \) is used to estimate the condition number of the matrix \( A \). If the reciprocal of the condition number is less than machine precision, \texttt{info = n + 1} is returned as a warning, but the routine still goes on to solve for \( X \) and compute error bounds as described below.

3. The system of equations is solved for \( X \) using the factored form of \( A \).

4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

**Input Parameters**

\textit{matrix\_layout}

Specifies whether matrix storage layout is row major (\texttt{LAPACK\_ROW\_MAJOR}) or column major (\texttt{LAPACK\_COL\_MAJOR}).

\textit{fact}

Must be \texttt{'F'} or \texttt{'N'}.

Specifies whether or not the factored form of the matrix \( A \) has been supplied on entry.

If \texttt{fact = 'F'}: on entry, \( dlf, df, duf, du2 \), and \( ipiv \) contain the factored form of \( A \); arrays \( dl, d, du, dlf, df, duf, du2 \), and \( ipiv \) will not be modified.

If \texttt{fact = 'N'}, the matrix \( A \) will be copied to \( dlf, df \), and \( duf \) and factored.

\textit{trans}

Must be \texttt{'N'}, \texttt{'T'}, or \texttt{'C'}.

Specifies the form of the system of equations:

If \texttt{trans = 'N'}, the system has the form \( A \cdot X = B \) (No transpose).

If \texttt{trans = 'T'}, the system has the form \( A^T \cdot X = B \) (Transpose).

If \texttt{trans = 'C'}, the system has the form \( A^T \cdot X = B \) (Conjugate transpose).

\( n \)

The number of linear equations, the order of the matrix \( A \); \( n \geq 0 \).

\( nrhs \)

The number of right hand sides, the number of columns of the matrices \( B \) and \( X \); \( nrhs \geq 0 \).

\( dl, d, du, dlf, df, duf, du2, b \)

Arrays:

\( dl \), size \( (n - 1) \), contains the subdiagonal elements of \( A \).

\( d \), size \( (n) \), contains the diagonal elements of \( A \).

\( du \), size \( (n - 1) \), contains the superdiagonal elements of \( A \).

\( dlf \), size \( (n - 1) \). If \texttt{fact = 'F'}, then \( dlf \) is an input argument and on entry contains the \( (n - 1) \) multipliers that define the matrix \( L \) from the \textit{LU} factorization of \( A \) as computed by \texttt{?gttrf}.

\( df \), size \( (n) \). If \texttt{fact = 'F'}, then \( df \) is an input argument and on entry contains the \( n \) diagonal elements of the upper triangular matrix \( U \) from the \textit{LU} factorization of \( A \).

\( duf \), size \( (n - 1) \). If \texttt{fact = 'F'}, then \( duf \) is an input argument and on entry contains the \( (n - 1) \) elements of the first superdiagonal of \( U \).
du2, size \((n-2)\). If \(\text{fact} = 'F'\), then \(du2\) is an input argument and on entry contains the \((n-2)\) elements of the second superdiagonal of \(U\).

\(b\), size \(\max(ldb*nrhs)\) for column major layout and \(\max(ldb*n)\) for row major layout, contains the right-hand side matrix \(B\).

\(ldb\)

The leading dimension of \(b\); \(ldb \geq \max(1, n)\) for column major layout and \(ldb \geq nrhs\) for row major layout.

\(ldx\)

The leading dimension of \(x\); \(ldx \geq \max(1, n)\) for column major layout and \(ldx \geq nrhs\) for row major layout.

\(ipiv\)

Array, size at least \(\max(1, n)\). If \(\text{fact} = 'F'\), then \(ipiv\) is an input argument and on entry contains the pivot indices, as returned by ?gttrf.

**Output Parameters**

\(x\)

Array, size \(\max(1, ldx*nrhs)\) for column major layout and \(\max(1, ldx*n)\) for row major layout.

If \(\text{info} = 0\) or \(\text{info} = n+1\), the array \(x\) contains the solution matrix \(X\).

\(dlf\)

If \(\text{fact} = 'N'\), then \(dlf\) is an output argument and on exit contains the \((n-1)\) multipliers that define the matrix \(L\) from the \(LU\) factorization of \(A\).

\(df\)

If \(\text{fact} = 'N'\), then \(df\) is an output argument and on exit contains the \(n\) diagonal elements of the upper triangular matrix \(U\) from the \(LU\) factorization of \(A\).

\(duf\)

If \(\text{fact} = 'N'\), then \(duf\) is an output argument and on exit contains the \((n-1)\) elements of the first superdiagonal of \(U\).

\(du2\)

If \(\text{fact} = 'N'\), then \(du2\) is an output argument and on exit contains the \((n-2)\) elements of the second superdiagonal of \(U\).

\(ipiv\)

The array \(ipiv\) is an output argument if \(\text{fact} = 'N'\) and, on exit, contains the pivot indices from the factorization \(A = L*U\); row \(i\) of the matrix was interchanged with row \(ipiv[i-1]\). The value of \(ipiv[i-1]\) will always be \(i\) or \(i+1\); \(ipiv[i-1]=i\) indicates a row interchange was not required.

\(rcond\)

An estimate of the reciprocal condition number of the matrix \(A\). If \(rcond\) is less than the machine precision (in particular, if \(rcond = 0\)), the matrix is singular to working precision. This condition is indicated by a return code of \(\text{info}>0\).

\(ferr\)

Array, size at least \(\max(1, nrhs)\). Contains the estimated forward error bound for each solution vector \(x_j\) (the \(j\)-th column of the solution matrix \(X\)). If \(xtrue\) is the true solution corresponding to \(x_j\), \(ferr[j-1]\) is an estimated upper bound for the magnitude of the largest element in \(x_j - xtrue\) divided by the magnitude of the largest element in \(x_j\). The estimate is as reliable as the estimate for \(rcond\), and is almost always a slight overestimate of the true error.
Array, size at least \(\max(1, \text{nrhs})\). Contains the component-wise relative backward error for each solution vector \(x_j\), that is, the smallest relative change in any element of \(A\) or \(B\) that makes \(x_j\) an exact solution.

**Return Values**

This function returns a value \(\text{info}\).

- If \(\text{info} = 0\), the execution is successful.
- If \(\text{info} = -i\), parameter \(i\) had an illegal value.
- If \(\text{info} = i\), and \(i \leq n\), then \(U_i\) is exactly zero. The factorization has not been completed unless \(i = n\), but the factor \(U\) is exactly singular, so the solution and error bounds could not be computed; \(rcond = 0\) is returned.
- If \(\text{info} = i\), and \(i = n + 1\), then \(U\) is nonsingular, but \(rcond\) is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of \(rcond\) would suggest.

**Include Files**

- mkl.h

**Description**

The ?dtsvb routine solves a system of linear equations \(A^TX = B\) for \(X\), where \(A\) is an \(n\)-by-\(n\) diagonally dominant tridiagonal matrix, the columns of matrix \(B\) are individual right-hand sides, and the columns of \(X\) are the corresponding solutions. The routine uses the BABE (Burning At Both Ends) algorithm.

Note that the equation \(A^TX = B\) may be solved by interchanging the order of the arguments \(\text{du}\) and \(\text{dl}\).

**Input Parameters**

\(n\) The order of \(A\), the number of rows in \(B\); \(n \geq 0\).
nrhs

The number of right-hand sides, the number of columns in $B$; $nrhs \geq 0$.

dl, d, du, b

Arrays: $dl$ (size $n - 1$), $d$ (size $n$), $du$ (size $n - 1$), $b$(max($ldb*nrhs$) for column major layout and max($ldb*n$) for row major layout).

The array $dl$ contains the $(n - 1)$ subdiagonal elements of $A$.

The array $d$ contains the diagonal elements of $A$.

The array $du$ contains the $(n - 1)$ superdiagonal elements of $A$.

The array $b$ contains the matrix $B$ whose columns are the right-hand sides for the systems of equations.

ldb

The leading dimension of $b$; $ldb \geq \max(1, n)$.

Output Parameters

dl

Overwritten by the $(n-1)$ elements of the subdiagonal of the lower triangular matrices $L_1$, $L_2$ from the factorization of $A$ (see dttrfb).

d

Overwritten by the $n$ diagonal element reciprocals of $U$.

b

Overwritten by the solution matrix $X$.

info

If $info = 0$, the execution is successful.

If $info = -i$, the $i$-th parameter had an illegal value.

If $info = i$, $u_{ii}$ is exactly zero, and the solution has not been computed. The factorization has not been completed unless $i = n$.

Application Notes

A diagonally dominant tridiagonal system is defined such that $|d_i| > |dl_{i-1}| + |du_i|$ for any $i$:

$\forall 1 < i < n$, and $|d_1| > |du_1|, |d_n| > |dl_{n-1}|$

The underlying BABE algorithm is designed for diagonally dominant systems. Such systems have no numerical stability issue unlike the canonical systems that use elimination with partial pivoting (see ?gtsv).

The diagonally dominant systems are much faster than the canonical systems.

NOTE

- The current implementation of BABE has a potential accuracy issue on very small or large data close to the underflow or overflow threshold respectively. Scale the matrix before applying the solver in the case of such input data.
- Applying the ?dtsvb factorization to non-diagonally dominant systems may lead to an accuracy loss, or false singularity detected due to no pivoting.

?posv
Computes the solution to the system of linear equations with a symmetric or Hermitian positive-definite coefficient matrix $A$ and multiple right-hand sides.
Syntax

```c

Description

The routine solves for \( X \) the real or complex system of linear equations \( A \times X = B \), where \( A \) is an \( n \)-by-\( n \) symmetric/Hermitian positive-definite matrix, the columns of matrix \( B \) are individual right-hand sides, and the columns of \( X \) are the corresponding solutions.

The Cholesky decomposition is used to factor \( A \) as
\[
A = U^T \times U \quad \text{(real flavors)} \quad \text{and} \quad A = U^H \times U \quad \text{(complex flavors)}, \quad \text{if} \; \text{uplo} = 'U',
\]
or
\[
A = L \times L^T \quad \text{(real flavors)} \quad \text{and} \quad A = L \times L^H \quad \text{(complex flavors)}, \quad \text{if} \; \text{uplo} = 'L',
\]
where \( U \) is an upper triangular matrix and \( L \) is a lower triangular matrix. The factored form of \( A \) is then used to solve the system of equations \( A \times X = B \).

The \texttt{dsposv} and \texttt{zcposv} are mixed precision iterative refinement subroutines for exploiting fast single precision hardware. They first attempt to factorize the matrix in single precision (\texttt{dsposv}) or single complex precision (\texttt{zcposv}) and use this factorization within an iterative refinement procedure to produce a solution with double precision (\texttt{dsposv}) / double complex precision (\texttt{zcposv}) normwise backward error quality (see below). If the approach fails, the method switches to a double precision or double complex precision factorization respectively and computes the solution.

The iterative refinement is not going to be a winning strategy if the ratio single precision/complex performance over double precision/double complex performance is too small. A reasonable strategy should take the number of right-hand sides and the size of the matrix into account. This might be done with a call to \texttt{ilaenv} in the future. At present, iterative refinement is implemented.

The iterative refinement process is stopped if
\[ \text{iter} > \text{itermax} \]
or for all the right-hand sides:
\[
\text{rnmr} < \sqrt{n} \times \text{xnrm} \times \text{anrm} \times \text{eps} \times \text{bwdmax},
\]
where
- \text{iter} is the number of the current iteration in the iterative refinement process
- \text{rnmr} is the infinity-norm of the residual
• \(\text{nrm}\) is the infinity-norm of the solution
• \(\text{anrm}\) is the infinity-operator-norm of the matrix \(A\)
• \(\text{eps}\) is the machine epsilon returned by \text{dlamch(’Epsilon’)}.

The values \text{itermax} and \text{bwdmax} are fixed to 30 and 1.0d+00 respectively.

**Input Parameters**

\text{matrix\_layout} Specifies whether matrix storage layout is row major (\text{LAPACK\_ROW\_MAJOR}) or column major (\text{LAPACK\_COL\_MAJOR}).

\text{uplo} Must be ‘U’ or ‘L’.

Indicates whether the upper or lower triangular part of \(A\) is stored:
If \text{uplo} = ‘U’, the upper triangle of \(A\) is stored.
If \text{uplo} = ‘L’, the lower triangle of \(A\) is stored.

\(n\) The order of matrix \(A\); \(n \geq 0\).

\(\text{nrhs}\) The number of right-hand sides, the number of columns in \(B\); \(\text{nrhs} \geq 0\).

\(a, b\) Arrays: \(a(\text{size max}(1, lda))\), \(b, \text{size max}(ldb*\text{nrhs})\) for column major layout and \(\text{max}(ldb*n)\) for row major layout. The array \(a\) contains the upper or the lower triangular part of the matrix \(A\) (see \text{uplo}).

Note that in the case of \text{zcposv} the imaginary parts of the diagonal elements need not be set and are assumed to be zero.

The array \(b\) contains the matrix \(B\) whose columns are the right-hand sides for the systems of equations.

\(lda\) The leading dimension of \(a\); \(lda \geq \text{max}(1, n)\).

\(ldb\) The leading dimension of \(b\); \(ldb \geq \text{max}(1, n)\) for column major layout and \(ldb \geq \text{nrhs}\) for row major layout.

\(ldx\) The leading dimension of the array \(x\); \(ldx \geq \text{max}(1, n)\) for column major layout and \(ldx \geq \text{nrhs}\) for row major layout.

**Output Parameters**

\(a\) If \(\text{info} = 0\), the upper or lower triangular part of \(a\) is overwritten by the Cholesky factor \(U\) or \(L\), as specified by \text{uplo}.

If iterative refinement has been successfully used (\(\text{info} = 0\) and \(\text{iter} \geq 0\)), then \(A\) is unchanged.

If double precision factorization has been used (\(\text{info} = 0\) and \(\text{iter} < 0\)), then the array \(A\) contains the factors \(L\) or \(U\) from the Cholesky factorization.

Overwritten by the solution matrix \(X\).

\(b\)

Array, size \(\text{max}(1, lda*\text{nrhs})\) for column major layout and \(\text{max}(1, ldb*n)\) for row major layout. If \(\text{info} = 0\), contains the \(n\)-by-\(\text{nrhs}\) solution matrix \(X\).
iter

- If \( \text{iter} < 0 \): iterative refinement has failed, double precision factorization has been performed
- If \( \text{iter} = -1 \): the routine fell back to full precision for implementation- or machine-specific reason
- If \( \text{iter} = -2 \): narrowing the precision induced an overflow, the routine fell back to full precision
- If \( \text{iter} = -3 \): failure of \text{spotrf} for \text{dsposv}, or \text{cpotrf} for \text{zcposv}
- If \( \text{iter} = -31 \): stop the iterative refinement after the 30th iteration.

If \( \text{iter} > 0 \): iterative refinement has been successfully used. Returns the number of iterations.

Return Values

This function returns a value \( \text{info} \).

- If \( \text{info} = 0 \), the execution is successful.
- If \( \text{info} = -i \), parameter \( i \) had an illegal value.
- If \( \text{info} = i \), the leading minor of order \( i \) (and therefore the matrix \( A \) itself) is not positive definite, so the factorization could not be completed, and the solution has not been computed.

Description

The routine uses the Cholesky factorization $A=U^T U$ (real flavors) / $A=U^H U$ (complex flavors) or $A=L*L^T$ (real flavors) / $A=L*L^H$ (complex flavors) to compute the solution to a real or complex system of linear equations $A*X = B$, where $A$ is a $n$-by-$n$ real symmetric/Hermitian positive definite matrix, the columns of matrix $B$ are individual right-hand sides, and the columns of $X$ are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine ?posvx performs the following steps:

1. If fact = 'E', real scaling factors $s$ are computed to equilibrate the system:
   $\text{diag}(s)*A*\text{diag}(s)*\text{inv}(\text{diag}(s))*X = \text{diag}(s)*B$.
   Whether or not the system will be equilibrated depends on the scaling of the matrix $A$, but if equilibration is used, $A$ is overwritten by $\text{diag}(s)*A*\text{diag}(s)$ and $B$ by $\text{diag}(s)*B$.

2. If fact = 'N' or 'E', the Cholesky decomposition is used to factor the matrix $A$ (after equilibration if fact = 'E') as
   $A = U^T U$ (real), $A = U^H U$ (complex), if uplo = 'U',
   or $A = L*L^T$ (real), $A = L*L^H$ (complex), if uplo = 'L',
   where $U$ is an upper triangular matrix and $L$ is a lower triangular matrix.

3. If the leading $i$-by-$i$ principal minor is not positive-definite, then the routine returns with info = $i$.
   Otherwise, the factored form of $A$ is used to estimate the condition number of the matrix $A$. If the reciprocal of the condition number is less than machine precision, info = $n + 1$ is returned as a warning, but the routine still goes on to solve for $X$ and compute error bounds as described below.

4. The system of equations is solved for $X$ using the factored form of $A$.

5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

6. If equilibration was used, the matrix $X$ is premultiplied by $\text{diag}(s)$ so that it solves the original system before equilibration.

Input Parameters

$\text{matrix_layout}$

Specifies whether matrix storage layout is row major ($\text{LAPACK_ROW_MAJOR}$) or column major ($\text{LAPACK_COL_MAJOR}$).

$\text{fact}$

Must be 'F', 'N', or 'E'.

Specifies whether or not the factored form of the matrix $A$ is supplied on entry, and if not, whether the matrix $A$ should be equilibrated before it is factored.

If fact = 'F': on entry, $af$ contains the factored form of $A$. If equed = 'Y', the matrix $A$ has been equilibrated with scaling factors given by $s$.

$a$ and $af$ will not be modified.

If fact = 'N', the matrix $A$ will be copied to $af$ and factored.

If fact = 'E', the matrix $A$ will be equilibrated if necessary, then copied to $af$ and factored.

$\text{uplo}$

Must be 'U' or 'L'.

Indicates whether the upper or lower triangular part of $A$ is stored:
If $uplo = 'U'$, the upper triangle of $A$ is stored.
If $uplo = 'L'$, the lower triangle of $A$ is stored.

$n$
The order of matrix $A; n \geq 0$.

$nrhs$
The number of right-hand sides, the number of columns in $B; nrhs \geq 0$.

$a$, $af$, $b$
Arrays: $a$(size max(1, $lda*n$)), $af$(size max(1, $ldaf*n$)), $b$, size max($ldb*nrhs$) for column major layout and max($ldb*n$) for row major layout, .
The array $a$ contains the matrix $A$ as specified by $uplo$. If $fact = 'F'$ and $equed = 'Y'$, then $A$ must have been equilibrated by the scaling factors in $s$, and $a$ must contain the equilibrated matrix $\text{diag}(s) \cdot A \cdot \text{diag}(s)$.
The array $af$ is an input argument if $fact = 'F'$. It contains the triangular factor $U$ or $L$ from the Cholesky factorization of $A$ in the same storage format as $A$. If $equed$ is not 'N', then $af$ is the factored form of the equilibrated matrix $\text{diag}(s) \cdot A \cdot \text{diag}(s)$.
The array $b$ contains the matrix $B$ whose columns are the right-hand sides for the systems of equations.

$lda$
The leading dimension of $a; lda \geq \text{max}(1, n)$.

$ldaf$
The leading dimension of $af; ldaf \geq \text{max}(1, n)$.

$db$
The leading dimension of $b; ldb \geq \text{max}(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout.

$equed$
Must be 'N' or 'Y'.
$equed$ is an input argument if $fact = 'F'$. It specifies the form of equilibration that was done:
if $equed = 'N'$, no equilibration was done (always true if $fact = 'N'$);
if $equed = 'Y'$, equilibration was done, that is, $A$ has been replaced by $\text{diag}(s) \cdot A \cdot \text{diag}(s)$.

$s$
Array, size ($n$). The array $s$ contains the scale factors for $A$. This array is an input argument if $fact = 'F'$ only; otherwise it is an output argument.
If $equed = 'N'$, $s$ is not accessed.
If $fact = 'F'$ and $equed = 'Y'$, each element of $s$ must be positive.

$ldx$
The leading dimension of the output array $x; ldx \geq \text{max}(1, n)$ for column major layout and $ldx \geq nrhs$ for row major layout.

**Output Parameters**

$x$
Array, size max(1, $ldx*nrhs$) for column major layout and max(1, $ldx*n$) for row major layout.
If $info = 0$ or $info = n+1$, the array $x$ contains the solution matrix $X$ to the original system of equations. Note that if $equed = 'Y$', $A$ and $B$ are modified on exit, and the solution to the equilibrated system is $\text{inv}(\text{diag}(s)) \times X$.

Array $a$ is not modified on exit if $fact = 'F'$ or '$N$', or if $fact = 'E'$ and $equed = 'N'$.

If $fact = 'E'$ and $equed = 'Y'$, $A$ is overwritten by $\text{diag}(s) \times A \times \text{diag}(s)$.

If $fact = 'N'$ or $'E'$, then $af$ is an output argument and on exit returns the triangular factor $U$ or $L$ from the Cholesky factorization $A=U^T \times U$ or $A=L \times L^T$ (real routines), $A=U^H \times U$ or $A=L \times L^H$ (complex routines) of the original matrix $A$ (if $fact = 'N'$), or of the equilibrated matrix $A$ (if $fact = 'E'$). See the description of $a$ for the form of the equilibrated matrix.

Overwritten by $\text{diag}(s) \times B$, if $equed = 'Y'$; not changed if $equed = 'N'$.

This array is an output argument if $fact \neq 'F'$. See the description of $s$ in Input Arguments section.

An estimate of the reciprocal condition number of the matrix $A$ after equilibration (if done). If $rcond$ is less than the machine precision (in particular, if $rcond = 0$), the matrix is singular to working precision. This condition is indicated by a return code of $info > 0$.

Array, size at least $\max(1, \text{nrhs})$. Contains the estimated forward error bound for each solution vector $x_j$ (the $j$-th column of the solution matrix $X$). If $xtrue$ is the true solution corresponding to $x_j$, $ferr[j-1]$ is an estimated upper bound for the magnitude of the largest element in $(x_j - xtrue)$ divided by the magnitude of the largest element in $x_j$. The estimate is as reliable as the estimate for $rcond$, and is almost always a slight overestimate of the true error.

Array, size at least $\max(1, \text{nrhs})$. Contains the component-wise relative backward error for each solution vector $x_j$, that is, the smallest relative change in any element of $A$ or $B$ that makes $x_j$ an exact solution.

If $fact \neq 'F'$, then $equed$ is an output argument. It specifies the form of equilibration that was done (see the description of $equed$ in Input Arguments section).

**Return Values**

This function returns a value $info$.

If $info = 0$, the execution is successful.

If $info = -i$, parameter $i$ had an illegal value.

If $info = i$, and $i \leq n$, the leading minor of order $i$ (and therefore the matrix $A$ itself) is not positive-definite, so the factorization could not be completed, and the solution and error bounds could not be computed; $rcond = 0$ is returned.
If \( info = i \) and \( i = n + 1 \), then \( U \) is nonsingular, but \( rcond \) is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of \( rcond \) would suggest.

Description

The routine uses the Cholesky factorization \( A=U^T U \) (real flavors) / \( A=U^H U \) (complex flavors) or \( A=L^T L^T \) (real flavors) / \( A=L^H L^H \) (complex flavors) to compute the solution to a real or complex system of linear equations \( A^T X = B \), where \( A \) is an \( n \times n \) real symmetric/Hermitian positive definite matrix, the columns of matrix \( B \) are individual right-hand sides, and the columns of \( X \) are the corresponding solutions. Both normwise and maximum componentwise error bounds are also provided on request. The routine returns a solution with a small guaranteed error (\( O(\text{eps}) \), where \( \text{eps} \) is the working machine precision) unless the matrix is very ill-conditioned, in which case a warning is returned. Relevant condition numbers are also calculated and returned.
The routine accepts user-provided factorizations and equilibration factors; see definitions of the \texttt{fact} and \texttt{equed} options. Solving with refinement and using a factorization from a previous call of the routine also produces a solution with $O(\varepsilon)$ errors or warnings but that may not be true for general user-provided factorizations and equilibration factors if they differ from what the routine would itself produce.

The routine \texttt{?posvxx} performs the following steps:

1. If \texttt{fact} = 'E', scaling factors are computed to equilibrate the system:
   \[
   \text{diag}(s)^*A^*\text{diag}(s)^*\text{inv}(\text{diag}(s))^*X = \text{diag}(s)^*B
   \]
   Whether or not the system will be equilibrated depends on the scaling of the matrix $A$, but if equilibration is used, $A$ is overwritten by $\text{diag}(s)^*A^*\text{diag}(s)$ and $B$ by $\text{diag}(s)^*B$.

2. If \texttt{fact} = 'N' or 'E', the Cholesky decomposition is used to factor the matrix $A$ (after equilibration if \texttt{fact} = 'E') as
   \[
   A = U^T * U \text{ (real), } A = U^H * U \text{ (complex), if } \texttt{uplo} = \text{'U'},
   \]
   or
   \[
   A = L * L^T \text{ (real), } A = L * L^H \text{ (complex), if } \texttt{uplo} = \text{'L'},
   \]
   where $U$ is an upper triangular matrix and $L$ is a lower triangular matrix.

3. If the leading $i$-by-$i$ principal minor is not positive-definite, the routine returns with \texttt{info} = $i$.
   Otherwise, the factored form of $A$ is used to estimate the condition number of the matrix $A$ (see the \texttt{rcond} parameter). If the reciprocal of the condition number is less than machine precision, the routine still goes on to solve for $X$ and compute error bounds.

4. The system of equations is solved for $X$ using the factored form of $A$.

5. By default, unless \texttt{params[0]} is set to zero, the routine applies iterative refinement to get a small error and error bounds. Refinement calculates the residual to at least twice the working precision.

6. If equilibration was used, the matrix $X$ is premultiplied by $\text{diag}(s)$ so that it solves the original system before equilibration.

\textbf{Input Parameters}

\begin{itemize}
  \item \texttt{matrix_layout} Specifies whether matrix storage layout is row major (\texttt{LAPACK_ROW_MAJOR}) or column major (\texttt{LAPACK_COL_MAJOR}).
  \item \texttt{fact} Must be 'F', 'N', or 'E'.
    Specifies whether or not the factored form of the matrix $A$ is supplied on entry, and if not, whether the matrix $A$ should be equilibrated before it is factored.
    If \texttt{fact} = 'F', on entry, \texttt{af} contains the factored form of $A$. If \texttt{equed} is not 'N', the matrix $A$ has been equilibrated with scaling factors given by $s$. Parameters $a$ and $af$ are not modified.
    If \texttt{fact} = 'N', the matrix $A$ will be copied to $af$ and factored.
    If \texttt{fact} = 'E', the matrix $A$ will be equilibrated, if necessary, copied to $af$ and factored.
  \item \texttt{uplo} Must be 'U' or 'L'.
    Indicates whether the upper or lower triangular part of $A$ is stored:
    If \texttt{uplo} = 'U', the upper triangle of $A$ is stored.
    If \texttt{uplo} = 'L', the lower triangle of $A$ is stored.
  \item \texttt{n} The number of linear equations; the order of the matrix $A$; $n \geq 0$.
\end{itemize}
nrhs

The number of right-hand sides; the number of columns of the matrices $B$ and $X$; $nrhs \geq 0$.

$a, af, b$

Arrays: $a$ (size $\max(\text{lda} \times n)$), $af$ (size $\max(\text{ldaf} \times n)$), $b$ (size $\max(1, \text{ldb} \times nrhs)$) for column major layout and $\max(1, \text{ldb} \times n)$ for row major layout.

The array $a$ contains the matrix $A$ as specified by $\text{uplo}$. If $\text{fact} = 'F'$ and $\text{equed} = 'Y'$, then $A$ must have been equilibrated by the scaling factors in $s$, and $a$ must contain the equilibrated matrix $\text{diag}(s) \times A \times \text{diag}(s)$.

The array $af$ is an input argument if $\text{fact} = 'F'$. It contains the triangular factor $U$ or $L$ from the Cholesky factorization of $A$ in the same storage format as $A$. If $\text{equed}$ is not 'N', then $af$ is the factored form of the equilibrated matrix $\text{diag}(s) \times A \times \text{diag}(s)$.

The array $b$ contains the matrix $B$ whose columns are the right-hand sides for the systems of equations.

$\text{lda}$

The leading dimension of the array $a$; $\text{lda} \geq \max(1, n)$.

$\text{ldaf}$

The leading dimension of the array $af$; $\text{ldaf} \geq \max(1, n)$.

$\text{equed}$

Must be 'N' or 'Y'.

$\text{equed}$ is an input argument if $\text{fact} = 'F'$. It specifies the form of equilibration that was done:

If $\text{equed} = 'N'$, no equilibration was done (always true if $\text{fact} = 'N'$).

If $\text{equed} = 'Y'$, both row and column equilibration was done, that is, $A$ has been replaced by $\text{diag}(s) \times A \times \text{diag}(s)$.

$s$

Array, size $(n)$. The array $s$ contains the scale factors for $A$. This array is an input argument if $\text{fact} = 'F'$ only; otherwise it is an output argument.

If $\text{equed} = 'N'$, $s$ is not accessed.

If $\text{fact} = 'F'$ and $\text{equed} = 'Y'$, each element of $s$ must be positive. Each element of $s$ should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

$\text{ldb}$

The leading dimension of the array $b$; $\text{ldb} \geq \max(1, n)$ for column major layout and $\text{ldb} \geq nrhs$ for row major layout.

$\text{ldx}$

The leading dimension of the output array $x$; $\text{ldx} \geq \max(1, n)$ for column major layout and $\text{ldx} \geq nrhs$ for row major layout.

$n\_err\_bnds$

Number of error bounds to return for each right hand side and each type (normwise or componentwise). See $err\_bnds\_norm$ and $err\_bnds\_comp$ descriptions in the Output Arguments section below.
Specifies the number of parameters set in params. If $\leq 0$, the params array is never referenced and default values are used.

Array, size max(1,$nparams$). Specifies algorithm parameters. If an entry is less than 0.0, that entry is filled with the default value used for that parameter. Only positions up to $nparams$ are accessed; defaults are used for higher-numbered parameters. If defaults are acceptable, you can pass $nparams = 0$, which prevents the source code from accessing the params argument.

params[0] : Whether to perform iterative refinement or not. Default: 1.0 (for single precision flavors), 1.0D+0 (for double precision flavors).

=0.0 No refinement is performed and no error bounds are computed.

=1.0 Use the extra-precise refinement algorithm.

(Other values are reserved for future use.)

params[1] : Maximum number of residual computations allowed for refinement.

Default 10.0

Aggressive Set to 100.0 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in err_bnds_norm and err_bnds_comp may no longer be trustworthy.

params[2] : Flag determining if the code will attempt to find a solution with a small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence).

**Output Parameters**

Array, size max(1, $ldx*nrhs$) for column major layout and max(1, $ldx*n$) for row major layout.

If $info = 0$, the array $x$ contains the solution $n$-by-$nrhs$ matrix $X$ to the original system of equations. Note that $A$ and $B$ are modified on exit if $equed\neq 'N'$, and the solution to the equilibrated system is:

$\text{inv(diag}(s)\text{)}*X$.

Array $a$ is not modified on exit if $fact = 'F'$ or $'N'$, or if $fact = 'E'$ and $equed = 'N'$.

If $fact = 'E'$ and $equed = 'Y'$, $A$ is overwritten by $\text{diag}(s)A\text{diag}(s)$. 
If `fact = 'N'` or `E'`, then `af` is an output argument and on exit returns the triangular factor `U` or `L` from the Cholesky factorization `A=U^T*U` or `A=L*L^T` (real routines), `A=U^H*U` or `A=L*L^H` (complex routines) of the original matrix `A` (if `fact = 'N'`), or of the equilibrated matrix `A` (if `fact = 'E'`). See the description of `a` for the form of the equilibrated matrix.

If `equed = 'N'`, `B` is not modified.

If `equed = 'Y'`, `B` is overwritten by `diag(s)*B`.

This array is an output argument if `fact='F'`. Each element of this array is a power of the radix. See the description of `s` in Input Arguments section.

Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix `A` after equilibration (if done). If `rcond` is less than the machine precision, in particular, if `rcond = 0`, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned.

Contains the reciprocal pivot growth factor:

\[ \frac{\|A\|}{\|L\|} \]

If this is much less than 1, the stability of the `LU` factorization of the (equilibrated) matrix `A` could be poor. This also means that the solution `X`, estimated condition numbers, and error bounds could be unreliable. If factorization fails with `0 < info < n`, this parameter contains the reciprocal pivot growth factor for the leading `info` columns of `A`.

Array, size at least `max(1, nrhs)`. Contains the componentwise relative backward error for each solution vector `x_j`, that is, the smallest relative change in any element of `A` or `B` that makes `x_j` an exact solution.

Array of size `nrhs*n_err_bnds`. For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the `i`-th solution vector

\[ \frac{ \max_j |x_{\text{true}}_{ij} - x_{ij}| }{ \max_j |x_{ij}| } \]

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned.

\[ err=1 \]

"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold `sqrt(n) * slamch(ε)` for single precision flavors and `sqrt(n) * dlamch(ε)` for double precision flavors.

\[ err=2 \]

"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold `sqrt(n) * slamch(ε)`
for single precision flavors and
sqrt(n)*dlamch(ε) for double precision flavors. This error bound should only be trusted if the previous boolean is true.

err=3

Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold
sqrt(n)*slamch(ε) for single precision flavors and sqrt(n)*dlamch(ε) for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers for some appropriately scaled matrix Z are:

\[ \|Z\|_\infty \cdot \|Z^{-1}\|_\infty \]

Let \( z = s \cdot a \), where \( s \) scales each row by a power of the radix so all absolute row sums of \( z \) are approximately 1.

The information for right-hand side \( i \), where \( 1 \leq i \leq \text{nrhs} \), and type of error \( \text{err} \) is stored in \( \text{err_bnds_norm}[(\text{err}-1)\cdot\text{nrhs} + i - 1] \).

Array of size \( \text{nrhs} \cdot \text{n_err_bnds} \). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the \( i \)-th solution vector:

\[
\max_j \left| \frac{X_{true,ij} - X_{ij}}{X_{true,ij}} \right|
\]

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (params[2] = 0.0), then \( \text{err_bnds_comp} \) is not accessed.

err=1

"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n)*slamch(ε) for single precision flavors and sqrt(n)*dlamch(ε) for double precision flavors.

err=2

"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n)*slamch(ε) for single precision flavors and sqrt(n)*dlamch(ε) for double precision flavors. This error bound should only be trusted if the previous boolean is true.
Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold $\sqrt{n} \cdot \text{slamch}(e)$ for single precision flavors and $\sqrt{n} \cdot \text{dlamch}(e)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers for some appropriately scaled matrix $Z$ are:

$$\|Z\| \cdot \|Z^{-1}\|$$

Let $z = s \cdot (a \cdot \text{diag}(x))$, where $x$ is the solution for the current right-hand side and $s$ scales each row of $a \cdot \text{diag}(x)$ by a power of the radix so all absolute row sums of $z$ are approximately 1.

The information for right-hand side $i$, where $1 \leq i \leq \text{nrhs}$, and type of error $\text{err}$ is stored in $\text{err_bnds_comp}[(\text{err}-1)\cdot\text{nrhs} + i - 1]$.

$\text{equed}$

If $\text{fact} \neq 'F'$, then $\text{equed}$ is an output argument. It specifies the form of equilibration that was done (see the description of $\text{equed}$ in Input Arguments section).

$\text{params}$

If an entry is less than 0.0, that entry is filled with the default value used for that parameter, otherwise the entry is not modified.

### Return Values

This function returns a value $\text{info}$.

If $\text{info} = 0$, the execution is successful. The solution to every right-hand side is guaranteed.

If $\text{info} = -i$, parameter $i$ had an illegal value.

If $0 < \text{info} < n$: $U_{\text{info},\text{info}}$ is exactly zero. The factorization has been completed, but the factor $U$ is exactly singular, so the solution and error bounds could not be computed; $\text{rcond} = 0$ is returned.

If $\text{info} = n+j$: The solution corresponding to the $j$-th right-hand side is not guaranteed. The solutions corresponding to other right-hand sides $k$ with $k > j$ may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested $\text{params}[2] = 0.0$, then the $j$-th right-hand side is the first with a normwise error bound that is not guaranteed (the smallest $j$ such that for column major layout $\text{err_bnds_norm}[j-1] = 0.0$ or $\text{err_bnds_comp}[j-1] = 0.0$; or for row major layout $\text{err_bnds_norm}[(j-1)\cdot\text{n_err_bnds}] = 0.0$ or $\text{err_bnds_comp}[(j-1)\cdot\text{n_err_bnds}] = 0.0$).

See the definition of $\text{err_bnds_norm}$ and $\text{err_bnds_comp}$ for $\text{err} = 1$. To get information about all of the right-hand sides, check $\text{err_bnds_norm}$ or $\text{err_bnds_comp}$.

lapack_int LAPACKE_zppsv (int matrix_layout , char uplo , lapack_int n , lapack_int nrhs , lapack_complex_double * ap , lapack_complex_double * b , lapack_int ldb );
```

Include Files

- mkl.h

Description

The routine solves for $X$ the real or complex system of linear equations $A*X = B$, where $A$ is an $n$-by-$n$ real symmetric/Hermitian positive-definite matrix stored in packed format, the columns of matrix $B$ are individual right-hand sides, and the columns of $X$ are the corresponding solutions.

The Cholesky decomposition is used to factor $A$ as

$$A = U^T * U$$ (real flavors) and $$A = U^H * U$$ (complex flavors), if uplo = 'U',

or

$$A = L * L^T$$ (real flavors) and $$A = L * L^H$$ (complex flavors), if uplo = 'L',

where $U$ is an upper triangular matrix and $L$ is a lower triangular matrix. The factored form of $A$ is then used to solve the system of equations $A*X = B$.

Input Parameters

- **matrix_layout**: Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **uplo**: Must be 'U' or 'L'.

  Indicates whether the upper or lower triangular part of $A$ is stored:

  - If uplo = 'U', the upper triangle of $A$ is stored.
  - If uplo = 'L', the lower triangle of $A$ is stored.

- **n**: The order of matrix $A$; $n \geq 0$.

- **nrhs**: The number of right-hand sides, the number of columns in $B$; $nrhs \geq 0$.

- **ap, b**: Arrays: $ap$ (size max(1,$n^*(n+1)/2$), $b$, size max($ldb*nrhs$) for column major layout and max($ldb*n$) for row major layout. The array $ap$ contains the upper or the lower triangular part of the matrix $A$ (as specified by uplo) in packed storage (see Matrix Storage Schemes).

  The array $b$ contains the matrix $B$ whose columns are the right-hand sides for the systems of equations.

- **ldb**: The leading dimension of $b$; $ldb \geq max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout.
Output Parameters

\[ ap \]
If \( info = 0 \), the upper or lower triangular part of \( A \) in packed storage is overwritten by the Cholesky factor \( U \) or \( L \), as specified by \( uplo \).

\[ b \]
Overwritten by the solution matrix \( X \).

Return Values

This function returns a value \( info \).
If \( info = 0 \), the execution is successful.
If \( info = -i \), parameter \( i \) had an illegal value.
If \( info = i \), the leading minor of order \( i \) (and therefore the matrix \( A \) itself) is not positive-definite, so the factorization could not be completed, and the solution has not been computed.

lapack_int LAPACKE_zppsvx( int matrix_layout, char fact, char uplo, lapack_int n, lapack_int nrhs, lapack_complex_double* ap, lapack_complex_double* afp, char* equed, double* s, lapack_complex_double* b, lapack_int ldb, lapack_complex_double* x, lapack_int ldx, double* rcond, double* ferr, double* berr );
```

Include Files

- mkl.h

Description

The routine uses the Cholesky factorization \( A = U^T U \) (real flavors) / \( A = U^H U \) (complex flavors) or \( A = L L^T \) (real flavors) / \( A = L L^H \) (complex flavors) to compute the solution to a real or complex system of linear equations \( A X = B \), where \( A \) is a \( n \)-by-\( n \) symmetric or Hermitian positive-definite matrix stored in packed format, the columns of matrix \( B \) are individual right-hand sides, and the columns of \( X \) are the corresponding solutions. Error bounds on the solution and a condition estimate are also provided.
The routine \texttt{?ppsvx} performs the following steps:

1. If \texttt{fact} = 'E', real scaling factors \( s \) are computed to equilibrate the system:
   \[
   \text{diag}(s) \cdot A \cdot \text{diag}(s) \cdot \text{inv} \{ \text{diag}(s) \} \cdot X = \text{diag}(s) \cdot B.
   \]
   Whether or not the system will be equilibrated depends on the scaling of the matrix \( A \), but if equilibration is used, \( A \) is overwritten by \( \text{diag}(s) \cdot A \cdot \text{diag}(s) \) and \( B \) by \( \text{diag}(s) \cdot B \).

2. If \texttt{fact} = 'N' or 'E', the Cholesky decomposition is used to factor the matrix \( A \) (after equilibration if \texttt{fact} = 'E') as
   \[
   A = U^T \cdot U \quad \text{(real)}, \quad A = U^H \cdot U \quad \text{(complex)}, \quad \text{if uplo} = 'U',
   \]
   or
   \[
   A = L \cdot L^T \quad \text{(real)}, \quad A = L \cdot L^H \quad \text{(complex)}, \quad \text{if uplo} = 'L',
   \]
   where \( U \) is an upper triangular matrix and \( L \) is a lower triangular matrix.

3. If the leading \( i \)-by-\( i \) principal minor is not positive-definite, then the routine returns with \texttt{info} = \( i \). Otherwise, the factored form of \( A \) is used to estimate the condition number of the matrix \( A \). If the reciprocal of the condition number is less than machine precision, \texttt{info} = \( n+1 \) is returned as a warning, but the routine still goes on to solve for \( X \) and compute error bounds as described below.

4. The system of equations is solved for \( X \) using the factored form of \( A \).

5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

6. If equilibration was used, the matrix \( X \) is premultiplied by \( \text{diag}(s) \) so that it solves the original system before equilibration.

\textbf{Input Parameters}

\begin{itemize}
  \item \texttt{matrix\_layout} \hspace{2cm} Specifies whether matrix storage layout is row major \texttt{(LAPACK\_ROW\_MAJOR)} or column major \texttt{(LAPACK\_COL\_MAJOR)}.
  \item \texttt{fact} \hspace{2cm} Must be 'F', 'N', or 'E'.
    Specifies whether or not the factored form of the matrix \( A \) is supplied on entry, and if not, whether the matrix \( A \) should be equilibrated before it is factored.
    If \texttt{fact} = 'F': on entry, \texttt{afp} contains the factored form of \( A \). If \texttt{equed} = 'Y', the matrix \( A \) has been equilibrated with scaling factors given by \texttt{s}.
    \texttt{ap} and \texttt{afp} will not be modified.
    If \texttt{fact} = 'N', the matrix \( A \) will be copied to \texttt{afp} and factored.
    If \texttt{fact} = 'E', the matrix \( A \) will be equilibrated if necessary, then copied to \texttt{afp} and factored.
  \item \texttt{uplo} \hspace{2cm} Must be 'U' or 'L'.
    Indicates whether the upper or lower triangular part of \( A \) is stored:
    If \texttt{uplo} = 'U', the upper triangle of \( A \) is stored.
    If \texttt{uplo} = 'L', the lower triangle of \( A \) is stored.
  \item \texttt{n} \hspace{2cm} The order of matrix \( A \); \( n \geq 0 \).
  \item \texttt{nrhs} \hspace{2cm} The number of right-hand sides; the number of columns in \( B \); \( nrhs \geq 0 \).
\end{itemize}
Arrays: (size max(1,\(n(n+1)/2\)), \(a fp\) (size max(1,\(n(n+1)/2\)), \(b\) of size max(1, \(ldb\*
rhs\)) for column major layout and max(1, \(ldb\*
\)) for row major layout.

The array \(ap\) contains the upper or lower triangle of the original symmetric/Hermitian matrix \(A\) in packed storage (see Matrix Storage Schemes). In case when \(fact = 'F'\) and \(equed = 'Y'\), \(ap\) must contain the equilibrated matrix \(\text{diag}(s)\*A\*\text{diag}(s)\).

The array \(a fp\) is an input argument if \(fact = 'F'\) and contains the triangular factor \(U\) or \(L\) from the Cholesky factorization of \(A\) in the same storage format as \(A\). If \(equed\) is not \('N'\), then \(a fp\) is the factored form of the equilibrated matrix \(A\).

The array \(b\) contains the matrix \(B\) whose columns are the right-hand sides for the systems of equations.

\(ldb\)

The leading dimension of \(b\); \(ldb \geq \max(1, n)\) for column major layout and \(ldb \geq \nrhs\) for row major layout.

\(equed\)

Must be \('N'\) or \('Y'\).

\(equed\) is an input argument if \(fact = 'F'\). It specifies the form of equilibration that was done:

if \(equed = 'N'\), no equilibration was done (always true if \(fact = 'N'\));

if \(equed = 'Y'\), equilibration was done, that is, \(A\) has been replaced by \(\text{diag}(s)\*A\*\text{diag}(s)\).

\(s\)

Array, size \((n)\). The array \(s\) contains the scale factors for \(A\). This array is an input argument if \(fact = 'F'\) only; otherwise it is an output argument.

If \(equed = 'N'\), \(s\) is not accessed.

If \(fact = 'F'\) and \(equed = 'Y'\), each element of \(s\) must be positive.

\(ldx\)

The leading dimension of the output array \(x\); \(ldx \geq \max(1, n)\) for column major layout and \(ldx \geq \nrhs\) for row major layout.

Output Parameters

\(x\)

Array, size max(1, \(ldx\*
rhs\)) for column major layout and max(1, \(ldx\*
\)) for row major layout.

If \(info = 0\) or \(info = n+1\), the array \(x\) contains the solution matrix \(X\) to the original system of equations. Note that if \(equed = 'Y'\), \(A\) and \(B\) are modified on exit, and the solution to the equilibrated system is \(\text{inv(diag}(s))\*X\).

\(ap\)

Array \(ap\) is not modified on exit if \(fact = 'F'\) or \('N'\), or if \(fact = 'E'\) and \(equed = 'N'\).

If \(fact = 'E'\) and \(equed = 'Y'\), \(ap\) is overwritten by \(\text{diag}(s)\*A\*\text{diag}(s)\).
If fact = 'N' or 'E', then afp is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U^T U$ or $A = L L^T$ (real routines), $A = U^H U$ or $A = L L^H$ (complex routines) of the original matrix $A$ (if fact = 'N'), or of the equilibrated matrix $A$ (if fact = 'E'). See the description of ap for the form of the equilibrated matrix.

b

Overwritten by $\text{diag}(s) B$, if equed = 'Y'; not changed if equed = 'N'.

s

This array is an output argument if fact≠'F'. See the description of s in Input Arguments section.

rcond

An estimate of the reciprocal condition number of the matrix $A$ after equilibration (if done). If rcond is less than the machine precision (in particular, if $\text{rcond} = 0$), the matrix is singular to working precision. This condition is indicated by a return code of info > 0.

ferr

Array, size at least $\max(1, \text{nrhs})$. Contains the estimated forward error bound for each solution vector $x_j$ (the j-th column of the solution matrix $X$). If $\text{xtrue}$ is the true solution corresponding to $x_j$, $\text{ferr}[j-1]$ is an estimated upper bound for the magnitude of the largest element in $(x_j - \text{xtrue})$ divided by the magnitude of the largest element in $x_j$. The estimate is as reliable as the estimate for $\text{rcond}$, and is almost always a slight overestimate of the true error.

berr

Array, size at least $\max(1, \text{nrhs})$. Contains the component-wise relative backward error for each solution vector $x_j$, that is, the smallest relative change in any element of $A$ or $B$ that makes $x_j$ an exact solution.

equed

If fact≠'F', then equed is an output argument. It specifies the form of equilibration that was done (see the description of equed in Input Arguments section).

Return Values

This function returns a value info.

If info=0, the execution is successful.

If info = -i, parameter i had an illegal value.

If info = i, and $i \leq n$, the leading minor of order i (and therefore the matrix $A$ itself) is not positive-definite, so the factorization could not be completed, and the solution and error bounds could not be computed; $\text{rcond} = 0$ is returned.

If info = i, and $i = n + 1$, then $U$ is nonsingular, but $\text{rcond}$ is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of $\text{rcond}$ would suggest.

Description

The routine solves for \( X \) the real or complex system of linear equations \( A \cdot X = B \), where \( A \) is an \( n \)-by-\( n \) symmetric/Hermitian positive definite band matrix, the columns of matrix \( B \) are individual right-hand sides, and the columns of \( X \) are the corresponding solutions.

The Cholesky decomposition is used to factor \( A \) as

\[
A = U^T \cdot U \quad (\text{real flavors}) \quad \text{and} \quad A = U^H \cdot U \quad (\text{complex flavors}), \quad \text{if} \quad uplo = 'U'
\]

or

\[
A = L \cdot L^T \quad (\text{real flavors}) \quad \text{and} \quad A = L \cdot L^H \quad (\text{complex flavors}), \quad \text{if} \quad uplo = 'L',
\]

where \( U \) is an upper triangular band matrix and \( L \) is a lower triangular band matrix, with the same number of superdiagonals or subdiagonals as \( A \). The factored form of \( A \) is then used to solve the system of equations \( A \cdot X = B \).

Input Parameters

- \texttt{matrix_layout}:
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- \texttt{uplo}:
  Must be 'U' or 'L'.
  Indicates whether the upper or lower triangular part of \( A \) is stored:
  If \texttt{uplo} = 'U', the upper triangle of \( A \) is stored.
  If \texttt{uplo} = 'L', the lower triangle of \( A \) is stored.
- \texttt{n}:
  The order of matrix \( A \); \( n \geq 0 \).
- \texttt{kd}:
  The number of superdiagonals of the matrix \( A \) if \texttt{uplo} = 'U', or the number of subdiagonals if \texttt{uplo} = 'L'; \( kd \geq 0 \).
nrhs

The number of right-hand sides, the number of columns in $B$; $nrhs \geq 0$.

$ab$, $b$

Arrays: $ab$(size max(1, $ldab \times n$)), $b$ of size max(1, $ldb \times nrhs$) for column major layout and max(1, $ldb \times n$) for row major layout. The array $ab$ contains the upper or the lower triangular part of the matrix $A$ (as specified by $uplo$) in band storage (see Matrix Storage Schemes).

The array $b$ contains the matrix $B$ whose columns are the right-hand sides for the systems of equations.

$ldab$

The leading dimension of the array $ab$; $ldab \geq kd + 1$.

$ldb$

The leading dimension of $b$; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout.

Output Parameters

$ab$

The upper or lower triangular part of $A$ (in band storage) is overwritten by the Cholesky factor $U$ or $L$, as specified by $uplo$, in the same storage format as $A$.

$b$

Overwritten by the solution matrix $X$.

Return Values

This function returns a value $info$.

If $info = 0$, the execution is successful.

If $info = -i$, parameter $i$ had an illegal value.

If $info = i$, the leading minor of order $i$ (and therefore the matrix $A$ itself) is not positive-definite, so the factorization could not be completed, and the solution has not been computed.

• mkl.h

Description
The routine uses the Cholesky factorization $A=U^T U$ (real flavors) / $A=U^H U$ (complex flavors) or $A=L*L^T$ (real flavors) / $A=L*L^H$ (complex flavors) to compute the solution to a real or complex system of linear equations $A*X = B$, where $A$ is a $n$-by-$n$ symmetric or Hermitian positive definite band matrix, the columns of matrix $B$ are individual right-hand sides, and the columns of $X$ are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine ?pbsvx performs the following steps:

1. If $\text{fact} = 'E'$, real scaling factors $s$ are computed to equilibrate the system:
   
   $\text{diag}(s) A \text{diag}(s) \text{inv(\text{diag}(s))} X = \text{diag}(s) B$

   Whether or not the system will be equilibrated depends on the scaling of the matrix $A$, but if equilibration is used, $A$ is overwritten by $\text{diag}(s) A \text{diag}(s)$ and $B$ by $\text{diag}(s) B$.

2. If $\text{fact} = 'N'$ or $'E'$, the Cholesky decomposition is used to factor the matrix $A$ (after equilibration if $\text{fact} = 'E'$) as

   $A = U^T U$ (real), $A = U^H U$ (complex), if $\text{uplo} = 'U'$,

   or $A = L*L^T$ (real), $A = L*L^H$ (complex), if $\text{uplo} = 'L'$,

   where $U$ is an upper triangular band matrix and $L$ is a lower triangular band matrix.

3. If the leading $i$-by-$i$ principal minor is not positive definite, then the routine returns with $\text{info} = i$.

   Otherwise, the factored form of $A$ is used to estimate the condition number of the matrix $A$. If the reciprocal of the condition number is less than machine precision, $\text{info} = n+1$ is returned as a warning, but the routine still goes on to solve for $X$ and compute error bounds as described below.

4. The system of equations is solved for $X$ using the factored form of $A$.

5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

6. If equilibration was used, the matrix $X$ is premultiplied by $\text{diag}(s)$ so that it solves the original system before equilibration.

Input Parameters

$\text{matrix_layout}$

  Specifies whether matrix storage layout is row major ($\text{LAPACK\_ROW\_MAJOR}$) or column major ($\text{LAPACK\_COL\_MAJOR}$).

$\text{fact}$

  Must be $'F'$, $'N'$, or $'E'$.
Specifies whether or not the factored form of the matrix $A$ is supplied on entry, and if not, whether the matrix $A$ should be equilibrated before it is factored.

If $\text{fact} = 'F'$: on entry, $\text{afb}$ contains the factored form of $A$. If $\text{equed} = 'Y'$, the matrix $A$ has been equilibrated with scaling factors given by $s$.

$\text{ab}$ and $\text{afb}$ will not be modified.

If $\text{fact} = 'N'$, the matrix $A$ will be copied to $\text{afb}$ and factored.

If $\text{fact} = 'E'$, the matrix $A$ will be equilibrated if necessary, then copied to $\text{afb}$ and factored.

$\text{uplo}$
Indicates whether the upper or lower triangular part of $A$ is stored:
- If $\text{uplo} = 'U'$, the upper triangle of $A$ is stored.
- If $\text{uplo} = 'L'$, the lower triangle of $A$ is stored.

$n$
The order of matrix $A$; $n \geq 0$.

$kd$
The number of superdiagonals or subdiagonals in the matrix $A$; $kd \geq 0$.

$\text{nrhs}$
The number of right-hand sides, the number of columns in $B$; $\text{nrhs} \geq 0$.

$\text{ab}$, $\text{afb}$, $\text{b}$
Arrays: $\text{ab}\text{(size max(1, ldab*n))}$, $\text{afb}\text{(size max(1, ldafb*n))}$, $\text{b}\text{of size max(1, ldb*nrhs)}$ for column major layout and max(1, ldb*n) for row major layout.

The array $\text{ab}$ contains the upper or lower triangle of the matrix $A$ in band storage (see Matrix Storage Schemes).

If $\text{fact} = 'F'$ and $\text{equed} = 'Y'$, then $\text{ab}$ must contain the equilibrated matrix $\text{diag}(s)*A*\text{diag}(s)$.

The array $\text{afb}$ is an input argument if $\text{fact} = 'F'$. It contains the triangular factor $U$ or $L$ from the Cholesky factorization of the band matrix $A$ in the same storage format as $A$. If $\text{equed} = 'Y'$, then $\text{afb}$ is the factored form of the equilibrated matrix $A$.

The array $\text{b}$ contains the matrix $B$ whose columns are the right-hand sides for the systems of equations.

$\text{ldab}$
The leading dimension of $\text{ab}$; $\text{ldab} \geq kd+1$.

$\text{ldafb}$
The leading dimension of $\text{afb}$; $\text{ldafb} \geq kd+1$.

$\text{ldb}$
The leading dimension of $\text{b}$; $\text{ldb} \geq \text{max(1, n)}$ for column major layout and $\text{ldb} \geq \text{nrhs}$ for row major layout.

$\text{equed}$
Must be 'N' or 'Y'.

$\text{equed}$ is an input argument if $\text{fact} = 'F'$. It specifies the form of equilibration that was done:
- If $\text{equed} = 'N'$, no equilibration was done (always true if $\text{fact} = 'N'$)
if equed = 'Y', equilibration was done, that is, A has been replaced by \( \text{diag}(s) \times A \times \text{diag}(s) \).

Array, size \((n)\). The array \(s\) contains the scale factors for \(A\). This array is an input argument if fact = 'F' only; otherwise it is an output argument.

If equed = 'N', \(s\) is not accessed.

If fact = 'F' and equed = 'Y', each element of \(s\) must be positive.

The leading dimension of the output array \(x\); \(ldx \geq \max(1, n)\) for column major layout and \(ldx \geq nrhs\) for row major layout.

**Output Parameters**

Array, size \(\max(1, ldx*nrhs)\) for column major layout and \(\max(1, ldx*n)\) for row major layout.

If info = 0 or info = \(n+1\), the array \(x\) contains the solution matrix \(X\) to the original system of equations. Note that if equed = 'Y', \(A\) and \(B\) are modified on exit, and the solution to the equilibrated system is \(\text{inv(\text{diag}(s)}) \times X\).

On exit, if fact = 'E' and equed = 'Y', \(A\) is overwritten by \(\text{diag}(s) \times A \times \text{diag}(s)\).

If fact = 'N' or 'E', then \(afb\) is an output argument and on exit returns the triangular factor \(U\) or \(L\) from the Cholesky factorization \(A=U^T \times U\) or \(A=L \times L^T\) (real routines), \(A=U^H \times U\) or \(A=L \times L^H\) (complex routines) of the original matrix \(A\) (if fact = 'N'), or of the equilibrated matrix \(A\) (if fact = 'E'). See the description of \(ab\) for the form of the equilibrated matrix.

Overwritten by \(\text{diag}(s) \times B\), if equed = 'Y'; not changed if equed = 'N'.

This array is an output argument if fact\#'F'. See the description of \(s\) in **Input Arguments** section.

An estimate of the reciprocal condition number of the matrix \(A\) after equilibration (if done). If rcond is less than the machine precision (in particular, if \(rcond = 0\)), the matrix is singular to working precision. This condition is indicated by a return code of info > 0.

Array, size at least \(\max(1, nrhs)\). Contains the estimated forward error bound for each solution vector \(x_j\) (the \(j\)-th column of the solution matrix \(X\)). If \(xtrue\) is the true solution corresponding to \(x_j\), \(ferr[j-1]\) is an estimated upper bound for the magnitude of the largest element in \((x_j - xtrue)\) divided by the magnitude of the largest element in \(x_j\). The estimate is as reliable as the estimate for rcond, and is almost always a slight overestimate of the true error.
berr

Array, size at least \( \max(1, nrhs) \). Contains the component-wise relative backward error for each solution vector \( x_j \), that is, the smallest relative change in any element of \( A \) or \( B \) that makes \( x_j \) an exact solution.

equed

If \texttt{fact}'F', then \texttt{equed} is an output argument. It specifies the form of equilibration that was done (see the description of \texttt{equed} in \textit{Input Arguments} section).

**Return Values**

This function returns a value \texttt{info}.

If \texttt{info} = 0, the execution is successful.

If \texttt{info} = -\texttt{i}, parameter \texttt{i} had an illegal value.

If \texttt{info} = \texttt{i}, and \( i \leq n \), the leading minor of order \( i \) (and therefore the matrix \( A \) itself) is not positive definite, so the factorization could not be completed, and the solution and error bounds could not be computed; \( rcond = 0 \) is returned. If \texttt{info} = \texttt{i}, and \( i = n + 1 \), then \( U \) is nonsingular, but \( rcond \) is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of \( rcond \) would suggest.

**Description**

The routine solves for \( X \) the real or complex system of linear equations \( A^*X = B \), where \( A \) is an \( n \)-by-\( n \) symmetric/Hermitian positive-definite tridiagonal matrix, the columns of matrix \( B \) are individual right-hand sides, and the columns of \( X \) are the corresponding solutions.

\( A \) is factored as \( A = L*D*L^T \) (real flavors) or \( A = L*D*L^H \) (complex flavors), and the factored form of \( A \) is then used to solve the system of equations \( A^*X = B \).
Input Parameters

matrix_layout

Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

\( n \)

The order of matrix \( A \); \( n \geq 0 \).

\( nrhs \)

The number of right-hand sides, the number of columns in \( B \); \( nrhs \geq 0 \).

d

Array, dimension at least \( \max(1, n) \). Contains the diagonal elements of the tridiagonal matrix \( A \).

e, b

Arrays: \( e \) (size \( n - 1 \)), \( b \) of size \( \max(1, ldb \times nrhs) \) for column major layout and \( \max(1, ldb \times n) \) for row major layout. The array \( e \) contains the \( (n - 1) \) subdiagonal elements of \( A \).

The array \( b \) contains the matrix \( B \) whose columns are the right-hand sides for the systems of equations.

\( ldb \)

The leading dimension of \( b \); \( ldb \geq \max(1, n) \) for column major layout and \( ldb \geq nrhs \) for row major layout.

Output Parameters

\( d \)

Overwritten by the \( n \) diagonal elements of the diagonal matrix \( D \) from the \( L^TDL^T \) (real)/ \( L^HDL^H \) (complex) factorization of \( A \).

\( e \)

Overwritten by the \( (n - 1) \) subdiagonal elements of the unit bidiagonal factor \( L \) from the factorization of \( A \).

\( b \)

Overwritten by the solution matrix \( X \).

Return Values

This function returns a value \( info \).

If \( info = 0 \), the execution is successful.

If \( info = -i \), parameter \( i \) had an illegal value.

If \( info = i \), the leading minor of order \( i \) (and therefore the matrix \( A \) itself) is not positive-definite, and the solution has not been computed. The factorization has not been completed unless \( i = n \).

Description

The routine uses the Cholesky factorization $A = L^TDL^T$ (real)/$A = L^HDL^H$ (complex) to compute the solution to a real or complex system of linear equations $AX = B$, where $A$ is a $n$-by-$n$ symmetric or Hermitian positive definite tridiagonal matrix, the columns of matrix $B$ are individual right-hand sides, and the columns of $X$ are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine ?ptsvx performs the following steps:

1. If $fact = 'N'$, the matrix $A$ is factored as $A = L^TDL^T$ (real flavors)/$A = L^HDL^H$ (complex flavors), where $L$ is a unit lower bidiagonal matrix and $D$ is diagonal. The factorization can also be regarded as having the form $A = U^TDL^T$ (real flavors)/$A = U^HL^H$ (complex flavors).
2. If the leading $i$-by-$i$ principal minor is not positive-definite, then the routine returns with $info = i$. Otherwise, the factored form of $A$ is used to estimate the condition number of the matrix $A$. If the reciprocal of the condition number is less than machine precision, $info = n+1$ is returned as a warning, but the routine still goes on to solve for $X$ and compute error bounds as described below.
3. The system of equations is solved for $X$ using the factored form of $A$.
4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

Input Parameters

$matrix_layout$  
Specifies whether matrix storage layout is row major ($LAPACK_ROW_MAJOR$) or column major ($LAPACK_COL_MAJOR$).

$fact$  
Must be 'F' or 'N'.

Specifies whether or not the factored form of the matrix $A$ is supplied on entry.

If $fact = 'F'$: on entry, $df$ and $ef$ contain the factored form of $A$. Arrays $d$, $e$, $df$, and $ef$ will not be modified.

If $fact = 'N'$, the matrix $A$ will be copied to $df$ and $ef$, and factored.

$n$  
The order of matrix $A$; $n \geq 0$.

$nrhs$  
The number of right-hand sides, the number of columns in $B$; $nrhs \geq 0$. 
Arrays: $d$ (size n), $df$ (size n).
The array $d$ contains the $n$ diagonal elements of the tridiagonal matrix $A$.
The array $df$ is an input argument if $fact = 'F'$ and on entry contains the $n$ diagonal elements of the diagonal matrix $D$ from the $L^TDL^T$ (real)/$L^HDL^H$ (complex) factorization of $A$.

Arrays: $e$ (size n-1), $ef$ (size n-1), $b$, size max($ldb*nrhs$) for column major layout and max($ldb*n$) for row major layout. The array $e$ contains the $(n-1)$ subdiagonal elements of the tridiagonal matrix $A$.
The array $ef$ is an input argument if $fact = 'F'$ and on entry contains the $(n-1)$ subdiagonal elements of the unit bidiagonal factor $L$ from the $L^TDL^T$ (real)/$L^HDL^H$ (complex) factorization of $A$.
The array $b$ contains the matrix $B$ whose columns are the right-hand sides for the systems of equations.

$ldb$
The leading dimension of $b$; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq \max(1, nrhs)$ for row major layout.

$ldx$
The leading dimension of $x$; $ldx \geq \max(1, n)$ for column major layout and $ldx \geq \max(1, nrhs)$ for row major layout.

Output Parameters

$x$
Array, size $\max(1, ldx*nrhs)$ for column major layout and $\max(1, ldx*n)$ for row major layout.
If $info = 0$ or $info = n+1$, the array $x$ contains the solution matrix $X$ to the system of equations.

$df$, $ef$
These arrays are output arguments if $fact = 'N'$. See the description of $df$, $ef$ in Input Arguments section.

$rcond$
An estimate of the reciprocal condition number of the matrix $A$ after equilibration (if done). If $rcond$ is less than the machine precision (in particular, if $rcond = 0$), the matrix is singular to working precision. This condition is indicated by a return code of $info > 0$.

$ferr$
Array, size at least $\max(1, nrhs)$. Contains the estimated forward error bound for each solution vector $x_j$ (the $j$-th column of the solution matrix $X$). If $xtrue$ is the true solution corresponding to $x_j$, $ferr_j$ is an estimated upper bound for the magnitude of the largest element in $(x_j - xtrue)$ divided by the magnitude of the largest element in $x_j$. The estimate is as reliable as the estimate for $rcond$, and is almost always a slight overestimate of the true error.

$berr$
Array, size at least $\max(1, nrhs)$. Contains the component-wise relative backward error for each solution vector $x_j$, that is, the smallest relative change in any element of $A$ or $B$ that makes $x_j$ an exact solution.
Return Values

This function returns a value info.

If info = 0, the execution is successful.

If info = -i, parameter i had an illegal value.

If info = i, and i≤n, the leading minor of order i (and therefore the matrix A itself) is not positive-definite, so the factorization could not be completed, and the solution and error bounds could not be computed; rcond =0 is returned.

If info = i, and i = n + 1, then U is nonsingular, but rcond is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of rcond would suggest.

Include Files

• mkl.h

Description

The routine solves for X the real or complex system of linear equations A*X = B, where A is an n-by-n symmetric matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

The diagonal pivoting method is used to factor A as A = U*D*U^T or A = L*D*L^T, where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

The factored form of A is then used to solve the system of equations A*X = B.
**Input Parameters**

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **uplo**
  Must be 'U' or 'L'.
  Indicates whether the upper or lower triangular part of A is stored:
  - If uplo = 'U', the upper triangle of A is stored.
  - If uplo = 'L', the lower triangle of A is stored.

- **n**
  The order of matrix A; n ≥ 0.

- **nrhs**
  The number of right-hand sides; the number of columns in B; nrhs ≥ 0.

- **a, b**
  Arrays: a(size max(1, lda*n)), b of size max(1, ldb*nrhs) for column major layout and max(1, ldb*n) for row major layout.
  The array a contains the upper or the lower triangular part of the symmetric matrix A (see uplo).
  The array b contains the matrix B whose columns are the right-hand sides for the systems of equations.

- **lda**
  The leading dimension of a; lda ≥ max(1, n).

- **ldb**
  The leading dimension of b; ldb ≥ max(1, n) for column major layout and ldb≥nrhs for row major layout.

**Output Parameters**

- **a**
  If info = 0, a is overwritten by the block-diagonal matrix D and the multipliers used to obtain the factor U (or L) from the factorization of A as computed by ?sytrf.

- **b**
  If info = 0, b is overwritten by the solution matrix X.

- **ipiv**
  Array, size at least max(1, n). Contains details of the interchanges and the block structure of D, as determined by ?sytrf.
  If ipiv[i-1] = k >0, then d_{ii} is a 1-by-1 diagonal block, and the i-th row and column of A was interchanged with the k-th row and column.
  If uplo = 'U' and ipiv[i] = ipiv[i-1] = -m < 0, then D has a 2-by-2 block in rows/columns i and i+1, and (i)-th row and column of A was interchanged with the m-th row and column.
  If uplo = 'L' and ipiv[i] = ipiv[i-1] = -m < 0, then D has a 2-by-2 block in rows/columns i and i+1, and (i+1)-th row and column of A was interchanged with the m-th row and column.

**Return Values**

This function returns a value info.

If info = 0, the execution is successful.
If info = -i, parameter i had an illegal value.

If info = i, d_{ii} is 0. The factorization has been completed, but D is exactly singular, so the solution could not be computed.

lapack_int LAPACK_dsysv_aa (int matrix_layout, char uplo, lapack_int n, lapack_int nrhs, double * A, lapack_int lda, lapack_int * ipiv, double * B, lapack_int ldb);

lapack_int LAPACK_csysv_aa (int matrix_layout, char uplo, lapack_int n, lapack_int nrhs, lapack_complex_float * A, lapack_int lda, lapack_int * ipiv, lapack_complex_float * B, lapack_int ldb);

lapack_int LAPACK_zsysv_aa (int matrix_layout, char uplo, lapack_int n, lapack_int nrhs, lapack_complex_double * A, lapack_int lda, lapack_int * ipiv, lapack_complex_double * B, lapack_int ldb);
```

Description
The ?sysv routine computes the solution to a complex system of linear equations A * X = B, where A is an n-by-n symmetric matrix and X and B are n-by-nrhs matrices.

Aasen's algorithm is used to factor A as A = U * T * U^T, if uplo = 'U', or A = L * T * L^T, if uplo = 'L', where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and T is symmetric tridiagonal. The factored form of A is then used to solve the system of equations A * X = B.

Input Parameters

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **uplo**
  - = 'U': The upper triangle of A is stored.
  - = 'L': The lower triangle of A is stored.

- **n**
  The number of linear equations; that is, the order of the matrix A. n ≥ 0.

- **nrhs**
  The number of right-hand sides; that is, the number of columns of the matrix B. nrhs ≥ 0.

- **A**
  Array of size max(1, lda*n). On entry, the symmetric matrix A. If uplo = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If uplo = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

- **lda**
  The leading dimension of the array A.
Array of size max(1, ldb*nrhs) for column-major layout and max(1, ldb*n) for row-major layout. On entry, the n-by-nrhs right-hand side matrix B.

The leading dimension of the array B. ldb ≥ max(1, n) for column-major layout and ldb ≥ nrhs for row-major layout.

On exit, if info = 0, the tridiagonal matrix T and the multipliers used to obtain the factor U or L from the factorization A = U*T*Uᵀ or A = L*T*Lᵀ as computed by ?sytrf.

Array of size n. On exit, it contains the details of the interchanges; that is, the row and column k of A were interchanged with the row and column ipiv(k).

On exit, if info = 0, the n-by-nrhs solution matrix X.

This function returns a value info.
= 0: Successful exit.
< 0: If info = -i, the i-th argument had an illegal value.
> 0: If info = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

Computes the solution to the system of linear equations with a real or complex symmetric coefficient matrix A and multiple right-hand sides.

Description
The routine solves for \( X \) the real or complex system of linear equations \( A*X = B \), where \( A \) is an \( n \)-by-\( n \) symmetric matrix, the columns of matrix \( B \) are individual right-hand sides, and the columns of \( X \) are the corresponding solutions.

The diagonal pivoting method is used to factor \( A \) as \( A = U*D*U^T \) or \( A = L*D*L^T \), where \( U \) (or \( L \)) is a product of permutation and unit upper (lower) triangular matrices, and \( D \) is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

The \(?sysv_rook\) routine is called to compute the factorization of a complex symmetric matrix \( A \) using the bounded Bunch-Kaufman ("rook") diagonal pivoting method.

The factored form of \( A \) is then used to solve the system of equations \( A*X = B \).

**Input Parameters**

- **matrix_layout**
  - Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **uplo**
  - Must be 'U' or 'L'.
  - Indicates whether the upper or lower triangular part of \( A \) is stored:
    - If \( uplo = 'U' \), the upper triangle of \( A \) is stored.
    - If \( uplo = 'L' \), the lower triangle of \( A \) is stored.

- **n**
  - The order of matrix \( A \); \( n \geq 0 \).

- **nrhs**
  - The number of right-hand sides; the number of columns in \( B \); \( nrhs \geq 0 \).

- **a, b**
  - Arrays: \( a(\text{size max}(1, lda*n)) \), \( b(\text{size max}(1, ldb*nrhs)) \) for column major layout and \( \text{max}(1, lda*n) \) for row major layout.
  - The array \( a \) contains the upper or the lower triangular part of the symmetric matrix \( A \) (see \( uplo \)). The second dimension of \( a \) must be at least \( \text{max}(1, n) \).
  - The array \( b \) contains the matrix \( B \) whose columns are the right-hand sides for the systems of equations. The second dimension of \( b \) must be at least \( \text{max}(1, nrhs) \).

- **lda**
  - The leading dimension of \( a \); \( lda \geq \text{max}(1, n) \).

- **ldb**
  - The leading dimension of \( b \); \( ldb \geq \text{max}(1, n) \) for column major layout and \( ldb \geq nrhs \) for row major layout.

**Output Parameters**

- **a**
  - If \( info = 0 \), \( a \) is overwritten by the block-diagonal matrix \( D \) and the multipliers used to obtain the factor \( U \) (or \( L \)) from the factorization of \( A \).

- **b**
  - If \( info = 0 \), \( b \) is overwritten by the solution matrix \( X \).

- **ipiv**
  - Array, size at least \( \text{max}(1, n) \). Contains details of the interchanges and the block structure of \( D \).
  - If \( ipiv[k-1] > 0 \), then rows and columns \( k \) and \( ipiv[k-1] \) were interchanged and \( D_{k,k} \) is a 1-by-1 diagonal block.
If uplo = 'U' and ipiv[k - 1] < 0 and ipiv[k - 2] < 0, then rows and columns k and \(-ipiv[k - 1]\) were interchanged, rows and columns \(k - 1\) and \(-ipiv[k - 2]\) were interchanged, and \(D_{k-1:k, k-1:k}\) is a 2-by-2 diagonal block.

If uplo = 'L' and ipiv[k - 1] < 0 and ipiv[k] < 0, then rows and columns k and \(-ipiv[k - 1]\) were interchanged, rows and columns \(k + 1\) and \(-ipiv[k]\) were interchanged, and \(D_{k:k+1, k:k+1}\) is a 2-by-2 diagonal block.

Return Values
This function returns a value info.
If info = 0, the execution is successful.
If info = -i, the i-th parameter had an illegal value.
If info = i, \(d_{ii}\) is 0. The factorization has been completed, but \(D\) is exactly singular, so the solution could not be computed.

\]

Description
?syrk computes the solution to a real or complex system of linear equations \(A * X = B\), where \(A\) is an \(n\times n\) symmetric matrix and \(X\) and \(B\) are \(n\times nrhs\) matrices.

The bounded Bunch-Kaufman (rook) diagonal pivoting method is used to factor \(A\) as \(A = P*U*\text{Diag}(U^T)*(P^T)\), if \(uplo = 'U'\), or \(A = P*L*\text{Diag}(L^T)*(P^T)\), if \(uplo = 'L'\), where \(U\) (or \(L\)) is unit upper (or lower) triangular matrix, \(U^T\) (or \(L^T\)) is the transpose of \(U\) (or \(L\)), \(P\) is a permutation matrix, \(P^T\) is the transpose of \(P\), and \(D\) is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

?sytrf_rk is called to compute the factorization of a real or complex symmetric matrix. The factored form of \(A\) is then used to solve the system of equations \(A * X = B\) by calling BLAS3 routine ?sytrs_3.
**Input Parameters**

- **matrix_layout**
  Specifies whether matrix storage layout is row major (`LAPACK_ROW_MAJOR`) or column major (`LAPACK_COL_MAJOR`).

- **uplo**
  Specifies whether the upper or lower triangular part of the symmetric matrix A is stored:
  - `'U'`: The upper triangle of A is stored.
  - `'L'`: The lower triangle of A is stored.

- **n**
  The number of linear equations; that is, the order of the matrix A. \( n \geq 0 \).

- **nrhs**
  The number of right-hand sides; that is, the number of columns of the matrix B. \( nrhs \geq 0 \).

- **A**
  Array of size \( \max(1, lda*n) \). On entry, the symmetric matrix A. If \( uplo = 'U' \), the leading \( n \)-by-\( n \) upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If \( uplo = 'L' \), the leading \( n \)-by-\( n \) lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

- **lda**
  The leading dimension of the array A.

- **B**
  Array of size \( \max(1, ldb*nrhs) \). On entry, the \( n \)-by-\( nrhs \) right-hand side matrix B.

- **ldb**
  The leading dimension of the array B. \( ldb \geq \max(1, n) \) for column-major layout and \( ldb \geq nrhs \) for row-major layout.

**Output Parameters**

- **A**
  On exit, if \( info = 0 \), the diagonal of the block diagonal matrix D and factors U or L as computed by ?sytrf_rk:
  - *Only* diagonal elements of the symmetric block diagonal matrix D on the diagonal of A; that is, \( D(k,k) = A(k,k) \). Superdiagonal (or subdiagonal) elements of D are stored on exit in array e.
  - If \( uplo = 'U' \), factor U in the superdiagonal part of A. If \( uplo = 'L' \), factor L in the subdiagonal part of A. For more information, see the description of the ?sytrf_rk routine.

- **e**
  Array of size \( n \). On exit, contains the output computed by the factorization routine ?sytrf_rk; that is, the superdiagonal (or subdiagonal) elements of the symmetric block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks. If \( uplo = 'U' \), \( e(i) = D(i-1,i), i=1:N-1 \), and \( e(1) \) is set to 0. If \( uplo = 'L' \), \( e(i) = D(i+1,i), i=1:N-1 \), and \( e(n) \) is set to 0.

**NOTE** For 1-by-1 diagonal block \( D(k) \), where \( 1 \leq k \leq n \), the element \( e(k) \) is set to 0 in both the \( uplo = 'U' \) and \( uplo = 'L' \) cases. For more information, see the description of the ?sytrf_rk routine.
ipiv

Array of size n. Details of the interchanges and the block structure of D, as determined by ?sytrf_rk. For more information, see the description of the ?sytrf_rk routine.

B

On exit, if info = 0, the n-by-nrhs solution matrix X.

Return Values

This function returns a value info.

= 0: Successful exit.
< 0: If info = -k, the kth argument had an illegal value.
> 0: If info = k, the matrix A is singular. If uplo = 'U', column k in the upper triangular part of A contains all zeros. If uplo = 'L', column k in the lower triangular part of A contains all zeros. Therefore D(k,k) is exactly zero, and superdiagonal elements of column k of U (or subdiagonal elements of column k of L) are all zeros. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

?sysvx

Uses the diagonal pivoting factorization to compute the solution to the system of linear equations with a real or complex symmetric coefficient matrix A, and provides error bounds on the solution.

Syntax

lapack_int LAPACKE_ssysvx( int matrix_layout, char fact, char uplo, lapack_int n, lapack_int nrhs, const float* a, lapack_int lda, float* af, lapack_int ldaf, lapack_int* ipiv, const float* b, lapack_int ldb, float* x, lapack_int ldx, float* rcond, float* ferr, float* berr );

• mkl.h

Description

The routine uses the diagonal pivoting factorization to compute the solution to a real or complex system of linear equations A*X = B, where A is a n-by-n symmetric matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.
The routine \texttt{sysvx} performs the following steps:

1. If \texttt{fact} = 'N', the diagonal pivoting method is used to factor the matrix \( A \). The form of the factorization is \( A = U*D*U^T \) or \( A = L*D*L^T \), where \( U \) (or \( L \)) is a product of permutation and unit upper (lower) triangular matrices, and \( D \) is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

2. If some \( d_{ii} = 0 \), so that \( D \) is exactly singular, then the routine returns with \( \text{info} = i \). Otherwise, the factored form of \( A \) is used to estimate the condition number of the matrix \( A \). If the reciprocal of the condition number is less than machine precision, \( \text{info} = n+1 \) is returned as a warning, but the routine still goes on to solve for \( X \) and compute error bounds as described below.

3. The system of equations is solved for \( X \) using the factored form of \( A \).

4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

**Input Parameters**

\texttt{matrix\_layout} 

Specifies whether matrix storage layout is row major (\texttt{LAPACK\_ROW\_MAJOR}) or column major (\texttt{LAPACK\_COL\_MAJOR}).

\texttt{fact}

Must be 'F' or 'N'.

\texttt{uplo}

Must be 'U' or 'L'.

\texttt{n}

The order of matrix \( A \); \( n \geq 0 \).

\texttt{nrhs}

The number of right-hand sides, the number of columns in \( B \); \( nrhs \geq 0 \).

\texttt{a, af, b}

Arrays: \( a(\text{size max}(1, lda*n)) \), \( af(\text{size max}(1, ldaf*n)) \), \( b(\text{size max}(1, ldb*nrhs)) \) for column major layout and \( \text{max}(1, ldb*n) \) for row major layout.

The array \( a \) contains the upper or the lower triangular part of the symmetric matrix \( A \) (see \texttt{uplo}).

The array \( af \) is an input argument if \texttt{fact} = 'F'. It contains the block diagonal matrix \( D \) and the multipliers used to obtain the factor \( U \) or \( L \) from the factorization \( A = U*D*U^T \) or \( A = L*D*L^T \) as computed by \texttt{?sytrf}.

The array \( b \) contains the matrix \( B \) whose columns are the right-hand sides for the systems of equations.

\texttt{lda}

The leading dimension of \( a \); \( lda \geq \text{max}(1, n) \).

\texttt{ldaf}

The leading dimension of \( af \); \( ldaf \geq \text{max}(1, n) \).
The leading dimension of \( b \); \( ldb \geq \max(1, n) \) for column major layout and \( ldb \geq nrhs \) for row major layout.

Array, size at least \( \max(1, n) \). The array \( ipiv \) is an input argument if \( fact = 'F' \). It contains details of the interchanges and the block structure of \( D \), as determined by \( ?sytrf \).

If \( ipiv[i-1] = k > 0 \), then \( d_{ii} \) is a 1-by-1 diagonal block, and the \( i \)-th row and column of \( A \) was interchanged with the \( k \)-th row and column.

If \( uplo = 'U' \) and \( ipiv[i] = ipiv[i-1] = -m < 0 \), then \( D \) has a 2-by-2 block in rows/columns \( i \) and \( i+1 \), and \( (i) \)-th row and column of \( A \) was interchanged with the \( m \)-th row and column.

If \( uplo = 'L' \) and \( ipiv[i] = ipiv[i-1] = -m < 0 \), then \( D \) has a 2-by-2 block in rows/columns \( i \) and \( i+1 \), and \( (i+1) \)-th row and column of \( A \) was interchanged with the \( m \)-th row and column.

The leading dimension of the output array \( x \); \( ldx \geq \max(1, n) \) for column major layout and \( ldx \geq nrhs \) for row major layout.

Output Parameters

\( x \)

Array, size \( \max(1, ldx*nrhs) \) for column major layout and \( \max(1, ldx*n) \) for row major layout.

If \( info = 0 \) or \( info = n+1 \), the array \( x \) contains the solution matrix \( X \) to the system of equations.

\( af, ipiv \)

These arrays are output arguments if \( fact = 'N' \).

See the description of \( af, ipiv \) in Input Arguments section.

\( rcond \)

An estimate of the reciprocal condition number of the matrix \( A \). If \( rcond \) is less than the machine precision (in particular, if \( rcond = 0 \)), the matrix is singular to working precision. This condition is indicated by a return code of \( info > 0 \).

\( ferr \)

Array, size at least \( \max(1, nrhs) \). Contains the estimated forward error bound for each solution vector \( x_j \) (the \( j \)-th column of the solution matrix \( X \)). If \( xtrue \) is the true solution corresponding to \( x_j \), \( ferr[j-1] \) is an estimated upper bound for the magnitude of the largest element in \( (x_j - xtrue) \) divided by the magnitude of the largest element in \( x_j \). The estimate is as reliable as the estimate for \( rcond \), and is almost always a slight overestimate of the true error.

\( berr \)

Array, size at least \( \max(1, nrhs) \). Contains the component-wise relative backward error for each solution vector \( x_j \), that is, the smallest relative change in any element of \( A \) or \( B \) that makes \( x_j \) an exact solution.

Return Values

This function returns a value \( info \).

If \( info = 0 \), the execution is successful.

If \( info = -i \), parameter \( i \) had an illegal value.
If \( info = i \), and \( i \leq n \), then \( d_{ii} \) is exactly zero. The factorization has been completed, but the block diagonal matrix \( D \) is exactly singular, so the solution and error bounds could not be computed; \( rcond = 0 \) is returned.

If \( info = i \), and \( i = n + 1 \), then \( D \) is nonsingular, but \( rcond \) is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of \( rcond \) would suggest.

**Include Files**

- mkl.h

**Description**

The routine uses the *diagonal pivoting* factorization to compute the solution to a real or complex system of linear equations \( A^tX = B \), where \( A \) is an \( n \)-by-\( n \) real symmetric/Hermitian matrix, the columns of matrix \( B \) are individual right-hand sides, and the columns of \( X \) are the corresponding solutions.

Both normwise and maximum componentwise error bounds are also provided on request. The routine returns a solution with a small guaranteed error \( O(\text{eps}) \), where \( \text{eps} \) is the working machine precision) unless the matrix is very ill-conditioned, in which case a warning is returned. Relevant condition numbers are also calculated and returned.
The routine accepts user-provided factorizations and equilibration factors; see definitions of the fact and equed options. Solving with refinement and using a factorization from a previous call of the routine also produces a solution with $O(\varepsilon)$ errors or warnings but that may not be true for general user-provided factorizations and equilibration factors if they differ from what the routine would itself produce.

The routine ?sysvxx performs the following steps:

1. If fact = 'E', scaling factors are computed to equilibrate the system:
   \[ \text{diag}(s) \cdot A \cdot \text{diag}(s) \cdot \text{inv}(\text{diag}(s)) \cdot X = \text{diag}(s) \cdot B \]
   Whether or not the system will be equilibrated depends on the scaling of the matrix $A$, but if equilibration is used, $A$ is overwritten by $\text{diag}(s) \cdot A \cdot \text{diag}(s)$ and $B$ by $\text{diag}(s) \cdot B$.

2. If fact = 'N' or 'E', the LU decomposition is used to factor the matrix $A$ (after equilibration if fact = 'E') as
   \[
   \begin{align*}
   A &= U \cdot D \cdot U^T, & \text{if } \text{uplo} = 'U', \\
   A &= L \cdot D \cdot L^T, & \text{if } \text{uplo} = 'L',
   \end{align*}
   \]
   where $U$ or $L$ is a product of permutation and unit upper (lower) triangular matrices, and $D$ is a symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

3. If some $D(i,i)=0$, so that $D$ is exactly singular, the routine returns with info = i. Otherwise, the factored form of $A$ is used to estimate the condition number of the matrix $A$ (see the rcond parameter). If the reciprocal of the condition number is less than machine precision, the routine still goes on to solve for $X$ and compute error bounds.

4. The system of equations is solved for $X$ using the factored form of $A$.

5. By default, unless params[0] is set to zero, the routine applies iterative refinement to get a small error and error bounds. Refinement calculates the residual to at least twice the working precision.

6. If equilibration was used, the matrix $X$ is premultiplied by $\text{diag}(r)$ so that it solves the original system before equilibration.

**Input Parameters**

- **matrix_layout**: Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **fact**: Must be 'F', 'N', or 'E'. Specifies whether or not the factored form of the matrix $A$ is supplied on entry, and if not, whether the matrix $A$ should be equilibrated before it is factored.

  - If fact = 'F', on entry, $af$ and $ipiv$ contain the factored form of $A$.
  - If equed is not 'N', the matrix $A$ has been equilibrated with scaling factors given by $s$. Parameters $a$, $af$, and $ipiv$ are not modified.
  - If fact = 'N', the matrix $A$ will be copied to $af$ and factored.
  - If fact = 'E', the matrix $A$ will be equilibrated, if necessary, copied to $af$ and factored.

- **uplo**: Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of $A$ is stored:

  - If uplo = 'U', the upper triangle of $A$ is stored.
  - If uplo = 'L', the lower triangle of $A$ is stored.

- **n**: The number of linear equations; the order of the matrix $A$; $n \geq 0$. 

---

Intel® Math Kernel Library Developer Reference

692
The number of right-hand sides; the number of columns of the matrices $B$ and $X$; $nrhs \geq 0$.

Arrays: $a(\text{size max}(1, \text{lda}*n))$, $af(\text{size max}(1, \text{ldaf}*n))$, $b$, $\text{size max}(\text{ldb}*nrhs)$ for column major layout and $\text{max}(\text{ldb}*n)$ for row major layout.

The array $a$ contains the symmetric matrix $A$ as specified by $\text{uplo}$. If $\text{uplo} = 'U'$, the leading $n$-by-$n$ upper triangular part of $a$ contains the upper triangular part of the matrix $A$ and the strictly lower triangular part of $a$ is not referenced. If $\text{uplo} = 'L'$, the leading $n$-by-$n$ lower triangular part of $a$ contains the lower triangular part of the matrix $A$ and the strictly upper triangular part of $a$ is not referenced.

The array $af$ is an input argument if $\text{fact} = 'F'$. It contains the block diagonal matrix $D$ and the multipliers used to obtain the factor $U$ and $L$ from the factorization $A = U*D*U^T$ or $A = L*D*L^T$ as computed by ?sytrf.

The array $b$ contains the matrix $B$ whose columns are the right-hand sides for the systems of equations.

The leading dimension of the array $a$; $\text{lda} \geq \text{max}(1, n)$.

The leading dimension of the array $af$; $\text{ldaf} \geq \text{max}(1, n)$.

Array, size at least $\text{max}(1, n)$. The array $ipiv$ is an input argument if $\text{fact} = 'F'$. It contains details of the interchanges and the block structure of $D$ as determined by ?sytrf. If $ipiv[k-1] > 0$, rows and columns $k$ and $ipiv[k-1]$ were interchanged and $D(k,k)$ is a 1-by-1 diagonal block.

If $\text{uplo} = 'U$' and $ipiv[i] = ipiv[i - 1] = m < 0$, $D$ has a 2-by-2 diagonal block in rows and columns $i$ and $i + 1$, and the $i$-th row and column of $A$ were interchanged with the $m$-th row and column.

If $\text{uplo} = 'L$' and $ipiv[i] = ipiv[i - 1] = m < 0$, $D$ has a 2-by-2 diagonal block in rows and columns $i$ and $i + 1$, and the $(i + 1)$-st row and column of $A$ were interchanged with the $m$-th row and column.

Must be 'N' or 'Y'.

equed is an input argument if $\text{fact} = 'F'$. It specifies the form of equilibration that was done:

If $\text{equed} = 'N'$, no equilibration was done (always true if $\text{fact} = 'N'$).

if $\text{equed} = 'Y'$, both row and column equilibration was done, that is, $A$ has been replaced by $\text{diag}(s)*A*\text{diag}(s)$.

Array, size $(n)$. The array $s$ contains the scale factors for $A$. If $\text{equed} = 'Y'$, $A$ is multiplied on the left and right by $\text{diag}(s)$.

This array is an input argument if $\text{fact} = 'F'$ only; otherwise it is an output argument.

If $\text{fact} = 'F'$ and $\text{equed} = 'Y'$, each element of $s$ must be positive.
Each element of $s$ should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

$ldb$

The leading dimension of the array $b$; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout.

$ldx$

The leading dimension of the output array $x$; $ldx \geq \max(1, n)$ for column major layout and $ldx \geq nrhs$ for row major layout.

$n_{err\_bnds}$

Number of error bounds to return for each right hand side and each type (normwise or componentwise). See $err\_bnds\_norm$ and $err\_bnds\_comp$ descriptions in the Output Arguments section below.

$nparams$

Specifies the number of parameters set in $params$. If $\leq 0$, the $params$ array is never referenced and default values are used.

$params$

Array, size $\max(1, nparams)$. Specifies algorithm parameters. If an entry is less than 0.0, that entry is filled with the default value used for that parameter. Only positions up to $nparams$ are accessed; defaults are used for higher-numbered parameters. If defaults are acceptable, you can pass $nparams = 0$, which prevents the source code from accessing the $params$ argument.

$params[0]$: Whether to perform iterative refinement or not. Default: 1.0 (for single precision flavors), 1.0D+0 (for double precision flavors).

$=0.0$ No refinement is performed and no error bounds are computed.

$=1.0$ Use the extra-precise refinement algorithm.

(Other values are reserved for future use.)

$params[1]$: Maximum number of residual computations allowed for refinement.

Default 10.0

Aggressive Set to 100.0 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in $err\_bnds\_norm$ and $err\_bnds\_comp$ may no longer be trustworthy.

$params[2]$: Flag determining if the code will attempt to find a solution with a small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence).
Output Parameters

$x$

Array, size $\text{max}(1, \ ldx*\text{nrhs})$ for column major layout and $\text{max}(1, \ ldx*n)$ for row major layout.

If $\text{info} = 0$, the array $x$ contains the solution $n$-by-$\text{nrhs}$ matrix $X$ to the original system of equations. Note that $A$ and $B$ are modified on exit if $\text{equed} \neq 'N'$, and the solution to the equilibrated system is:

$$\text{inv(diag}(s)\text{)*}X.$$

If $\text{fact} = 'E'$ and $\text{equed} = 'Y'$, overwritten by $\text{diag}(s)*A*\text{diag}(s)$.

$a$

If $\text{fact} = 'N'$, $af$ is an output argument and on exit returns the block diagonal matrix $D$ and the multipliers used to obtain the factor $U$ or $L$ from the factorization $A = U*D*U^T$ or $A = L*D*L^T$.

$b$

If $\text{equed} = 'N'$, $B$ is not modified.

If $\text{equed} = 'Y'$, $B$ is overwritten by $\text{diag}(s)*B$.

$s$

This array is an output argument if $\text{fact} \neq 'F'$'. Each element of this array is a power of the radix. See the description of $s$ in Input Arguments section.

$rcond$

Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix $A$ after equilibration (if done). If $rcond$ is less than the machine precision, in particular, if $rcond = 0$, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned.

$rpvgrw$

Contains the reciprocal pivot growth factor:

$$\|A\|/\|U\|$$

If this is much less than 1, the stability of the $LU$ factorization of the (equilibrated) matrix $A$ could be poor. This also means that the solution $X$, estimated condition numbers, and error bounds could be unreliable. If factorization fails with $0 < \text{info} \leq n$, this parameter contains the reciprocal pivot growth factor for the leading $\text{info}$ columns of $A$.

$berr$

Array, size at least $\text{max}(1, \ \text{nrhs})$. Contains the componentwise relative backward error for each solution vector $x_j$, that is, the smallest relative change in any element of $A$ or $B$ that makes $x_j$ an exact solution.

$\text{err_bnds_norm}$

Array of size $\text{nrhs}*\text{n_err_bnds}$. For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the $i$-th solution vector

$$\max_j \left|X_{true}^{ji} - X_{ji}\right| /
\max_j \left|X_{ji}\right|$$

The array is indexed by the type of error information as described below. Up to three pieces of information are returned.
**err=1**  
"Trust/don’t trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold \( \sqrt{n} \times \text{slamch}(\varepsilon) \) for single precision flavors and \( \sqrt{n} \times \text{dlamch}(\varepsilon) \) for double precision flavors.

**err=2**  
"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold \( \sqrt{n} \times \text{slamch}(\varepsilon) \) for single precision flavors and \( \sqrt{n} \times \text{dlamch}(\varepsilon) \) for double precision flavors. This error bound should only be trusted if the previous boolean is true.

**err=3**  
Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold \( \sqrt{n} \times \text{slamch}(\varepsilon) \) for single precision flavors and \( \sqrt{n} \times \text{dlamch}(\varepsilon) \) for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers for some appropriately scaled matrix \( Z \) are:

\[
\|Z\|_\infty \cdot \|Z^{-1}\|_\infty
\]

Let \( z = s \times a \), where \( s \) scales each row by a power of the radix so all absolute row sums of \( z \) are approximately 1.

The information for right-hand side \( i \), where \( 1 \leq i \leq \text{nrhs} \), and type of error \( err \) is stored in \( \text{err_bnds_norm}[(\text{err}-1) \times \text{nrhs} + i - 1] \).

Array of size \( \text{nrhs} \times \text{n_err_bnds} \). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the \( i \)-th solution vector:

\[
\max_j \frac{|X_{true_{ij}} - X_{ij}|}{|X_{ij}|}
\]

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (\( \text{params}[2] = 0.0 \)), then \( \text{err_bnds_comp} \) is not accessed.

**err=1**  
"Trust/don’t trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold \( \sqrt{n} \times \text{slamch}(\varepsilon) \) for single precision flavors and \( \sqrt{n} \times \text{dlamch}(\varepsilon) \) for double precision flavors.
err=2

"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} \times \text{slamch}(\varepsilon)$ for single precision flavors and $\sqrt{n} \times \text{dlamch}(\varepsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.

err=3

Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold $\sqrt{n} \times \text{slamch}(\varepsilon)$ for single precision flavors and $\sqrt{n} \times \text{dlamch}(\varepsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers for some appropriately scaled matrix $Z$ are:

$$\|Z\| \cdot \|Z^{-1}\|$$

Let $z = s \times (a \times \text{diag}(x))$, where $x$ is the solution for the current right-hand side and $s$ scales each row of $a \times \text{diag}(x)$ by a power of the radix so all absolute row sums of $z$ are approximately 1.

The information for right-hand side $i$, where $1 \leq i \leq \text{nrhs}$, and type of error err is stored in $\text{err_bnds_comp}[(\text{err}-1) \times \text{nrhs} + i - 1]$.

ipiv

If fact = 'N', ipiv is an output argument and on exit contains details of the interchanges and the block structure $D_i$ as determined by ssytrf for single precision flavors and dsytrf for double precision flavors.

equed

If fact≠'F', then equed is an output argument. It specifies the form of equilibration that was done (see the description of equed in Input Arguments section).

params

If an entry is less than 0.0, that entry is filled with the default value used for that parameter, otherwise the entry is not modified.

Return Values

This function returns a value info.

If info = 0, the execution is successful. The solution to every right-hand side is guaranteed.

If info = -i, parameter i had an illegal value.

If 0 < info<n: $U_{info,info}$ is exactly zero. The factorization has been completed, but the factor $U$ is exactly singular, so the solution and error bounds could not be computed; rcond = 0 is returned.

If info = n+j: The solution corresponding to the j-th right-hand side is not guaranteed. The solutions corresponding to other right-hand sides $k$ with $k > j$ may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested params[2] = 0.0, then the j-th right-hand side is the first with a normwise error bound that is not guaranteed (the smallest $j$ such that for column major layout $\text{err_bnds_norm}[j - 1] = 0.0$ or $\text{err_bnds_comp}[j - 1] = 0.0$; or for row major
The routine solves for \( X \) the complex system of linear equations \( A^*X = B \), where \( A \) is an \( n \)-by-\( n \) symmetric matrix, the columns of matrix \( B \) are individual right-hand sides, and the columns of \( X \) are the corresponding solutions.

The diagonal pivoting method is used to factor \( A \) as \( U*D*U^H \) or \( L*D*L^H \), where \( U \) (or \( L \)) is a product of permutation and unit upper (lower) triangular matrices, and \( D \) is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

The factored form of \( A \) is then used to solve the system of equations \( A^*X = B \).

### Input Parameters

- **\( \text{matrix_layout} \)**
  - Specifies whether matrix storage layout is row major (**LAPACK_ROW_MAJOR**) or column major (**LAPACK_COL_MAJOR**).
  - Must be 'U' or 'L'.

- **\( \text{uplo} \)**
  - Indicates whether the upper or lower triangular part of \( A \) is stored and how \( A \) is factored:
    - If \( \text{uplo} = 'U' \), the array \( a \) stores the upper triangular part of the matrix \( A \), and \( A \) is factored as \( U*D*U^H \).
    - If \( \text{uplo} = 'L' \), the array \( a \) stores the lower triangular part of the matrix \( A \), and \( A \) is factored as \( L*D*L^H \).

- **\( n \)**
  - The order of matrix \( A \); \( n \geq 0 \).

- **\( \text{nrhs} \)**
  - The number of right-hand sides, the number of columns in \( B \); \( \text{nrhs} \geq 0 \).
Arrays: $a$ (size max(1, $lda \cdot n$)), $b$ of size max(1, $ldb \cdot nrhs$) for column major layout and max(1, $ldb \cdot n$) for row major layout. The array $a$ contains the upper or the lower triangular part of the Hermitian matrix $A$ (see $uplo$).

The array $b$ contains the matrix $B$ whose columns are the right-hand sides for the systems of equations.

The leading dimension of $a$; $lda \geq \max(1, n)$.

The leading dimension of $b$; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout.

Output Parameters

$a$

If $info = 0$, $a$ is overwritten by the block-diagonal matrix $D$ and the multipliers used to obtain the factor $U$ (or $L$) from the factorization of $A$ as computed by $\text{?hetrf}$.

$b$

If $info = 0$, $b$ is overwritten by the solution matrix $X$.

$ipiv$

Array, size at least max(1, n). Contains details of the interchanges and the block structure of $D$, as determined by $\text{?hetrf}$.

If $ipiv[i-1] = k > 0$, then $d_{ii}$ is a 1-by-1 diagonal block, and the $i$-th row and column of $A$ was interchanged with the $k$-th row and column.

If $uplo = 'U$' and $ipiv[i] = ipiv[i-1] = -m < 0$, then $D$ has a 2-by-2 block in rows/columns $i$ and $i+1$, and $(i)$-th row and column of $A$ was interchanged with the $m$-th row and column.

If $uplo = 'L$' and $ipiv[i] = ipiv[i-1] = -m < 0$, then $D$ has a 2-by-2 block in rows/columns $i$ and $i+1$, and $(i+1)$-th row and column of $A$ was interchanged with the $m$-th row and column.

Return Values

This function returns a value $info$.

If $info = 0$, the execution is successful.

If $info = -i$, parameter $i$ had an illegal value.

If $info = i$, $d_{ii}$ is 0. The factorization has been completed, but $D$ is exactly singular, so the solution could not be computed.

See Also

Matrix Storage Schemes

$\text{hesv_aa}$

Computes the solution to system of linear equations for HE matrices.

LAPACK DECL lapack_int LAPACKE_chesv_aa (int matrix_layout, char uplo, lapack_int n, lapack_int nrhs, lapack_complex_float * a, lapack_int lda, lapack_int * ipiv, lapack_complex_float * b, lapack_int ldb );
LAPACK DECL lapack_int LAPACKE_chesv_aa_work (int matrix_layout, char uplo, lapack_int n, lapack_int nrhs, lapack_complex_float * a, lapack_int lda, lapack_int * ipiv, lapack_complex_float * b, lapack_int ldb, lapack_complex_float * work, lapack_int lwork);

Description

?hesv_aa computes the solution to a complex system of linear equations \( A \times X = B \), where \( A \) is an \( n \)-by-\( n \) Hermitian matrix and \( X \) and \( B \) are \( n \)-by-\( nrhs \) matrices. Aasen’s algorithm is used to factor \( A \) as

\[
A = U \times T \times U^H \text{ if } uplo = 'U', \text{ or } \\
A = L \times T \times L^H \text{ if } uplo = 'L',
\]

where \( U \) (or \( L \)) is a product of permutation and unit upper (lower) triangular matrices, and \( T \) is Hermitian and tridiagonal. The factored form of \( A \) is then used to solve the system of equations \( A \times X = B \).

If ( lwork &lt; n ), TRS is done with Level BLAS 2. If ( lwork \geq n ), TRS is done with Level BLAS 3. If ( lwork = -1 ), then a workspace query is assumed; the routine only calculates the optimal size of the ( work ) array, returns this value as the first entry of the ( work ) array, and no error message related to ( lwork ) is issued by \text{xerbla}.</td>
</tr>
</tbody>
</table>
Output Parameters

\( a \)
On exit, if \( info = 0 \), the tridiagonal matrix \( T \) and the multipliers used to obtain the factor \( U \) or \( L \) from the factorization \( A = U^*T^*U^H \) or \( A = L^*T^*L^H \) as computed by ?hetrf_aa.

\( ipiv \)
Array of size \( (n) \) On exit, it contains the details of the interchanges: row and column \( k \) of \( A \) were interchanged with the row and column \( ipiv[k] \).

\( b \)
On exit, if \( info = 0 \), the \( n \)-by-\( nrhs \) solution matrix \( X \).

\( work \)
Array of size \( (\max(1, lwork)) \). On exit, if \( info = 0 \), \( work[0] \) returns the optimal \( lwork \).

Return Values

This function returns a value \( info \).

If \( info = 0 \): successful exit.

If \( info < 0 \): if \( info = -i \), the \( i \)-th argument had an illegal value.

If \( info > 0 \): if \( info = i \), \( D_{i,i} \) is exactly zero. The factorization has been completed, but the block diagonal matrix \( D \) is exactly singular, so the solution could not be computed.

?hesv_rk
?hesv_rk computes the solution to a system of linear equations \( A \times X = B \) for Hermitian matrices.

```
lapack_int LAPACK_chesv_rk (int matrix_layout, char uplo, lapack_int n, lapack_int nrhs, lapack_complex_float * A, lapack_int lda, lapack_complex_float * e, lapack_int * ipiv, lapack_complex_float * B, lapack_int ldb);
```

Description

?hesv_rk computes the solution to a complex system of linear equations \( A \times X = B \), where \( A \) is an \( n \)-by-\( n \) Hermitian matrix and \( X \) and \( B \) are \( n \)-by-\( nrhs \) matrices.

The bounded Bunch-Kaufman (rook) diagonal pivoting method is used to factor \( A \) as \( A = P \times U^*D^*(U^H)(P^T) \), if \( uplo = 'U' \), or \( A = P \times L^*D^*(L^H)(P^T) \), if \( uplo = 'L' \), where \( U \) (or \( L \)) is unit upper (or lower) triangular matrix, \( U^H \) (or \( L^H \)) is the conjugate of \( U \) (or \( L \)), \( P \) is a permutation matrix, \( P^T \) is the transpose of \( P \), and \( D \) is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

?hetrf_rk is called to compute the factorization of a complex Hermitian matrix. The factored form of \( A \) is then used to solve the system of equations \( A \times X = B \) by calling BLAS3 routine ?hetrs_3.

Input Parameters

\( matrix_layout \)
Specifies whether matrix storage layout is row major (\( \text{LAPACK\_ROW\_MAJOR} \)) or column major (\( \text{LAPACK\_COL\_MAJOR} \)).

\( uplo \)
Specifies whether the upper or lower triangular part of the Hermitian matrix \( A \) is stored:
- \( '=' \) \( 'U' \): The upper triangle of \( A \) is stored.
- \( '=' \) \( 'L' \): The lower triangle of \( A \) is stored.
The number of linear equations; that is, the order of the matrix A. \( n \geq 0 \).

The number of right-hand sides; that is, the number of columns of the matrix B. \( nrhs \geq 0 \).

Array of size \( \max(1, lda* n) \). On entry, the Hermitian matrix A. If \( uplo = 'U' \): the leading \( n \)-by-\( n \) upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If \( uplo = 'L' \): the leading \( n \)-by-\( n \) lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

The leading dimension of the array A.

On entry, the \( n \)-by-\( nrhs \) right-hand side matrix B.

The size of B is \( \max(1, ldb*nrhs) \) for column-major layout and \( \max(1, ldb*n) \) for row-major layout.

The leading dimension of the array B. \( ldb \geq \max(1, n) \) for column-major layout and \( ldb \geq nrhs \) for row-major layout.

Output Parameters

A

On exit, if \( info = 0 \), diagonal of the block diagonal matrix D and factors U or L as computed by \( ?hetrf_rk \):

- Only diagonal elements of the Hermitian block diagonal matrix D on the diagonal of A; that is, \( D(k,k) = A(k,k) \); (superdiagonal (or subdiagonal) elements of D are stored on exit in array e).

  -and-

- If \( uplo = 'U' \), factor U in the superdiagonal part of A. If \( uplo = 'L' \), factor L in the subdiagonal part of A.

For more information, see the description of the \( ?hetrf_rk \) routine.

Array of size \( n \). On exit, contains the output computed by the factorization routine \( ?hetrf_rk \); that is, the superdiagonal (or subdiagonal) elements of the Hermitian block diagonal matrix D with 1-by-1 or 2-by-2 diagonal blocks:

- If \( uplo = 'U' \), \( e(i) = D(i-1,i), i=2:N, e(1) \) is set to 0.
- If \( uplo = 'L' \), \( e(i) = D(i+1,i), i=1:N-1, e(n) \) is set to 0.

**NOTE** For a 1-by-1 diagonal block \( D(k) \), where \( 1 \leq k \leq n \), the element \( e(k) \) is set to 0 in both the \( uplo = 'U' \) and \( uplo = 'L' \) cases.

For more information, see the description of the \( ?hetrf_rk \) routine.

ipiv

Array of size \( n \). Details of the interchanges and the block structure of D, as determined by \( ?hetrf_rk \).

B

On exit, if \( info = 0 \), the \( n \)-by-\( nrhs \) solution matrix X.
**Return Values**

This function returns a value \( info \).

- \( = 0 \): Successful exit.
- \(< 0\): If \( info = -k \), the \( k \)th argument had an illegal value.
- \( > 0\): If \( info = k \), the matrix \( A \) is singular. If \( uplo = 'U' \), column \( k \) in the upper triangular part of \( A \) contains all zeros. If \( uplo = 'L' \), column \( k \) in the lower triangular part of \( A \) contains all zeros. Therefore \( D(k,k) \) is exactly zero, and superdiagonal elements of column \( k \) of \( U \) (or subdiagonal elements of column \( k \) of \( L \)) are all zeros. The factorization has been completed, but the block diagonal matrix \( D \) is exactly singular, and division by zero will occur if it is used to solve a system of equations.

**hesvx**

*Uses the diagonal pivoting factorization to compute the solution to the complex system of linear equations with a Hermitian coefficient matrix \( A \), and provides error bounds on the solution.*

**Syntax**

```c
lapack_int LAPACKE_chesvx( int matrix_layout, char fact, char uplo, lapack_int n,
lapack_int nrhs, const lapack_complex_float* a, lapack_int lda, lapack_complex_float* af,
lapack_int ldaf, lapack_int* ipiv, const lapack_complex_float* b, lapack_int ldb,
lapack_complex_float* x, lapack_int ldx, float* rcond, float* ferr, float* berr );

lapack_int LAPACKE_zhesvx( int matrix_layout, char fact, char uplo, lapack_int n,
lapack_int nrhs, const lapack_complex_double* a, lapack_int lda, lapack_complex_double* af,
lapack_int ldaf, lapack_int* ipiv, const lapack_complex_double* b, lapack_int ldb,
lapack_complex_double* x, lapack_int ldx, double* rcond, double* ferr, double* berr );
```

**Include Files**

- mkl.h

**Description**

The routine uses the diagonal pivoting factorization to compute the solution to a complex system of linear equations \( A^*X = B \), where \( A \) is an \( n \)-by-\( n \) Hermitian matrix, the columns of matrix \( B \) are individual right-hand sides, and the columns of \( X \) are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine \( ?hesvx \) performs the following steps:

1. If \( fact = 'N' \), the diagonal pivoting method is used to factor the matrix \( A \). The form of the factorization is \( A = U^*D^*U \) or \( A = L^*D^*L \), where \( U \) (or \( L \)) is a product of permutation and unit upper (lower) triangular matrices, and \( D \) is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.
2. If some \( d_{i,i} = 0 \), so that \( D \) is exactly singular, then the routine returns with \( info = i \). Otherwise, the factored form of \( A \) is used to estimate the condition number of the matrix \( A \). If the reciprocal of the condition number is less than machine precision, \( info = n+1 \) is returned as a warning, but the routine still goes on to solve for \( X \) and compute error bounds as described below.
3. The system of equations is solved for \( X \) using the factored form of \( A \).
4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
Input Parameters

matrix_layout

Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

fact

Must be 'F' or 'N'.

Specifies whether or not the factored form of the matrix A has been supplied on entry.

If fact = 'F': on entry, af and ipiv contain the factored form of A. Arrays a, af, and ipiv are not modified.

If fact = 'N', the matrix A is copied to af and factored.

uplo

Must be 'U' or 'L'.

Indicates whether the upper or lower triangular part of A is stored and how A is factored:

If uplo = 'U', the array a stores the upper triangular part of the Hermitian matrix A, and A is factored as $U^*D*U^H$.

If uplo = 'L', the array a stores the lower triangular part of the Hermitian matrix A; A is factored as $L^*D*L^H$.

n

The order of matrix A; $n \geq 0$.

nrhs

The number of right-hand sides, the number of columns in B; $nrhs \geq 0$.

a, af, b

Arrays: $a$ (size max(1, lda*n)), $af$ (size max(1, ldaf*n)), $b$ of size max(1, ldb*nrhs) for column major layout and max(1, ldb*n) for row major layout.

The array a contains the upper or the lower triangular part of the Hermitian matrix A (see uplo).

The array af is an input argument if fact = 'F'. It contains he block diagonal matrix D and the multipliers used to obtain the factor $U$ or $L$ from the factorization $A = U^*D*U^H$ or $A = L^*D*L^H$ as computed by ?hetrf.

The array b contains the matrix B whose columns are the right-hand sides for the systems of equations.

lda

The leading dimension of $a$; $lda \geq \text{max}(1, n)$.

ldaf

The leading dimension of $af$; $ldaf \geq \text{max}(1, n)$.

ldb

The leading dimension of $b$; $ldb \geq \text{max}(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout.

ipiv

Array, size at least max(1, n). The array ipiv is an input argument if fact = 'F'. It contains details of the interchanges and the block structure of $D$, as determined by ?hetrf.

If $ipiv[i-1] = k > 0$, then $d_{ii}$ is a 1-by-1 diagonal block, and the i-th row and column of A was interchanged with the k-th row and column.
If uplo = 'U' and ipiv[i] = ipiv[i-1] = -m < 0, then D has a 2-by-2 block in rows/columns i and i+1, and (i)-th row and column of A was interchanged with the m-th row and column.

If uplo = 'L' and ipiv[i] = ipiv[i-1] = -m < 0, then D has a 2-by-2 block in rows/columns i and i+1, and (i+1)-th row and column of A was interchanged with the m-th row and column.

ldx
The leading dimension of the output array x; ldx≥ max(1, n) for column major layout and ldx≥nrhs for row major layout.

Output Parameters

x
Array, size max(1, ldx*nrhs) for column major layout and max(1, ldx*n) for row major layout.
If info = 0 or info = n+1, the array x contains the solution matrix X to the system of equations.

af, ipiv
These arrays are output arguments if fact = 'N'. See the description of af, ipiv in Input Arguments section.

rcond
An estimate of the reciprocal condition number of the matrix A. If rcond is less than the machine precision (in particular, if rcond = 0), the matrix is singular to working precision. This condition is indicated by a return code of info > 0.

ferr
Array, size at least max(1, nrhs). Contains the estimated forward error bound for each solution vector x_j (the j-th column of the solution matrix X). If xtrue is the true solution corresponding to x_j, ferr[j-1] is an estimated upper bound for the magnitude of the largest element in (x_j - xtrue) divided by the magnitude of the largest element in x_j. The estimate is as reliable as the estimate for rcon, and is almost always a slight overestimate of the true error.

berr
Array, size at least max(1, nrhs). Contains the component-wise relative backward error for each solution vector x_j, that is, the smallest relative change in any element of A or B that makes x_j an exact solution.

Return Values

This function returns a value info.
If info = 0, the execution is successful.
If info = -i, parameter i had an illegal value.
If info = i, and i≤n, then d_ii is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution and error bounds could not be computed; rcond = 0 is returned.
If info = i, and i = n + 1, then D is nonsingular, but rcond is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of rcond would suggest.

```

**Include Files**

- mkl.h

**Description**

The routine uses the diagonal pivoting factorization to compute the solution to a complex/double complex system of linear equations $A^*X = B$, where $A$ is an $n$-by-$n$ Hermitian matrix, the columns of matrix $B$ are individual right-hand sides, and the columns of $X$ are the corresponding solutions.

Both normwise and maximum componentwise error bounds are also provided on request. The routine returns a solution with a small guaranteed error ($O(\varepsilon)$, where $\varepsilon$ is the working machine precision) unless the matrix is very ill-conditioned, in which case a warning is returned. Relevant condition numbers are also calculated and returned.

The routine accepts user-provided factorizations and equilibration factors; see definitions of the fact and equed options. Solving with refinement and using a factorization from a previous call of the routine also produces a solution with $O(\varepsilon)$ errors or warnings but that may not be true for general user-provided factorizations and equilibration factors if they differ from what the routine would itself produce.

The routine **hesvxx** performs the following steps:

1. If **fact** = 'E', scaling factors are computed to equilibrate the system:
   
   $\text{diag}(s)^*A^{*}\text{diag}(s)^*\text{inv}(\text{diag}(s))^*X = \text{diag}(s)^*B$
   
   Whether or not the system will be equilibrated depends on the scaling of the matrix $A$, but if equilibration is used, $A$ is overwritten by $\text{diag}(s)^*A^{*}\text{diag}(s)$ and $B$ by $\text{diag}(s)^*B$.

2. If **fact** = 'N' or 'E', the LU decomposition is used to factor the matrix $A$ (after equilibration if **fact** = 'E') as
   
   $A = U^{*}D^{*}U^{T}$, if uplo = 'U',
   
   or $A = L^{*}D^{*}L^{T}$, if uplo = 'L',
   
   where $U$ or $L$ is a product of permutation and unit upper (lower) triangular matrices, and $D$ is a symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.
3. If some $D(i,i)=0$, so that $D$ is exactly singular, the routine returns with $info = i$. Otherwise, the factored form of $A$ is used to estimate the condition number of the matrix $A$ (see the $rcond$ parameter). If the reciprocal of the condition number is less than machine precision, the routine still goes on to solve for $X$ and compute error bounds.

4. The system of equations is solved for $X$ using the factored form of $A$.

5. By default, unless $params[0]$ is set to zero, the routine applies iterative refinement to get a small error and error bounds. Refinement calculates the residual to at least twice the working precision.

6. If equilibration was used, the matrix $X$ is premultiplied by $diag(r)$ so that it solves the original system before equilibration.

**Input Parameters**

- **matrix_layout**: Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **fact**: Must be 'F', 'N', or 'E'.

  Specifies whether or not the factored form of the matrix $A$ is supplied on entry, and if not, whether the matrix $A$ should be equilibrated before it is factored.

  If fact = 'F', on entry, $af$ and $ipiv$ contain the factored form of $A$. If $equed$ is not 'N', the matrix $A$ has been equilibrated with scaling factors given by $s$. Parameters $a$, $af$, and $ipiv$ are not modified.

  If fact = 'N', the matrix $A$ will be copied to $af$ and factored.

  If fact = 'E', the matrix $A$ will be equilibrated, if necessary, copied to $af$ and factored.

- **uplo**: Must be 'U' or 'L'.

  Indicates whether the upper or lower triangular part of $A$ is stored:

  If uplo = 'U', the upper triangle of $A$ is stored.

  If uplo = 'L', the lower triangle of $A$ is stored.

- **n**: The number of linear equations; the order of the matrix $A$; $n \geq 0$.

- **nrhs**: The number of right-hand sides; the number of columns of the matrices $B$ and $X$; $nrhs \geq 0$.

- **a, af, b**: Arrays: $a$ (size max($lda*n$)), $af$ (size max($ldaf*n$)), $b$ (size max($ldb*nrhs$) for column major layout and max($ldb*n$) for row major layout).

  The array $a$ contains the Hermitian matrix $A$ as specified by uplo. If uplo = 'U', the leading $n$-by-$n$ upper triangular part of $a$ contains the upper triangular part of the matrix $A$ and the strictly lower triangular part of $a$ is not referenced. If uplo = 'L', the leading $n$-by-$n$ lower triangular part of $a$ contains the lower triangular part of the matrix $A$ and the strictly upper triangular part of $a$ is not referenced.

  The array $af$ is an input argument if fact = 'F'. It contains the block diagonal matrix $D$ and the multipliers used to obtain the factor $U$ and $L$ from the factorization $A = U^T*D*U$ or $A = L*D*L^T$ as computed by ?hetrf.
The array \( b \) contains the matrix \( B \) whose columns are the right-hand sides for the systems of equations.

\[ \text{lda} \]

The leading dimension of the array \( a \); \( \text{lda} \geq \max(1, n) \).

\[ \text{ldaf} \]

The leading dimension of the array \( af \); \( \text{ldaf} \geq \max(1, n) \).

\[ \text{ipiv} \]

Array, size at least \( \max(1, n) \). The array \( \text{ipiv} \) is an input argument if \( \text{fact} = 'F' \). It contains details of the interchanges and the block structure of \( D \) as determined by \( \text{?sytrf} \).

If \( \text{ipiv}[k-1] > 0 \), rows and columns \( k \) and \( \text{ipiv}[k-1] \) were interchanged and \( D_{k,k} \) is a 1-by-1 diagonal block.

If \( \text{uplo} = 'U' \) and \( \text{ipiv}[i] = \text{ipiv}[i - 1] = m < 0 \), \( D \) has a 2-by-2 diagonal block in rows and columns \( i \) and \( i + 1 \), and the \( i \)-th row and column of \( A \) were interchanged with the \( m \)-th row and column.

If \( \text{uplo} = 'L' \) and \( \text{ipiv}[i] = \text{ipiv}[i - 1] = m < 0 \), \( D \) has a 2-by-2 diagonal block in rows and columns \( i \) and \( i + 1 \), and the \((i + 1)\)-st row and column of \( A \) were interchanged with the \( m \)-th row and column.

\[ \text{equed} \]

Must be \( 'N' \) or \( 'Y' \).

\( \text{equed} \) is an input argument if \( \text{fact} = 'F' \). It specifies the form of equilibration that was done:

If \( \text{equed} = 'N' \), no equilibration was done (always true if \( \text{fact} = 'N' \)).

If \( \text{equed} = 'Y' \), both row and column equilibration was done, that is, \( A \) has been replaced by \( \text{diag}(s) \cdot A \cdot \text{diag}(s) \).

\[ s \]

Array, size \( (n) \). The array \( s \) contains the scale factors for \( A \). If \( \text{equed} = 'Y' \), \( A \) is multiplied on the left and right by \( \text{diag}(s) \).

This array is an input argument if \( \text{fact} = 'F' \) only; otherwise it is an output argument.

If \( \text{fact} = 'F' \) and \( \text{equed} = 'Y' \), each element of \( s \) must be positive.

Each element of \( s \) should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

\[ \text{ldb} \]

The leading dimension of the array \( b \); \( \text{ldb} \geq \max(1, n) \) for column major layout and \( \text{ldb} \geq \text{nrhs} \) for row major layout.

\[ \text{ldx} \]

The leading dimension of the output array \( x \); \( \text{ldx} \geq \max(1, n) \) for column major layout and \( \text{ldx} \geq \text{nrhs} \) for row major layout.

\[ n\_err\_bnds \]

Number of error bounds to return for each right hand side and each type (normwise or componentwise). See \( \text{err_bnds_norm} \) and \( \text{err_bnds_comp} \) descriptions in the Output Arguments section below.
Specifies the number of parameters set in `params`. If ≤ 0, the `params` array is never referenced and default values are used.

`params` Array, size max(1, `nparams`). Specifies algorithm parameters. If an entry is less than 0.0, that entry is filled with the default value used for that parameter. Only positions up to `nparams` are accessed; defaults are used for higher-numbered parameters. If defaults are acceptable, you can pass `nparams = 0`, which prevents the source code from accessing the `params` argument.

- `params[0]`: Whether to perform iterative refinement or not. Default: 1.0 (for single precision flavors), 1.0D+0 (for double precision flavors).
  - =0.0 No refinement is performed and no error bounds are computed.
  - =1.0 Use the extra-precise refinement algorithm.
  (Other values are reserved for future use.)
- `params[1]`: Maximum number of residual computations allowed for refinement.
  - Default: 10
  - Aggressive: Set to 100 to permit convergence using approximate factorizations or factorizations other than LU. If the factorization uses a technique other than Gaussian elimination, the guarantees in `err_bnds_norm` and `err_bnds_comp` may no longer be trustworthy.
- `params[2]`: Flag determining if the code will attempt to find a solution with a small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence).

### Output Parameters

- `x`: Array, size max(1, `ldx*nrhs`) for column major layout and max(1, `ldx*n`) for row major layout.
  - If `info = 0`, the array `x` contains the solution `n`-by-`nrhs` matrix `X` to the original system of equations. Note that `A` and `B` are modified on exit if `equed='N'`, and the solution to the equilibrated system is: `inv(diag(s))*X`.
  - If `fact = 'E'` and `equed = 'Y'`, overwritten by `diag(s)*A*diag(s)`.
- `af`:
  - If `fact = 'N'`, `af` is an output argument and on exit returns the block diagonal matrix `D` and the multipliers used to obtain the factor `U` or `L` from the factorization `A = U*D*U^T` or `A = L*D*L^T`.
  - If `equed = 'N'`, `B` is not modified.
If \texttt{equed} = 'Y', \( B \) is overwritten by \( \text{diag}(s) \cdot B \).

This array is an output argument if \texttt{fact} = 'F'. Each element of this array is a power of the radix. See the description of \( s \) in Input Arguments section.

\( s \)

Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix \( A \) after equilibration (if done). If \( rcond \) is less than the machine precision, in particular, if \( rcond = 0 \), the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned.

\( rcond \)

Contains the reciprocal pivot growth factor:

\[ \frac{\|A\|}{\|U\|} \]

If this is much less than 1, the stability of the \( LU \) factorization of the (equilibrated) matrix \( A \) could be poor. This also means that the solution \( X \), estimated condition numbers, and error bounds could be unreliable. If factorization fails with \( 0 < \text{info} \leq n \), this parameter contains the reciprocal pivot growth factor for the leading \( \text{info} \) columns of \( A \).

\( rpvgrw \)

Array, size at least \( \max(1, \text{nrhs}) \). Contains the component-wise relative backward error for each solution vector \( x_j \), that is, the smallest relative change in any element of \( A \) or \( B \) that makes \( x_j \) an exact solution.

\( berr \)

Array of size \( \text{nrhs} \times \text{n_err_bnds} \). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the \( i \)-th solution vector

\[ \frac{\max_j |X_{true,j} - X_{i,j}|}{\max_j |X_{i,j}|} \]

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned.

\( err\_bnds\_norm \)

- \( err = 1 \)
  - "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold \( \sqrt{n} \cdot \text{slamch}(\varepsilon) \) for \texttt{chesvxx} and \( \sqrt{n} \cdot \text{dlamch}(\varepsilon) \) for \texttt{zhesvxx}.

- \( err = 2 \)
  - "Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold \( \sqrt{n} \cdot \text{slamch}(\varepsilon) \) for \texttt{chesvxx} and \( \sqrt{n} \cdot \text{dlamch}(\varepsilon) \) for \texttt{zhesvxx}. This error bound should only be trusted if the previous boolean is true.

- \( err = 3 \)
  - Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold \( \sqrt{n} \cdot \text{slamch}(\varepsilon) \) for \texttt{chesvxx} and \( \sqrt{n} \cdot \text{dlamch}(\varepsilon) \) for \texttt{zhesvxx} to determine if
the error estimate is "guaranteed". These reciprocal condition numbers for some appropriately scaled matrix $Z$ are:

$$\|Z\|_\infty \cdot \|Z^{-1}\|_\infty$$

Let $z=s^*a$, where $s$ scales each row by a power of the radix so all absolute row sums of $z$ are approximately 1.

The information for right-hand side $i$, where $1 \leq i \leq \text{nrhs}$, and type of error $\text{err}$ is stored in $\text{err_bnds_norm[ ( (\text{err}-1) \* \text{nrhs} + i - 1 )]}$.

Array of size $\text{nrhs} \* \text{n_err_bnds}$. For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the $i$-th solution vector:

$$\max \frac{|X_{true,j_i} - X_{j_i}|}{|X_{j_i}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested ($\text{params[2]} = 0.0$), then $\text{err_bnds_comp}$ is not accessed.

$\text{err}=1$ "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} \* \text{slamch(\epsilon)}$ for chesvxx and $\sqrt{n} \* \text{dlamch(\epsilon)}$ for zhesvxx.

$\text{err}=2$ "Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} \* \text{slamch(\epsilon)}$ for chesvxx and $\sqrt{n} \* \text{dlamch(\epsilon)}$ for zhesvxx. This error bound should only be trusted if the previous boolean is true.

$\text{err}=3$ Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold $\sqrt{n} \* \text{slamch(\epsilon)}$ for chesvxx and $\sqrt{n} \* \text{dlamch(\epsilon)}$ for zhesvxx to determine if the error estimate is "guaranteed". These reciprocal condition numbers for some appropriately scaled matrix $Z$ are:

$$\|Z\|_\infty \cdot \|Z^{-1}\|_\infty$$
Let \( z = s \cdot (a \cdot \text{diag}(x)) \), where \( x \) is the solution for the current right-hand side and \( s \) scales each row of \( a \cdot \text{diag}(x) \) by a power of the radix so all absolute row sums of \( z \) are approximately 1.

The information for right-hand side \( i \), where \( 1 \leq i \leq \text{nrhs} \), and type of error \( \text{err} \) is stored in \( \text{err}_\text{bnds}_\text{comp}[(\text{err}-1)\times\text{nrhs} + i - 1] \).

\( \text{ipiv} \)

If \( \text{fact} = 'N' \), \( \text{ipiv} \) is an output argument and on exit contains details of the interchanges and the block structure \( D \), as determined by \text{ssytrf} for single precision flavors and \text{dsytrf} for double precision flavors.

\( \text{equed} \)

If \( \text{fact} ≠ 'F' \), then \( \text{equed} \) is an output argument. It specifies the form of equilibration that was done (see the description of \( \text{equed} \) in Input Arguments section).

\( \text{params} \)

If an entry is less than 0.0, that entry is filled with the default value used for that parameter, otherwise the entry is not modified.

**Return Values**

This function returns a value \( \text{info} \).

If \( \text{info} = 0 \), the execution is successful. The solution to every right-hand side is guaranteed.

If \( \text{info} = -i \), the \( i \)-th parameter had an illegal value.

If \( 0 < \text{info}; \text{U}_\text{info}.\text{info} \) is exactly zero. The factorization has been completed, but the factor \( U \) is exactly singular, so the solution and error bounds could not be computed; \( rcond = 0 \) is returned.

If \( \text{info} = n+j \); The solution corresponding to the \( j \)-th right-hand side is not guaranteed. The solutions corresponding to other right-hand sides \( k \) with \( k > j \) may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested \( \text{params}[2] = 0.0 \), then the \( j \)-th right-hand side is the first with a normwise error bound that is not guaranteed (the smallest \( j \) such that for column major layout \( \text{err}_\text{bnds}_\text{norm}[j - 1] = 0.0 \) or \( \text{err}_\text{bnds}_\text{comp}[j - 1] = 0.0 \); or for row major layout \( \text{err}_\text{bnds}_\text{norm}[(j - 1)\times\text{n_err_bnds}] = 0.0 \) or \( \text{err}_\text{bnds}_\text{comp}[(j - 1)\times\text{n_err_bnds}] = 0.0 \). See the definition of \( \text{err}_\text{bnds}_\text{norm} \) and \( \text{err}_\text{bnds}_\text{comp} \) for \( \text{err} = 1 \). To get information about all of the right-hand sides, check \( \text{err}_\text{bnds}_\text{norm} \) or \( \text{err}_\text{bnds}_\text{comp} \).

Description

The routine solves for $X$ the real or complex system of linear equations $A*X = B$, where $A$ is an $n$-by-$n$ symmetric matrix stored in packed format, the columns of matrix $B$ are individual right-hand sides, and the columns of $X$ are the corresponding solutions.

The diagonal pivoting method is used to factor $A$ as $A = U*D*U^T$ or $A = L*D*L^T$, where $U$ (or $L$) is a product of permutation and unit upper (lower) triangular matrices, and $D$ is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

The factored form of $A$ is then used to solve the system of equations $A*X = B$.

Input Parameters

**Description**
The routine uses the diagonal pivoting factorization to compute the solution to a real or complex system of linear equations $A*X = B$, where $A$ is a $n$-by-$n$ symmetric matrix stored in packed format, the columns of matrix $B$ are individual right-hand sides, and the columns of $X$ are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine ?spsvx performs the following steps:

1. If fact = 'N', the diagonal pivoting method is used to factor the matrix $A$. The form of the factorization is $A = U*D*U^T$ or $A = L*D*L^T$, where $U$ (or $L$) is a product of permutation and unit upper (lower) triangular matrices, and $D$ is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

2. If some $d_{ii}= 0$, so that $D$ is exactly singular, then the routine returns with info = $i$. Otherwise, the factored form of $A$ is used to estimate the condition number of the matrix $A$. If the reciprocal of the condition number is less than machine precision, info = $n+1$ is returned as a warning, but the routine still goes on to solve for $X$ and compute error bounds as described below.

3. The system of equations is solved for $X$ using the factored form of $A$.

4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

**Input Parameters**

- **matrix_layout**: Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **fact**: Must be 'F' or 'N'.
  
  Specifies whether or not the factored form of the matrix $A$ has been supplied on entry.

  If fact = 'F': on entry, afp and ipiv contain the factored form of $A$. Arrays $ap$, afp, and ipiv are not modified.

  If fact = 'N', the matrix $A$ is copied to afp and factored.

- **uplo**: Must be 'U' or 'L'.
  
  Indicates whether the upper or lower triangular part of $A$ is stored and how $A$ is factored:

  If uplo = 'U', the array $ap$ stores the upper triangular part of the symmetric matrix $A$, and $A$ is factored as $U*D*U^T$.

  If uplo = 'L', the array $ap$ stores the lower triangular part of the symmetric matrix $A$; $A$ is factored as $L*D*L^T$.

- **n**: The order of matrix $A$; $n \geq 0$.

- **nrhs**: The number of right-hand sides, the number of columns in $B$; $nrhs \geq 0$.

- **ap, afp, b**: Arrays: $ap$ (size max(1,$n*(n+1)/2$), afp (size max(1,$n*(n+1)/2$), bof size max(1, $ldb*nrhs$) for column major layout and max(1, $ldb*n$) for row major layout.

  The array $ap$ contains the upper or lower triangle of the symmetric matrix $A$ in packed storage (see Matrix Storage Schemes).
The array `afp` is an input argument if `fact = 'F'`. It contains the block diagonal matrix `D` and the multipliers used to obtain the factor `U` or `L` from the factorization `A = U*D*U^T` or `A = L*D*L^T` as computed by `?sptrf`, in the same storage format as `A`.

The array `b` contains the matrix `B` whose columns are the right-hand sides for the systems of equations.

`ldb` The leading dimension of `b`; `ldb ≥ max(1, n)` for column major layout and `ldb≥nrhs` for row major layout.

`ipiv` Array, size at least `max(1, n)`. The array `ipiv` is an input argument if `fact = 'F'`. It contains details of the interchanges and the block structure of `D`, as determined by `?sptrf`.

If `ipiv[i-1] = k > 0`, then `d_{ii}` is a 1-by-1 block, and the `i`-th row and column of `A` was interchanged with the `k`-th row and column.

If `uplo = 'U'` and `ipiv[i]=ipiv[i-1] = -m < 0`, then `D` has a 2-by-2 block in rows/columns `i` and `i+1`, and `i`-th row and column of `A` was interchanged with the `m`-th row and column.

If `uplo = 'L'` and `ipiv[i-1] =ipiv[i] = -m < 0`, then `D` has a 2-by-2 block in rows/columns `i` and `i+1`, and `(i+1)`-th row and column of `A` was interchanged with the `m`-th row and column.

`ldx` The leading dimension of the output array `x`; `ldx≥ max(1, n)` for column major layout and `ldx≥nrhs` for row major layout.

Output Parameters

`x` Array, size `max(1, ldx*nrhs)` for column major layout and `max(1, ldx*n)` for row major layout.

If `info = 0` or `info = n+1`, the array `x` contains the solution matrix `X` to the system of equations.

`afp, ipiv` These arrays are output arguments if `fact = 'N'`. See the description of `afp, ipiv in Input Arguments` section.

`rcond` An estimate of the reciprocal condition number of the matrix `A`. If `rcond` is less than the machine precision (in particular, if `rcond = 0`), the matrix is singular to working precision. This condition is indicated by a return code of `info > 0`.

`ferr, berr` Arrays, size at least `max(1, nrhs)`. Contain the component-wise forward and relative backward errors, respectively, for each solution vector.

Return Values

This function returns a value `info`.

If `info = 0`, the execution is successful.

If `info = -i`, parameter `i` had an illegal value.

If `info = i`, and `i≤n`, then `d_{ii}` is exactly zero. The factorization has been completed, but the block diagonal matrix `D` is exactly singular, so the solution and error bounds could not be computed; `rcond = 0` is returned.
If $info = i$, and $i = n + 1$, then $D$ is nonsingular, but $rcond$ is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of $rcond$ would suggest.

Description

The routine solves for $X$ the system of linear equations $A*X = B$, where $A$ is an $n$-by-$n$ Hermitian matrix stored in packed format, the columns of matrix $B$ are individual right-hand sides, and the columns of $X$ are the corresponding solutions.

The diagonal pivoting method is used to factor $A$ as $A = U*D*U^H$ or $A = L*D*L^H$, where $U$ (or $L$) is a product of permutation and unit upper (lower) triangular matrices, and $D$ is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

The factored form of $A$ is then used to solve the system of equations $A*X = B$.

Input Parameters

- `matrix_layout` Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- `uplo` Must be 'U' or 'L'.
  Indicates whether the upper or lower triangular part of $A$ is stored:
  - If `uplo` = 'U', the upper triangle of $A$ is stored.
  - If `uplo` = 'L', the lower triangle of $A$ is stored.
- `n` The order of matrix $A$; $n \geq 0$.
- `nrhs` The number of right-hand sides; the number of columns in $B$; $nrhs \geq 0$.
- `ap`, `b` Arrays: `ap` (size max(1,$n*(n+1)/2$), bof size max(1, $ldb*nrhs$)) for column major layout and max(1, $ldb*n$) for row major layout.
The array `ap` contains the factor $U$ or $L$, as specified by `uplo`, in packed storage (see Matrix Storage Schemes).

The array `b` contains the matrix $B$ whose columns are the right-hand sides for the systems of equations.

`ldb` The leading dimension of `b`; `ldb` ≥ max(1, `n`) for column major layout and `ldb` ≥ nrhs for row major layout.

### Output Parameters

**ap**

The block-diagonal matrix $D$ and the multipliers used to obtain the factor $U$ (or $L$) from the factorization of $A$ as computed by ?hptrf, stored as a packed triangular matrix in the same storage format as $A$.

**b**

If `info` = 0, `b` is overwritten by the solution matrix $X$.

**ipiv**

Array, size at least max(1, `n`). Contains details of the interchanges and the block structure of $D$, as determined by ?hptrf.

If `ipiv[i-1]` = `k` > 0, then $d_{ii}$ is a 1-by-1 block, and the $i$-th row and column of $A$ was interchanged with the $k$-th row and column.

If `uplo` = 'U' and `ipiv[i]`=`ipiv[i-1]` = `-m` < 0, then $D$ has a 2-by-2 block in rows/columns $i$ and $i+1$, and $i$-th row and column of $A$ was interchanged with the $m$-th row and column.

If `uplo` = 'L' and `ipiv[i-1]`=`ipiv[i]` = `-m` < 0, then $D$ has a 2-by-2 block in rows/columns $i$ and $i+1$, and ($i+1$)-th row and column of $A$ was interchanged with the $m$-th row and column.

### Return Values

This function returns a value `info`.

If `info` = 0, the execution is successful.

If `info` = `-i`, parameter `i` had an illegal value.

If `info` = `i`, $d_{ii}$ is 0. The factorization has been completed, but $D$ is exactly singular, so the solution could not be computed.

**Description**
The routine uses the diagonal pivoting factorization to compute the solution to a complex system of linear equations $A \times X = B$, where $A$ is an $n$-by-$n$ Hermitian matrix stored in packed format, the columns of matrix $B$ are individual right-hand sides, and the columns of $X$ are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine `zhpsvx` performs the following steps:

1. If `fact = 'N'`, the diagonal pivoting method is used to factor the matrix $A$. The form of the factorization is $A = U \times D \times U^H$ or $A = L \times D \times L^H$, where $U$ (or $L$) is a product of permutation and unit upper (lower) triangular matrices, and $D$ is a Hermitian and block diagonal with $1$-by-$1$ and $2$-by-$2$ diagonal blocks.

2. If some $d_{ij} = 0$, so that $D$ is exactly singular, then the routine returns with $info = i$. Otherwise, the factored form of $A$ is used to estimate the condition number of the matrix $A$. If the reciprocal of the condition number is less than machine precision, $info = n+1$ is returned as a warning, but the routine still goes on to solve for $X$ and compute error bounds as described below.

3. The system of equations is solved for $X$ using the factored form of $A$.

4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

**Input Parameters**

- **matrix_layout**
  Specifies whether matrix storage layout is row major (`LAPACK_ROW_MAJOR`) or column major (`LAPACK_COL_MAJOR`).

- **fact**
  Must be 'F' or 'N'.
  Specifies whether or not the factored form of the matrix $A$ has been supplied on entry.
  If `fact = 'F'`: on entry, $afp$ and $ipiv$ contain the factored form of $A$. Arrays $ap$, $afp$, and $ipiv$ are not modified.
  If `fact = 'N'`, the matrix $A$ is copied to $afp$ and factored.

- **uplo**
  Must be 'U' or 'L'.
  Indicates whether the upper or lower triangular part of $A$ is stored and how $A$ is factored:
  - If `uplo = 'U'`, the array $ap$ stores the upper triangular part of the Hermitian matrix $A$, and $A$ is factored as $U \times D \times U^H$.
  - If `uplo = 'L'`, the array $ap$ stores the lower triangular part of the Hermitian matrix $A$, and $A$ is factored as $L \times D \times L^H$.

- **n**
  The order of matrix $A$; $n \geq 0$. 

---

719
nrhs
The number of right-hand sides, the number of columns in B; $nrhs \geq 0$.

$ap, afp, b$
Arrays: $ap$ (size max(1, $n^*$(n+1)/2)), $afp$ (size max(1, $n^*$(n+1)/2)), $b$ of size max(1, $ldb^*nrhs$) for column major layout and max(1, $ldb^*n$) for row major layout.

The array $ap$ contains the upper or lower triangle of the Hermitian matrix $A$ in packed storage (see Matrix Storage Schemes).

The array $afp$ is an input argument if $fact = 'F'$. It contains the block diagonal matrix $D$ and the multipliers used to obtain the factor $U$ or $L$ from the factorization $A = U^D U^H$ or $A = L^D L^H$ as computed by ?hptrf, in the same storage format as $A$.

The array $b$ contains the matrix $B$ whose columns are the right-hand sides for the systems of equations.

ldb
The leading dimension of $b$; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout.

ipiv
Array, size at least $\max(1, n)$. The array $ipiv$ is an input argument if $fact = 'F'$. It contains details of the interchanges and the block structure of $D$, as determined by ?hptrf.

If $ipiv[i-1] = k > 0$, then $d_{ii}$ is a 1-by-1 block, and the $i$-th row and column of $A$ was interchanged with the $k$-th row and column.

If $uplo = 'U'$ and $ipiv[i] = ipiv[i-1] = -m < 0$, then $D$ has a 2-by-2 block in rows/columns $i$ and $i+1$, and $i$-th row and column of $A$ was interchanged with the $m$-th row and column.

If $uplo = 'L'$ and $ipiv[i] = ipiv[i-1] = -m < 0$, then $D$ has a 2-by-2 block in rows/columns $i$ and $i+1$, and $(i+1)$-th row and column of $A$ was interchanged with the $m$-th row and column.

ldx
The leading dimension of the output array $x$; $ldx \geq \max(1, n)$ for column major layout and $ldx \geq nrhs$ for row major layout.

Output Parameters

$x$
Array, size max(1, $ldx^*nrhs$) for column major layout and max(1, $ldx^*n$) for row major layout.

If $info = 0$ or $info = n+1$, the array $x$ contains the solution matrix $X$ to the system of equations.

$afp, ipiv$
These arrays are output arguments if $fact = 'N'$. See the description of $afp, ipiv$ in Input Arguments section.

rcond
An estimate of the reciprocal condition number of the matrix $A$. If $rcond$ is less than the machine precision (in particular, if $rcond = 0$), the matrix is singular to working precision. This condition is indicated by a return code of $info > 0$.

ferr
Array, size at least max(1, $nrhs$). Contains the estimated forward error bound for each solution vector $x_j$ (the $j$-th column of the solution matrix $X$). If $xtrue$ is the true solution corresponding to $x_j$, $ferr[j-1]$
is an estimated upper bound for the magnitude of the largest element in \((x_j - x_{true})\) divided by the magnitude of the largest element in \(x_j\).
The estimate is as reliable as the estimate for \(rcond\), and is almost always a slight overestimate of the true error.

**Return Values**

This function returns a value \(info\). If \(info = 0\), the execution is successful. If \(info = -i\), parameter \(i\) had an illegal value.

If \(info = i\), and \(i \leq n\), then \(d_{ii}\) is exactly zero. The factorization has been completed, but the block diagonal matrix \(D\) is exactly singular, so the solution and error bounds could not be computed; \(rcond = 0\) is returned.

If \(info = i\), and \(i = n + 1\), then \(D\) is nonsingular, but \(rcond\) is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of \(rcond\) would suggest.

**LAPACK Least Squares and Eigenvalue Problem Routines**

This section includes descriptions of LAPACK computational routines and driver routines for solving linear least squares problems, eigenvalue and singular value problems, and performing a number of related computational tasks. For a full reference on LAPACK routines and related information see [LUG].

**Least Squares Problems.** A typical least squares problem is as follows: given a matrix \(A\) and a vector \(b\), find the vector \(x\) that minimizes the sum of squares \(\sum_i ((Ax)_i - b_i)^2\) or, equivalently, find the vector \(x\) that minimizes the 2-norm \(||Ax - b||_2\).

In the most usual case, \(A\) is an \(m\)-by-\(n\) matrix with \(m \geq n\) and \(\text{rank}(A) = n\). This problem is also referred to as finding the least squares solution to an overdetermined system of linear equations (here we have more equations than unknowns). To solve this problem, you can use the QR factorization of the matrix \(A\) (see QR Factorization).

If \(m < n\) and \(\text{rank}(A) = m\), there exist an infinite number of solutions \(x\) which exactly satisfy \(Ax = b\), and thus minimize the norm \(||Ax - b||_2\). In this case it is often useful to find the unique solution that minimizes \(||x||_2\). This problem is referred to as finding the minimum-norm solution to an underdetermined system of linear equations (here we have more unknowns than equations). To solve this problem, you can use the LQ factorization of the matrix \(A\) (see LQ Factorization).

In the general case you may have a rank-deficient least squares problem, with \(\text{rank}(A) < \min(m, n)\); find the minimum-norm least squares solution that minimizes both \(||x||_2\) and \(||Ax - b||_2\). In this case (or when the rank of \(A\) is in doubt) you can use the QR factorization with pivoting or singular value decomposition (see Singular Value Decomposition).

**Eigenvalue Problems.** The eigenvalue problems (from German "eigen" "own") are stated as follows: given a matrix \(A\), find the eigenvalues \(\lambda\) and the corresponding eigenvectors \(z\) that satisfy the equation \(Az = \lambda z\) (right eigenvectors \(z\)) or the equation...
\( z^H A = \lambda z^H \) (left eigenvectors \( z \)).

If \( A \) is a real symmetric or complex Hermitian matrix, the above two equations are equivalent, and the problem is called a symmetric eigenvalue problem. Routines for solving this type of problems are described in the section Symmetric Eigenvalue Problems.

Routines for solving eigenvalue problems with nonsymmetric or non-Hermitian matrices are described in the section Nonsymmetric Eigenvalue Problems.

The library also includes routines that handle generalized symmetric-definite eigenvalue problems: find the eigenvalues \( \lambda \) and the corresponding eigenvectors \( x \) that satisfy one of the following equations:

\[ Az = \lambda Bz, \quad ABz = \lambda z, \quad \text{or} \quad BAz = \lambda z, \]

where \( A \) is symmetric or Hermitian, and \( B \) is symmetric positive-definite or Hermitian positive-definite. Routines for reducing these problems to standard symmetric eigenvalue problems are described in the section Generalized Symmetric-Definite Eigenvalue Problems.

To solve a particular problem, you usually call several computational routines. Sometimes you need to combine the routines of this chapter with other LAPACK routines described in "LAPACK Routines: Linear Equations" as well as with BLAS routines described in "BLAS and Sparse BLAS Routines".

For example, to solve a set of least squares problems minimizing \( \| Ax - b \|^2 \) for all columns \( b \) of a given matrix \( B \) (where \( A \) and \( B \) are real matrices), you can call \( ?geqrf \) to form the factorization \( A = QR \), then call \( ?ormqr \) to compute \( C = Q^H B \) and finally call the BLAS routine \( ?trsm \) to solve for \( X \) the system of equations \( RX = C \).

Another way is to call an appropriate driver routine that performs several tasks in one call. For example, to solve the least squares problem the driver routine \( ?gels \) can be used.

**LAPACK Least Squares and Eigenvalue Problem Computational Routines**

In the sections that follow, the descriptions of LAPACK computational routines are given. These routines perform distinct computational tasks that can be used for:

- Orthogonal Factorizations
- Singular Value Decomposition
- Symmetric Eigenvalue Problems
- Generalized Symmetric-Definite Eigenvalue Problems
- Nonsymmetric Eigenvalue Problems
- Generalized Nonsymmetric Eigenvalue Problems
- Generalized Singular Value Decomposition

See also the respective driver routines.

**Orthogonal Factorizations: LAPACK Computational Routines**

This section describes the LAPACK routines for the \( QR (RQ) \) and \( LQ (QL) \) factorization of matrices. Routines for the \( RZ \) factorization as well as for generalized \( QR \) and \( RQ \) factorizations are also included.

**QR Factorization.** Assume that \( A \) is an \( m \)-by-\( n \) matrix to be factored.

If \( m \geq n \), the \( QR \) factorization is given by

\[
A = Q \begin{pmatrix} R \\ 0 \end{pmatrix} = \begin{pmatrix} Q_1, \ Q_2 \end{pmatrix} \begin{pmatrix} R \\ 0 \end{pmatrix}
\]

where \( R \) is an \( n \)-by-\( n \) upper triangular matrix with real diagonal elements, and \( Q \) is an \( m \)-by-\( m \) orthogonal (or unitary) matrix.
You can use the QR factorization for solving the following least squares problem: minimize $||Ax - b||^2$ where $A$ is a full-rank $m$-by-$n$ matrix ($m \geq n$). After factoring the matrix, compute the solution $x$ by solving $Rx = (Q_1)^\top b$.

If $m < n$, the QR factorization is given by

$$A = QR = Q(R_1R_2)$$

where $R$ is trapezoidal, $R_1$ is upper triangular and $R_2$ is rectangular.

$Q$ is represented as a product of $\min(m, n)$ elementary reflectors. Routines are provided to work with $Q$ in this representation.

**LQ Factorization** LQ factorization of an $m$-by-$n$ matrix $A$ is as follows. If $m \leq n$,

$$A = \begin{pmatrix} L & 0 \end{pmatrix} Q = \begin{pmatrix} L & 0 \end{pmatrix} \begin{pmatrix} Q_1 \\ Q_2 \end{pmatrix} = \begin{pmatrix} LQ_1 \end{pmatrix}$$

where $L$ is an $m$-by-$m$ lower triangular matrix with real diagonal elements, and $Q$ is an $n$-by-$n$ orthogonal (or unitary) matrix.

If $m > n$, the LQ factorization is

$$A = \begin{pmatrix} L_1 \\ L_2 \end{pmatrix} Q$$

where $L_1$ is an $n$-by-$n$ lower triangular matrix, $L_2$ is rectangular, and $Q$ is an $n$-by-$n$ orthogonal (or unitary) matrix.

You can use the LQ factorization to find the minimum-norm solution of an underdetermined system of linear equations $Ax = b$ where $A$ is an $m$-by-$n$ matrix of rank $m$ ($m < n$). After factoring the matrix, compute the solution vector $x$ as follows: solve $Ly = b$ for $y$, and then compute $x = (Q_1)^\top y$.

Table "Computational Routines for Orthogonal Factorization" lists LAPACK routines that perform orthogonal factorization of matrices.

`?geqrf`

*Computes the QR factorization of a general m-by-n matrix.*

**Syntax**

```c
lapack_int LAPACKE_sgeqrf (int matrix_layout, lapack_int m, lapack_int n, float* a, lapack_int lda, float* tau);
lapack_int LAPACKE_dgeqrf (int matrix_layout, lapack_int m, lapack_int n, double* a, lapack_int lda, double* tau);
lapack_int LAPACKE_cgeqrf (int matrix_layout, lapack_int m, lapack_int n, lapack_complex_float* a, lapack_int lda, lapack_complex_float* tau);
lapack_int LAPACKE_zgeqrf (int matrix_layout, lapack_int m, lapack_int n, lapack_complex_double* a, lapack_int lda, lapack_complex_double* tau);
```

**Include Files**

- mkl.h

**Description**

The routine forms the QR factorization of a general m-by-n matrix \( A \) (see Orthogonal Factorizations). No pivoting is performed.

The routine does not form the matrix \( Q \) explicitly. Instead, \( Q \) is represented as a product of \( \min(m, n) \) elementary reflectors. Routines are provided to work with \( Q \) in this representation.

**NOTE**

This routine supports the Progress Routine feature. See Progress Function section for details.

**Input Parameters**

- `matrix_layout`: Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- `m`: The number of rows in the matrix \( A \) (\( m \geq 0 \)).
- `n`: The number of columns in \( A \) (\( n \geq 0 \)).
- `a`: Array \( a \) of size \( \max(1, lda*n) \) for column major layout and \( \max(1, lda*m) \) for row major layout contains the matrix \( A \).
- `lda`: The leading dimension of \( a \); at least \( \max(1, m) \) for column major layout and at least \( \max(1, n) \) for row major layout.
Output Parameters

Overwritten by the factorization data as follows:

The elements on and above the diagonal of the array contain the \( \min(m, n) \) -by-\( n \) upper trapezoidal matrix \( R \) (\( R \) is upper triangular if \( m \geq n \)); the elements below the diagonal, with the array \( \tau \), present the orthogonal matrix \( Q \) as a product of \( \min(m, n) \) elementary reflectors (see Orthogonal Factorizations).

\( \tau \)

Array, size at least \( \text{max}(1, \min(m, n)) \). Contains scalars that define elementary reflectors for the matrix \( Q \) in its decomposition in a product of elementary reflectors (see Orthogonal Factorizations).

Return Values

This function returns a value \( \text{info} \).

If \( \text{info}=0 \), the execution is successful.

If \( \text{info} = -i \), the \( i \)-th parameter had an illegal value.

Application Notes

The computed factorization is the exact factorization of a matrix \( A + E \), where

\[ ||E||_2 = O(\varepsilon) ||A||_2. \]

The approximate number of floating-point operations for real flavors is

\[
\begin{align*}
(4/3)n^3 & \quad \text{if } m = n, \\
(2/3)n^2(3m-n) & \quad \text{if } m > n, \\
(2/3)m^2(3n-m) & \quad \text{if } m < n.
\end{align*}
\]

The number of operations for complex flavors is 4 times greater.

To solve a set of least squares problems minimizing \[ ||A\mathbf{x} - \mathbf{b}\|_2 \] for all columns \( \mathbf{b} \) of a given matrix \( \mathbf{B} \), you can call the following:

\( \text{?geqrf (this routine)} \)

to factorize \( A = QR \);

\( \text{ormqr} \)

to compute \( C = Q^T\mathbf{B} \) (for real matrices);

\( \text{unmqr} \)

to compute \( C = Q^H\mathbf{B} \) (for complex matrices);

\( \text{trsm} \) (a BLAS routine)

to solve \( R\mathbf{X} = \mathbf{C} \).

(The columns of the computed \( \mathbf{X} \) are the least squares solution vectors \( \mathbf{x} \).)

To compute the elements of \( Q \) explicitly, call

\( \text{orgqr} \) \quad \text{(for real matrices)}

\( \text{ungqr} \) \quad \text{(for complex matrices)}.

Description

The routine forms the QR factorization of a general m-by-n matrix A (see Orthogonal Factorizations). No pivoting is performed. The diagonal entries of R are real and nonnegative.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of min(m, n) elementary reflectors. Routines are provided to work with Q in this representation.

**NOTE**

This routine supports the Progress Routine feature. See Progress Function section for details.

Input Parameters

- `matrix_layout` Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- `m` The number of rows in the matrix A \((m \geq 0)\).
- `n` The number of columns in A \((n \geq 0)\).
- `a` Array, size max(1,lda*n) for column major layout and max(1,lda*m) for row major layout, containing the matrix A.
- `lda` The leading dimension of a; at least max(1, m) for column major layout and at least max(1, n) for row major layout.

Output Parameters

- `a` Overwritten by the factorization data as follows:
  - The elements on and above the diagonal of the array contain the min(m,n)-by-n upper trapezoidal matrix R (R is upper triangular if m \(\geq n\)); the elements below the diagonal, with the array `tau`, present the orthogonal matrix Q as a product of min(m,n) elementary reflectors (see Orthogonal Factorizations).
  - The diagonal elements of the matrix R are real and non-negative.
tau

Array, size at least max (1, min(m, n)). Contains scalars that define elementary reflectors for the matrix Q in its decomposition in a product of elementary reflectors (see Orthogonal Factorizations).

Return Values
This function returns a value info.
If info=0, the execution is successful.
If info = -i, the i-th parameter had an illegal value.

Application Notes
The computed factorization is the exact factorization of a matrix A + E, where

\[ ||E||_2 = O(\varepsilon) ||A||_2. \]

The approximate number of floating-point operations for real flavors is

\[
\begin{align*}
(4/3)n^3 & \quad \text{if } m = n, \\
(2/3)n^2(3m-n) & \quad \text{if } m > n, \\
(2/3)m^2(3n-m) & \quad \text{if } m < n.
\end{align*}
\]

The number of operations for complex flavors is 4 times greater.
To solve a set of least squares problems minimizing \[ ||A*x - b||_2 \] for all columns b of a given matrix B, you can call the following:

?geqrf (this routine)  
   to factorize \( A = QR; \)
ormqr  
   to compute \( C = Q^T*B \) (for real matrices);
unmqr  
   to compute \( C = QH*B \) (for complex matrices);
trsm (a BLAS routine)  
   to solve \( R*X = C. \)

(The columns of the computed \( X \) are the least squares solution vectors \( x \).)
To compute the elements of \( Q \) explicitly, call

orgqr  
   (for real matrices)
unngqr  
   (for complex matrices).

mkl_progress

Matrix Storage Schemes

?geqrt  
Computes a blocked QR factorization of a general real or complex matrix using the compact WY representation of Q.

Syntax

```
lapack_int LAPACKE_sgeqrt (int matrix_layout, lapack_int m, lapack_int n, lapack_int nb, float* a, lapack_int lda, float* t, lapack_int ldt);
```
lapack_int LAPACKE_dgeqrt (int matrix_layout, lapack_int m, lapack_int n, lapack_int nb, double* a, lapack_int lda, double* t, lapack_int ldt);
lapack_int LAPACKE_cgeqrt (int matrix_layout, lapack_int m, lapack_int n, lapack_int nb, lapack_complex_float* a, lapack_int lda, lapack_complex_float* t, lapack_int ldt);
lapack_int LAPACKE_zgeqrt (int matrix_layout, lapack_int m, lapack_int n, lapack_int nb, lapack_complex_double* a, lapack_int lda, lapack_complex_double* t, lapack_int ldt);

Include Files
- mkl.h

Description
The strictly lower triangular matrix $V$ contains the elementary reflectors $H(i)$ in the $i$th column below the diagonal. For example, if $m=5$ and $n=3$, the matrix $V$ is

$$
V = \begin{bmatrix}
1 \\
v_1 & 1 \\
v_1 & v_2 & 1 \\
v_1 & v_2 & v_3 \\
v_1 & v_2 & v_3 \\
\end{bmatrix}
$$

where $v_i$ represents one of the vectors that define $H(i)$. The vectors are returned in the lower triangular part of array $a$.

NOTE
The 1s along the diagonal of $V$ are not stored in $a$.

Let $k = \min(m, n)$. The number of blocks is $b = \text{ceiling}(k/nb)$, where each block is of order $nb$ except for the last block, which is of order $ib = k - (b-1)*nb$. For each of the $b$ blocks, a upper triangular block reflector factor is computed: $t_1, t_2, \ldots, t_b$. The $nb$-by-$nb$ (and $ib$-by-$ib$ for the last block) $t$s are stored in the $nb$-by-$n$ array $t$ as $t = (t_1t_2 \ldots t_b)$.

Input Parameters

- **matrix_layout**: Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- **m**: The number of rows in the matrix $A$ ($m \geq 0$).
- **n**: The number of columns in $A$ ($n \geq 0$).
- **nb**: The block size to be used in the blocked QR ($\min(m, n) \geq nb \geq 1$).
- **a**: Array $a$ of size max(1, $lda*n$) for column major layout and max(1, $lda*m$) for row major layout contains the $m$-by-$n$ matrix $A$. 

**Output Parameters**

*a*

Overwritten by the factorization data as follows:
The elements on and above the diagonal of the array contain the \( \min(m, n) \)-by-\( n \) upper trapezoidal matrix \( R \) (\( R \) is upper triangular if \( m \geq n \)); the elements below the diagonal, with the array \( t \), present the orthogonal matrix \( Q \) as a product of \( \min(m, n) \) elementary reflectors (see Orthogonal Factorizations).

\( t \)

Array, size \( \max(1, ldt*\min(m, n)) \) for column major layout and \( \max(1, ldt*nb) \) for row major layout.

The upper triangular block reflector's factors stored as a sequence of upper triangular blocks.

**Return Values**

This function returns a value \( info \).

If \( info=0 \), the execution is successful.

If \( info < 0 \) and \( info = -i \), the \( i \)-th parameter had an illegal value.

**?gemqrt**

Multiplies a general matrix by the orthogonal/unitary matrix \( Q \) of the QR factorization formed by \( ?geqrt \).

**Syntax**

```c
lapack_int LAPACKE_sgemqrt (int matrix_layout, char side, char trans, lapack_int m, lapack_int n, lapack_int k, lapack_int nb, const float* v, lapack_int ldv, const float* t, lapack_int ldt, float* c, lapack_int ldc);

lapack_int LAPACKE_dgemqrt (int matrix_layout, char side, char trans, lapack_int m, lapack_int n, lapack_int k, lapack_int nb, const double* v, lapack_int ldv, const double* t, lapack_int ldt, double* c, lapack_int ldc);

lapack_int LAPACKE_cgemqrt (int matrix_layout, char side, char trans, lapack_int m, lapack_int n, lapack_int k, lapack_int nb, const lapack_complex_float* v, lapack_int ldv, const lapack_complex_float* t, lapack_int ldt, lapack_complex_float* c, lapack_int ldc);

lapack_int LAPACKE_zgemqrt (int matrix_layout, char side, char trans, lapack_int m, lapack_int n, lapack_int k, lapack_int nb, const lapack_complex_double* v, lapack_int ldv, const lapack_complex_double* t, lapack_int ldt, lapack_complex_double* c, lapack_int ldc);
```

**Include Files**

- mkl.h

**Description**

The \( ?gemqrt \) routine overwrites the general real or complex \( m \)-by-\( n \) matrix \( C \) with
where $Q$ is a real orthogonal (complex unitary) matrix defined as the product of $k$ elementary reflectors

$$Q = H(1) H(2) \ldots H(k) = I - V^T V$$

for real flavors, and

$$Q = H(1) H(2) \ldots H(k) = I - V^H V$$

for complex flavors,

generated using the compact WY representation as returned by geqrt. $Q$ is of order $m$ if $side = 'L'$ and of order $n$ if $side = 'R'$.

### Input Parameters

- **matrix_layout**: Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- **side**:
  - 'L': apply $Q$, $Q^T$, or $Q^H$ from the left.
  - 'R': apply $Q$, $Q^T$, or $Q^H$ from the right.
- **trans**:  
  - 'N', no transpose, apply $Q$.
  - 'T', transpose, apply $Q^T$.
  - 'C', transpose, apply $Q^H$.
- **m**: The number of rows in the matrix $C$, ($m \geq 0$).
- **n**: The number of columns in the matrix $C$, ($n \geq 0$).
- **k**: The number of elementary reflectors whose product defines the matrix $Q$.
- **Constraints:**
  - If $side = 'L'$, $m \geq k \geq 0$
  - If $side = 'R'$, $n \geq k \geq 0$.
- **nb**: The block size used for the storage of $t$, $k \geq nb \geq 1$. This must be the same value of $nb$ used to generate $t$ in geqrt.
- **v**: Array of size max($1, ldv * k$) for column major layout, max($1, ldv * m$) for row major layout and $side = 'L'$, and max($1, ldv * n$) for row major layout and $side = 'R'$.
  The $i$th column must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \ldots, k$, as returned by geqrt in the first $k$ columns of its array argument $a$.
- **ldv**: The leading dimension of the array $v$.
  - if $side = 'L'$, $ldv$ must be at least max($1, m$) for column major layout and max($1, k$) for row major layout;
  - if $side = 'R'$, $ldv$ must be at least max($1, n$) for column major layout and max($1, k$) for row major layout.
- **t**: Array, size max($1, ldt * \min(m, n)$) for column major layout and max($1, ldt * nb$) for row major layout.
The upper triangular factors of the block reflectors as returned by `geqrt`.

`ldt`

The leading dimension of the array `c`. `ldt` must be at least `nb` for column major layout and `max(1, k)` for row major layout.

`c`

The `m`-by-`n` matrix `C`.

`ldc`

The leading dimension of the array `c`. `ldc` must be at least `max(1, m)` for column major layout and `max(1, n)` for row major layout.

**Output Parameters**

`c`  
Overwritten by the product `Q^*C, C^*Q, Q^T*C, C^*Q^T, Q^H*C, or C^*Q^H` as specified by `side` and `trans`.

**Return Values**

This function returns a value `info`.

If `info=0`, the execution is successful.

If `info = -i`, the `i`-th parameter had an illegal value.

`?geqpf`

*Computes the QR factorization of a general `m`-by-`n` matrix with pivoting.*

**Syntax**

```c
lapack_int LAPACKE_sgeqpf (int matrix_layout, lapack_int m, lapack_int n, float* a,
lapack_int lda, lapack_int* jpvt, float* tau);

lapack_int LAPACKE_dgeqpf (int matrix_layout, lapack_int m, lapack_int n, double* a,
lapack_int lda, lapack_int* jpvt, double* tau);

lapack_int LAPACKE_cgeqpf (int matrix_layout, lapack_int m, lapack_int n,
lapack_complex_float* a, lapack_int lda, lapack_int* jpvt, lapack_complex_float* tau);

lapack_int LAPACKE_zgeqpf (int matrix_layout, lapack_int m, lapack_int n,
lapack_complex_double* a, lapack_int lda, lapack_int* jpvt, lapack_complex_double* tau);
```

**Include Files**

- `mkl.h`

**Description**

The routine is deprecated and has been replaced by routine `geqp3`.

The routine `?geqpf` forms the QR factorization of a general `m`-by-`n` matrix `A` with column pivoting: `A*P = Q*R` (see Orthogonal Factorizations). Here `P` denotes an `n`-by-`n` permutation matrix.

The routine does not form the matrix `Q` explicitly. Instead, `Q` is represented as a product of `min(m, n)` elementary reflectors. Routines are provided to work with `Q` in this representation.

**Input Parameters**

`matrix_layout`  
Specifies whether matrix storage layout is row major (`LAPACK_ROW_MAJOR`) or column major (`LAPACK_COL_MAJOR`).
The number of rows in the matrix $A$ ($n \geq 0$).

The number of columns in $A$ ($n \geq 0$).

Array $a$ of size max(1, $lda \times n$) for column major layout and max(1, $lda \times m$) for row major layout contains the matrix $A$.

The leading dimension of $a$; at least max(1, $m$) for column major layout and max(1, $n$) for row major layout.

Array, size at least max(1, $n$).

On entry, if $jpvt[i - 1] > 0$, the $i$-th column of $A$ is moved to the beginning of $A*P$ before the computation, and fixed in place during the computation.

If $jpvt[i - 1] = 0$, the $i$-th column of $A$ is a free column (that is, it may be interchanged during the computation with any other free column).

Output Parameters

Overwritten by the factorization data as follows:

The elements on and above the diagonal of the array contain the min($m,n$)-by-$n$ upper trapezoidal matrix $R$ ($R$ is upper triangular if $m \geq n$); the elements below the diagonal, with the array $tau$, present the orthogonal matrix $Q$ as a product of min($m,n$) elementary reflectors (see Orthogonal Factorizations).

Array, size at least max $(1, \min(m, n))$. Contains additional information on the matrix $Q$.

Overwritten by details of the permutation matrix $P$ in the factorization $A*P = Q*R$. More precisely, the columns of $A*P$ are the columns of $A$ in the following order:

\[ jpvt[0], \, jpvt[1], \, ..., \, jpvt[n - 1]. \]

Return Values

This function returns a value $info$.

If $info=0$, the execution is successful.

If $info = -i$, the $i$-th parameter had an illegal value.

Application Notes

The computed factorization is the exact factorization of a matrix $A + E$, where

\[ \|E\|_2 = O(\varepsilon) \|A\|_2. \]

The approximate number of floating-point operations for real flavors is

\[ (4/3)n^3 \quad \text{if } m = n, \]
\[ (2/3)n^2(3m-n) \quad \text{if } m > n, \]
\[ (2/3)m^2(3n-m) \quad \text{if } m < n. \]

The number of operations for complex flavors is 4 times greater.
To solve a set of least squares problems minimizing \( \| A^*x - b \|_2 \) for all columns \( b \) of a given matrix \( B \), you can call the following:

- \(?\text{geqp}f\) (this routine) to factorize \( A^*P = Q^*R \);
- \(\text{ormqr}\) to compute \( C = Q^T*B \) (for real matrices);
- \(\text{unmqr}\) to compute \( C = Q^H*B \) (for complex matrices);
- \(\text{trsm}\) (a BLAS routine) to solve \( R*X = C \).

(The columns of the computed \( X \) are the permuted least squares solution vectors \( x \); the output array \( \text{jpvt} \) specifies the permutation order.)

To compute the elements of \( Q \) explicitly, call

- \(\text{orgqr}\) (for real matrices)
- \(\text{ungqr}\) (for complex matrices).

\(\text{?\text{geqp}3}\)

\textit{Computes the QR factorization of a general } m \text{-by-} n \text{ matrix with column pivoting using level 3 BLAS.}

**Syntax**

\begin{verbatim}
lapack_int LAPACKE_sgeqp3 (int matrix_layout, lapack_int m, lapack_int n, float* a, lapack_int lda, lapack_int* jpvt, float* tau);

lapack_int LAPACKE_dgeqp3 (int matrix_layout, lapack_int m, lapack_int n, double* a, lapack_int lda, lapack_int* jpvt, double* tau);

lapack_int LAPACKE_cgeqp3 (int matrix_layout, lapack_int m, lapack_int n, lapack_complex_float* a, lapack_int lda, lapack_int* jpvt, lapack_complex_float* tau);

lapack_int LAPACKE_zgeqp3 (int matrix_layout, lapack_int m, lapack_int n, lapack_complex_double* a, lapack_int lda, lapack_int* jpvt, lapack_complex_double* tau);
\end{verbatim}

**Include Files**

- \textit{mkl.h}

**Description**

The routine forms the QR factorization of a general \( m \)-by-\( n \) matrix \( A \) with column pivoting: \( A^*P = Q^*R \) (see Orthogonal Factorizations) using Level 3 BLAS. Here \( P \) denotes an \( n \)-by-\( n \) permutation matrix. Use this routine instead of \text{geqp}f for better performance.

The routine does not form the matrix \( Q \) explicitly. Instead, \( Q \) is represented as a product of \( \min(m, n) \) elementary reflectors. Routines are provided to work with \( Q \) in this representation.

**Input Parameters**

- \textit{matrix_layout}
  - Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- \textit{m}
  - The number of rows in the matrix \( A \) \((m \geq 0)\).
- \textit{n}
  - The number of columns in \( A \) \((n \geq 0)\).
Array $a$ of size $\max(1, lda \times n)$ for column major layout and $\max(1, lda \times m)$ for row major layout contains the matrix $A$.

The leading dimension of $a$; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout.

Array, size at least $\max(1, n)$.

On entry, if $jpvt[i - 1] \neq 0$, the $i$-th column of $A$ is moved to the beginning of $AP$ before the computation, and fixed in place during the computation.

If $jpvt[i - 1] = 0$, the $i$-th column of $A$ is a free column (that is, it may be interchanged during the computation with any other free column).

Output Parameters

Overwritten by the factorization data as follows:

The elements on and above the diagonal of the array contain the $\min(m,n)$-by-$n$ upper trapezoidal matrix $R$ ($R$ is upper triangular if $m \geq n$); the elements below the diagonal, with the array $tau$, present the orthogonal matrix $Q$ as a product of $\min(m,n)$ elementary reflectors (see Orthogonal Factorizations).

Array, size at least $\max(1, \min(m, n))$. Contains scalar factors of the elementary reflectors for the matrix $Q$.

Overwritten by details of the permutation matrix $P$ in the factorization $A*P = Q*R$. More precisely, the columns of $AP$ are the columns of $A$ in the following order:

$jpvt[0], jpvt[1], ..., jpvt[n - 1]$.

Return Values

This function returns a value $info$.

If $info = 0$, the execution is successful.

If $info = -i$, the $i$-th parameter had an illegal value.

Application Notes

To solve a set of least squares problems minimizing $||A*x - b||_2$ for all columns $b$ of a given matrix $B$, you can call the following:

- `?geqp3` (this routine) to factorize $A*P = Q*R$;
- `ormqr` to compute $C = Q^T*B$ (for real matrices);
- `unmqr` to compute $C = Q^H*B$ (for complex matrices);
- `trsm` (a BLAS routine) to solve $R*X = C$.

(The columns of the computed $X$ are the permuted least squares solution vectors $x$; the output array $jpvt$ specifies the permutation order.)

To compute the elements of $Q$ explicitly, call

- `orgqr` (for real matrices)
ungqr (for complex matrices).

?orgqr
Generates the real orthogonal matrix Q of the QR
factorization formed by ?geqrf.

Syntax
lapack_int LAPACKE_sorgqr (int matrix_layout, lapack_int m, lapack_int n, lapack_int k,
float* a, lapack_int lda, const float* tau);
lapack_int LAPACKE_dorgqr (int matrix_layout, lapack_int m, lapack_int n, lapack_int k,
double* a, lapack_int lda, const double* tau);

Include Files
• mkl.h

Description
The routine generates the whole or part of m-by-m orthogonal matrix Q of the QR
factorization formed by the routine ?geqrf or geqpf. Use this routine after a call to sgeqrf/dgeqrf or sgeqpf/dgeqpf.

Usually Q is determined from the QR factorization of an m by p matrix A with m≥p. To compute the whole matrix Q, use:
LAPACK_?orgqr(matrix_layout, m, m, p, a, lda, tau)

To compute the leading p columns of Q (which form an orthonormal basis in the space spanned by the
columns of A):
LAPACK_?orgqr(matrix_layout, m, p, p, a, lda)

To compute the matrix Q^k of the QR factorization of leading k columns of the matrix A:
LAPACK_?orgqr(matrix_layout, m, m, k, a, lda, tau)

To compute the leading k columns of Q^k (which form an orthonormal basis in the space spanned by leading k
columns of the matrix A):
LAPACK_?orgqr(matrix_layout, m, k, k, a, lda, tau)

Input Parameters

matrix_layout
Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR)
or column major (LAPACK_COL_MAJOR).

m
The order of the orthogonal matrix Q (m≥ 0).

n
The number of columns of Q to be computed
(0 ≤ n ≤ m).

k
The number of elementary reflectors whose product defines the matrix Q (0
≤ k ≤ n).

a, tau
Arrays:
a and tau are the arrays returned by sgeqrf / dgeqrf or sgeqpf / dgeqpf.
The size of $a$ is max(1, $lda*n$) for column major layout and max(1, $lda*m$) for row major layout.

The size of $tau$ must be at least max(1, $k$).

lda

The leading dimension of $a$; at least max(1, $m$) for column major layout and max(1, $n$) for row major layout.

Output Parameters

$a$

Overwritten by $n$ leading columns of the $m$-by-$m$ orthogonal matrix $Q$.

Return Values

This function returns a value $info$.

If $info=0$, the execution is successful.

If $info = -i$, the $i$-th parameter had an illegal value.

Application Notes

The computed $Q$ differs from an exactly orthogonal matrix by a matrix $E$ such that

$$||E||_2 = O(\varepsilon)||A||_2$$

where $\varepsilon$ is the machine precision.

The total number of floating-point operations is approximately $4*m*n*k - 2*(m + n)*k^2 + (4/3)*k^3$.

If $n = k$, the number is approximately $(2/3)*n^2*(3m - n)$.

The complex counterpart of this routine is ungqr.

?ormqr

Multiples a real matrix by the orthogonal matrix $Q$ of the QR factorization formed by ?geqrf or ?geqpf.

Syntax

```c
lapack_int LAPACKE_sormqr (int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int k, const float* a, lapack_int lda, const float* tau, float* c,
apack_int ldc);

lapack_int LAPACKE_dormqr (int matrix_layout, char side, char trans, lapack_int m,
apack_int n, lapack_int k, const double* a, lapack_int lda, const double* tau, double* c,
apack_int ldc);
```

Include Files

- mkl.h

Description

The routine multiplies a real matrix $C$ by $Q$ or $Q^T$, where $Q$ is the orthogonal matrix $Q$ of the QR factorization formed by the routine ?geqrf or ?geqpf.

Depending on the parameters side left_right and trans, the routine can form one of the matrix products $Q* C$, $Q^T * C$, $C* Q$, or $C^* Q^T$ (overwriting the result on $C$).

Input Parameters

matrix_layout

Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
**side**

Must be either 'L' or 'R'.

If side='L', Q or QT is applied to C from the left.
If side='R', Q or QT is applied to C from the right.

**trans**

Must be either 'N' or 'T'.

If trans='N', the routine multiplies C by Q.
If trans='T', the routine multiplies C by QT.

**m**

The number of rows in the matrix C (m ≥ 0).

**n**

The number of columns in C (n ≥ 0).

**k**

The number of elementary reflectors whose product defines the matrix Q.

Constraints:
0 ≤ k ≤ m if side='L';
0 ≤ k ≤ n if side='R'.

**a, tau, c**

Arrays:
a and tau are the arrays returned by sgeqrf / dgeqrf or sgeqpf / dgeqpf.
The size of a is max(1, lda*k) for column major layout, max(1, lda*m) for row major layout and side = 'L', and max(1, lda*n) for row major layout and side = 'R'.
The size of tau must be at least max(1, k).
Array c of size max(1, ldc*n) for column major layout and max(1, ldc*m) for row major layout contains the m-by-n matrix C.

**lda**

The leading dimension of a. Constraints:
if side = 'L', lda ≥ max(1, m) for column major layout and max(1, k) for row major layout;
if side = 'R', lda ≥ max(1, n) for column major layout and max(1, k) for row major layout.

**ldc**

The leading dimension of c. Constraint:
ldc ≥ max(1, m) for column major layout and max(1, n) for row major layout.

**Output Parameters**

**c**

Overwritten by the product Q*C, Q*T*C, C*Q, or C*Q*(Q as specified by side and trans).

**Return Values**

This function returns a value info.
If info=0, the execution is successful.
If info = -i, the i-th parameter had an illegal value.

**Application Notes**

The complex counterpart of this routine is unmqr.
Generates the complex unitary matrix $Q$ of the $QR$ factorization formed by \texttt{?geqrf}.

**Syntax**

```c
#include <mkl.h>

lapack_int LAPACKE_cungqr (int matrix_layout, lapack_int m, lapack_int n, lapack_int k,
lapack_complex_float* a, lapack_int lda, const lapack_complex_float* tau);

lapack_int LAPACKE_zungqr (int matrix_layout, lapack_int m, lapack_int n, lapack_int k,
lapack_complex_double* a, lapack_int lda, const lapack_complex_double* tau);
```

**Include Files**

- mkl.h

**Description**

The routine generates the whole or part of $m$-by-$m$ unitary matrix $Q$ of the $QR$ factorization formed by the routines \texttt{?geqrf} or \texttt{geqpf}. Use this routine after a call to \texttt{cgeqrf/zgeqrf} or \texttt{cgeqpf/zgeqpf}.

Usually $Q$ is determined from the $QR$ factorization of an $m$ by $p$ matrix $A$ with $m \geq p$. To compute the whole matrix $Q$, use:

```c
LAPACKE_?ungqr(matrix_layout, m, m, p, a, lda, tau)
```

To compute the leading $p$ columns of $Q$ (which form an orthonormal basis in the space spanned by the columns of $A$):

```c
LAPACKE_?ungqr(matrix_layout, m, p, p, a, lda, tau)
```

To compute the matrix $Q^k$ of the $QR$ factorization of the leading $k$ columns of the matrix $A$:

```c
LAPACKE_?ungqr(matrix_layout, m, m, k, a, lda, tau)
```

To compute the leading $k$ columns of $Q^k$ (which form an orthonormal basis in the space spanned by the leading $k$ columns of the matrix $A$):

```c
LAPACKE_?ungqr(matrix_layout, m, k, k, a, lda, tau)
```

**Input Parameters**

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **m**
  The order of the unitary matrix $Q$ ($m \geq 0$).

- **n**
  The number of columns of $Q$ to be computed ($0 \leq n \leq m$).

- **k**
  The number of elementary reflectors whose product defines the matrix $Q$ ($0 \leq k \leq n$).

- **a, tau**
  Arrays: $a$ and $tau$ are the arrays returned by \texttt{cgeqrf/zgeqrf} or \texttt{cgeqpf/zgeqpf}.

  The size of $a$ is max($1, lda*n$) for column major layout and max($1, lda*m$) for row major layout.

  The size of $tau$ must be at least max($1, k$).
The leading dimension of \( a \); at least \( \max(1, m) \) for column major layout and \( \max(1, n) \) for row major layout.

**Output Parameters**

\( a \)

**Return Values**

This function returns a value \( \text{info} \).

If \( \text{info}=0 \), the execution is successful.

If \( \text{info} = -i \), the \( i \)-th parameter had an illegal value.

**Application Notes**

The computed \( Q \) differs from an exactly unitary matrix by a matrix \( E \) such that \( \| E \|_2 = O(\varepsilon) \| A \|_2 \), where \( \varepsilon \) is the machine precision.

The total number of floating-point operations is approximately \( 16*m*n*k - 8*(m + n)*k^2 + (16/3)*k^3 \).

If \( n = k \), the number is approximately \( (8/3)*n^2*(3m - n) \).

The real counterpart of this routine is \text{orgqr}.

\text{?unmqr}

*Multiplies a complex matrix by the unitary matrix \( Q \) of the QR factorization formed by ?geqrf.*

**Syntax**

```c
lapack_int LAPACKE_cunmqr (int matrix_layout, char side, char trans, lapack_int m, lapack_int n, lapack_int k, const lapack_complex_float* a, lapack_int lda, const lapack_complex_float* tau, lapack_complex_float* c, lapack_int ldc);

lapack_int LAPACKE_zunmqr (int matrix_layout, char side, char trans, lapack_int m, lapack_int n, lapack_int k, const lapack_complex_double* a, lapack_int lda, const lapack_complex_double* tau, lapack_complex_double* c, lapack_int ldc);
```

**Include Files**

- mkl.h

**Description**

The routine multiplies a rectangular complex matrix \( C \) by \( Q \) or \( Q^H \), where \( Q \) is the unitary matrix \( Q \) of the QR factorization formed by the routines ?geqrf or geqpf.

Depending on the parameters \( \text{side} \) and \( \text{trans} \), the routine can form one of the matrix products \( Q^*C \), \( Q^H*C \), \( C^*Q \), or \( C^*Q^H \) (overwriting the result on \( C \)).

**Input Parameters**

\text{matrix_layout}

Specifies whether matrix storage layout is row major (\text{LAPACK\_ROW\_MAJOR}) or column major (\text{LAPACK\_COL\_MAJOR}).

\text{side}

Must be either \'L\' or \'R\'.

If \( \text{side} = \'L\' \), \( Q \) or \( Q^H \) is applied to \( C \) from the left.

If \( \text{side} = \'R\' \), \( Q \) or \( Q^H \) is applied to \( C \) from the right.
**trans**

Must be either 'N' or 'C'.

If $\text{trans} = 'N'$, the routine multiplies $C$ by $Q$.

If $\text{trans} = 'C'$, the routine multiplies $C$ by $Q^H$.

**m**

The number of rows in the matrix $C$ ($m \geq 0$).

**n**

The number of columns in $C$ ($n \geq 0$).

**k**

The number of elementary reflectors whose product defines the matrix $Q$.

Constraints:

$0 \leq k \leq m$ if $\text{side} = 'L'$;

$0 \leq k \leq n$ if $\text{side} = 'R'$.

**a, c, tau**

Arrays:

$a$ size $\max(1, lda \times k)$ for column major layout, $\max(1, lda \times m)$ for row major layout when $\text{side} = 'L'$, and $\max(1, lda \times n)$ for row major layout when $\text{side} = 'R'$ and $\tau$ are the arrays returned by $\text{cgeqrf} / \text{zgeqrf}$ or $\text{cgeqpf} / \text{zgeqpf}$.

The size of $\tau$ must be at least $\max(1, k)$.

$c$ size $\max(1, ldc \times n)$ for column major layout and $\max(1, ldc \times m)$ for row major layout) contains the $m$-by-$n$ matrix $C$.

**lda**

The leading dimension of $a$. Constraints:

$lda \geq \max(1, m)$ for column major layout and $lda \geq \max(1, k)$ for row major layout if $\text{side} = 'L'$;

$lda \geq \max(1, n)$ for column major layout and $lda \geq \max(1, k)$ for row major layout if $\text{side} = 'R'$.

**ldc**

The leading dimension of $c$. Constraint:

$ldc \geq \max(1, m)$ for column major layout and $\max(1, n)$ for row major layout.

**Output Parameters**

**c**

Overwritten by the product $Q\times C$, $Q^H\times C$, $C\times Q$, or $C\times Q^H$ (as specified by $\text{side}$ and $\text{trans}$).

**Return Values**

This function returns a value $info$.

If $info=0$, the execution is successful.

If $info = -i$, the $i$-th parameter had an illegal value.

**Application Notes**

The real counterpart of this routine is $\text{ormqr}$.

$\text{?gelqf}$

*Computes the LQ factorization of a general $m$-by-$n$ matrix.*
Syntax

```c
lapack_int LAPACKE_sgelqf (int matrix_layout, lapack_int m, lapack_int n, float* a,
                           lapack_int lda, float* tau);

lapack_int LAPACKE_dgelqf (int matrix_layout, lapack_int m, lapack_int n, double* a,
                           lapack_int lda, double* tau);

lapack_int LAPACKE_cgelqf (int matrix_layout, lapack_int m, lapack_int n,
                           lapack_complex_float* a, lapack_int lda, lapack_complex_float* tau);

lapack_int LAPACKE_zgelqf (int matrix_layout, lapack_int m, lapack_int n,
                           lapack_complex_double* a, lapack_int lda, lapack_complex_double* tau);
```

Include Files

- mkl.h

Description

The routine forms the $LQ$ factorization of a general $m$-by-$n$ matrix $A$ (see Orthogonal Factorizations). No pivoting is performed.

The routine does not form the matrix $Q$ explicitly. Instead, $Q$ is represented as a product of $\min(m, n)$ elementary reflectors. Routines are provided to work with $Q$ in this representation.

NOTE
This routine supports the Progress Routine feature. See Progress Function section for details.

Input Parameters

- `matrix_layout` Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- `m` The number of rows in the matrix $A$ ($m \geq 0$).

- `n` The number of columns in $A$ ($n \geq 0$).

- `a` Array $a$ of size $\max(1, lda*n)$ for column major layout and $\max(1, lda*m)$ for row major layout contains the matrix $A$.

- `lda` The leading dimension of $a$; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout.

Output Parameters

- `a` Overwritten by the factorization data as follows:
  The elements on and below the diagonal of the array contain the $m$-by-$\min(m,n)$ lower trapezoidal matrix $L$ ($L$ is lower triangular if $m \leq n$); the elements above the diagonal, with the array `tau`, represent the orthogonal matrix $Q$ as a product of elementary reflectors.

- `tau` Array, size at least $\max(1, \min(m, n))$.
  Contains scalars that define elementary reflectors for the matrix $Q$ (see Orthogonal Factorizations).
Return Values
This function returns a value info.
If info=0, the execution is successful.
If info = -i, the i-th parameter had an illegal value.

Application Notes
The computed factorization is the exact factorization of a matrix \( A + E \), where
\[
||E||_2 = O(\varepsilon) \quad ||A||_2.
\]
The approximate number of floating-point operations for real flavors is
\[
\begin{align*}
(4/3)n^3 & \quad \text{if } m = n, \\
(2/3)n^2(3m-n) & \quad \text{if } m > n, \\
(2/3)m^2(3n-m) & \quad \text{if } m < n.
\end{align*}
\]
The number of operations for complex flavors is 4 times greater.
To find the minimum-norm solution of an underdetermined least squares problem minimizing \( ||Ax - b||_2 \) for all columns \( b \) of a given matrix \( B \), you can call the following:
- ?gelqf (this routine) to factorize \( A = LQ \);
- trsm (a BLAS routine) to solve \( Ly = B \) for \( Y \);
- ormlq to compute \( X = (Q_1)^T Y \) (for real matrices);
- unmlq to compute \( X = (Q_1)^H Y \) (for complex matrices).
(The columns of the computed \( X \) are the minimum-norm solution vectors \( x \). Here \( A \) is an \( m \)-by-\( n \) matrix with \( m < n \); \( Q_1 \) denotes the first \( m \) columns of \( Q \).
To compute the elements of \( Q \) explicitly, call
- orglq (for real matrices)
- ungq (for complex matrices).

See Also
- mkl_progress

Matrix Storage Schemes

?orglq
Generates the real orthogonal matrix \( Q \) of the \( LQ \) factorization formed by ?gelqf.

Syntax
- \[
\text{lapack_int LAPACKE_sorglq (int matrix_layout, lapack_int m, lapack_int n, lapack_int k, float* a, lapack_int lda, const float* tau);}
\]
- \[
\text{lapack_int LAPACKE_dorglq (int matrix_layout, lapack_int m, lapack_int n, lapack_int k, double* a, lapack_int lda, const double* tau);}
\]
Include Files

- mkl.h

Description

The routine generates the whole or part of \( n \)-by-\( n \) orthogonal matrix \( Q \) of the \( LQ \) factorization formed by the routines \texttt{gelqf}. Use this routine after a call to \texttt{sgelqf/dgelqf}.

Usually \( Q \) is determined from the \( LQ \) factorization of an \( p \)-by-\( n \) matrix \( A \) with \( n \geq p \). To compute the whole matrix \( Q \), use:

\[
\text{info} = \text{LAPACKE}_?orglq(matrix\_layout, n, n, p, a, lda, tau)
\]

To compute the leading \( p \) rows of \( Q \), which form an orthonormal basis in the space spanned by the rows of \( A \), use:

\[
\text{info} = \text{LAPACKE}_?orglq(matrix\_layout, p, n, p, a, lda, tau)
\]

To compute the matrix \( Q^k \) of the \( LQ \) factorization of the leading \( k \) rows of \( A \), use:

\[
\text{info} = \text{LAPACKE}_?orglq(matrix\_layout, n, n, k, a, lda, tau)
\]

To compute the leading \( k \) rows of \( Q^k \), which form an orthonormal basis in the space spanned by the leading \( k \) rows of \( A \), use:

\[
\text{info} = \text{LAPACKE}_?orgqr(matrix\_layout, k, n, k, a, lda, tau)
\]

Input Parameters

- \texttt{matrix\_layout}:
  Specifies whether matrix storage layout is row major (\texttt{LAPACK\_ROW\_MAJOR}) or column major (\texttt{LAPACK\_COL\_MAJOR}).

- \texttt{m}:
  The number of rows of \( Q \) to be computed \((0 \leq m \leq n)\).

- \texttt{n}:
  The order of the orthogonal matrix \( Q \) \((n \geq m)\).

- \texttt{k}:
  The number of elementary reflectors whose product defines the matrix \( Q \) \((0 \leq k \leq m)\).

- \texttt{a}, \texttt{tau}:
  Arrays: \texttt{a} \((\text{size max}(1, lda*n) \text{ for column major layout and max}(1, lda*m) \text{ for row major layout})\) and \texttt{tau} are the arrays returned by \texttt{sgelqf/dgelqf}.
  The size of \texttt{tau} must be at least \text{max}(1, k).

- \texttt{lda}:
  The leading dimension of \texttt{a}; at least \text{max}(1, k) for column major layout and \text{max}(1, n) for row major layout.

Output Parameters

- \texttt{a}:
  Overwritten by \( m \) leading rows of the \( n \)-by-\( n \) orthogonal matrix \( Q \).

Return Values

This function returns a value \texttt{info}.

If \texttt{info}=0, the execution is successful.

If \texttt{info} = \(-i\), the \( i\)-th parameter had an illegal value.
Application Notes

The computed $Q$ differs from an exactly orthogonal matrix by a matrix $E$ such that $||E||_2 = O(\varepsilon) * ||A||_2$, where $\varepsilon$ is the machine precision.

The total number of floating-point operations is approximately $4*m*n*k - 2*(m + n)*k^2 + (4/3)*k^3$.

If $m = k$, the number is approximately $(2/3)*m^2*(3n - m)$.

The complex counterpart of this routine is ?unglq.

?ormlq
Multiplies a real matrix by the orthogonal matrix Q of the LQ factorization formed by ?gelqf.

Syntax

```c
lapack_int LAPACKE_sormlq (int matrix_layout, char side, char trans, lapack_int m, lapack_int n, lapack_int k, const float* a, lapack_int lda, const float* tau, float* c, lapack_int ldc);

lapack_int LAPACKE_dormlq (int matrix_layout, char side, char trans, lapack_int m, lapack_int n, lapack_int k, const double* a, lapack_int lda, const double* tau, double* c, lapack_int ldc);
```

Include Files

- mkl.h

Description

The routine multiplies a real $m$-by-$n$ matrix $C$ by $Q$ or $Q^T$, where $Q$ is the orthogonal matrix $Q$ of the $LQ$ factorization formed by the routine ?gelqf.

Depending on the parameters side and trans, the routine can form one of the matrix products $Q*C$, $Q^T*C$, $C*Q$, or $C^*Q^T$ (overwriting the result on $C$).

Input Parameters

- `matrix_layout` Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- side Must be either 'L' or 'R'.
  - If `side` = 'L', $Q$ or $Q^T$ is applied to $C$ from the left.
  - If `side` = 'R', $Q$ or $Q^T$ is applied to $C$ from the right.

- trans Must be either 'N' or 'T'.
  - If `trans` = 'N', the routine multiplies $C$ by $Q$.
  - If `trans` = 'T', the routine multiplies $C$ by $Q^T$.

- `m` The number of rows in the matrix $C$ ($m \geq 0$).

- `n` The number of columns in $C$ ($n \geq 0$).

- `k` The number of elementary reflectors whose product defines the matrix $Q$.

Constraints:

- $0 \leq k \leq m$ if `side` = 'L';
0 ≤ k ≤ n if side = 'R'.

Arrays:

a and tau are arrays returned by ?gelqf.

The size of a must be:

For side = 'L' and column major layout, max(1, lda*m).
For side = 'R' and column major layout, max(1, lda*n).
For row major layout regardless of side, max(1, lda*k).

The dimension of tau must be at least max(1, k).

c(size max(1, ldc*n) for column major layout and max(1, ldc*m for row major layout) contains the m-by-n matrix C.

Output Parameters

c

Overwritten by the product Q* C, Q^T* C, C* Q, or C* Q^T (as specified by side and trans).

Return Values

This function returns a value info.
If info=0, the execution is successful.
If info = -i, the i-th parameter had an illegal value.

Application Notes

The complex counterpart of this routine is unmlq.

?unglq
Generates the complex unitary matrix Q of the LQ factorization formed by ?gelqf.

Syntax

lapack_int LAPACKE_cunglq (int matrix_layout, lapack_int m, lapack_int n, lapack_int k, lapack_complex_float* a, lapack_int lda, const lapack_complex_float* tau);

lapack_int LAPACKE_zunglq (int matrix_layout, lapack_int m, lapack_int n, lapack_int k, lapack_complex_double* a, lapack_int lda, const lapack_complex_double* tau);

Include Files

• mkl.h

Description
The routine generates the whole or part of \( n \times n \) unitary matrix \( Q \) of the \( LQ \) factorization formed by the routines \texttt{gelqf}. Use this routine after a call to \texttt{cgelqf/zgelqf}.

Usually \( Q \) is determined from the \( LQ \) factorization of an \( p \times n \) matrix \( A \) with \( n < p \). To compute the whole matrix \( Q \), use:

```plaintext
info = LAPACKE_?unglq(matrix_layout, n, n, p, a, lda, tau)
```

To compute the leading \( p \) rows of \( Q \), which form an orthonormal basis in the space spanned by the rows of \( A \), use:

```plaintext
info = LAPACKE_?unglq(matrix_layout, p, n, p, a, lda, tau)
```

To compute the matrix \( Q^k \) of the \( LQ \) factorization of the leading \( k \) rows of \( A \), use:

```plaintext
info = LAPACKE_?unglq(matrix_layout, n, n, k, a, lda, tau)
```

To compute the leading \( k \) rows of \( Q^k \), which form an orthonormal basis in the space spanned by the leading \( k \) rows of \( A \), use:

```plaintext
info = LAPACKE_?ungqr(matrix_layout, k, n, k, a, lda, tau)
```

### Input Parameters

- **matrix_layout**
  - Specifies whether matrix storage layout is row major (\texttt{LAPACK_ROW_MAJOR}) or column major (\texttt{LAPACK_COL_MAJOR}).

- **m**
  - The number of rows of \( Q \) to be computed (\( 0 \leq m \leq n \)).

- **n**
  - The order of the unitary matrix \( Q \) (\( n \geq m \)).

- **k**
  - The number of elementary reflectors whose product defines the matrix \( Q \) (\( 0 \leq k \leq m \)).

- **a, tau**
  - Arrays: \( a \) (size \( \max(1, \text{lda} \times n) \) for column major layout and \( \max(1, \text{lda} \times m) \) for row major layout) and \( tau \) are the arrays returned by \texttt{cgelqf/zgelqf}.
  - The dimension of \( tau \) must be at least \( \max(1, k) \).

- **lda**
  - The leading dimension of \( a \); at least \( \max(1, k) \) for column major layout and \( \max(1, n) \) for row major layout.

### Output Parameters

- **a**
  - Overwritten by \( m \) leading rows of the \( n \times n \) unitary matrix \( Q \).

### Return Values

This function returns a value \( info \).

- If \( info = 0 \), the execution is successful.
- If \( info = -i \), the \( i \)-th parameter had an illegal value.

### Application Notes

The computed \( Q \) differs from an exactly unitary matrix by a matrix \( E \) such that \( \| E \|_2 = O(\varepsilon) \times \| A \|_2 \)

where \( \varepsilon \) is the machine precision.

The total number of floating-point operations is approximately \( 16 \times m \times n \times k - 8 \times (m + n) \times k^2 + (16/3) \times k^3 \).

If \( m = k \), the number is approximately \((8/3) \times m^2 \times (3n - m)\).

The real counterpart of this routine is \texttt{orglq}. 

746
?unmlq
Multiplies a complex matrix by the unitary matrix Q of the LQ factorization formed by ?gelqf.

Syntax

```c
lapack_int LAPACKE_cunmlq (int matrix_layout, char side, char trans, lapack_int m, lapack_int n, lapack_int k, const lapack_complex_float* a, lapack_int lda, const lapack_complex_float* tau, lapack_complex_float* c, lapack_int ldc);
```

```c
lapack_int LAPACKE_zunmlq (int matrix_layout, char side, char trans, lapack_int m, lapack_int n, lapack_int k, const lapack_complex_double* a, lapack_int lda, const lapack_complex_double* tau, lapack_complex_double* c, lapack_int ldc);
```

Include Files

- mkl.h

Description

The routine multiplies a real m-by-n matrix C by Q or Q^H, where Q is the unitary matrix Q of the LQ factorization formed by the routine gelqf.

Depending on the parameters side and trans, the routine can form one of the matrix products Q*C, Q^H*C, C*Q, or C*Q^H (overwriting the result on C).

Input Parameters

- `matrix_layout`
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- `side`
  Must be either 'L' or 'R'.
  - If side = 'L', Q or Q^H is applied to C from the left.
  - If side = 'R', Q or Q^H is applied to C from the right.

- `trans`
  Must be either 'N' or 'C'.
  - If trans = 'N', the routine multiplies C by Q.
  - If trans = 'C', the routine multiplies C by Q^H.

- `m`
  The number of rows in the matrix C (m ≥ 0).

- `n`
  The number of columns in C (n ≥ 0).

- `k`
  The number of elementary reflectors whose product defines the matrix Q. Constraints:
  - 0 ≤ k ≤ m if side = 'L';
  - 0 ≤ k ≤ n if side = 'R'.

- `a`, `c`, `tau`
  Arrays:
  - `a` and `tau` are arrays returned by ?gelqf.
  - The size of `a` must be:
    - For side = 'L' and column major layout, max(1, lda*m).
    - For side = 'R' and column major layout, max(1, lda*n).
For row major layout regardless of side, max(1, lda*k).
The size of tau must be at least max(1, k).
c(size max(1, ldc*n) for column major layout and max(1, ldc*m for row major layout) contains the m-by-n matrix C.

lda
The leading dimension of a. For column major layout, lda≥ max(1, k). For row major layout, if side = 'L', lda≥ max(1, m), or, if side = 'R', lda≥ max(1, n).

ldc
The leading dimension of c; ldc≥ max(1, m) for column major layout and max(1, n) for row major layout.

Output Parameters

c
Overwritten by the product Q*C, Q^H*C, C*Q, or C*Q^H (as specified by side and trans).

Return Values

This function returns a value info.
If info=0, the execution is successful.
If info = -i, the i-th parameter had an illegal value.

Application Notes

The real counterpart of this routine is ormlq.

?geqlf
Computes the QL factorization of a general m-by-n matrix.

Syntax

lapack_int LAPACKE_sgelqf (int matrix_layout, lapack_int m, lapack_int n, float* a, lapack_int lda, float* tau);

lapack_int LAPACKE_dgelqf (int matrix_layout, lapack_int m, lapack_int n, double* a, lapack_int lda, double* tau);

lapack_int LAPACKE_cgelqf (int matrix_layout, lapack_int m, lapack_int n, lapack_complex_float* a, lapack_int lda, lapack_complex_float* tau);

lapack_int LAPACKE_zgelqf (int matrix_layout, lapack_int m, lapack_int n, lapack_complex_double* a, lapack_int lda, lapack_complex_double* tau);

Include Files

• mkl.h

Description

The routine forms the QL factorization of a general m-by-n matrix A (see Orthogonal Factorizations). No pivoting is performed.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of min(m, n) elementary reflectors. Routines are provided to work with Q in this representation.
NOTE
This routine supports the Progress Routine feature. See Progress Function section for details.

Input Parameters

matrix_layout
Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

m
The number of rows in the matrix \( A \) (\( m \geq 0 \)).

n
The number of columns in \( A \) (\( n \geq 0 \)).

a
Array \( a \) of size \( \max(1, lda*n) \) for column major layout and \( \max(1, lda*m) \) for row major layout contains the matrix \( A \).

lda
The leading dimension of \( a \); at least \( \max(1, m) \) for column major layout and \( \max(1, n) \) for row major layout.

Output Parameters

a
Overwritten on exit by the factorization data as follows:
if \( m \geq n \), the lower triangle of the subarray \( a(m-n+1:m, 1:n) \) contains the \( n \)-by-\( n \) lower triangular matrix \( L \); if \( m \leq n \), the elements on and below the \( (n-m) \)-th superdiagonal contain the \( m \)-by-\( n \) lower trapezoidal matrix \( L \); in both cases, the remaining elements, with the array \( tau \), represent the orthogonal/unitary matrix \( Q \) as a product of elementary reflectors.

tau
Array, size at least \( \max(1, \min(m, n)) \). Contains scalar factors of the elementary reflectors for the matrix \( Q \) (see Orthogonal Factorizations).

Return Values
This function returns a value \( info \).
If \( info=0 \), the execution is successful.
If \( info = -i \), the \( i \)-th parameter had an illegal value.

Application Notes
Related routines include:

- orgql to generate matrix \( Q \) (for real matrices);
- ungql to generate matrix \( Q \) (for complex matrices);
- ormql to apply matrix \( Q \) (for real matrices);
- unmql to apply matrix \( Q \) (for complex matrices).

See Also
mkl_progress

Matrix Storage Schemes
?orgql
Generates the real matrix Q of the QL factorization formed by ?geqlf.

Syntax

lapack_int LAPACKE_sorgql (int matrix_layout, lapack_int m, lapack_int n, lapack_int k,
float* a, lapack_int lda, const float* tau);

lapack_int LAPACKE_dorgql (int matrix_layout, lapack_int m, lapack_int n, lapack_int k,
double* a, lapack_int lda, const double* tau);

Include Files

• mkl.h

Description

The routine generates an m-by-n real matrix Q with orthonormal columns, which is defined as the last n columns of a product of k elementary reflectors \( H(i) \) of order m: \( Q = H(k) \cdots H(2)H(1) \) as returned by the routines ?geqlf. Use this routine after a call to ?sgeqlf/dgeqlf.

Input Parameters

- **matrix_layout**
  Specifications whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **m**
  The number of rows of the matrix Q (\( m \geq 0 \)).

- **n**
  The number of columns of the matrix Q (\( m \geq n \geq 0 \)).

- **k**
  The number of elementary reflectors whose product defines the matrix Q (\( n \geq k \geq 0 \)).

- **a, tau**
  Arrays: a (size max(1, lda*n) for column major layout and max(1, lda*m) for row major layout), tau.
  On entry, the (n - k + i)th column of a must contain the vector which defines the elementary reflector \( H(i) \), for \( i = 1,2,\ldots,k \), as returned by ?sgeqlf/dgeqlf in the last k columns of its array argument a; tau[i - 1] must contain the scalar factor of the elementary reflector \( H(i) \), as returned by ?sgeqlf/dgeqlf;
  The size of tau must be at least max(1, k).

- **lda**
  The leading dimension of a; at least max(1, m) for column major layout and max(1, n) for row major layout.

Output Parameters

- **a**
  Overwritten by the last n columns of the m-by-m orthogonal matrix Q.

Return Values

This function returns a value info.
If info=0, the execution is successful.
If info = -i, the i-th parameter had an illegal value.
Application Notes
The complex counterpart of this routine is ungql.

?ungql
Generates the complex matrix Q of the QL factorization formed by ?geqlf.

Syntax

```c
lapack_int LAPACKE_cungql (int matrix_layout, lapack_int m, lapack_int n, lapack_int k,
                         lapack_complex_float* a, lapack_int lda, const lapack_complex_float* tau);
```

```c

                         lapack_complex_double* a, lapack_int lda, const lapack_complex_double* tau);
```

Include Files

- mkl.h

Description

The routine generates an m-by-n complex matrix Q with orthonormal columns, which is defined as the last n columns of a product of k elementary reflectors \( H(i) \) of order m: \( Q = H(k) \cdots H(2)H(1) \) as returned by the routines geqlf/zgeqlf. Use this routine after a call to cgeqlf/zgeqlf.

Input Parameters

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **m**
  The number of rows of the matrix Q \((m\geq 0)\).

- **n**
  The number of columns of the matrix Q \((m\geq n\geq 0)\).

- **k**
  The number of elementary reflectors whose product defines the matrix Q \((n\geq k \geq 0)\).

- **a, tau**
  Arrays: a (size max(1, lda*n) for column major layout and max(1, lda*m) for row major layout), tau.
  On entry, the \((n - k + i)\)th column of a must contain the vector which defines the elementary reflector \( H(i) \), for i = 1,2,...,k, as returned by cgeqlf/zgeqlf in the last k columns of its array argument a;
  \( tau[i - 1] \) must contain the scalar factor of the elementary reflector \( H(i) \), as returned by cgeqlf/zgeqlf;
  The size of \( tau \) must be at least max(1, k).

- **lda**
  The leading dimension of a; at least max(1, m) for column major layout and max(1, n) for row major layout.

Output Parameters

- **a**
  Overwritten by the last n columns of the m-by-m unitary matrix Q.

Return Values

This function returns a value info.
If info=0, the execution is successful.
If info = -i, the i-th parameter had an illegal value.

Application Notes
The real counterpart of this routine is orgql.

.ormql
Multiplying a real matrix by the orthogonal matrix Q of the QL factorization formed by ?geqlf.

Syntax

```c
lapack_int LAPACKE_sormql (int matrix_layout, char side, char trans, lapack_int m, lapack_int n, lapack_int k, const float* a, lapack_int lda, const float* tau, float* c, lapack_int ldc);
```

Include Files
- mkl.h

Description
The routine multiplies a real m-by-n matrix C by Q or QT, where Q is the orthogonal matrix Q of the QL factorization formed by the routine geqlf.

Depending on the parameters side and trans, the routine ormlq can form one of the matrix products Q*C, Q^T*C, C*Q, or C*Q^T (overwriting the result over C).

Input Parameters

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **side**
  Must be either 'L' or 'R'.
  - If side = 'L', Q or QT is applied to C from the left.
  - If side = 'R', Q or QT is applied to C from the right.

- **trans**
  Must be either 'N' or 'T'.
  - If trans = 'N', the routine multiplies C by Q.
  - If trans = 'T', the routine multiplies C by QT.

- **m**
  The number of rows in the matrix C (m ≥ 0).

- **n**
  The number of columns in C (n ≥ 0).

- **k**
  The number of elementary reflectors whose product defines the matrix Q.
  Constraints:
  - 0 ≤ k ≤ m if side = 'L';
  - 0 ≤ k ≤ n if side = 'R'.

752
Arrays: $a$, $\tau$, $c$.

The size of $a$ must be:

For column major layout regardless of $\text{side}$, $\max(1, \text{lda} \times k)$.

For $\text{side} = \text{'L'}$ and row major layout, $\max(1, \text{lda} \times m)$.

For $\text{side} = \text{'R'}$ and row major layout, $\max(1, \text{lda} \times n)$.

On entry, the $i$th column of $a$ must contain the vector which defines the elementary reflector $H_i$, for $i = 1, 2, ..., k$, as returned by \texttt{sgeqlf/dgeqlf} in the last $k$ columns of its array argument $a$.

$\tau[i-1]$ must contain the scalar factor of the elementary reflector $H_i$, as returned by \texttt{sgeqlf/dgeqlf}.

The size of $\tau$ must be at least $\max(1, k)$.

$c$(size $\max(1, \text{ldc} \times n)$ for column major layout and $\max(1, \text{ldc} \times m)$ for row major layout) contains the $m$-by-$n$ matrix $C$.

$\text{lda}$

The leading dimension of $a$;

if $\text{side} = \text{'L'}$, $\text{lda} \geq \max(1, m)$ for column major layout and $\max(1, k)$ for row major layout;

if $\text{side} = \text{'R'}$, $\text{lda} \geq \max(1, n)$ for column major layout and $\max(1, k)$ for row major layout.

$\text{ldc}$

The leading dimension of $c$; $\text{ldc} \geq \max(1, m)$ for column major layout and $\max(1, n)$ for row major layout.

Output Parameters

$c$

Overwritten by the product $Q^*C$, $Q^*C$, $C^*Q$, or $C^*Q^*$ (as specified by $\text{side}$ and $\text{trans}$).

Return Values

This function returns a value $\text{info}$.

If $\text{info}=0$, the execution is successful.

If $\text{info} = -i$, the $i$-th parameter had an illegal value.

Application Notes

The complex counterpart of this routine is \texttt{unmql}.

\texttt{?unmql}

\textit{Multiplies a complex matrix by the unitary matrix $Q$ of the QL factorization formed by \texttt{?geqlf}.}

Syntax

\begin{verbatim}
lapack_int LAPACKE_cunmql (int matrix_layout, char side, char trans, lapack_int m, lapack_int n, lapack_int k, const lapack_complex_float* a, lapack_int lda, const lapack_complex_float* tau, lapack_complex_float* c, lapack_int ldc);

lapack_int LAPACKE_zunmql (int matrix_layout, char side, char trans, lapack_int m, lapack_int n, lapack_int k, const lapack_complex_double* a, lapack_int lda, const lapack_complex_double* tau, lapack_complex_double* c, lapack_int ldc);
\end{verbatim}
Include Files

• mkl.h

Description

The routine multiplies a complex $m$-by-$n$ matrix $C$ by $Q$ or $Q^H$, where $Q$ is the unitary matrix $Q$ of the $QL$ factorization formed by the routine geqlf.

Depending on the parameters $side$ and $trans$, the routine unmql can form one of the matrix products $Q*C$, $Q^H*C$, $C*Q$, or $C*Q^H$ (overwriting the result over $C$).

Input Parameters

(matrix_layout)

Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

(side)

Must be either 'L' or 'R'.

If $side$ = 'L', $Q$ or $Q^H$ is applied to $C$ from the left.

If $side$ = 'R', $Q$ or $Q^H$ is applied to $C$ from the right.

(trans)

Must be either 'N' or 'C'.

If $trans$ = 'N', the routine multiplies $C$ by $Q$.

If $trans$ = 'C', the routine multiplies $C$ by $Q^H$.

$m$

The number of rows in the matrix $C$ ($m \geq 0$).

$n$

The number of columns in $C$ ($n \geq 0$).

$k$

The number of elementary reflectors whose product defines the matrix $Q$.

Constraints:

$0 \leq k \leq m$ if $side$ = 'L';

$0 \leq k \leq n$ if $side$ = 'R'.

(a, tau, c)

Arrays: $a$, $tau$, $c$.

The size of $a$ must be:

For column major layout regardless of $side$, max(1, $lda*k$).

For $side$ = 'L' and row major layout, max(1, $lda*m$).

For $side$ = 'R' and row major layout, max(1, $lda*n$).

On entry, the $i$-th column of $a$ must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, ..., k$, as returned by cgeqlf/zgeqlf in the last $k$ columns of its array argument $a$.

$tau[i - 1]$ must contain the scalar factor of the elementary reflector $H(i)$, as returned by cgeqlf/zgeqlf.

The size of $tau$ must be at least max(1, $k$).

$c$(size max(1, $ldc*n$) for column major layout and max(1, $ldc*m$ for row major layout) contains the $m$-by-$n$ matrix $C$.

$lda$

The leading dimension of $a$. 

If \( \text{side} = 'L' \), \( \text{lda} \geq \max(1, \ m) \) for column major layout and \( \max(1, \ k) \) for row major layout.

If \( \text{side} = 'R' \), \( \text{lda} \geq \max(1, \ n) \) for column major layout and \( \max(1, \ k) \) for row major layout.

\( \text{ldc} \)

The leading dimension of \( c \); \( \text{ldc} \geq \max(1, \ m) \) for column major layout and \( \max(1, \ n) \) for row major layout.

**Output Parameters**

\( c \)

Overwritten by the product \( Q*C, Q^H*C, C*Q \), or \( C*Q^H \) (as specified by \( \text{side} \) and \( \text{trans} \)).

**Return Values**

This function returns a value \( \text{info} \).

If \( \text{info}=0 \), the execution is successful.

If \( \text{info} = -i \), the \( i \)-th parameter had an illegal value.

**Application Notes**

The real counterpart of this routine is \texttt{ormql}.

\texttt{?gerqf}

*Computes the RQ factorization of a general \( m \)-by-\( n \) matrix.*

**Syntax**

\[

\text{lapack_int LAPACKE_zgerqf} & \quad (\text{int } \text{matrix_layout}, \text{lapack_int } m, \text{lapack_int } n, \\
& \quad \text{lapack_complex_double* } a, \text{lapack_int } \text{lda}, \text{lapack_complex_double* } \text{tau});
\end{align*}
\]

**Include Files**

- \texttt{mkl.h}

**Description**

The routine forms the \( RQ \) factorization of a general \( m \)-by-\( n \) matrix \( A \) (see Orthogonal Factorizations). No pivoting is performed.

The routine does not form the matrix \( Q \) explicitly. Instead, \( Q \) is represented as a product of \( \min(m, n) \) \textit{elementary reflectors}. Routines are provided to work with \( Q \) in this representation.

\textbf{NOTE}

This routine supports the Progress Routine feature. See Progress Function section for details.
Input Parameters

\textit{matrix\_layout} Specifies whether matrix storage layout is row major (LAPACK\_ROW\_MAJOR) or column major (LAPACK\_COL\_MAJOR).

\textit{m} The number of rows in the matrix \( A \) (\( m \geq 0 \)).

\textit{n} The number of columns in \( A \) (\( n \geq 0 \)).

\textit{a} Array \( a \) of size \( \max(1, lda \times n) \) for column major layout and \( \max(1, lda \times m) \) for row major layout contains the \( m \)-by-\( n \) matrix \( A \).

\textit{lda} The leading dimension of \( a \); at least \( \max(1, m) \) for column major layout and \( \max(1, n) \) for row major layout.

Output Parameters

\textit{a} Overwritten on exit by the factorization data as follows:

- if \( m \leq n \), the upper triangle of the subarray \( a(1:m, n-m+1:n) \) contains the \( m \)-by-\( m \) upper triangular matrix \( R \);
- if \( m \geq n \), the elements on and above the \((m-n)\)th subdiagonal contain the \( m \)-by-\( n \) upper trapezoidal matrix \( R \);

in both cases, the remaining elements, with the array \( \tau \), represent the orthogonal/unitary matrix \( Q \) as a product of \( \min(m, n) \) elementary reflectors.

\textit{tau} Array, size at least \( \max(1, \min(m, n)) \). (See Orthogonal Factorizations.)

Contains scalar factors of the elementary reflectors for the matrix \( Q \).

Return Values

This function returns a value \( info \).

If \( info=0 \), the execution is successful.

If \( info = -i \), the \( i \)-th parameter had an illegal value.

Description

The routine generates an m-by-n real matrix with orthonormal rows, which is defined as the last m rows of a
product of k elementary reflectors H(i) of order n: Q = H(1)* H(2)*...*H(k) as returned by the routines
gerqf. Use this routine after a call to sgerqf/dgerqf.

Input Parameters

- `matrix_layout`: Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR)
  or column major (LAPACK_COL_MAJOR).
- `m`: The number of rows of the matrix Q (m ≥ 0).
- `n`: The number of columns of the matrix Q (n ≥ m).
- `k`: The number of elementary reflectors whose product defines the matrix Q
  (m ≥ k ≥ 0).
- `a, tau`: Arrays: a(size max(1, lda*n) for column major layout and max(1, lda*m)
  for row major layout), tau.

  On entry, the (m - k + i)-th row of a must contain the vector which defines
  the elementary reflector H(i), for i = 1,2,...,k, as returned by sgerqf/
dgerqf in the last k rows of its array argument a;

  tau[i - 1] must contain the scalar factor of the elementary reflector H(i),
  as returned by sgerqf/dgerqf;

  The size of tau must be at least max(1, k).

- `lda`: The leading dimension of a; at least max(1, m)for column major layout and
  max(1, n) for row major layout.

Output Parameters

- `a`: Overwritten by the last m rows of the n-by-n orthogonal matrix Q.

Return Values

This function returns a value info.

If info=0, the execution is successful.

If info = -i, the i-th parameter had an illegal value.
Application Notes

The complex counterpart of this routine is `ungrq`.

`?ungrq`  
*Generates the complex matrix Q of the RQ factorization formed by ?gerqf.*

Syntax

```c
lapack_int LAPACKE_cungrq (int matrix_layout, lapack_int m, lapack_int n, lapack_int k, 
lapack_complex_float* a, lapack_int lda, const lapack_complex_float* tau);

lapack_int LAPACKE_zungrq (int matrix_layout, lapack_int m, lapack_int n, lapack_int k, 
lapack_complex_double* a, lapack_int lda, const lapack_complex_double* tau);
```

Include Files

- `mkl.h`

Description

The routine generates an \( m \)-by-\( n \) complex matrix with orthonormal rows, which is defined as the last \( m \) rows of a product of \( k \) elementary reflectors \( H(i) \) of order \( n \): 

\[
Q = \prod_{i=1}^{k} H(i)^H
\]

as returned by the routines `gerqf`. Use this routine after a call to `cgerqf/zgerqf`.

Input Parameters

- `matrix_layout`  
  Specifies whether matrix storage layout is row major (`LAPACK_ROW_MAJOR`) or column major (`LAPACK_COL_MAJOR`).
- `m`  
  The number of rows of the matrix \( Q \) (\( m \geq 0 \)).
- `n`  
  The number of columns of the matrix \( Q \) (\( n \geq m \)).
- `k`  
  The number of elementary reflectors whose product defines the matrix \( Q \) (\( m \geq k \geq 0 \)).
- `a`, `tau`  
  Arrays: \( a \) (size max(1, \( lda \times n \)) for column major layout and max(1, \( lda \times m \)) for row major layout), \( tau \).
  On entry, the \( (m - k + i) \)th row of \( a \) must contain the vector which defines the elementary reflector \( H(i) \), for \( i = 1,2,...,k \), as returned by `cgerqf/zgerqf` in the last \( k \) rows of its array argument \( a \);
  \( tau[i - 1] \) must contain the scalar factor of the elementary reflector \( H(i) \), as returned by `cgerqf/zgerqf`;
  The size of \( tau \) must be at least max(1, \( k \)).
- `lda`  
  The leading dimension of \( a \); at least max(1, \( m \)) for column major layout and max(1, \( n \)) for row major layout.

Output Parameters

- `a`  
  Overwritten by the \( m \) last rows of the \( n \)-by-\( n \) unitary matrix \( Q \).

Return Values

This function returns a value \( info \).
If $\text{info}=0$, the execution is successful.

If $\text{info} = -i$, the $i$-th parameter had an illegal value.

**Application Notes**

The real counterpart of this routine is orgrq.

**ormrq**

*Multiplying a real matrix by the orthogonal matrix $Q$ of the $RQ$ factorization formed by ?gerqf.*

**Syntax**

```c
lapack_int LAPACKE_sormrq (int matrix_layout, char side, char trans, lapack_int m, lapack_int n, lapack_int k, const float* a, lapack_int lda, const float* tau, float* c, lapack_int ldc);
```

```c
lapack_int LAPACKE_dormrq (int matrix_layout, char side, char trans, lapack_int m, lapack_int n, lapack_int k, const double* a, lapack_int lda, const double* tau, double* c, lapack_int ldc);
```

**Include Files**

- mkl.h

**Description**

The routine multiplies a real $m$-by-$n$ matrix $C$ by $Q$ or $Q^T$, where $Q$ is the real orthogonal matrix defined as a product of $k$ elementary reflectors $H_i: Q = H_1H_2 \ldots H_k$ as returned by the $RQ$ factorization routine ?gerqf.

Depending on the parameters `side` and `trans`, the routine can form one of the matrix products $Q^*C$, $Q^T*C$, $C*Q$, or $C*Q^T$ (overwriting the result over $C$).

**Input Parameters**

- `matrix_layout` Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- `side` Must be either 'L' or 'R'.
  - If `side` = 'L', $Q$ or $Q^T$ is applied to $C$ from the left.
  - If `side` = 'R', $Q$ or $Q^T$ is applied to $C$ from the right.
- `trans` Must be either 'N' or 'T'.
  - If `trans` = 'N', the routine multiplies $C$ by $Q$.
  - If `trans` = 'T', the routine multiplies $C$ by $Q^T$.
- `m` The number of rows in the matrix $C$ ($m \geq 0$).
- `n` The number of columns in $C$ ($n \geq 0$).
- `k` The number of elementary reflectors whose product defines the matrix $Q$.

Constraints:
- $0 \leq k \leq m$, if `side` = 'L';
- $0 \leq k \leq n$, if `side` = 'R'.

LAPACK Routines
Arrays: $a$ (size for $side$ = 'L': max(1, $lda*m$) for column major layout and max(1, $lda*k$) for row major layout; for $side$ = 'R': max(1, $lda*n$) for column major layout and max(1, $lda*k$) for row major layout), $tau$, $c$ (size max(1, $ldc*n$) for column major layout and max(1, $ldc*m$) for row major layout).

On entry, the $i$th row of $a$ must contain the vector which defines the elementary reflector $H_i$, for $i = 1,2,...,k$, as returned by sgerqf/dgerqf in the last $k$ rows of its array argument $a$.

$tau[i - 1]$ must contain the scalar factor of the elementary reflector $H_i$, as returned by sgerqf/dgerqf.

The size of $tau$ must be at least max(1, $k$).

$c$ contains the $m$-by-$n$ matrix $C$.

$lda$ The leading dimension of $a$; $lda \geq$ max(1, $k$) for column major layout. For row major layout, $lda \geq$ max(1, $m$) if $side$ = 'L', and $lda \geq$ max(1, $n$) if $side$ = 'R'.

$ldc$ The leading dimension of $c$; $ldc \geq$ max(1, $m$) for column major layout and max(1, $n$) for row major layout.

Output Parameters

$c$ Overwritten by the product $Q\cdot C$, $Q^T\cdot C$, $C\cdot Q$, or $C\cdot Q^T$ (as specified by $side$ and $trans$).

Return Values

This function returns a value $info$.

If $info=0$, the execution is successful.

If $info = -i$, the $i$-th parameter had an illegal value.

Application Notes

The complex counterpart of this routine is unmrq.

?unmrq

Multiplies a complex matrix by the unitary matrix $Q$ of the RQ factorization formed by ?gerqf.

Syntax

```c
lapack_int LAPACKE_cunmrq (int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int k, const lapack_complex_float* a, lapack_int lda,
const lapack_complex_float* tau, lapack_complex_float* c, lapack_int ldc);

lapack_int LAPACKE_zunmrq (int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int k, const lapack_complex_double* a, lapack_int lda,
const lapack_complex_double* tau, lapack_complex_double* c, lapack_int ldc);
```

Include Files

- mkl.h
Description

The routine multiplies a complex $m$-by-$n$ matrix $C$ by $Q$ or $Q^H$, where $Q$ is the complex unitary matrix defined as a product of $k$ elementary reflectors $H(i)$ of order $n$: $Q = H(1)^* H(2)^* \ldots H(k)^*$ as returned by the RQ factorization routine \texttt{gerqf}.

Depending on the parameters \texttt{side} and \texttt{trans}, the routine can form one of the matrix products $Q*C$, $Q^H*C$, $C*Q$, or $C*Q^H$ (overwriting the result over $C$).

Input Parameters

- **matrix_layout**
  Specifies whether matrix storage layout is row major (\texttt{LAPACK Row Major}) or column major (\texttt{LAPACK Col Major}).

- **side**
  Must be either 'L' or 'R'.
  - If \texttt{side} = 'L', $Q$ or $Q^H$ is applied to $C$ from the left.
  - If \texttt{side} = 'R', $Q$ or $Q^H$ is applied to $C$ from the right.

- **trans**
  Must be either 'N' or 'C'.
  - If \texttt{trans} = 'N', the routine multiplies $C$ by $Q$.
  - If \texttt{trans} = 'C', the routine multiplies $C$ by $Q^H$.

- **m**
  The number of rows in the matrix $C$ ($m \geq 0$).

- **n**
  The number of columns in $C$ ($n \geq 0$).

- **k**
  The number of elementary reflectors whose product defines the matrix $Q$.
  Constraints:
  - $0 \leq k \leq m$, if \texttt{side} = 'L';
  - $0 \leq k \leq n$, if \texttt{side} = 'R'.

- **a**, **tau**, **c**
  Arrays: $a$ (size for \texttt{side} = 'L': max(1, $lda*m$) for column major layout and max(1, $lda*k$) for row major layout; for \texttt{side} = 'R': max(1, $lda*n$) for column major layout and max(1, $lda*k$) for row major layout), \texttt{tau}, \texttt{c} (size max(1, $ldc*n$) for column major layout and max(1, $ldc*m$) for row major layout).

  On entry, the $i$th row of $a$ must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \ldots, k$, as returned by \texttt{cgerqf/zgerqf} in the last $k$ rows of its array argument $a$.

  \texttt{tau[i - 1]} must contain the scalar factor of the elementary reflector $H(i)$, as returned by \texttt{cgerqf/zgerqf}.

  The size of \texttt{tau} must be at least max(1, $k$).

- **lda**
  The leading dimension of $a$; $lda \geq$ max(1, $k$) for column major layout. For row major layout, $lda \geq$ max(1, $m$) if \texttt{side} = 'L', and $lda \geq$ max(1, $n$) if \texttt{side} = 'R'.

- **ldc**
  The leading dimension of $c$; $ldc \geq$ max(1, $m$) for column major layout and max(1, $n$) for row major layout.
Output Parameters

c
Overwritten by the product \( Q^*C, Q^{H}*C, C^*Q, \) or \( C^*Q^H \) (as specified by \textit{side} and \textit{trans}).

Return Values

This function returns a value \textit{info}.

If \( \textit{info}=0 \), the execution is successful.

If \( \textit{info} = -i \), the \( i \)-th parameter had an illegal value.

Application Notes

The real counterpart of this routine is \texttt{ormrq}.

\(?tzrzf\)

\textit{Reduces the upper trapezoidal matrix \textit{A} to upper triangular form.}

Syntax

\begin{verbatim}
lapack_int LAPACKE_stzrzf (int matrix_layout, lapack_int m, lapack_int n, float* a, lapack_int lda, float* tau);
lapack_int LAPACKE_dtzrzf (int matrix_layout, lapack_int m, lapack_int n, double* a, lapack_int lda, double* tau);
lapack_int LAPACKE_ctzrzf (int matrix_layout, lapack_int m, lapack_int n, lapack_complex_float* a, lapack_int lda, lapack_complex_float* tau);
lapack_int LAPACKE_ztzrzf (int matrix_layout, lapack_int m, lapack_int n, lapack_complex_double* a, lapack_int lda, lapack_complex_double* tau);
\end{verbatim}

Include Files

- \texttt{mkl.h}

Description

The routine reduces the \( m \)-by-\( n \) \((m \leq n)\) real/complex upper trapezoidal matrix \( A \) to upper triangular form by means of orthogonal/unitary transformations. The upper trapezoidal matrix \( A = [A1 \hspace{1em} A2] = [A1:m, 1:m, A1:m, m+1:n] \) is factored as

\[ A = [R0]^*Z, \]

where \( Z \) is an \( n \)-by-\( n \) orthogonal/unitary matrix, \( R \) is an \( m \)-by-\( m \) upper triangular matrix, and \( 0 \) is the \( m \)-by-\( (n-m) \) zero matrix.

The \(?tzrzf\) routine replaces the deprecated \(?tzrqf\) routine.

Input Parameters

\begin{verbatim}
matrix_layout
\end{verbatim}

Specifies whether matrix storage layout is row major (\texttt{LAPACK_ROW_MAJOR}) or column major (\texttt{LAPACK_COL_MAJOR}).

\begin{verbatim}
m
\end{verbatim}
The number of rows in the matrix \( A \) \((n \geq 0)\).

\begin{verbatim}
n
\end{verbatim}
The number of columns in \( A \) \((n \geq m)\).
\(a\) is an array of size \(\max(1, \text{lda} \times n)\) for column major layout and \(\max(1, \text{lda} \times m)\) for row major layout.

The leading \(m\)-by-\(n\) upper trapezoidal part of the array \(a\) contains the matrix \(A\) to be factorized.

\(\text{lda}\)

The leading dimension of \(a\); at least \(\max(1, m)\) for column major layout and \(\max(1, n)\) for row major layout.

**Output Parameters**

\(a\)

Overwritten on exit by the factorization data as follows:

the leading \(m\)-by-\(m\) upper triangular part of \(a\) contains the upper triangular matrix \(R\), and elements \(m + 1\) to \(n\) of the first \(m\) rows of \(a\), with the array \(\text{tau}\), represent the orthogonal matrix \(Z\) as a product of \(m\) elementary reflectors.

\(\text{tau}\)

Array, size at least \(\max(1, m)\). Contains scalar factors of the elementary reflectors for the matrix \(Z\).

**Return Values**

This function returns a value \(\text{info}\).

If \(\text{info} = 0\), the execution is successful.

If \(\text{info} = -i\), the \(i\)-th parameter had an illegal value.

**Application Notes**

The factorization is obtained by Householder's method. The \(k\)-th transformation matrix, \(Z(k)\), which is used to introduce zeros into the \((m - k + 1)\)-th row of \(A\), is given in the form

\[
Z(k) = \begin{bmatrix}
I & 0 \\
0 & T(k)
\end{bmatrix}
\]

where for real flavors

\[
T(k) = I - t \alpha k^* \alpha(k)^T, \quad \alpha(k) = \begin{bmatrix} 1 \\ 0 \\ z(k) \end{bmatrix}
\]

and for complex flavors

\[
T(k) = I - t \alpha k^* \alpha(k)^H, \quad \alpha(k) = \begin{bmatrix} 1 \\ 0 \\ z(k) \end{bmatrix}
\]

\(\text{tau}\) is a scalar and \(z(k)\) is an \(l\)-element vector. \(\text{tau}\) and \(z(k)\) are chosen to annihilate the elements of the \(k\)-th row of \(A_2\).

The scalar \(\text{tau}\) is returned in the \(k\)-th element of \(\text{tau}\) and the vector \(u(k)\) in the \(k\)-th row of \(A\), such that the elements of \(z(k)\) are stored in the last \(m - n\) elements of the \(k\)-th row of array \(a\).

The elements of \(R\) are returned in the upper triangular part of \(A\).
The matrix $Z$ is given by
\[ Z = Z(1)*Z(2)*...*Z(m). \]

Related routines include:
- `ormrz` to apply matrix $Q$ (for real matrices)
- `unmrz` to apply matrix $Q$ (for complex matrices).

**?ormrz**

*Multiplies a real matrix by the orthogonal matrix defined from the factorization formed by `?tzrzf`.*

**Syntax**

```c
lapack_int LAPACKE_sormrz (int matrix_layout, char side, char trans, lapack_int m, lapack_int n, lapack_int k, lapack_int l, const float* a, lapack_int lda, const float* tau, float* c, lapack_int ldc);

lapack_int LAPACKE_dormrz (int matrix_layout, char side, char trans, lapack_int m, lapack_int n, lapack_int k, lapack_int l, const double* a, lapack_int lda, const double* tau, double* c, lapack_int ldc);
```

**Include Files**

- `mkl.h`

**Description**

The `?ormrz` routine multiplies a real $m$-by-$n$ matrix $C$ by $Q$ or $Q^T$, where $Q$ is the real orthogonal matrix defined as a product of $k$ elementary reflectors $H(i)$ of order $n$: $Q = H(1)*H(2)*...*H(k)$ as returned by the factorization routine `?tzrzf`.

Depending on the parameters `side` and `trans`, the routine can form one of the matrix products $Q*C$, $Q^T*C$, $C*Q$, or $C*Q^T$ (overwriting the result over $C$).

The matrix $Q$ is of order $m$ if `side` = 'L' and of order $n$ if `side` = 'R'.

The `?ormrz` routine replaces the deprecated `?latzm` routine.

**Input Parameters**

- `matrix_layout` Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- `side` Must be either 'L' or 'R'.
  - If `side` = 'L', $Q$ or $Q^T$ is applied to $C$ from the left.
  - If `side` = 'R', $Q$ or $Q^T$ is applied to $C$ from the right.
- `trans` Must be either 'N' or 'T'.
  - If `trans` = 'N', the routine multiplies $C$ by $Q$.
  - If `trans` = 'T', the routine multiplies $C$ by $Q^T$.
- `m` The number of rows in the matrix $C$ ($m \geq 0$).
- `n` The number of columns in $C$ ($n \geq 0$).
The number of elementary reflectors whose product defines the matrix \( Q \).

Constraints:

- \( 0 \leq k \leq m \), if \( \text{side} = 'L' \);
- \( 0 \leq k \leq n \), if \( \text{side} = 'R' \).

The number of columns of the matrix \( A \) containing the meaningful part of
the Householder reflectors. Constraints:

- \( 0 \leq l \leq m \), if \( \text{side} = 'L' \);
- \( 0 \leq l \leq n \), if \( \text{side} = 'R' \).

Arrays: \( a \) (size for \( \text{side} = 'L' \): \( \max(1, \text{lda}*m) \) for column major layout and
\( \max(1, \text{lda}*k) \) for row major layout; for \( \text{side} = 'R' \): \( \max(1, \text{lda}*b) \) for column major layout and \( \max(1, \text{lda}*k) \) for row major layout), \( \tau \), \( c \) (size \( \max(1, \text{ldc}*n) \) for column major layout and \( \max(1, \text{ldc}*m) \) for row major layout).

On entry, the \( i \)th row of \( a \) must contain the vector which defines the
elementary reflector \( H(i) \), for \( i = 1, 2, \ldots, k \), as returned by \( \text{stzrzf/dtzrzf} \)
in the last \( k \) rows of its array argument \( a \).

\( \tau[i - 1] \) must contain the scalar factor of the elementary reflector \( H(i) \),
as returned by \( \text{stzrzf/dtzrzf} \).

The size of \( \tau \) must be at least \( \max(1, k) \).

\( c \) contains the \( m \)-by-\( n \) matrix \( C \).

The leading dimension of \( a \); \( \text{lda} \geq \max(1, k) \) for column major layout. For row
major layout, \( \text{lda} \geq \max(1, m) \) if \( \text{side} = 'L' \), and \( \text{lda} \geq \max(1, n) \) if \( \text{side} = 'R' \).

The leading dimension of \( c \); \( \text{ldc} \geq \max(1, m) \) for column major layout and
\( \max(1, n) \) for row major layout.

Output Parameters

\( c \)

Overwritten by the product \( Q^*C \), \( Q^T*C \), \( C^*Q \), or \( C^TQ \) (as specified by \( \text{side} \)
and \( \text{trans} \)).

Return Values

This function returns a value \( \text{info} \).

If \( \text{info}=0 \), the execution is successful.

If \( \text{info} = -i \), the \( i \)-th parameter had an illegal value.

Application Notes

The complex counterpart of this routine is \( \text{unmrz} \).

\( \text{unmrz} \)

Multiplies a complex matrix by the unitary matrix
defined from the factorization formed by \( \text{stzrzf} \).
Syntax

```c
lapack_int LAPACKE_cunmrz (int matrix_layout, char side, char trans, lapack_int m,
    lapack_int n, lapack_int k, lapack_int l, const lapack_complex_float* a, lapack_int lda,
    const lapack_complex_float* tau, lapack_complex_float* c, lapack_int ldc);
```

```c
lapack_int LAPACKE_zunmrz (int matrix_layout, char side, char trans, lapack_int m,
    lapack_int n, lapack_int k, lapack_int l, const lapack_complex_double* a, lapack_int lda,
    const lapack_complex_double* tau, lapack_complex_double* c, lapack_int ldc);
```

Include Files

- mkl.h

Description

The routine multiplies a complex \( m \)-by-\( n \) matrix \( C \) by \( Q \) or \( Q^H \), where \( Q \) is the unitary matrix defined as a product of \( k \) elementary reflectors \( H(i) \):

\[
Q = H(1)^H \cdot H(2)^H \cdot \ldots \cdot H(k)^H \quad \text{as returned by the factorization routine tzrzf}.
\]

Depending on the parameters \( side \) and \( trans \), the routine can form one of the matrix products \( Q^*C \), \( Q^H C \), \( C^*Q \), or \( C^*Q^H \) (overwriting the result over \( C \)).

The matrix \( Q \) is of order \( m \) if \( side = 'L' \) and of order \( n \) if \( side = 'R' \).

Input Parameters

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **side**
  Must be either 'L' or 'R'.
  - If \( side = 'L' \), \( Q \) or \( Q^H \) is applied to \( C \) from the left.
  - If \( side = 'R' \), \( Q \) or \( Q^H \) is applied to \( C \) from the right.

- **trans**
  Must be either 'N' or 'C'.
  - If \( trans = 'N' \), the routine multiplies \( C \) by \( Q \).
  - If \( trans = 'C' \), the routine multiplies \( C \) by \( Q^H \).

- **m**
  The number of rows in the matrix \( C \) (\( m \geq 0 \)).

- **n**
  The number of columns in \( C \) (\( n \geq 0 \)).

- **k**
  The number of elementary reflectors whose product defines the matrix \( Q \).
  Constraints:
  - \( 0 \leq k \leq m \), if \( side = 'L' \);  
  - \( 0 \leq k \leq n \), if \( side = 'R' \).

- **l**
  The number of columns of the matrix \( A \) containing the meaningful part of the Householder reflectors. Constraints:
  - \( 0 \leq l \leq m \), if \( side = 'L' \);  
  - \( 0 \leq l \leq n \), if \( side = 'R' \).
Arrays: \( a \) (size for \( \text{side} = 'L' \): \( \max(1, lda*m) \) for column major layout and \( \max(1, lda*k) \) for row major layout; for \( \text{side} = 'R' \): \( \max(1, lda*b) \) for column major layout and \( \max(1, lda*k) \) for row major layout), \( \tau_a, c \) (size \( \max(1, ldc*n) \) for column major layout and \( \max(1, ldc*m) \) for row major layout).

On entry, the \( i \)th row of \( a \) must contain the vector which defines the elementary reflector \( H(i) \), for \( i = 1,2,...,k \), as returned by \texttt{ctzrzf/ztzrzf} in the last \( k \) rows of its array argument \( a \).

\( \tau_a[i - 1] \) must contain the scalar factor of the elementary reflector \( H(i) \), as returned by \texttt{ctzrzf/ztzrzf}.

The size of \( \tau_a \) must be at least \( \max(1, k) \).

\( c \) contains the \( m \)-by-\( n \) matrix \( C \).

\( \ell_a \) The leading dimension of \( a \); \( \ell_a \geq \max(1, k) \) for column major layout. For row major layout, \( \ell_a \geq \max(1, m) \) if \( \text{side} = 'L' \), and \( \ell_a \geq \max(1, n) \) if \( \text{side} = 'R' \).

\( \ell_c \) The leading dimension of \( c \); \( \ell_c \geq \max(1, m) \) for column major layout and \( \max(1, n) \) for row major layout.

Output Parameters

\( c \) Overwritten by the product \( Q*C, Q^H*C, C*Q \), or \( C*Q^H \) (as specified by \text{side} and \text{trans}).

Return Values

This function returns a value \( \text{info} \).

If \( \text{info}=0 \), the execution is successful.

If \( \text{info} = -i \), the \( i \)-th parameter had an illegal value.

Application Notes

The real counterpart of this routine is \texttt{ormrz}.

\texttt{?ggqrf}

Computes the generalized QR factorization of two matrices.

Syntax

\begin{verbatim}
lapack_int LAPACKE_sggqrf (int matrix_layout, lapack_int n, lapack_int m, lapack_int p, float* a, lapack_int lda, float* taua, float* b, lapack_int ldb, float* taub);

- mkl.h

Description

The routine forms the generalized QR factorization of an \( n \)-by-\( m \) matrix \( A \) and an \( n \)-by-\( p \) matrix \( B \) as \( A = Q^*R \), \( B = Q^*T^*Z \), where \( Q \) is an \( n \)-by-\( n \) orthogonal/unitary matrix, \( Z \) is a \( p \)-by-\( p \) orthogonal/unitary matrix, and \( R \) and \( T \) assume one of the forms:

\[
R = \begin{cases} \\
\begin{pmatrix} R_{11} \\ 0 \end{pmatrix} & , \quad \text{if } n \geq m \\
\end{cases} \\
\begin{pmatrix} n - m \\ m - n \end{pmatrix} \\
\end{cases}
\]

or

\[
R = \begin{cases} \\
\begin{pmatrix} R_{11} & R_{12} \\ R_{11} & R_{12} \end{pmatrix} & , \quad \text{if } n < m \\
\end{cases} \\
\end{cases}
\]

where \( R_{11} \) is upper triangular, and

\[
T = \begin{cases} \\
\begin{pmatrix} p - n & n \\ n & T_{11} \end{pmatrix} & , \quad \text{if } n \leq p, \\
\end{cases} \\
\begin{pmatrix} p & \end{pmatrix} \\
\begin{pmatrix} p \\ T_{21} \end{pmatrix} \\
\end{cases}
\]

where \( T_{12} \) or \( T_{21} \) is a \( p \)-by-\( p \) upper triangular matrix.

In particular, if \( B \) is square and nonsingular, the GQR factorization of \( A \) and \( B \) implicitly gives the QR factorization of \( B^{-1}A \) as:

\[
B^{-1}A = Z^* (T^{-1}R) \quad \text{(for real flavors)} \quad \text{or} \quad B^{-1}A = Z^H (T^{-1}R) \quad \text{(for complex flavors)}.
\]

Input Parameters

- \textit{matrix\_layout} Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- \textit{n} The number of rows of the matrices \( A \) and \( B \) (\( n \geq 0 \)).

- \textit{m} The number of columns in \( A \) (\( m \geq 0 \)).

- \textit{p} The number of columns in \( B \) (\( p \geq 0 \)).

- \( a, b \)

  Array \( a \) of size max(1, \( lda \times m \)) for column major layout and max(1, \( lda \times n \)) for row major layout contains the matrix \( A \).

  Array \( b \) of size max(1, \( ldb \times p \)) for column major layout and max(1, \( ldb \times n \)) for row major layout contains the matrix \( B \).
The leading dimension of \(a\); at least max(1, \(n\)) for column major layout and at least max(1, \(m\)) for row major layout.

The leading dimension of \(b\); at least max(1, \(n\)) for column major layout and at least max(1, \(p\)) for row major layout.

**Output Parameters**

Overwritten by the factorization data as follows:

on exit, the elements on and above the diagonal of the array \(a\) contain the \(\min(n,m)\)-by-\(m\) upper trapezoidal matrix \(R\) \((R\) is upper triangular if \(n\geq m\)); the elements below the diagonal, with the array \(\text{taua}\), represent the orthogonal/unitary matrix \(Q\) as a product of \(\min(n,m)\) elementary reflectors;

if \(n\leq p\), the upper triangle of the subarray \(b(1:n, p-n+1:p)\) contains the \(n\)-by-\(n\) upper triangular matrix \(T\);

if \(n > p\), the elements on and above the \((n-p)\)th subdiagonal contain the \(n\)-by-\(p\) upper trapezoidal matrix \(T\); the remaining elements, with the array \(\text{taub}\), represent the orthogonal/unitary matrix \(Z\) as a product of elementary reflectors.

Arrays, size at least max (1, \(\min(n, m)\)) for \(\text{taua}\) and at least max (1, \(\min(n, p)\)) for \(\text{taub}\). The array \(\text{taua}\) contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix \(Q\).

The array \(\text{taub}\) contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix \(Z\).

**Return Values**

This function returns a value  \(\text{info}\).

If  \(\text{info}=0\), the execution is successful.

If  \(\text{info} = -i\), the \(i\)-th parameter had an illegal value.

**Application Notes**

The matrix \(Q\) is represented as a product of elementary reflectors

\[ Q = H(1)H(2) \ldots H(k) \text{, where } k = \min(n,m). \]

Each \(H(i)\) has the form

\[ H(i) = I - \tau_a^*v^*v \]  for real flavors, or

\[ H(i) = I - \tau_a^*v^Hv \]  for complex flavors,

where \(\tau_a\) is a real/complex scalar, and \(v\) is a real/complex vector with \(v_j = 0\) for \(1 \leq j \leq i-1\), \(v_i = 1\).

On exit, for \(1 \leq j \leq n\), \(v_j\) is stored in \(a[(j - 1) + (i - 1)*\text{lda}]\) for column major layout and in \(a[(j - 1)*\text{lda} + (i - 1)]\) for row major layout and \(\tau_a\) is stored in \(\text{taua}[i-1]\)

The matrix \(Z\) is represented as a product of elementary reflectors

\[ Z = H(1)H(2) \ldots H(k) \text{, where } k = \min(n,p). \]

Each \(H(i)\) has the form

\[ H(i) = I - \tau_b^*v^*v \]  for real flavors, or

\[ H(i) = I - \tau_b^*v^Hv \]  for complex flavors,
where $\tau_b$ is a real/complex scalar, and $v$ is a real/complex vector with $v_{p-k+1} = 1$, $v_j = 0$ for $p-k+1 < j < p$.

On exit, for $1 \leq j \leq p-k+i-1$, $v_j$ is stored in $b[(n-k+i-1) + (j-1)*ldb]$ for column major layout and in $b[(n-k+i-1)*ldb + (j-1)]$ for row major layout and $\tau_b$ is stored in $taub[i-1]$.

?qgrqf

Computes the generalized RQ factorization of two matrices.

**Syntax**

```c

lapack_int LAPACKE_sggrqf (int matrix_layout, lapack_int m, lapack_int p, lapack_int n, float* a, lapack_int lda, float* taua, float* b, lapack_int ldb, float* taub);

lapack_int LAPACKE_dggrqf (int matrix_layout, lapack_int m, lapack_int p, lapack_int n, double* a, lapack_int lda, double* taua, double* b, lapack_int ldb, double* taub);

lapack_int LAPACKE_cggrqf (int matrix_layout, lapack_int m, lapack_int p, lapack_int n, lapack_complex_float* a, lapack_int lda, lapack_complex_float* taua, lapack_complex_float* b, lapack_int ldb, lapack_complex_float* taub);

lapack_int LAPACKE_zggrqf (int matrix_layout, lapack_int m, lapack_int p, lapack_int n, lapack_complex_double* a, lapack_int lda, lapack_complex_double* taua, lapack_complex_double* b, lapack_int ldb, lapack_complex_double* taub);
```

**Include Files**

**Description**

The routine forms the generalized RQ factorization of an $m$-by-$n$ matrix $A$ and an $p$-by-$n$ matrix $B$ as $A = R \cdot Q$, $B = Z^T \cdot Q$, where $Q$ is an $n$-by-$n$ orthogonal/unitary matrix, $Z$ is a $p$-by-$p$ orthogonal/unitary matrix, and $R$ and $T$ assume one of the forms:

\[
R = \begin{cases} 
  \begin{pmatrix} n-m & m \\ m & R_{12} \end{pmatrix}, & \text{if } m \leq n, \\
  \begin{pmatrix} n \\ m-n \end{pmatrix} \begin{pmatrix} R_{11} \\ R_{21} \end{pmatrix}, & \text{if } m > n, 
\end{cases}
\]

where $R_{11}$ or $R_{21}$ is upper triangular, and

\[
T = \begin{cases} 
  \begin{pmatrix} n \\ p-n \end{pmatrix} T_{11}, & \text{if } p \geq n, \\
  \begin{pmatrix} T_{11} \\ 0 \end{pmatrix}, & \text{else} 
\end{cases}
\]
where $T_{11}$ is upper triangular.

In particular, if $B$ is square and nonsingular, the GRQ factorization of $A$ and $B$ implicitly gives the RQ factorization of $A^*B^{-1}$ as:

\[
A^*B^{-1} = (R^*T^{-1})^*Z^T \text{ (for real flavors) or } A^*B^{-1} = (R^*T^{-1})^*Z^H \text{ (for complex flavors)}.
\]

**Input Parameters**

- **matrix_layout**
  Specifies whether matrix storage layout is row major (**LAPACK_ROW_MAJOR**) or column major (**LAPACK_COL_MAJOR**).

- **m**
  The number of rows of the matrix $A$ ($m \geq 0$).

- **p**
  The number of rows in $B$ ($p \geq 0$).

- **n**
  The number of columns of the matrices $A$ and $B$ ($n \geq 0$).

- **a, b**
  Arrays:
  - $a$ (size max(1, $lda \times n$) for column major layout and max(1, $lda \times m$) for row major layout) contains the $m$-by-$n$ matrix $A$.
  - $b$ (size max(1, $ldb \times n$) for column major layout and max(1, $ldb \times p$) for row major layout) contains the $p$-by-$n$ matrix $B$.

- **lda**
  The leading dimension of $a$; at least max(1, $m$) for column major layout and max(1, $n$) for row major layout.

- **ldb**
  The leading dimension of $b$; at least max(1, $p$) for column major layout and max(1, $n$) for row major layout.

**Output Parameters**

- **a, b**
  Overwritten by the factorization data as follows:
  - on exit, if $m \leq n$, element $R_{i,j} (1 \leq i \leq n, 1 \leq j \leq m)$ of upper triangular matrix $R$ is stored in $a[(i-1) + (n-m+j-1) \times lda]$ for column major layout and in $a[(i-1) \times lda + (n-m+j-1)]$ for row major layout.
  - if $m > n$, the elements on and above the $(m-n)$th subdiagonal contain the $m$-by-$n$ upper trapezoidal matrix $R$;
  - the remaining elements, with the array $taua$, represent the orthogonal/unitary matrix $Q$ as a product of elementary reflectors.

  The elements on and above the diagonal of the array $b$ contain the min($p,n$)-by-$n$ upper trapezoidal matrix $T$ ($T$ is upper triangular if $p \geq n$); the elements below the diagonal, with the array $taub$, represent the orthogonal/unitary matrix $Z$ as a product of elementary reflectors.

- **taua, taub**
  Arrays, size at least max(1, min($m, n$)) for $taua$ and at least max(1, min($p, n$)) for $taub$.

  The array $taua$ contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix $Q$. 
The array \( taub \) contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix \( Z \).

Return Values
This function returns a value \( info \).
If \( info = 0 \), the execution is successful.
If \( info = -i \), the \( i \)-th parameter had an illegal value.

Application Notes
The matrix \( Q \) is represented as a product of elementary reflectors
\[
Q = H(1)H(2)\ldots H(k), \text{ where } k = \min(m,n).
\]
Each \( H(i) \) has the form
\[
H(i) = I - taua v^* v^T \text{ for real flavors, or}
H(i) = I - taub v^* v^H \text{ for complex flavors},
\]
where \( taua \) is a real/complex scalar, and \( v \) is a real/complex vector with \( v_{n-k+i} = 1, v_{n-k+i+1:n} = 0 \).
On exit, \( v_1:n-k+i-1 \) is stored in \( a(m-k+i, 1:n-k+i-1) \) and \( taua \) is stored in \( taua[i-1] \).

The matrix \( Z \) is represented as a product of elementary reflectors
\[
Z = H(1)H(2)\ldots H(k), \text{ where } k = \min(p,n).
\]
Each \( H(i) \) has the form
\[
H(i) = I - taub v^* v^T \text{ for real flavors, or}
H(i) = I - taub v^* v^H \text{ for complex flavors},
\]
where \( taub \) is a real/complex scalar, and \( v \) is a real/complex vector with \( v_{1:i-1} = 0, v_{i} = 1 \).
On exit, \( v_{i+1:p} \) is stored in \( b(i+1:p, i) \) and \( taub \) is stored in \( taub[i-1] \).

\tpqrt

*Computes a blocked QR factorization of a real or complex "triangular-pentagonal" matrix, which is composed of a triangular block and a pentagonal block, using the compact WY representation for \( Q \).*

Syntax

```c
lapack_int LAPACKE_stpqrt (int matrix_layout, lapack_int m, lapack_int n, lapack_int l, lapack_int nb, float* a, lapack_int lda, float* b, lapack_int ldb, float* t, lapack_int ldt);

lapack_int LAPACKE_dtpqrt (int matrix_layout, lapack_int m, lapack_int n, lapack_int l, lapack_int nb, double* a, lapack_int lda, double* b, lapack_int ldb, double* t, lapack_int ldt);

lapack_int LAPACKE_ctpqrt (int matrix_layout, lapack_int m, lapack_int n, lapack_int l, lapack_int nb, lapack_complex_float* a, lapack_int lda, lapack_complex_float* b, lapack_int ldb, lapack_complex_float* t, lapack_int ldt);

lapack_int LAPACKE_ztpqrt (int matrix_layout, lapack_int m, lapack_int n, lapack_int l, lapack_int nb, lapack_complex_double* a, lapack_int lda, lapack_complex_double* b, lapack_int ldb, lapack_complex_double* t, lapack_int ldt);
```
Include Files
• mkl.h

Description
The input matrix $C$ is an $(n+m)$-by-$n$ matrix

$$C = \begin{bmatrix}
A & \text{upper triangular} \\
B & \text{pentagonal}
\end{bmatrix}$$

where $A$ is an $n$-by-$n$ upper triangular matrix, and $B$ is an $m$-by-$n$ pentagonal matrix consisting of an $(m-l)$-by-$n$ rectangular matrix $B1$ on top of an $l$-by-$n$ upper trapezoidal matrix $B2$:

$$B = \begin{bmatrix}
B1 & (m-l)\times n \text{ rectangular} \\
B2 & l\times n \text{ upper trapezoidal}
\end{bmatrix}$$

The upper trapezoidal matrix $B2$ consists of the first $l$ rows of an $n$-by-$n$ upper triangular matrix, where $0 \leq l \leq \min(m,n)$. If $l=0$, $B$ is an $m$-by-$n$ rectangular matrix. If $m=l=n$, $B$ is upper triangular. The elementary reflectors $H(i)$ are stored in the $i$th column below the diagonal in the $(n+m)$-by-$n$ input matrix $C$. The structure of vectors defining the elementary reflectors is illustrated by:

$$\begin{bmatrix}
I & \text{identity} \\
V & \text{pentagonal}
\end{bmatrix}$$

The elements of the unit matrix $I$ are not stored. Thus, $V$ contains all of the necessary information, and is returned in array $b$.

**NOTE**
Note that $V$ has the same form as $B$:

$$V = \begin{bmatrix}
V1 & (m-l)\times n \text{ rectangular} \\
V2 & l\times n \text{ upper trapezoidal}
\end{bmatrix}$$

The columns of $V$ represent the vectors which define the $H(i)$.s.

The number of blocks is $k = \text{ceiling}(n/nb)$, where each block is of order $nb$ except for the last block, which is of order $ib = n - (k-1)*nb$. For each of the $k$ blocks, an upper triangular block reflector factor is computed: $T1, T2, \ldots, Tk$. The $nb$-by-$nb$ ($ib$-by-$ib$ for the last block) $T$s are stored in the $nb$-by-$n$ array $t$ as $t = [T1 T2 \ldots Tk]$.

Input Parameters

- **matrix_layout**
  Specifies whether matrix storage layout is row major (**LAPACK_ROW_MAJOR**) or column major (**LAPACK_COL_MAJOR**).

- **m**
  The total number of rows in the matrix $B$ ($m \geq 0$).

- **n**
  The number of columns in $B$ and the order of the triangular matrix $A$ ($n \geq 0$).
The number of rows of the upper trapezoidal part of $B$ ($\min(m, n) \geq l \geq 0$).

The block size to use in the blocked QR factorization ($n \geq nb \geq 1$).

Arrays: $a$ size $lda*n$ contains the $n$-by-$n$ upper triangular matrix $A$.

$b$ size $\max(1, ldb*n)$ for column major layout and $\max(1, ldb*m)$ for row major layout, the pentagonal $m$-by-$n$ matrix $B$. The first $(m-l)$ rows contain the rectangular $B1$ matrix, and the next $l$ rows contain the upper trapezoidal $B2$ matrix.

The leading dimension of $a$; at least $\max(1, n)$.

The leading dimension of $b$; at least $\max(1, m)$ for column major layout and at least $\max(1, n)$ for row major layout.

The leading dimension of $t$; at least $nb$ for column major layout and at least $\max(1, n)$ for row major layout.

Output Parameters

The elements on and above the diagonal of the array contain the upper triangular matrix $R$.

The pentagonal matrix $V$.

Array, size $ldt*n$ for column major layout and $ldt*nb$ for row major layout.

The upper triangular block reflectors stored in compact form as a sequence of upper triangular blocks.

Return Values

This function returns a value $info$.

If $info=0$, the execution is successful.

If $info = -i$, the $i$-th parameter had an illegal value.

?tpmqrt

Applies a real or complex orthogonal matrix obtained from a "triangular-pentagonal" complex block reflector to a general real or complex matrix, which consists of two blocks.

Syntax

```c
lapack_int LAPACKE_stpmqrt (int matrix_layout, char side, char trans, lapack_int m, lapack_int n, lapack_int k, lapack_int l, lapack_int nb, const float* v, lapack_int ldv, const float* t, lapack_int ldt, float* a, lapack_int lda, float* b, lapack_int ldb);
```

```c
lapack_int LAPACKE_dtpmqrt (int matrix_layout, char side, char trans, lapack_int m, lapack_int n, lapack_int k, lapack_int l, lapack_int nb, const double* v, lapack_int ldv, const double* t, lapack_int ldt, double* a, lapack_int lda, double* b, lapack_int ldb);
```
lapack_int LAPACKE_ctpmqrt (int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int k, lapack_int l, lapack_int nb, const lapack_complex_float* v,
lapack_int ldv, const lapack_complex_float* t, lapack_int ldt, lapack_complex_float* a,
lapack_int lda, lapack_complex_float* b, lapack_int ldb);

lapack_int LAPACKE_ztpmqrt (int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int k, lapack_int l, lapack_int nb, const lapack_complex_double* v,
lapack_int ldv, const lapack_complex_double* t, lapack_int ldt,
lapack_complex_double* a, lapack_int lda, lapack_complex_double* b, lapack_int ldb);

Include Files
• mkl.h

Description

The columns of the pentagonal matrix $V$ contain the elementary reflectors $H(1), H(2), \ldots, H(k)$; $V$ is composed of a rectangular block $V_1$ and a trapezoidal block $V_2$:

$$V = \begin{bmatrix} V_1 \\ V_2 \end{bmatrix}$$

The size of the trapezoidal block $V_2$ is determined by the parameter $l$, where $0 \leq l \leq k$. $V_2$ is upper trapezoidal, consisting of the first $l$ rows of a $k$-by-$k$ upper triangular matrix.

If $l=k$, $V_2$ is upper triangular;

If $l=0$, there is no trapezoidal block, so $V = V_1$ is rectangular.

If $side = 'L'$:

$$C = \begin{bmatrix} A \\ B \end{bmatrix}$$

where $A$ is $k$-by-$n$, $B$ is $m$-by-$n$ and $V$ is $m$-by-$k$.

If $side = 'R'$:

$$C = \begin{bmatrix} A & B \end{bmatrix}$$

where $A$ is $m$-by-$k$, $B$ is $m$-by-$n$ and $V$ is $n$-by-$k$.

The real/complex orthogonal matrix $Q$ is formed from $V$ and $T$.

If $\text{trans}='N'$ and $\text{side}='L'$, $C$ contains $Q \ast C$ on exit.

If $\text{trans}='T'$ and $\text{side}='L'$, $C$ contains $Q^T \ast C$ on exit.

If $\text{trans}='C'$ and $\text{side}='L'$, $C$ contains $Q^H \ast C$ on exit.

If $\text{trans}='N'$ and $\text{side}='R'$, $C$ contains $C \ast Q$ on exit.

If $\text{trans}='T'$ and $\text{side}='R'$, $C$ contains $C \ast Q^T$ on exit.

If $\text{trans}='C'$ and $\text{side}='R'$, $C$ contains $C \ast Q^H$ on exit.
## Input Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>matrix_layout</code></td>
<td>Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).</td>
</tr>
</tbody>
</table>
| `side` | `'L'`: apply $Q$, $Q^T$, or $Q^H$ from the left.  
`'R'`: apply $Q$, $Q^T$, or $Q^H$ from the right. |
| `trans` | `'N'`, no transpose, apply $Q$.  
`'T'`, transpose, apply $Q^T$.  
`'C'`, transpose, apply $Q^H$. |
| `m` | The number of rows in the matrix $B$, ($m \geq 0$). |
| `n` | The number of columns in the matrix $B$, ($n \geq 0$). |
| `k` | The number of elementary reflectors whose product defines the matrix $Q$, ($k \geq 0$). |
| `l` | The order of the trapezoidal part of $V$ ($k \geq l \geq 0$). |
| `nb` | The block size used for the storage of $t$, $k \geq nb \geq 1$. This must be the same value of $nb$ used to generate $t$ in `tpqrt`. |
| `v` | Size $ldv*k$ for column major layout; $ldv*m$ for row major layout and `side` = `'L'`, $ldv*n$ for row major layout and `side` = `'R'`.  
The $i$th column must contain the vector which defines the elementary reflector $H(i)$, for $i = 1,2,\ldots,k$, as returned by `tpqrt` in array argument $b$. |
| `ldv` | The leading dimension of the array $v$.  
If `side` = `'L'`, $ldv$ must be at least max(1, $m$) for column major layout and max(1, $k$) for row major layout;  
If `side` = `'R'`, $ldv$ must be at least max(1, $n$) for column major layout and max(1, $k$) for row major layout. |
| `t` | Array, size $ldt*k$ for column major layout and $ldt*nb$ for row major layout.  
The upper triangular factors of the block reflectors as returned by `tpqrt`. |
| `ldt` | The leading dimension of the array $t$. $ldt$ must be at least $nb$ for column major layout and max(1, $k$) for row major layout. |
| `a` | If `side` = `'L'`, size $lda*n$ for column major layout and $lda*k$ for row major layout.  
If `side` = `'R'`, size $lda*k$ for column major layout and $lda*m$ for row major layout.  
The $k$-by-$n$ or $m$-by-$k$ matrix $A$. |
| `lda` | The leading dimension of the array $a$.  
If `side` = `'L'`, $lda$ must be at least max(1, $k$) for column major layout and max(1, $n$) for row major layout. |
If `side = 'R'`, `lda` must be at least \( \max(1, m) \) for column major layout and \( \max(1, k) \) for row major layout.

\( b \)
Size \( ldb \times n \) for column major layout and \( ldb \times m \) for row major layout.

The \( n \)-by-\( n \) matrix \( B \).

\( ldb \)
The leading dimension of the array \( b \). \( ldb \) must be at least \( \max(1, m) \) for column major layout and \( \max(1, n) \) for row major layout.

**Output Parameters**

\( a \)
Overwritten by the corresponding block of the product \( Q^*C, C^*Q, Q^T*C, C^*Q^T, Q^H*C, \) or \( C^*Q^H \).

\( b \)
Overwritten by the corresponding block of the product \( Q^*C, C^*Q, Q^T*C, C^*Q^T, Q^H*C, \) or \( C^*Q^H \).

**Return Values**

This function returns a value \( info \).

If \( info = 0 \), the execution is successful.

If \( info = -i \), the \( i \)-th parameter had an illegal value.

**Singular Value Decomposition: LAPACK Computational Routines**

This section describes LAPACK routines for computing the singular value decomposition (SVD) of a general \( m \)-by-\( n \) matrix \( A \):

\[
A = U \Sigma V^H.
\]

In this decomposition, \( U \) and \( V \) are unitary (for complex \( A \)) or orthogonal (for real \( A \)); \( \Sigma \) is an \( m \)-by-\( n \) diagonal matrix with real diagonal elements \( \sigma_i \):

\[
\sigma_1 \geq \sigma_2 \geq ... \geq \sigma_{\min(m,n)} \geq 0.
\]

The diagonal elements \( \sigma_i \) are singular values of \( A \). The first \( \min(m, n) \) columns of the matrices \( U \) and \( V \) are, respectively, left and right singular vectors of \( A \). The singular values and singular vectors satisfy

\[
A u_i = \sigma_i u_i \quad \text{and} \quad A^H v_i = \sigma_i v_i
\]

where \( u_i \) and \( v_i \) are the \( i \)-th columns of \( U \) and \( V \), respectively.

To find the SVD of a general matrix \( A \), call the LAPACK routine \(?gebrd\) or \(?gbbrd\) for reducing \( A \) to a bidiagonal matrix \( B \) by a unitary (orthogonal) transformation: \( A = QBP^H \). Then call \(?bdsqr\), which forms the SVD of a bidiagonal matrix: \( B = U \Sigma V^H \).

Thus, the sought-for SVD of \( A \) is given by \( A = U \Sigma V^H = (QU_i) \Sigma (V_j P_j^H) \).

Table "Computational Routines for Singular Value Decomposition (SVD)" lists LAPACK routines that perform singular value decomposition of matrices.

**Syntax**

```c
lapack_int LAPACKE_sgebrd( int matrix_layout, lapack_int m, lapack_int n, float* a, lapack_int lda, float* d, float* e, float* tauq, float* taup );

lapack_int LAPACKE_dgebrd( int matrix_layout, lapack_int m, lapack_int n, double* a, lapack_int lda, double* d, double* e, double* tauq, double* taup );
```

**Figure "Decision Tree: Singular Value Decomposition"** presents a decision tree that helps you choose the right sequence of routines for SVD, depending on whether you need singular values only or singular vectors as well, whether $A$ is real or complex, and so on.

You can use the SVD to find a minimum-norm solution to a (possibly) rank-deficient least squares problem of minimizing $||Ax - b||^2$. The effective rank $k$ of the matrix $A$ can be determined as the number of singular values which exceed a suitable threshold. The minimum-norm solution is

$$x = V_k (\Sigma_k)^{-1} c$$

where $\Sigma_k$ is the leading $k$-by-$k$ submatrix of $\Sigma$, the matrix $V_k$ consists of the first $k$ columns of $V = PV_1$, and the vector $c$ consists of the first $k$ elements of $U^H b = U_1^H C_1 b$.

**?gebrd**

*Reduces a general matrix to bidiagonal form.*
lapack_int LAPACKE_cgebrd( int matrix_layout, lapack_int m, lapack_int n, 
apack_complex_float* a, lapack_int lda, float* d, float* e, lapack_complex_float* 
tauq, lapack_complex_float* taup );

lapack_int LAPACKE_zgebrd( int matrix_layout, lapack_int m, lapack_int n, 
apack_complex_double* a, lapack_int lda, double* d, double* e, lapack_complex_double* 
tauq, lapack_complex_double* taup );

Include Files

• mkl.h

Description

The routine reduces a general m-by-n matrix A to a bidiagonal matrix B by an orthogonal (unitary) transformation.

If m≥n, the reduction is given by \( A = QBP^H = \begin{pmatrix} B_1 \end{pmatrix}^H \),

where \( B_1 \) is an n-by-n upper diagonal matrix, Q and P are orthogonal or, for a complex A, unitary matrices; 
\( Q_1 \) consists of the first \( n \) columns of Q.

If \( m < n \), the reduction is given by

\[ A = Q*B*P^H = Q_1*(B_1*0)*P^H = Q_1*B_1*P_1^H, \]

where \( B_1 \) is an m-by-m lower diagonal matrix, Q and P are orthogonal or, for a complex A, unitary matrices; 
\( P_1 \) consists of the first \( m \) columns of P.

The routine does not form the matrices Q and P explicitly, but represents them as products of elementary reflectors. Routines are provided to work with the matrices Q and P in this representation:

If the matrix A is real,

• to compute Q and P explicitly, call orgbr.
• to multiply a general matrix by Q or P, call ormbr.

If the matrix A is complex,

• to compute Q and P explicitly, call ungbr.
• to multiply a general matrix by Q or P, call unmbrr.

Input Parameters

\( \text{matrix\_layout} \quad \text{Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).} \)

\( m \quad \text{The number of rows in the matrix A (} m \geq 0). \)

\( n \quad \text{The number of columns in A (} n \geq 0). \)

\( a \quad \text{Arrays:} \)

\( a(\text{size max}(1, \text{lda}*n) \text{ for column major layout and max}(1, \text{lda}*m) \text{ for row major layout}) \text{ contains the matrix A.} \)

\( lda \quad \text{The leading dimension of a; at least max}(1, m) \text{ for column major layout and at least max}(1, n) \text{ for row major layout.} \)
Output Parameters

If \( m \geq n \), the diagonal and first super-diagonal of \( a \) are overwritten by the upper bidiagonal matrix \( B \). The elements below the diagonal, with the array \( \text{taug} \), represent the orthogonal matrix \( Q \) as a product of elementary reflectors, and the elements above the first superdiagonal, with the array \( \text{taup} \), represent the orthogonal matrix \( P \) as a product of elementary reflectors.

If \( m < n \), the diagonal and first sub-diagonal of \( a \) are overwritten by the lower bidiagonal matrix \( B \). The elements below the first subdiagonal, with the array \( \text{taug} \), represent the orthogonal matrix \( Q \) as a product of elementary reflectors, and the elements above the diagonal, with the array \( \text{taup} \), represent the orthogonal matrix \( P \) as a product of elementary reflectors.

\( d \)

Array, size at least \( \max(1, \min(m, n)) \).
Contains the diagonal elements of \( B \).

\( e \)

Array, size at least \( \max(1, \min(m, n) - 1) \). Contains the off-diagonal elements of \( B \).

\( \text{taug}, \text{taup} \)

Arrays, size at least \( \max(1, \min(m, n)) \). The scalar factors of the elementary reflectors which represent the orthogonal or unitary matrices \( P \) and \( Q \).

Return Values

This function returns a value \( \text{info} \).

If \( \text{info} = 0 \), the execution is successful.
If \( \text{info} = -i \), the \( i \)-th parameter had an illegal value.

Application Notes

The computed matrices \( Q, B, \) and \( P \) satisfy \( QBP^H = A + E \), where \( \| E \|_2 = c(n)\varepsilon \| A \|_2 \), \( c(n) \) is a modestly increasing function of \( n \), and \( \varepsilon \) is the machine precision.

The approximate number of floating-point operations for real flavors is
\[
\begin{align*}
(4/3)n^2*(3m - n) & \text{ for } m \geq n, \\
(4/3)m^2*(3n - m) & \text{ for } m < n.
\end{align*}
\]

The number of operations for complex flavors is four times greater.

If \( n \) is much less than \( m \), it can be more efficient to first form the \( QR \) factorization of \( A \) by calling \( \text{geqrf} \) and then reduce the factor \( R \) to bidiagonal form. This requires approximately \( 2*n^2*(m + n) \) floating-point operations.

If \( m \) is much less than \( n \), it can be more efficient to first form the \( LQ \) factorization of \( A \) by calling \( \text{gelqf} \) and then reduce the factor \( L \) to bidiagonal form. This requires approximately \( 2*m^2*(m + n) \) floating-point operations.

\( \text{?gbbrd} \)

Reduces a general band matrix to bidiagonal form.
**Syntax**

```c
lapack_int LAPACKE_sgbbrd( int matrix_layout, char vect, lapack_int m, lapack_int n, lapack_int ncc, lapack_int kl, lapack_int ku, float* ab, lapack_int ldab, float* d, float* e, float* q, lapack_int ldq, float* pt, lapack_int ldpt, float* c, lapack_int ldc);

lapack_int LAPACKE_dgbbrd( int matrix_layout, char vect, lapack_int m, lapack_int n, lapack_int ncc, lapack_int kl, lapack_int ku, double* ab, lapack_int ldab, double* d, double* e, double* q, lapack_int ldq, double* pt, lapack_int ldpt, double* c, lapack_int ldc);

lapack_int LAPACKE_cgbbrd( int matrix_layout, char vect, lapack_int m, lapack_int n, lapack_int ncc, lapack_int kl, lapack_int ku, lapack_complex_float* ab, lapack_int ldab, float* d, float* e, lapack_complex_float* q, lapack_int ldq, lapack_complex_float* pt, lapack_int ldpt, lapack_complex_float* c, lapack_int ldc);

lapack_int LAPACKE_zgbbrd( int matrix_layout, char vect, lapack_int m, lapack_int n, lapack_int ncc, lapack_int kl, lapack_int ku, lapack_complex_double* ab, lapack_int ldab, double* d, double* e, lapack_complex_double* q, lapack_int ldq, lapack_complex_double* pt, lapack_int ldpt, lapack_complex_double* c, lapack_int ldc);
```

**Include Files**

- `mkl.h`

**Description**

The routine reduces an \( m \times n \) band matrix \( A \) to upper bidiagonal matrix \( B \): \( A = Q^*B^*P^H \). Here the matrices \( Q \) and \( P \) are orthogonal (for real \( A \)) or unitary (for complex \( A \)). They are determined as products of Givens rotation matrices, and may be formed explicitly by the routine if required. The routine can also update a matrix \( C \) as follows: \( C = Q^*C \).

**Input Parameters**

- `matrix_layout`
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- `vect`
  Must be 'N' or 'Q' or 'P' or 'B'.
  - If `vect = 'N'`, neither \( Q \) nor \( P^H \) is generated.
  - If `vect = 'Q'`, the routine generates the matrix \( Q \).
  - If `vect = 'P'`, the routine generates the matrix \( P^H \).
  - If `vect = 'B'`, the routine generates both \( Q \) and \( P^H \).

- `m`
  The number of rows in the matrix \( A \) \((m \geq 0)\).

- `n`
  The number of columns in \( A \) \((n \geq 0)\).

- `ncc`
  The number of columns in \( C \) \((ncc \geq 0)\).

- `kl`
  The number of sub-diagonals within the band of \( A \) \((kl \geq 0)\).

- `ku`
  The number of super-diagonals within the band of \( A \) \((ku \geq 0)\).

**Arrays**
$ab$ (size max(1, $ldab*n$) for column major layout and max(1, $ldab*m$) for row major layout) contains the matrix $A$ in band storage (see Matrix Storage Schemes).

c (size max(1, $ldc*ncc$) for column major layout and max(1, $ldc*m$) for row major layout) contains an $m$-by-$ncc$ matrix $C$.

If $ncc = 0$, the array $c$ is not referenced.

$ldab$  
The leading dimension of the array $ab$ ($ldab \geq kl + ku + 1$).

$ldq$  
The leading dimension of the output array $q$.

$ldpt$  
The leading dimension of the output array $pt$.

$ldc$  
The leading dimension of the array $c$.

$ldc \geq \max(1, m)$ if $ncc > 0$; $ldc \geq 1$ if $ncc = 0$.

### Output Parameters

$ab$  
Overwritten by values generated during the reduction.

$d$  
Array, size at least max(1, $\min(m, n)$). Contains the diagonal elements of the matrix $B$.

$e$  
Array, size at least $\max(1, \min(m, n) - 1)$. Contains the off-diagonal elements of $B$.

$q$, $pt$  
Arrays:

$q$ size max(1, $ldq*m$) contains the output $m$-by-$m$ matrix $Q$.

$pt$ size max(1, $ldpt*n$) contains the output $n$-by-$n$ matrix $P^T$.

$c$  
Overwritten by the product $Q^H*C$.

$c$ is not referenced if $ncc = 0$.

### Return Values

This function returns a value $info$.

If $info = 0$, the execution is successful.

If $info = -i$, the $i$-th parameter had an illegal value.

### Application Notes

The computed matrices $Q$, $B$, and $P$ satisfy $Q*B*P^H = A + E$, where $\|E\|_2 = c(n)\varepsilon \|A\|_2$, $c(n)$ is a modestly increasing function of $n$, and $\varepsilon$ is the machine precision.

If $m = n$, the total number of floating-point operations for real flavors is approximately the sum of:

$6*n^2*(kl + ku)$ if $vect = 'N'$ and $ncc = 0$,

$3*n^2*ncc*(kl + ku - 1)/(kl + ku)$ if $C$ is updated, and

$3*n^3*(kl + ku - 1)/(kl + ku)$ if either $Q$ or $P^H$ is generated (double this if both).
To estimate the number of operations for complex flavors, use the same formulas with the coefficients 20 and 10 (instead of 6 and 3).

?orgbr
Generates the real orthogonal matrix Q or \( P^T \) determined by ?gebrd.

**Syntax**

```c
lapack_int LAPACKE_sorgbr (int matrix_layout, char vect, lapack_int m, lapack_int n, lapack_int k, float* a, lapack_int lda, const float* tau);
lapack_int LAPACKE_dorgbr (int matrix_layout, char vect, lapack_int m, lapack_int n, lapack_int k, double* a, lapack_int lda, const double* tau);
```

**Include Files**
- mkl.h

**Description**

The routine generates the whole or part of the orthogonal matrices \( Q \) and \( P^T \) formed by the routines ?gebrd. Use this routine after a call to ?gebrd. All valid combinations of arguments are described in *Input parameters*. In most cases you need the following:

To compute the whole \( m \)-by-\( m \) matrix \( Q \):

```c
LAPACKE_sorgbr(matrix_layout, 'Q', m, m, n, a, lda, tau )
```

(note that the array \( a \) must have at least \( m \) columns).

To form the \( n \) leading columns of \( Q \) if \( m > n \):

```c
LAPACKE_sorgbr(matrix_layout, 'Q', m, n, n, a, lda, tau )
```

To compute the whole \( n \)-by-\( n \) matrix \( P^T \):

```c
LAPACKE_sorgbr(matrix_layout, 'P', n, n, m, a, lda, tau )
```

(note that the array \( a \) must have at least \( n \) rows).

To form the \( m \) leading rows of \( P^T \) if \( m < n \):

```c
LAPACKE_sorgbr(matrix_layout, 'P', m, n, m, a, lda, tau )
```

**Input Parameters**

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **vect**
  Must be 'Q' or 'P'.
  If \( vect = 'Q' \), the routine generates the matrix \( Q \).
  If \( vect = 'P' \), the routine generates the matrix \( P^T \).

- **m, n**
  The number of rows (\( m \)) and columns (\( n \)) in the matrix \( Q \) or \( P^T \) to be returned (\( m \geq 0, n \geq 0 \)).
  If \( vect = 'Q' \), \( m \geq n \geq \text{min}(m, k) \).
  If \( vect = 'P' \), \( n \geq m \geq \text{min}(n, k) \).
If $\text{vect} = 'Q'$, the number of columns in the original $m$-by-$k$ matrix reduced by \texttt{gebrd}.

If $\text{vect} = 'P'$, the number of rows in the original $k$-by-$n$ matrix reduced by \texttt{gebrd}.

$a$ Array, size at least $lda\times n$ for column major layout and $lda\times m$ for row major layout. The vectors which define the elementary reflectors, as returned by \texttt{gebrd}.

$lda$ The leading dimension of the array $a$. $lda \geq \max(1, m)$ for column major layout and at least $\max(1, n)$ for row major layout.

$\tau$ Array, size $\min(m, k)$ if $\text{vect} = 'Q'$, $\min(n, k)$ if $\text{vect} = 'P'$.
Scalar factor of the elementary reflector $H(i)$ or $G(i)$, which determines $Q$ and $P^T$ as returned by \texttt{gebrd} in the array $tauq$ or $taup$.

**Output Parameters**

$a$ Overwritten by the orthogonal matrix $Q$ or $P^T$ (or the leading rows or columns thereof) as specified by $\text{vect}$, $m$, and $n$.

**Return Values**

This function returns a value $\text{info}$.

If $\text{info}=0$, the execution is successful.

If $\text{info} = -i$, the $i$-th parameter had an illegal value.

**Application Notes**

The computed matrix $Q$ differs from an exactly orthogonal matrix by a matrix $E$ such that $\|E\|_2 = O(\varepsilon)$.

The approximate numbers of floating-point operations for the cases listed in Description are as follows:

To form the whole of $Q$:

\[(4/3)\times n\times (3m^2 - 3m\times n + n^2) \quad \text{if} \quad m > n;\]

\[(4/3)\times m^3 \quad \text{if} \quad m \leq n.\]

To form the $n$ leading columns of $Q$ when $m > n$:

\[(2/3)\times n^2\times (3m - n) \quad \text{if} \quad m > n.\]

To form the whole of $P^T$:

\[(4/3)\times n^3 \quad \text{if} \quad m \geq n;\]

\[(4/3)\times m\times (3n^2 - 3m\times n + m^2) \quad \text{if} \quad m < n.\]

To form the $m$ leading columns of $P^T$ when $m < n$:

\[(2/3)\times n^2\times (3m - n) \quad \text{if} \quad m > n.\]

The complex counterpart of this routine is \texttt{ungbr}.

\texttt{ormbr}

*Multiplies an arbitrary real matrix by the real orthogonal matrix $Q$ or $P^T$ determined by \texttt{gebrd}*
Syntax

```c
lapack_int LAPACKE_sormbr (int matrix_layout, char vect, char side, char trans,
    lapack_int m, lapack_int n, lapack_int k, const float* a, lapack_int lda, const float* 
    tau, float* c, lapack_int ldc);
```

```c
lapack_int LAPACKE_dormbr (int matrix_layout, char vect, char side, char trans,
    lapack_int m, lapack_int n, lapack_int k, const double* a, lapack_int lda, const 
    double* tau, double* c, lapack_int ldc);
```

Include Files

- mkl.h

Description

Given an arbitrary real matrix \( C \), this routine forms one of the matrix products \( Q^* C \), \( Q^T C \), \( C^* Q \), \( C^* Q^T \), \( P^* C \), \( C^* P \), \( C^* P^T \), where \( Q \) and \( P \) are orthogonal matrices computed by a call to \texttt{gebrd}. The routine overwrites the product on \( C \).

Input Parameters

In the descriptions below, \( r \) denotes the order of \( Q \) or \( P^T \):

If \( \text{side} = 'L' \), \( r = m \); if \( \text{side} = 'R' \), \( r = n \).

- `matrix_layout` Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- `vect` Must be 'Q' or 'P'.
  - If `vect` = 'Q', then \( Q \) or \( Q^T \) is applied to \( C \).
  - If `vect` = 'P', then \( P \) or \( P^T \) is applied to \( C \).
- `side` Must be 'L' or 'R'.
  - If `side` = 'L', multipliers are applied to \( C \) from the left.
  - If `side` = 'R', they are applied to \( C \) from the right.
- `trans` Must be 'N' or 'T'.
  - If `trans` = 'N', then \( Q \) or \( P \) is applied to \( C \).
  - If `trans` = 'T', then \( Q^T \) or \( P^T \) is applied to \( C \).
- `m` The number of rows in \( C \).
- `n` The number of columns in \( C \).
- `k` One of the dimensions of \( A \) in \texttt{gebrd}:
  - If `vect` = 'Q', the number of columns in \( A \);
  - If `vect` = 'P', the number of rows in \( A \).
  - Constraints: \( m \geq 0 \), \( n \geq 0 \), \( k \geq 0 \).
- `a`, `c` Arrays:
  - `a` is the array \( a \) as returned by \texttt{gebrd}.
  - The size of \( a \) depends on the value of the `matrix_layout`, `vect`, and `side` parameters:
<table>
<thead>
<tr>
<th>matrix_layout</th>
<th>vect</th>
<th>side</th>
<th>size</th>
</tr>
</thead>
<tbody>
<tr>
<td>column major</td>
<td>'Q'</td>
<td>-</td>
<td>max(1, lda*k)</td>
</tr>
<tr>
<td>column major</td>
<td>'P'</td>
<td>'L'</td>
<td>max(1, lda*m)</td>
</tr>
<tr>
<td>column major</td>
<td>'P'</td>
<td>'R'</td>
<td>max(1, lda*n)</td>
</tr>
<tr>
<td>row major</td>
<td>'Q'</td>
<td>'L'</td>
<td>max(1, lda*m)</td>
</tr>
<tr>
<td>row major</td>
<td>'Q'</td>
<td>'R'</td>
<td>max(1, lda*n)</td>
</tr>
<tr>
<td>row major</td>
<td>'P'</td>
<td>-</td>
<td>max(1, lda*k)</td>
</tr>
</tbody>
</table>

\(c\) (size max(1, ldc*n)) for column major layout and max(1, ldc*m) for row major layout) holds the matrix \(C\).

**lda**

The leading dimension of \(a\). Constraints:

\[\text{lda} \geq \max(1, r)\] for column major layout and at least \(\max(1, k)\) for row major layout if \(\text{vect} = 'Q'\);

\[\text{lda} \geq \max(1, \min(r,k))\] for column major layout and at least \(\max(1, r)\) for row major layout if \(\text{vect} = 'P'\).

**ldc**

The leading dimension of \(c\); \(\text{ldc} \geq \max(1, m)\) for column major layout and \(\text{ldc} \geq \max(1, n)\) for row major layout.

**tau**

Array, size at least \(\max(1, \min(r,k))\).

For \(\text{vect} = 'Q'\), the array \(\tau_{aq}\) as returned by \(?\gebrd\). For \(\text{vect} = 'P'\), the array \(\tau_{ap}\) as returned by \(?\gebrd\).

**Output Parameters**

\(c\)

Overwritten by the product \(Q^*C\), \(Q^T*C\), \(C^*Q\), \(C^*Q^T\), \(P^*C\), \(P^T*C\), \(C^*P\), or \(C^*P^T\), as specified by \(\text{vect}, \text{side}, \text{and trans}\).

**Return Values**

This function returns a value \(\text{info}\).

If \(\text{info}=0\), the execution is successful.

If \(\text{info} = -i\), the \(i\)-th parameter had an illegal value.

**Application Notes**

The computed product differs from the exact product by a matrix \(E\) such that \(\|E\|_2 = O(\varepsilon) * \|C\|_2\).

The total number of floating-point operations is approximately

\[2*n*k(2*m - k)\] if \(\text{side} = 'L'\) and \(m \geq k\);

\[2*m*k(2*n - k)\] if \(\text{side} = 'R'\) and \(n \geq k\);

\[2*m^2*n\] if \(\text{side} = 'L'\) and \(m < k\);

\[2*n^2*m\] if \(\text{side} = 'R'\) and \(n < k\).

The complex counterpart of this routine is \(\text{unmbr}\).
?ungbr
Generates the complex unitary matrix Q or PH determined by ?gebrd.

Syntax

```c
lapack_int LAPACKE_cungbr (int matrix_layout, char vect, lapack_int m, lapack_int n, lapack_int k, lapack_complex_float* a, lapack_int lda, const lapack_complex_float* tau);

lapack_int LAPACKE_zungbr (int matrix_layout, char vect, lapack_int m, lapack_int n, lapack_int k, lapack_complex_double* a, lapack_int lda, const lapack_complex_double* tau);
```

Include Files

- mkl.h

Description

The routine generates the whole or part of the unitary matrices Q and PH formed by the routines gebrd. Use this routine after a call to cgebrd/zgebrd. All valid combinations of arguments are described in Input Parameters; in most cases you need the following:

To compute the whole m-by-m matrix Q, use:

```c
LAPACKE_?ungbr(matrix_layout, 'Q', m, m, n, a, lda, tau)
```
(note that the array a must have at least m columns).

To form the n leading columns of Q if m > n, use:

```c
LAPACKE_?ungbr(matrix_layout, 'Q', m, n, n, a, lda, tau)
```

To compute the whole n-by-n matrix PH, use:

```c
LAPACKE_?ungbr(matrix_layout, 'P', n, n, m, a, lda, tau)
```
(note that the array a must have at least n rows).

To form the m leading rows of PH if m < n, use:

```c
LAPACKE_?ungbr(matrix_layout, 'P', m, m, n, a, lda, tau)
```

Input Parameters

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **vect**
  Must be 'Q' or 'P'.
  If vect = 'Q', the routine generates the matrix Q.
  If vect = 'P', the routine generates the matrix PH.

- **m**
  The number of required rows of Q or PH.

- **n**
  The number of required columns of Q or PH.

- **k**
  One of the dimensions of A in ?gebrd:
  If vect = 'Q', the number of columns in A;
  If vect = 'P', the number of rows in A.

Constraints: m≥ 0, n≥ 0, k≥ 0.
For \( \text{vect} = 'Q' \): \( k \leq n \leq m \) if \( m > k \), or \( m = n \) if \( m \leq k \).
For \( \text{vect} = 'P' \): \( k \leq m \leq n \) if \( n > k \), or \( m = n \) if \( n \leq k \).

Arrays:

- \( a \)
  - \( a \), size at least \( lda \times n \) for column major layout and \( lda \times m \) for row major layout, is the array \( a \) as returned by \(?\text{gebrd}\).

- \( lda \)
  - The leading dimension of \( a \); at least \( \max(1, m) \) for column major layout and \( \max(1, n) \) for row major layout.

- \( \tau \)
  - For \( \text{vect} = 'Q' \), the array \( \tau_q \) as returned by \(?\text{gebrd}\). For \( \text{vect} = 'P' \), the array \( \tau_p \) as returned by \(?\text{gebrd}\).
  - The dimension of \( \tau \) must be at least \( \max(1, \min(m, k)) \) for \( \text{vect} = 'Q' \), or \( \max(1, \min(m, k)) \) for \( \text{vect} = 'P' \).

Output Parameters

- \( a \)
  - Overwritten by the orthogonal matrix \( Q \) or \( P^T \) (or the leading rows or columns thereof) as specified by \( \text{vect} \), \( m \), and \( n \).

Return Values

This function returns a value \( \text{info} \).

If \( \text{info}=0 \), the execution is successful.

If \( \text{info} = -i \), the \( i \)-th parameter had an illegal value.

Application Notes

The computed matrix \( Q \) differs from an exactly orthogonal matrix by a matrix \( E \) such that \( \|E\|_2 = O(\varepsilon) \).

The approximate numbers of possible floating-point operations are listed below:

To compute the whole matrix \( Q \):

- \((16/3) n(3m^2 - 3m^*n + n^2)\) if \( m > n \);
- \((16/3) m^3 \) if \( m \leq n \).

To form the \( n \) leading columns of \( Q \) when \( m > n \):

- \((8/3) n^2 (3m - n^2)\).

To compute the whole matrix \( P^H \):

- \((16/3) n^3 \) if \( m \geq n \);
- \((16/3) m(3n^2 - 3m^*n + m^2) \) if \( m < n \).

To form the \( m \) leading columns of \( P^H \) when \( m < n \):

- \((8/3) n^2 (3m - n^2) \) if \( m > n \).

The real counterpart of this routine is \text{orgbr}.

?\text{unmbr}

Multiplies an arbitrary complex matrix by the unitary matrix \( Q \) or \( P \) determined by \(?\text{gebrd}\).
Syntax

```c
lapack_int LAPACKE_cunmbr (int matrix_layout, char vect, char side, char trans,
                        lapack_int m, lapack_int n, lapack_int k, const lapack_complex_float* a, lapack_int lda,
                        const lapack_complex_float* tau, lapack_complex_float* c, lapack_int ldc);

lapack_int LAPACKE_zunmbr (int matrix_layout, char vect, char side, char trans,
                        lapack_int m, lapack_int n, lapack_int k, const lapack_complex_double* a, lapack_int lda,
                        const lapack_complex_double* tau, lapack_complex_double* c, lapack_int ldc);
```

Include Files

- mkl.h

Description

Given an arbitrary complex matrix \( C \), this routine forms one of the matrix products \( Q^*C \), \( Q^H* C \), \( C*Q \), \( C*Q^H \), \( P*C \), \( P^H*C \), \( C*P \), or \( C*P^H \), where \( Q \) and \( P \) are unitary matrices computed by a call to `gebrd/gebrd`. The routine overwrites the product on \( C \).

Input Parameters

In the descriptions below, \( r \) denotes the order of \( Q \) or \( P^H \):

If \( side = 'L' \), \( r = m \); if \( side = 'R' \), \( r = n \).

- **matrix_layout**: Specifies whether matrix storage layout is row major (`LAPACK_ROW_MAJOR`) or column major (`LAPACK_COL_MAJOR`).

- **vect**: Must be `'Q'` or `'P'`.
  - If `vect = 'Q'`, then \( Q \) or \( Q^H \) is applied to \( C \).
  - If `vect = 'P'`, then \( P \) or \( P^H \) is applied to \( C \).

- **side**: Must be `'L'` or `'R'`.
  - If `side = 'L'`, multipliers are applied to \( C \) from the left.
  - If `side = 'R'`, they are applied to \( C \) from the right.

- **trans**: Must be `'N'` or `'C'`.
  - If `trans = 'N'`, then \( Q \) or \( P \) is applied to \( C \).
  - If `trans = 'C'`, then \( Q^H \) or \( P^H \) is applied to \( C \).

- **m**: The number of rows in \( C \).
- **n**: The number of columns in \( C \).
- **k**: One of the dimensions of \( A \) in `gebrd`:
  - If `vect = 'Q'`, the number of columns in \( A \);
  - If `vect = 'P'`, the number of rows in \( A \).

Constraints: \( m \geq 0 \), \( n \geq 0 \), \( k \geq 0 \).

- **a**, **c**: Arrays:
  - \( a \) is the array \( a \) as returned by `gebrd`.
  - The size of \( a \) depends on the value of the `matrix_layout`, `vect`, and `side` parameters:
<table>
<thead>
<tr>
<th>matrix_layout</th>
<th>vect</th>
<th>side</th>
<th>size</th>
</tr>
</thead>
<tbody>
<tr>
<td>column major</td>
<td>'Q'</td>
<td>-</td>
<td>(\max(1, \text{lda} \times k))</td>
</tr>
<tr>
<td>column major</td>
<td>'P'</td>
<td>'L'</td>
<td>(\max(1, \text{lda} \times m))</td>
</tr>
<tr>
<td>column major</td>
<td>'P'</td>
<td>'R'</td>
<td>(\max(1, \text{lda} \times n))</td>
</tr>
<tr>
<td>row major</td>
<td>'Q'</td>
<td>'L'</td>
<td>(\max(1, \text{lda} \times m))</td>
</tr>
<tr>
<td>row major</td>
<td>'Q'</td>
<td>'R'</td>
<td>(\max(1, \text{lda} \times n))</td>
</tr>
<tr>
<td>row major</td>
<td>'P'</td>
<td>-</td>
<td>(\max(1, \text{lda} \times k))</td>
</tr>
</tbody>
</table>

\(c(\text{size } \max(1, \text{ldc} \times n))\) for column major layout and \(\max(1, \text{ldc} \times m)\) for row major layout holds the matrix \(C\).

\(\text{lda}\)

The leading dimension of \(a\). Constraints:

- \(\text{lda} \geq \max(1, r)\) for column major layout and at least \(\max(1, k)\) for row major layout if \(\text{vect} = 'Q'\);
- \(\text{lda} \geq \max(1, \min(r, k))\) for column major layout and at least \(\max(1, r)\) for row major layout if \(\text{vect} = 'P'\).

\(\text{ldc}\)

The leading dimension of \(C\); \(\text{ldc} \geq \max(1, m)\).

\(\text{tau}\)

Array, size at least \(\max(1, \min(r, k))\).

For \(\text{vect} = 'Q'\), the array \(\text{tauq}\) as returned by ?gebrd. For \(\text{vect} = 'P'\), the array \(\text{taup}\) as returned by ?gebrd.

**Output Parameters**

\(c\)

Overwritten by the product \(Q \times C\), \(Q^H \times C\), \(C \times Q\), \(C \times Q^H\), \(P \times C\), \(P^H \times C\), \(C \times P\), or \(C \times P^H\), as specified by \(\text{vect}, \text{side}, \) and \(\text{trans}\).

**Return Values**

This function returns a value \(\text{info}\).

If \(\text{info}=0\), the execution is successful.

If \(\text{info} = -i\), the \(i\)-th parameter had an illegal value.

**Application Notes**

The computed product differs from the exact product by a matrix \(E\) such that \(\|E\|_2 = O(\epsilon) \times \|C\|_2\).

The total number of floating-point operations is approximately

- \(8 \times n \times k(2 \times m - k)\) if \(\text{side} = 'L'\) and \(m \geq k\);
- \(8 \times m \times k(2 \times n - k)\) if \(\text{side} = 'R'\) and \(n \geq k\);
- \(8 \times m \times n\) if \(\text{side} = 'L'\) and \(m < k\);
- \(8 \times n \times n\) if \(\text{side} = 'R'\) and \(n < k\).
The real counterpart of this routine is ormb.

?bdsqr
Computes the singular value decomposition of a general matrix that has been reduced to bidiagonal form.

Syntax

lapack_int LAPACKE_sbdsqr( int matrix_layout, char uplo, lapack_int n, lapack_int ncvt, lapack_int nru, lapack_int ncc, float* d, float* e, float* vt, lapack_int ldvt, float* u, lapack_int ldu, float* c, lapack_int ldc );

lapack_int LAPACKE_dbdsqr( int matrix_layout, char uplo, lapack_int n, lapack_int ncvt, lapack_int nru, lapack_int ncc, double* d, double* e, double* vt, lapack_int ldvt, double* u, lapack_int ldu, double* c, lapack_int ldc );

lapack_int LAPACKE_cbdsqr( int matrix_layout, char uplo, lapack_int n, lapack_int ncvt, lapack_int nru, lapack_int ncc, float* d, float* e, lapack_complex_float* vt, lapack_int ldvt, lapack_complex_float* u, lapack_int ldu, lapack_complex_float* c, lapack_int ldc );

lapack_int LAPACKE_zbdsqr( int matrix_layout, char uplo, lapack_int n, lapack_int ncvt, lapack_int nru, lapack_int ncc, double* d, double* e, lapack_complex_double* vt, lapack_int ldvt, lapack_complex_double* u, lapack_int ldu, lapack_complex_double* c, lapack_int ldc );

Include Files

- mkl.h

Description

The routine computes the singular values and, optionally, the right and/or left singular vectors from the Singular Value Decomposition (SVD) of a real n-by-n (upper or lower) bidiagonal matrix B using the implicit zero-shift QR algorithm. The SVD of B has the form $B = Q S P^H$ where $S$ is the diagonal matrix of singular values, $Q$ is an orthogonal matrix of left singular vectors, and $P$ is an orthogonal matrix of right singular vectors. If left singular vectors are requested, this subroutine actually returns $U^*Q$ instead of $Q$, and, if right singular vectors are requested, this subroutine returns $P^H*VT$ instead of $P^H$, for given real/complex input matrices $U$ and $VT$. When $U$ and $VT$ are the orthogonal/unitary matrices that reduce a general matrix $A$ to bidiagonal form: $A = U^*B*VT$, as computed by ?gebrd, then

$A = (U^*Q)*S*(P^H*VT)$

is the SVD of $A$. Optionally, the subroutine may also compute $Q^H*C$ for a given real/complex input matrix $C$.

Input Parameters

matrix_layout
Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

uplo
Must be 'U' or 'L'.
If uplo = 'U', $B$ is an upper bidiagonal matrix.
If uplo = 'L', $B$ is a lower bidiagonal matrix.

n
The order of the matrix $B$ ($n \geq 0$).
The number of columns of the matrix $VT$, that is, the number of right singular vectors ($ncvt \geq 0$).

Set $ncvt = 0$ if no right singular vectors are required.

The number of rows in $U$, that is, the number of left singular vectors ($nru \geq 0$).

Set $nru = 0$ if no left singular vectors are required.

The number of columns in the matrix $C$ used for computing the product $Q^H \cdot C$ ($ncc \geq 0$). Set $ncc = 0$ if no matrix $C$ is supplied.

Arrays:

$d$, $e$

$d$ contains the diagonal elements of $B$.

The size of $d$ must be at least $\max(1, n)$.

$e$ contains the $(n-1)$ off-diagonal elements of $B$.

The size of $e$ must be at least $\max(1, n - 1)$.

Arrays:

$vt$, $u$, $c$

$vt$, size $\max(1, ldvt*ncvt)$ for column major layout and $\max(1, ldvt*n)$ for row major layout, contains an $n$-by-$ncvt$ matrix $VT$.

$vt$ is not referenced if $ncvt = 0$.

$u$, size $\max(1, ldu*n)$ for column major layout and $\max(1, ldu*nru)$ for row major layout, contains an $nru$ by $n$ matrix $U$.

$u$ is not referenced if $nru = 0$.

$c$, size $\max(1, ldc*ncc)$ for column major layout and $\max(1, ldc*n)$ for row major layout, contains the $n$-by-$ncc$ matrix $C$ for computing the product $Q^H \cdot C$.

The leading dimension of $vt$. Constraints:

$ldvt \geq \max(1, n)$ if $ncvt > 0$ for column major layout and $ldvt \geq \max(1, ncvt)$ for row major layout;

$ldvt \geq 1$ if $ncvt = 0$.

The leading dimension of $u$. Constraint:

$ldu \geq \max(1, nru)$ for column major layout and $ldu \geq \max(1, n)$ for row major layout.

The leading dimension of $c$. Constraints:

$ldc \geq \max(1, n)$ if $ncc > 0$ for column major layout and $ldc \geq \max(1, ncc)$ for row major layout; $ldc \geq 1$ otherwise.

**Output Parameters**

$d$

On exit, if $info = 0$, overwritten by the singular values in decreasing order (see $info$).

$e$

On exit, if $info = 0$, $e$ is destroyed. See also $info$ below.
Overwritten by the product $Q^H*C$.

On exit, this array is overwritten by $P^*VT$. Not referenced if $ncvt = 0$.

On exit, this array is overwritten by $U*Q$. Not referenced if $nru = 0$.

**Return Values**

This function returns a value $info$.

If $info = 0$, the execution is successful.

If $info = -i$, the $i$-th parameter had an illegal value.

If $info > 0$,

If $ncvt = nru = ncc = 0$,

- $info = 1$, a split was marked by a positive value in $e$
- $info = 2$, the current block of $z$ not diagonalized after $100*n$ iterations (in the inner while loop)
- $info = 3$, termination criterion of the outer while loop is not met (the program created more than $n$ unreduced blocks).

In all other cases when $ncvt$, $nru$, or $ncc > 0$, the algorithm did not converge; $d$ and $e$ contain the elements of a bidiagonal matrix that is orthogonally similar to the input matrix $B$; if $info = i$, $i$ elements of $e$ have not converged to zero.

**Application Notes**

Each singular value and singular vector is computed to high relative accuracy. However, the reduction to bidiagonal form (prior to calling the routine) may decrease the relative accuracy in the small singular values of the original matrix if its singular values vary widely in magnitude.

If $s_i$ is an exact singular value of $B$, and $s_j$ is the corresponding computed value, then

$$|s_i - s_j| \leq p^*(m, n) * \varepsilon * s_i$$

where $p(m, n)$ is a modestly increasing function of $m$ and $n$, and $\varepsilon$ is the machine precision.

If only singular values are computed, they are computed more accurately than when some singular vectors are also computed (that is, the function $p(m, n)$ is smaller).

If $u_i$ is the corresponding exact left singular vector of $B$, and $w_i$ is the corresponding computed left singular vector, then the angle $\theta(u_i, w_i)$ between them is bounded as follows:

$$\theta(u_i, w_i) \leq p(m, n) * \varepsilon / \min_{i \neq j}(|s_i - s_j|/|s_i + s_j|).$$

Here $\min_{i \neq j}(|s_i - s_j|/|s_i + s_j|)$ is the relative gap between $s_i$ and the other singular values. A similar error bound holds for the right singular vectors.

The total number of real floating-point operations is roughly proportional to $n^2$ if only the singular values are computed. About $6n^2*nru$ additional operations ($12n^2*nru$ for complex flavors) are required to compute the left singular vectors and about $6n^2*ncvt$ operations ($12n^2*ncvt$ for complex flavors) to compute the right singular vectors.

?bdsdc

*Computes the singular value decomposition of a real bidiagonal matrix using a divide and conquer method.*
Syntax

```c
lapack_int LAPACKE_sbdsc (int matrix_layout, char uplo, char compq, lapack_int n, float* d, float* e, float* u, lapack_int ldu, float* vt, lapack_int ldvt, float* q, lapack_int* iq);
```

```c
lapack_int LAPACKE_dbdsc (int matrix_layout, char uplo, char compq, lapack_int n, double* d, double* e, double* u, lapack_int ldu, double* vt, lapack_int ldvt, double* q, lapack_int* iq);
```

Include Files
- mkl.h

Description

The routine computes the Singular Value Decomposition (SVD) of a real \( n \)-by-\( n \) (upper or lower) bidiagonal matrix \( B \): \( B = U \Sigma V^T \), using a divide and conquer method, where \( \Sigma \) is a diagonal matrix with non-negative diagonal elements (the singular values of \( B \)), and \( U \) and \( V \) are orthogonal matrices of left and right singular vectors, respectively. \( \text{?bdsdc} \) can be used to compute all singular values, and optionally, singular vectors or singular vectors in compact form.

This routine uses \( \text{?lasd0} \), \( \text{?lasd1} \), \( \text{?lasd2} \), \( \text{?lasd3} \), \( \text{?lasd4} \), \( \text{?lasd5} \), \( \text{?lasd6} \), \( \text{?lasd7} \), \( \text{?lasd8} \), \( \text{?lasd9} \), \( \text{?lasda} \), \( \text{?lasdq} \), \( \text{?lasdt} \).

Input Parameters

- \textit{matrix_layout}
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- \textit{uplo}
  Must be 'U' or 'L'.
  If \( \text{uplo} = 'U' \), \( B \) is an upper bidiagonal matrix.
  If \( \text{uplo} = 'L' \), \( B \) is a lower bidiagonal matrix.

- \textit{compq}
  Must be 'N', 'P', or 'I'.
  If \( \text{compq} = 'N' \), compute singular values only.
  If \( \text{compq} = 'P' \), compute singular values and compute singular vectors in compact form.
  If \( \text{compq} = 'I' \), compute singular values and singular vectors.

- \textit{n}
  The order of the matrix \( B \) (\( n \geq 0 \)).

- \textit{d, e}
  Arrays:
  \( d \) contains the \( n \) diagonal elements of the bidiagonal matrix \( B \). The size of \( d \) must be at least \( \max(1, n) \).
  \( e \) contains the off-diagonal elements of the bidiagonal matrix \( B \). The size of \( e \) must be at least \( \max(1, n) \).

- \textit{ldu}
  The leading dimension of the output array \( u \); \( ldu \geq 1 \).
  If singular vectors are desired, then \( ldu \geq \max(1, n) \), regardless of the value of \textit{matrix_layout}.

- \textit{ldvt}
  The leading dimension of the output array \( vt \); \( ldvt \geq 1 \).
If singular vectors are desired, then $ldvt \geq \max(1, n)$, regardless of the value of $\text{matrix\_layout}$.

**Output Parameters**

- $d$
  - If $info = 0$, overwritten by the singular values of $B$.
  - On exit, $e$ is overwritten.

- $u$, $vt$, $q$
  - Arrays: $u(\text{size } ldu*n)$, $vt(\text{size } ldvt*n)$, $q(\text{size } \geq n*(11 + 2*smlsiz + 8*\text{int}(\log_2(n/(smlsiz+1))))$ where $smlsiz$ is returned by $\text{ilaenv}$ and is equal to maximum size of the subproblems at the bottom of the computation tree.
  - If $\text{compq} = 'I'$, then on exit $u$ contains the left singular vectors of the bidiagonal matrix $B$, unless $info \neq 0$ (see $info$). For other values of $\text{compq}$, $u$ is not referenced.
  - If $\text{compq} = 'I'$, then on exit $vt^T$ contains the right singular vectors of the bidiagonal matrix $B$, unless $info \neq 0$ (see $info$). For other values of $\text{compq}$, $vt$ is not referenced.
  - If $\text{compq} = 'P'$, then on exit, if $info = 0$, $q$ and $iq$ contain the left and right singular vectors in a compact form. Specifically, $q$ contains all the float (for $\text{sbdsdc}$) or double (for $\text{dbdsdc}$) data for singular vectors. For other values of $\text{compq}$, $q$ is not referenced.

- $iq$
  - Array: $iq(\text{size } \geq n*(3 + 3*\text{int}(\log_2(n/(smlsiz+1))))$ where $smlsiz$ is returned by $\text{ilaenv}$ and is equal to maximum size of the subproblems at the bottom of the computation tree.
  - If $\text{compq} = 'P'$, then on exit, if $info = 0$, $q$ and $iq$ contain the left and right singular vectors in a compact form. Specifically, $iq$ contains all the lapack_int data for singular vectors. For other values of $\text{compq}$, $iq$ is not referenced.

**Return Values**

This function returns a value $info$.

- If $info = 0$, the execution is successful.
- If $info = -i$, the $i$-th parameter had an illegal value.
- If $info = i$, the algorithm failed to compute a singular value. The update process of divide and conquer failed.

**Symmetric Eigenvalue Problems: LAPACK Computational Routines**

Symmetric eigenvalue problems are posed as follows: given an $n$-by-$n$ real symmetric or complex Hermitian matrix $A$, find the eigenvalues $\lambda$ and the corresponding eigenvectors $z$ that satisfy the equation $Az = \lambda z$ (or, equivalently, $z^H A = \lambda z^H$).

In such eigenvalue problems, all $n$ eigenvalues are real not only for real symmetric but also for complex Hermitian matrices $A$, and there exists an orthonormal system of $n$ eigenvectors. If $A$ is a symmetric or Hermitian positive-definite matrix, all eigenvalues are positive.
To solve a symmetric eigenvalue problem with LAPACK, you usually need to reduce the matrix to tridiagonal form and then solve the eigenvalue problem with the tridiagonal matrix obtained. LAPACK includes routines for reducing the matrix to a tridiagonal form by an orthogonal (or unitary) similarity transformation $A = QTQ^H$ as well as for solving tridiagonal symmetric eigenvalue problems. These routines are listed in Table "Computational Routines for Solving Symmetric Eigenvalue Problems".

There are different routines for symmetric eigenvalue problems, depending on whether you need all eigenvectors or only some of them or eigenvalues only, whether the matrix $A$ is positive-definite or not, and so on.

These routines are based on three primary algorithms for computing eigenvalues and eigenvectors of symmetric problems: the divide and conquer algorithm, the QR algorithm, and bisection followed by inverse iteration. The divide and conquer algorithm is generally more efficient and is recommended for computing all eigenvalues and eigenvectors. Furthermore, to solve an eigenvalue problem using the divide and conquer algorithm, you need to call only one routine. In general, more than one routine has to be called if the QR algorithm or bisection followed by inverse iteration is used.

                        lapack_int lda, double* d, double* e, double* tau);
```

Include Files

- mkl.h

Description

The routine reduces a real symmetric matrix \( A \) to symmetric tridiagonal form \( T \) by an orthogonal similarity transformation: \( A = Q^TQ^2 \). The orthogonal matrix \( Q \) is not formed explicitly but is represented as a product of \( n-1 \) elementary reflectors. Routines are provided for working with \( Q \) in this representation (see Application Notes below).

Input Parameters

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **uplo**
  Must be ‘U’ or ‘L’.
  If \( uplo = 'U' \), \( A \) stores the upper triangular part of \( A \).
  If \( uplo = 'L' \), \( A \) stores the lower triangular part of \( A \).

- **n**
  The order of the matrix \( A \) (\( n \geq 0 \)).

- **a**
  \( a \) (size max(1, lda\(n\))) is an array containing either upper or lower triangular part of the matrix \( A \), as specified by \( uplo \). If \( uplo = 'U' \), the leading \( n \)-by-\( n \) upper triangular part of \( a \) contains the upper triangular part of the matrix \( A \), and the strictly lower triangular part of \( A \) is not referenced. If \( uplo = 'L' \), the leading \( n \)-by-\( n \) lower triangular part of \( a \) contains the lower triangular part of the matrix \( A \), and the strictly upper triangular part of \( A \) is not referenced.

- **lda**
  The leading dimension of \( a \); at least max(1, \( n \)).

Output Parameters

- **a**
  On exit, if \( uplo = 'U' \), the diagonal and first superdiagonal of \( A \) are overwritten by the corresponding elements of the tridiagonal matrix \( T \), and the elements above the first superdiagonal, with the array \( tau \), represent the orthogonal matrix \( Q \) as a product of elementary reflectors;
  if \( uplo = 'L' \), the diagonal and first subdiagonal of \( A \) are overwritten by the corresponding elements of the tridiagonal matrix \( T \), and the elements below the first subdiagonal, with the array \( tau \), represent the orthogonal matrix \( Q \) as a product of elementary reflectors.

- **d**, **e**, **tau**
  Arrays:
  - \( d \) contains the diagonal elements of the matrix \( T \).
The size of \( d \) must be at least \( \max(1, n) \).

\( e \) contains the off-diagonal elements of \( T \).

The size of \( e \) must be at least \( \max(1, n-1) \).

\( \tau \) stores \((n-1)\) scalars that define elementary reflectors in decomposition of the orthogonal matrix \( Q \) in a product of \( n-1 \) elementary reflectors. \( \tau(n) \) is used as workspace.

The size of \( \tau \) must be at least \( \max(1, n) \).

**Return Values**

This function returns a value \( \text{info} \).

If \( \text{info} = 0 \), the execution is successful.

If \( \text{info} = -i \), the \( i \)-th parameter had an illegal value.

**Application Notes**

The computed matrix \( T \) is exactly similar to a matrix \( A+E \), where \( ||E||_2 = c(n) \cdot \epsilon \cdot ||A||_2 \), \( c(n) \) is a modestly increasing function of \( n \), and \( \epsilon \) is the machine precision.

The approximate number of floating-point operations is \((4/3)n^3\).

After calling this routine, you can call the following:

- \( \text{orgtr} \) to form the computed matrix \( Q \) explicitly
- \( \text{ormtr} \) to multiply a real matrix by \( Q \).

The complex counterpart of this routine is \( \text{?hetrd} \).

\( \text{?orgtr} \)

Generates the real orthogonal matrix \( Q \) determined by \( \text{?sytrd} \).

**Syntax**

```c
lapack_int LAPACKE_sorgtr (int matrix_layout, char uplo, lapack_int n, float* a, lapack_int lda, const float* tau);

lapack_int LAPACKE_dorgtr (int matrix_layout, char uplo, lapack_int n, double* a, lapack_int lda, const double* tau);
```

**Include Files**

- mkl.h

**Description**

The routine explicitly generates the \( n \)-by-\( n \) orthogonal matrix \( Q \) formed by \( \text{?sytrd} \) when reducing a real symmetric matrix \( A \) to tridiagonal form: \( A = Q^T T Q \). Use this routine after a call to \( \text{?sytrd} \).

**Input Parameters**

- \( \text{matrix_layout} \)
  
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- \( \text{uplo} \)
  
  Must be ‘U’ or ‘L’.
Use the same \textit{uplo} as supplied to \texttt{?sytrd}.

\texttt{n} \\

The order of the matrix \( Q (n \geq 0) \).

\texttt{a, tau} \\

Arrays:

\texttt{a} (size max(1, \texttt{lda}*n)) is the array \( a \) as returned by \texttt{?sytrd}.

\texttt{tau} is the array \( \tau \) as returned by \texttt{?sytrd}.

The size of \( \tau \) must be at least max(1, \( n-1 \)).

\texttt{lda} \\

The leading dimension of \( a \); at least max(1, \( n \)).

\textbf{Output Parameters} \\

\texttt{a} \\

Overwritten by the orthogonal matrix \( Q \).

\textbf{Return Values} \\

This function returns a value \( \texttt{info} \).

If \( \texttt{info}=0 \), the execution is successful.

If \( \texttt{info} = -i \), the \( i \)-th parameter had an illegal value.

\textbf{Application Notes} \\

The computed matrix \( Q \) differs from an exactly orthogonal matrix by a matrix \( E \) such that \(||E||_2 = O(\epsilon)\), where \( \epsilon \) is the machine precision.

The approximate number of floating-point operations is \((4/3)n^3\).

The complex counterpart of this routine is \texttt{ungtr}.

\texttt{?ormtr} \texttt{Multiplies a real matrix by the real orthogonal matrix} \\
\texttt{Q determined by \texttt{?sytrd}.} \\

\textbf{Syntax} \\

\begin{verbatim}
lapack_int LAPACKE_sormtr (int matrix_layout, char side, char uplo, char trans, 
lapack_int m, lapack_int n, const float* a, lapack_int lda, const float* tau, float* c, 
lapack_int ldc);

lapack_int LAPACKE_dormtr (int matrix_layout, char side, char uplo, char trans, 
lapack_int m, lapack_int n, const double* a, lapack_int lda, const double* tau, double* c, 
lapack_int ldc);
\end{verbatim}

\textbf{Include Files} \\

\begin{itemize}
  \item mkl.h
\end{itemize}

\textbf{Description} \\

The routine multiplies a real matrix \( C \) by \( Q \) or \( Q^T \), where \( Q \) is the orthogonal matrix \( Q \) formed by \texttt{sytrd} when reducing a real symmetric matrix \( A \) to tridiagonal form: \( A = Q^T \Sigma Q \). Use this routine after a call to \texttt{?sytrd}.

Depending on the parameters \texttt{side} and \texttt{trans}, the routine can form one of the matrix products \( Q^T C, Q^T Q, \) \( C \), or \( C^T Q \) (overwriting the result on \( C \)).
Input Parameters

In the descriptions below, $r$ denotes the order of $Q$:

If $side = 'L'$, $r = m$; if $side = 'R'$, $r = n$.

- **matrix_layout**: Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **side**: Must be either 'L' or 'R'.
  - If $side = 'L'$, $Q$ or $Q^T$ is applied to $C$ from the left.
  - If $side = 'R'$, $Q$ or $Q^T$ is applied to $C$ from the right.

- **uplo**: Must be 'U' or 'L'.
  - Use the same uplo as supplied to ?sytrd.

- **trans**: Must be either 'N' or 'T'.
  - If $trans = 'N'$, the routine multiplies $C$ by $Q$.
  - If $trans = 'T'$, the routine multiplies $C$ by $Q^T$.

- **m**: The number of rows in the matrix $C$ ($m \geq 0$).

- **n**: The number of columns in $C$ ($n \geq 0$).

- **a, c, tau**: $a$ (size $\max(1, lda \times r)$) and $tau$ are the arrays returned by ?sytrd.
  - The size of $tau$ must be at least $\max(1, r-1)$.
  - $c$ (size $\max(1, ldc \times n)$ for column major layout and $\max(1, ldc \times m)$ for row major layout) contains the matrix $C$.

- **lda**: The leading dimension of $a$; $lda \geq \max(1, r)$.

- **ldc**: The leading dimension of $c$; $ldc \geq \max(1, m)$ for column major layout and at least $\max(1, n)$ for row major layout.

Output Parameters

- **c**: Overwritten by the product $Q \times C$, $Q^T \times C$, $C \times Q$, or $C \times Q^T$ (as specified by $side$ and $trans$).

Return Values

This function returns a value $info$.

- If $info=0$, the execution is successful.
- If $info = -i$, the $i$-th parameter had an illegal value.

Application Notes

- The computed product differs from the exact product by a matrix $E$ such that $||E||_2 = O(\varepsilon) \times ||C||_2$.

- The total number of floating-point operations is approximately $2 \times m^2 \times n$, if $side = 'L'$, or $2 \times n^2 \times m$, if $side = 'R'$.

- The complex counterpart of this routine is unmtr.
Hetrd
Reduces a complex Hermitian matrix to tridiagonal form.

Syntax

```c
lapack_int LAPACKE_chetrd( int matrix_layout, char uplo, lapack_int n,
                         lapack_complex_float* a, lapack_int lda, float* d, float* e, lapack_complex_float* tau );

lapack_int LAPACKE_zhetrd( int matrix_layout, char uplo, lapack_int n,
                         lapack_complex_double* a, lapack_int lda, double* d, double* e, lapack_complex_double* tau );
```

Include Files

- mkl.h

Description

The routine reduces a complex Hermitian matrix $A$ to symmetric tridiagonal form $T$ by a unitary similarity transformation: $A = Q^*TQ$. The unitary matrix $Q$ is not formed explicitly but is represented as a product of $n-1$ elementary reflectors. Routines are provided to work with $Q$ in this representation.

Input Parameters

- `matrix_layout` Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- `uplo` Must be 'U' or 'L'.

  If `uplo` = 'U', $a$ stores the upper triangular part of $A$.

  If `uplo` = 'L', $a$ stores the lower triangular part of $A$.

- `n` The order of the matrix $A$ ($n \geq 0$).

- `a` ($\text{size max}(1, \text{lda} \times n)$) is an array containing either upper or lower triangular part of the matrix $A$, as specified by `uplo`. If `uplo` = 'U', the leading $n$-by-$n$ upper triangular part of $a$ contains the upper triangular part of the matrix $A$, and the strictly lower triangular part of $A$ is not referenced. If `uplo` = 'L', the leading $n$-by-$n$ lower triangular part of $a$ contains the lower triangular part of the matrix $A$, and the strictly upper triangular part of $A$ is not referenced.

  The leading dimension of $a$; at least max(1, $n$).

Output Parameters

- `a`

  On exit, if `uplo` = 'U', the diagonal and first superdiagonal of $A$ are overwritten by the corresponding elements of the tridiagonal matrix $T$, and the elements above the first superdiagonal, with the array `tau`, represent the orthogonal matrix $Q$ as a product of elementary reflectors;
if uplo = 'L', the diagonal and first subdiagonal of A are overwritten by
the corresponding elements of the tridiagonal matrix T, and the elements
below the first subdiagonal, with the array tau, represent the orthogonal
matrix Q as a product of elementary reflectors.

d, e

Arrays:
d contains the diagonal elements of the matrix T.
The dimension of d must be at least max(1, n).
e contains the off-diagonal elements of T.
The dimension of e must be at least max(1, n-1).

tau

Array, size at least max(1, n-1). Stores (n-1) scalars that define elementary
reflectors in decomposition of the unitary matrix Q in a product of n-1
elementary reflectors.

Return Values
This function returns a value info.
If info=0, the execution is successful.
If info = -i, the i-th parameter had an illegal value.

Application Notes
The computed matrix T is exactly similar to a matrix A + E, where ||E||_2 = c(n)*\epsilon*||A||_2, c(n) is a
modestly increasing function of n, and \epsilon is the machine precision.
The approximate number of floating-point operations is (16/3) n^3.
After calling this routine, you can call the following:
    ungtr              to form the computed matrix Q explicitly
    unmtr              to multiply a complex matrix by Q.
The real counterpart of this routine is ?sytrd.

?ungtr
Generates the complex unitary matrix Q determined
by ?hetrd.

Syntax
lapack_int LAPACKE_cungtr (int matrix_layout, char uplo, lapack_int n,
lapack_complex_float* a, lapack_int lda, const lapack_complex_float* tau);  
lapack_int LAPACKE_zungtr (int matrix_layout, char uplo, lapack_int n,
lapack_complex_double* a, lapack_int lda, const lapack_complex_double* tau);

Include Files
• mkl.h

Description
The routine explicitly generates the n-by-n unitary matrix Q formed by ?hetrd when reducing a complex
Hermitian matrix A to tridiagonal form: A = Q^*T*Q^H. Use this routine after a call to ?hetrd.
Input Parameters

**matrix_layout**
Specifies whether matrix storage layout is row major (**LAPACK_ROW_MAJOR**) or column major (**LAPACK_COL_MAJOR**).

**uplo**
Must be 'U' or 'L'.
Use the same **uplo** as supplied to **?hetrd**.

**n**
The order of the matrix **Q** (**n** ≥ 0).

**a, tau**
Arrays:
- **a** (size max(1, **lda***(**n**))) is the array **a** as returned by **?hetrd**.
- **tau** is the array **tau** as returned by **?hetrd**.

**lda**
The dimension of **tau** must be at least max(1, **n**-1).
The leading dimension of **a**; at least max(1, **n**).

Output Parameters

**a**
Overwritten by the unitary matrix **Q**.

Return Values

This function returns a value **info**.
If **info**=0, the execution is successful.
If **info** = -i, the i-th parameter had an illegal value.

Application Notes

The computed matrix **Q** differs from an exactly unitary matrix by a matrix **E** such that \( ||E||_2 = O(\varepsilon) \), where \( \varepsilon \) is the machine precision.
The approximate number of floating-point operations is \( (16/3) n^3 \).
The real counterpart of this routine is **orgtr**.

**?unmtr**
*Multiplies a complex matrix by the complex unitary matrix Q determined by ?hetrd.*

Syntax

```c
#include <mkl.h>

lapack_int LAPACKE_cunmtr (int matrix_layout, char side, char uplo, char trans,
                         lapack_int m, lapack_int n, const lapack_complex_float* a,
                         lapack_int lda, const lapack_complex_float* tau,
                         lapack_complex_float* c, lapack_int ldc);

lapack_int LAPACKE_zunmtr (int matrix_layout, char side, char uplo, char trans,
                         lapack_int m, lapack_int n, const lapack_complex_double* a,
                         lapack_int lda, const lapack_complex_double* tau,
                         lapack_complex_double* c, lapack_int ldc);
```

Include Files

- mkl.h

Description
The routine multiplies a complex matrix $C$ by $Q$ or $Q^H$, where $Q$ is the unitary matrix $Q$ formed by `?hetrd` when reducing a complex Hermitian matrix $A$ to tridiagonal form: $A = QTQ^H$. Use this routine after a call to `?hetrd`.

Depending on the parameters `side` and `trans`, the routine can form one of the matrix products $Q^C$, $QH^C$, $C^Q$, or $C^QH$ (overwriting the result on $C$).

**Input Parameters**

In the descriptions below, $r$ denotes the order of $Q$:

If `side` = 'L', $r = m$; if `side` = 'R', $r = n$.

- **matrix_layout**
  Specifies whether matrix storage layout is row major (`LAPACK_ROW_MAJOR`) or column major (`LAPACK_COL_MAJOR`).

- **side**
  Must be either 'L' or 'R'.
  - If `side` = 'L', $Q$ or $Q^H$ is applied to $C$ from the left.
  - If `side` = 'R', $Q$ or $Q^H$ is applied to $C$ from the right.

- **uplo**
  Must be 'U' or 'L'.
  Use the same `uplo` as supplied to `?hetrd`.

- **trans**
  Must be either 'N' or 'T'.
  - If `trans` = 'N', the routine multiplies $C$ by $Q$.
  - If `trans` = 'C', the routine multiplies $C$ by $Q^H$.

- **m**
  The number of rows in the matrix $C$ ($m \geq 0$).

- **n**
  The number of columns in $C$ ($n \geq 0$).

- **a, c, tau**
  $a$ (size max(1, $lda \times r$)) and $tau$ are the arrays returned by `?hetrd`.
  The dimension of $tau$ must be at least max(1, $r-1$).
  $c$(size max(1, $ldc \times n$) for column major layout and max(1, $ldc \times m$) for row major layout) contains the matrix $C$.

- **lda**
  The leading dimension of $a$; $lda \geq \text{max}(1, r)$.

- **ldc**
  The leading dimension of $c$; $ldc \geq \text{max}(1, n)$ for column major layout and $ldc \geq \text{max}(1, m)$ for row major layout.

**Output Parameters**

- **c**
  Overwritten by the product $Q^C$, $Q^H^C$, $C^Q$, or $C^QH$ (as specified by `side` and `trans`).

**Return Values**

This function returns a value `info`.

- If `info`=0, the execution is successful.
- If `info` = $-i$, the $i$-th parameter had an illegal value.
Application Notes

The computed product differs from the exact product by a matrix $E$ such that $||E||_2 = O(\varepsilon) * ||C||_2$, where $\varepsilon$ is the machine precision.

The total number of floating-point operations is approximately $8m^2n$ if $side = 'L'$ or $8n^2m$ if $side = 'R'$.

The real counterpart of this routine is `ormtr`.

`?sptrd`

Reduces a real symmetric matrix to tridiagonal form using packed storage.

Syntax

```c
lapack_int LAPACKE_ssptrd (int matrix_layout, char uplo, lapack_int n, float* ap, float* d, float* e, float* tau);

lapack_int LAPACKE_dsptrd (int matrix_layout, char uplo, lapack_int n, double* ap, double* d, double* e, double* tau);
```

Include Files

- mkl.h

Description

The routine reduces a packed real symmetric matrix $A$ to symmetric tridiagonal form $T$ by an orthogonal similarity transformation: $A = Q*T*Q^T$. The orthogonal matrix $Q$ is not formed explicitly but is represented as a product of $n-1$ elementary reflectors. Routines are provided for working with $Q$ in this representation. See Application Notes below for details.

Input Parameters

- `matrix_layout` Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- `uplo` Must be 'U' or 'L'.
  - If `uplo` = 'U', `ap` stores the packed upper triangle of $A$.
  - If `uplo` = 'L', `ap` stores the packed lower triangle of $A$.

- `n` The order of the matrix $A$ ($n \geq 0$).

- `ap` Array, size at least max(1, n(n+1)/2). Contains either upper or lower triangle of $A$ (as specified by `uplo`) in the packed form described in Matrix Storage Schemes.

Output Parameters

- `ap` Overwritten by the tridiagonal matrix $T$ and details of the orthogonal matrix $Q$, as specified by `uplo`.

- `d`, `e`, `tau` Arrays:
  - $d$ contains the diagonal elements of the matrix $T$.
  - The dimension of $d$ must be at least max(1, n).
  - $e$ contains the off-diagonal elements of $T$. 

The dimension of \( e \) must be at least \( \max(1, n-1) \).

\( \tau \) Stores \((n-1)\) scalars that define elementary reflectors in decomposition of the matrix \( Q \) in a product of \( n-1 \) reflectors.

The dimension of \( \tau \) must be at least \( \max(1, n-1) \).

**Return Values**

This function returns a value \( info \).

If \( info=0 \), the execution is successful.

If \( info = -i \), the \( i \)-th parameter had an illegal value.

**Application Notes**

The matrix \( Q \) is represented as a product of \( n-1 \) elementary reflectors, as follows:

- If \( uplo = 'U' \), \( Q = H(n-1) \ldots H(2)H(1) \)
  
  Each \( H(i) \) has the form
  \[
  H(i) = I - \tau *v*v^T
  \]
  
  where \( \tau \) is a real scalar and \( v \) is a real vector with \( v(i+1:n) = 0 \) and \( v(i) = 1 \).
  
  On exit, \( \tau \) is stored in \( \tau[i-1] \), and \( v(1:i-1) \) is stored in \( AP \), overwriting \( A(l:i-1, i+1) \).

- If \( uplo = 'L' \), \( Q = H(1)H(2) \ldots H(n-1) \)
  
  Each \( H(i) \) has the form
  \[
  H(i) = I - \tau *v*v^T
  \]
  
  where \( \tau \) is a real scalar and \( v \) is a real vector with \( v(1:i) = 0 \) and \( v(i+1) = 1 \).
  
  On exit, \( \tau \) is stored in \( \tau[i-1] \), and \( v(i+2:n) \) is stored in \( AP \), overwriting \( A(i+2:n, i) \).

The computed matrix \( T \) is exactly similar to a matrix \( A+E \), where \( ||E||_2 = \epsilon *||A||_2 \), \( c(n) \) is a modestly increasing function of \( n \), and \( \epsilon \) is the machine precision. The approximate number of floating-point operations is \((4/3)n^3\).

After calling this routine, you can call the following:

- opgtr to form the computed matrix \( Q \) explicitly
- opmtr to multiply a real matrix by \( Q \).

The complex counterpart of this routine is hptrd.

**?opgtr**

Generates the real orthogonal matrix \( Q \) determined by ?sptrd.

**Syntax**

```c
lapack_int LAPACKE_sopgtr (char matrix_layout, char uplo, int n, const float* ap, const float* tau, float* q, int ldq);

lapack_int LAPACKE_dopgtr (char matrix_layout, char uplo, int n, const double* ap, const double* tau, double* q, int ldq);
```
Include Files
• mkl.h

Description
The routine explicitly generates the \( n \)-by-\( n \) orthogonal matrix \( Q \) formed by \( \text{sptrd} \) when reducing a packed real symmetric matrix \( A \) to tridiagonal form: \( A = Q^T T Q \). Use this routine after a call to \( \text{?sptrd} \).

Input Parameters

\( \text{matrix}_\text{layout} \)

Specifies whether matrix storage layout is row major (\text{LAPACK\_ROW\_MAJOR}) or column major (\text{LAPACK\_COL\_MAJOR}).

\( \text{uplo} \)

Must be ‘U’ or ‘L’. Use the same \( \text{uplo} \) as supplied to \( \text{?sptrd} \).

\( n \)

The order of the matrix \( Q \) (\( n \geq 0 \)).

\( \text{ap, tau} \)

Arrays \( \text{ap} \) and \( \text{tau} \), as returned by \( \text{?sptrd} \).

The size of \( \text{ap} \) must be at least \( \text{max}(1, n(n+1)/2) \).

The size of \( \text{tau} \) must be at least \( \text{max}(1, n-1) \).

\( \text{ldq} \)

The leading dimension of the output array \( q \); at least \( \text{max}(1, n) \).

Output Parameters

\( q \)

Array, size (size \( \text{max}(1, \text{ldq} \times n) \)).

Contains the computed matrix \( Q \).

Return Values
This function returns a value \( \text{info} \).

If \( \text{info}=0 \), the execution is successful.

If \( \text{info} = -i \), the \( i \)-th parameter had an illegal value.

Application Notes
The computed matrix \( Q \) differs from an exactly orthogonal matrix by a matrix \( E \) such that \( \|E\|_2 = O(\epsilon) \), where \( \epsilon \) is the machine precision.

The approximate number of floating-point operations is \( (4/3) n^3 \).

The complex counterpart of this routine is \( \text{upgtr} \).

\( \text{?opmtr} \)

\text{Multiplies a real matrix by the real orthogonal matrix} \ Q \ \text{determined by} \ ?\text{sptrd}.

Syntax
lapack_int \text{LAPACKE\_sopmtr} (int \text{matrix\_layout}, char \text{side}, char \text{uplo}, char \text{trans},

Include Files

- mkl.h

Description

The routine multiplies a real matrix $C$ by $Q$ or $Q^T$, where $Q$ is the orthogonal matrix formed by sptrd when reducing a packed real symmetric matrix $A$ to tridiagonal form: $A = Q^* T Q$. Use this routine after a call to ?sptrd.

Depending on the parameters side and trans, the routine can form one of the matrix products $Q^* C$, $Q^T C$, $C^* Q$, or $C^* Q^T$ (overwriting the result on $C$).

Input Parameters

In the descriptions below, $r$ denotes the order of $Q$:

If side = 'L', $r = m$; if side = 'R', $r = n$.

- matrix_layout
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- side
  Must be either 'L' or 'R'.
  - If side = 'L', $Q$ or $Q^T$ is applied to $C$ from the left.
  - If side = 'R', $Q$ or $Q^T$ is applied to $C$ from the right.

- uplo
  Must be 'U' or 'L'.
  Use the same uplo as supplied to ?sptrd.

- trans
  Must be either 'N' or 'T'.
  - If trans = 'N', the routine multiplies $C$ by $Q$.
  - If trans = 'T', the routine multiplies $C$ by $Q^T$.

- m
  The number of rows in the matrix $C$ ($m \geq 0$).

- n
  The number of columns in $C$ ($n \geq 0$).

- ap, tau, c
  $ap$ and $tau$ are the arrays returned by ?sptrd.
  The dimension of $ap$ must be at least max(1, $r(r+1)/2$).
  The dimension of $tau$ must be at least max(1, $r-1$).
  $c$(size max(1, $ldc*n$) for column major layout and max(1, $ldc*m$) for row major layout) contains the matrix $C$.

- ldc
  The leading dimension of $c$; $ldc \geq$ max(1, $n$) for column major layout and $ldc \geq$ max(1, $m$) for row major layout.

Output Parameters

- c
  Overwritten by the product $Q^* C$, $Q^T C$, $C^* Q$, or $C^* Q^T$ (as specified by $side$ and $trans$).

Return Values

This function returns a value info.
If $info=0$, the execution is successful.

If $info = -i$, the $i$-th parameter had an illegal value.

**Application Notes**

The computed product differs from the exact product by a matrix $E$ such that $||E||_2 = O(\varepsilon) ||C||_2$, where $\varepsilon$ is the machine precision.

The total number of floating-point operations is approximately $2^*m^2*n$ if $side = 'L'$, or $2^*n^2*m$ if $side = 'R'$.

The complex counterpart of this routine is upmtr.

**?hprrd**

Reduces a complex Hermitian matrix to tridiagonal form using packed storage.

**Syntax**

```c
lapack_int LAPACKE_chptrd( int matrix_layout, char uplo, lapack_int n,
lapack_complex_float* ap, float* d, float* e, lapack_complex_float* tau );
```

```c
lapack_int LAPACKE_zhptrd( int matrix_layout, char uplo, lapack_int n,
lapack_complex_double* ap, double* d, double* e, lapack_complex_double* tau );
```

**Include Files**

- mkl.h

**Description**

The routine reduces a packed complex Hermitian matrix $A$ to symmetric tridiagonal form $T$ by a unitary similarity transformation: $A = Q*T*Q^H$. The unitary matrix $Q$ is not formed explicitly but is represented as a product of $n-1$ elementary reflectors. Routines are provided for working with $Q$ in this representation (see Application Notes below).

**Input Parameters**

- **matrix_layout**
  
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **uplo**
  
  Must be 'U' or 'L'.

  - If $uplo = 'U'$, $ap$ stores the packed upper triangle of $A$.
  - If $uplo = 'L'$, $ap$ stores the packed lower triangle of $A$.

- **n**

  The order of the matrix $A$ ($n \geq 0$).

- **ap**

  Array, size at least max(1, $n(n+1)/2$). Contains either upper or lower triangle of $A$ (as specified by $uplo$) in the packed form described in Matrix Storage Schemes.

**Output Parameters**

- **ap**

  Overwritten by the tridiagonal matrix $T$ and details of the unitary matrix $Q$, as specified by $uplo$.

- **d, e**

  Arrays:
\(d\) contains the diagonal elements of the matrix \(T\).
The size of \(d\) must be at least \(\max(1, n)\).

\(e\) contains the off-diagonal elements of \(T\).
The size of \(e\) must be at least \(\max(1, n-1)\).

\(\text{tau}\)
Array, size at least \(\max(1, n-1)\). Stores \((n-1)\) scalars that define elementary reflectors in decomposition of the unitary matrix \(Q\) in a product of reflectors.

**Return Values**
This function returns a value \(\text{info}\).

If \(\text{info}=0\), the execution is successful.

If \(\text{info} = -i\), the \(i\)-th parameter had an illegal value.

**Application Notes**
The computed matrix \(T\) is exactly similar to a matrix \(A + E\), where \(||E||_2 = c(n) \times \varepsilon \times ||A||_2\), \(c(n)\) is a modestly increasing function of \(n\), and \(\varepsilon\) is the machine precision.

The approximate number of floating-point operations is \((16/3) n^3\).

After calling this routine, you can call the following:

\text{upgtr} to form the computed matrix \(Q\) explicitly
\text{upmtr} to multiply a complex matrix by \(Q\).

The real counterpart of this routine is \text{sptrd}.

**?upgtr**
*Generates the complex unitary matrix \(Q\) determined by ?hptrd.*

**Syntax**

```c
lapack_int LAPACKE_cupgtr (int matrix_layout, char uplo, lapack_int n, const
lapack_complex_float* ap, const lapack_complex_float* tau, lapack_complex_float* q,
lapack_int ldq);
```

```c
lapack_int LAPACKE_zupgtr (int matrix_layout, char uplo, lapack_int n, const
lapack_complex_double* ap, const lapack_complex_double* tau, lapack_complex_double* q,
lapack_int ldq);
```

**Include Files**

- \text{mkl.h}

**Description**
The routine explicitly generates the \(n\)-by-\(n\) unitary matrix \(Q\) formed by \text{hptrd} when reducing a packed complex Hermitian matrix \(A\) to tridiagonal form: \(A = Q^* T \times Q^H\). Use this routine after a call to ?hptrd.
Input Parameters

- **matrix_layout**: Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- **uplo**: Must be 'U' or 'L'. Use the same uplo as supplied to ?hptrd.
- **n**: The order of the matrix Q (n ≥ 0).
- **ap, tau**: Arrays ap and tau, as returned by ?hptrd. The dimension of ap must be at least max(1, n(n+1)/2). The dimension of tau must be at least max(1, n-1).
- **ldq**: The leading dimension of the output array q; at least max(1, n).

Output Parameters

- **q**: Array, size (size max(1, ldq*n)). Contains the computed matrix Q.

Return Values

This function returns a value info.
- If info=0, the execution is successful.
- If info = -i, the i-th parameter had an illegal value.

Application Notes

The computed matrix Q differs from an exactly orthogonal matrix by a matrix E such that \( ||E||_2 = O(\varepsilon) \), where \( \varepsilon \) is the machine precision.

The approximate number of floating-point operations is \( (16/3)n^3 \).

The real counterpart of this routine is opgtr.

**?upmtr**

*Multiplies a complex matrix by the unitary matrix Q determined by ?hptrd.*

Syntax

```c
lapack_int LAPACKE_cupmtr (int matrix_layout, char side, char uplo, char trans,
lapack_int m, lapack_int n, const lapack_complex_float* ap, const lapack_complex_float* tau, lapack_complex_float* c, lapack_int ldc);
```

```c
lapack_int LAPACKE_zupmtr (int matrix_layout, char side, char uplo, char trans,
lapack_int m, lapack_int n, const lapack_complex_double* ap, const
lapack_complex_double* tau, lapack_complex_double* c, lapack_int ldc);
```

Include Files

- mkl.h

Description
The routine multiplies a complex matrix $C$ by $Q$ or $Q^H$, where $Q$ is the unitary matrix formed by hptrd when reducing a packed complex Hermitian matrix $A$ to tridiagonal form: $A = Q^T*Q^H$. Use this routine after a call to ?hptrd.

Depending on the parameters side and trans, the routine can form one of the matrix products $Q*C$, $Q^H*C$, $C*Q$, or $C*Q^H$ (overwriting the result on $C$).

**Input Parameters**

In the descriptions below, $r$ denotes the order of $Q$:

If side = 'L', $r = m$; if side = 'R', $r = n$.

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **side**
  Must be either 'L' or 'R'.
  - If side = 'L', $Q$ or $Q^H$ is applied to $C$ from the left.
  - If side = 'R', $Q$ or $Q^H$ is applied to $C$ from the right.

- **uplo**
  Must be 'U' or 'L'.
  Use the same uplo as supplied to ?hptrd.

- **trans**
  Must be either 'N' or 'T'.
  - If trans = 'N', the routine multiplies $C$ by $Q$.
  - If trans = 'T', the routine multiplies $C$ by $Q^H$.

- **m**
  The number of rows in the matrix $C$ ($m \geq 0$).

- **n**
  The number of columns in $C$ ($n \geq 0$).

- **ap, tau, c,**
  $ap$ and $tau$ are the arrays returned by ?hptrd.
  - The size of $ap$ must be at least max(1, $r(r+1)/2$).
  - The size of $tau$ must be at least max(1, $r-1$).
  - $c$(size max(1, $ldc*n$) for column major layout and max(1, $ldc*m$) for row major layout) contains the matrix $C$.

- **ldc**
  The leading dimension of $c$; $ldc \geq$ max(1, $m$) for column major layout and $ldc \geq$ max(1, $n$) for row major layout.

**Output Parameters**

- **c**
  Overwritten by the product $Q*C$, $Q^H*C$, $C*Q$, or $C*Q^H$ (as specified by side and trans).

**Return Values**

This function returns a value $info$.

- If $info=0$, the execution is successful.
- If $info = -i$, the $i$-th parameter had an illegal value.
Application Notes

The computed product differs from the exact product by a matrix $E$ such that $||E||_2 = O(\varepsilon)*||C||_2$, where $\varepsilon$ is the machine precision.

The total number of floating-point operations is approximately $8*{m}^2*{n}$ if $side = 'L'$ or $8*{n}^2*{m}$ if $side = 'R'$.

The real counterpart of this routine is $\text{opmtr}$.

**sbtrd**

Reduces a real symmetric band matrix to tridiagonal form.

**Syntax**

```c
lapack_int LAPACKE_ssbtrd (int matrix_layout, char vect, char uplo, lapack_int n, lapack_int kd, float* ab, lapack_int ldab, float* d, float* e, float* q, lapack_int ldq);
lapack_int LAPACKE_dsbtrd (int matrix_layout, char vect, char uplo, lapack_int n, lapack_int kd, double* ab, lapack_int ldab, double* d, double* e, double* q, lapack_int ldq);
```

**Include Files**

- mkl.h

**Description**

The routine reduces a real symmetric band matrix $A$ to symmetric tridiagonal form $T$ by an orthogonal similarity transformation: $A = Q*T*Q^T$. The orthogonal matrix $Q$ is determined as a product of Givens rotations.

If required, the routine can also form the matrix $Q$ explicitly.

**Input Parameters**

- $matrix\_layout$ 
  Specifies whether matrix storage layout is row major ($\text{LAPACK\_ROW\_MAJOR}$) or column major ($\text{LAPACK\_COL\_MAJOR}$).

- $vect$ 
  Must be 'V', 'N', or 'U'.
  - If $vect = 'V'$, the routine returns the explicit matrix $Q$.
  - If $vect = 'N$', the routine does not return $Q$.
  - If $vect = 'U'$, the routine updates matrix $X$ by forming $X*Q$.

- $uplo$ 
  Must be 'U' or 'L'.
  - If $uplo = 'U'$, $ab$ stores the upper triangular part of $A$.
  - If $uplo = 'L'$, $ab$ stores the lower triangular part of $A$.

- $n$ 
  The order of the matrix $A$ ($n \geq 0$).

- $kd$ 
  The number of super- or sub-diagonals in $A$ ($kd \geq 0$).
**ab, q**

- **ab**: An array containing either
  - upper or lower triangular part of the matrix A (as specified by `uplo`) in band storage format.
  - 
  - **q**: An array.
    - If `vect` = 'U', the q array must contain an n-by-n matrix X.
    - If `vect` = 'N' or 'V', the q parameter need not be set.

**ldab**

- The leading dimension of ab; at least \( kd + 1 \) for column major layout and \( n \) for row major layout.

**ldq**

- The leading dimension of q. Constraints:
  - \( ldq \geq \max(1, n) \) if `vect` = 'V' or 'U';
  - \( ldq \geq 1 \) if `vect` = 'N'.

**Output Parameters**

- **ab**
  - On exit, the diagonal elements of the array ab are overwritten by the diagonal elements of the tridiagonal matrix T. If \( kd > 0 \), the elements on the first superdiagonal (if `uplo` = 'U') or the first subdiagonal (if `uplo` = 'L') are overwritten by the off-diagonal elements of T. The rest of ab is overwritten by values generated during the reduction.

- **d, e, q**
  - Arrays:
    - \( d \) contains the diagonal elements of the matrix T.
    - The size of d must be at least \( \max(1, n) \).
    - \( e \) contains the off-diagonal elements of T.
    - The size of e must be at least \( \max(1, n-1) \).
    - \( q \) is not referenced if `vect` = 'N'.
    - If `vect` = 'V', q contains the n-by-n matrix Q.
    - If `vect` = 'U', q contains the product X* Q.

**Return Values**

This function returns a value `info`.

- If `info`=0, the execution is successful.
- If `info` = -i, the i-th parameter had an illegal value.

**Application Notes**

The computed matrix T is exactly similar to a matrix \( A+E \), where \( ||E||_2 = c(n) \varepsilon ||A||_2 \), \( c(n) \) is a modestly increasing function of \( n \), and \( \varepsilon \) is the machine precision. The computed matrix Q differs from an exactly orthogonal matrix by a matrix E such that \( ||E||_2 = O(\varepsilon) \).

The total number of floating-point operations is approximately \( 6n^2kd \) if `vect` = 'N', with \( 3n^3(kd-1)/kd \) additional operations if `vect` = 'V'.

The complex counterpart of this routine is `hbtrd`.
?hbtrd
Reduces a complex Hermitian band matrix to tridiagonal form.

Syntax

```c
lapack_int LAPACKE_chbtrd( int matrix_layout, char vect, char uplo, lapack_int n, lapack_int kd, lapack_complex_float* ab, lapack_int ldab, float* d, float* e, lapack_complex_float* q, lapack_int ldq );
```

```c
lapack_int LAPACKE_zhbtrd( int matrix_layout, char vect, char uplo, lapack_int n, lapack_int kd, lapack_complex_double* ab, lapack_int ldab, double* d, double* e, lapack_complex_double* q, lapack_int ldq );
```

Include Files

- mkl.h

Description

The routine reduces a complex Hermitian band matrix $A$ to symmetric tridiagonal form $T$ by a unitary similarity transformation: $A = Q^*TQ^H$. The unitary matrix $Q$ is determined as a product of Givens rotations. If required, the routine can also form the matrix $Q$ explicitly.

Input Parameters

- **matrix_layout**
  
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **vect**
  
  Must be 'V', 'N', or 'U'.
  
  If $\text{vect} = 'V'$, the routine returns the explicit matrix $Q$.
  
  If $\text{vect} = 'N'$, the routine does not return $Q$.
  
  If $\text{vect} = 'U'$, the routine updates matrix $X$ by forming $Q^*X$.

- **uplo**
  
  Must be 'U' or 'L'.
  
  If $\text{uplo} = 'U'$, $ab$ stores the upper triangular part of $A$.
  
  If $\text{uplo} = 'L'$, $ab$ stores the lower triangular part of $A$.

- **n**
  
  The order of the matrix $A (n \geq 0)$.

- **kd**
  
  The number of super- or sub-diagonals in $A (kd \geq 0)$.

- **ab**
  
  $(size$ least max$(1, ldab*n))$ for column major layout and at least max$(1, ldab*(kd+1))$ for row major layout) is an array containing either upper or lower triangular part of the matrix $A$ (as specified by $\text{uplo}$) in band storage format.

- **q**
  
  $(size max(1, ldq*n))$ is an array.
  
  If $\text{vect} = 'U'$, the $q$ array must contain an $n$-by-$n$ matrix $X$.
  
  If $\text{vect} = 'N'$ or 'V', the $q$ parameter need not be set.'

- **ldab**
  
  The leading dimension of $ab$; at least $kd+1$ for column major layout and $n$ for row major layout.
The leading dimension of `q`. Constraints:

- `ldq ≥ max(1, n)` if `vect = 'V'` or `U`;
- `ldq ≥ 1` if `vect = 'N'`.

**Output Parameters**

- `ab`: On exit, the diagonal elements of the array `ab` are overwritten by the diagonal elements of the tridiagonal matrix `T`. If `kd > 0`, the elements on the first superdiagonal (if `uplo = 'U'`) or the first subdiagonal (if `uplo = 'L'`) are overwritten by the off-diagonal elements of `T`. The rest of `ab` is overwritten by values generated during the reduction.

- `d, e`: Arrays:
  - `d` contains the diagonal elements of the matrix `T`. The dimension of `d` must be at least `max(1, n)`.
  - `e` contains the off-diagonal elements of `T`. The dimension of `e` must be at least `max(1, n-1)`.

- `q`: If `vect = 'N'`, `q` is not referenced.
  - If `vect = 'V'`, `q` contains the `n`-by-`n` matrix `Q`.
  - If `vect = 'U'`, `q` contains the product `X* Q`.

**Return Values**

This function returns a value `info`.

- If `info=0`, the execution is successful.
- If `info = -i`, the `i`-th parameter had an illegal value.

**Application Notes**

The computed matrix `T` is exactly similar to a matrix `A + E`, where `||E||_2 = c(n) * ε * ||A||_2`, `c(n)` is a modestly increasing function of `n`, and `ε` is the machine precision. The computed matrix `Q` differs from an exactly unitary matrix by a matrix `E` such that `||E||_2 = O(ε)`.

The total number of floating-point operations is approximately `20n^2 * kd` if `vect = 'N'`, with `10n^3 * (kd-1) / kd` additional operations if `vect = 'V'`.

The real counterpart of this routine is `sbtrd`.

`?sterf`  
*Computes all eigenvalues of a real symmetric tridiagonal matrix using QR algorithm.*

**Syntax**

```c
lapack_int LAPACKE_ssterf (lapack_int n, float* d, float* e);
lapack_int LAPACKE_dsterf (lapack_int n, double* d, double* e);
```

**Include Files**

- `mkl.h`
Description

The routine computes all the eigenvalues of a real symmetric tridiagonal matrix $T$ (which can be obtained by reducing a symmetric or Hermitian matrix to tridiagonal form). The routine uses a square-root-free variant of the QR algorithm.

If you need not only the eigenvalues but also the eigenvectors, call steqr.

Input Parameters

$n$  
The order of the matrix $T$ ($n \geq 0$).

$d$, $e$  
Arrays:
$d$ contains the diagonal elements of $T$.

The dimension of $d$ must be at least max(1, $n$).

$e$ contains the off-diagonal elements of $T$.

The dimension of $e$ must be at least max(1, $n$-1).

Output Parameters

$d$  
The $n$ eigenvalues in ascending order, unless info $> 0$.

See also info.

$e$  
On exit, the array is overwritten; see info.

Return Values

This function returns a value info.

If info=0, the execution is successful.

If info $= i$, the algorithm failed to find all the eigenvalues after 30$n$ iterations:

$i$ off-diagonal elements have not converged to zero. On exit, $d$ and $e$ contain, respectively, the diagonal and off-diagonal elements of a tridiagonal matrix orthogonally similar to $T$.

If info $= -i$, the $i$-th parameter had an illegal value.

Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix $T+\mathbf{E}$ such that $||\mathbf{E}||_2 = O(\varepsilon) * ||T||_2$, where $\varepsilon$ is the machine precision.

If $\lambda_i$ is an exact eigenvalue, and $m_i$ is the corresponding computed value, then

$|\mu_i - \lambda_i| \leq c(n) * \varepsilon * ||T||_2$

where $c(n)$ is a modestly increasing function of $n$.

The total number of floating-point operations depends on how rapidly the algorithm converges. Typically, it is about $14n^2$.

?steqr

Computes all eigenvalues and eigenvectors of a symmetric or Hermitian matrix reduced to tridiagonal form (QR algorithm).
Syntax

```c
lapack_int LAPACKE_ssteqr(int matrix_layout, char compz, lapack_int n, float* d, float* e, float* z, lapack_int ldz);
```

```c
lapack_int LAPACKE_dsteqr(int matrix_layout, char compz, lapack_int n, double* d, double* e, double* z, lapack_int ldz);
```

```c
lapack_int LAPACKE_csteqr(int matrix_layout, char compz, lapack_int n, float* d, float* e, lapack_complex_float* z, lapack_int ldz);
```

```c
lapack_int LAPACKE_zsteqr(int matrix_layout, char compz, lapack_int n, double* d, double* e, lapack_complex_double* z, lapack_int ldz);
```

Include Files

- mkl.h

Description

The routine computes all the eigenvalues and (optionally) all the eigenvectors of a real symmetric tridiagonal matrix \( T \). In other words, the routine can compute the spectral factorization: \( T = Z \Lambda Z^T \). Here \( \Lambda \) is a diagonal matrix whose diagonal elements are the eigenvalues \( \lambda_i \); \( Z \) is an orthogonal matrix whose columns are eigenvectors. Thus, \( Tz_i = \lambda_i z_i \) for \( i = 1, 2, \ldots, n \).

The routine normalizes the eigenvectors so that \( ||z_i||_2 = 1 \).

You can also use the routine for computing the eigenvalues and eigenvectors of an arbitrary real symmetric (or complex Hermitian) matrix \( A \) reduced to tridiagonal form \( T \): \( A = Q^*TQ \). In this case, the spectral factorization is as follows: \( A = Q^*TQ = (Q^*\Lambda Q)^H \). Before calling \?steqr, you must reduce \( A \) to tridiagonal form and generate the explicit matrix \( Q \) by calling the following routines:

<table>
<thead>
<tr>
<th>Storage Type</th>
<th>for real matrices:</th>
<th>for complex matrices:</th>
</tr>
</thead>
<tbody>
<tr>
<td>full storage</td>
<td>?sytrd, ?orgtr</td>
<td>?hetrd, ?ungtr</td>
</tr>
<tr>
<td>packed storage</td>
<td>?sptrd, ?opgtr</td>
<td>?hptrd, ?upgtr</td>
</tr>
<tr>
<td>band storage</td>
<td>?sbtrd(vect='V')</td>
<td>?hbtrd(vect='V')</td>
</tr>
</tbody>
</table>

If you need eigenvalues only, it's more efficient to call \?sterf. If \( T \) is positive-definite, \?pteqr can compute small eigenvalues more accurately than \?steqr.

To solve the problem by a single call, use one of the divide and conquer routines \?stevd, \?syevd, \?spevd, or \?sbevd for real symmetric matrices or \?heevd, \?hevd, or \?hbevd for complex Hermitian matrices.

Input Parameters

- **matrix_layout**
  - Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **compz**
  - Must be 'N' or 'I' or 'V'.
  - If \( \text{compz} = 'N' \), the routine computes eigenvalues only.
  - If \( \text{compz} = 'I' \), the routine computes the eigenvalues and eigenvectors of the tridiagonal matrix \( T \).
If \( \text{compz} = \text{'V'} \), the routine computes the eigenvalues and eigenvectors of the original symmetric matrix. On entry, \( z \) must contain the orthogonal matrix used to reduce the original matrix to tridiagonal form.

\[ n \]

The order of the matrix \( T \) \((n \geq 0)\).

\[ d, e \]

Arrays:

\( d \) contains the diagonal elements of \( T \).

The size of \( d \) must be at least \( \max(1, n) \).

\( e \) contains the off-diagonal elements of \( T \).

The size of \( e \) must be at least \( \max(1, n-1) \).

\[ z \]

Array, size \( \max(1, ldz \times n) \).

If \( \text{compz} = \text{'N'} \) or \( \text{'I'} \), \( z \) need not be set.

If \( \text{vect} = \text{'V'} \), \( z \) must contain the orthogonal matrix used in the reduction to tridiagonal form.

\[ ldz \]

The leading dimension of \( z \). Constraints:

\( ldz \geq 1 \) if \( \text{compz} = \text{'N'} \);

\( ldz \geq \max(1, n) \) if \( \text{compz} = \text{'V'} \) or \( \text{'I'} \).

**Output Parameters**

\[ d \]

The \( n \) eigenvalues in ascending order, unless \( \text{info} > 0 \).

See also \( \text{info} \).

\[ e \]

On exit, the array is overwritten; see \( \text{info} \).

\[ z \]

If \( \text{info} = 0 \), contains the \( n \)-by-\( n \) matrix the columns of which are orthonormal eigenvectors (the \( i \)-th column corresponds to the \( i \)-th eigenvalue).

**Return Values**

This function returns a value \( \text{info} \).

If \( \text{info}=0 \), the execution is successful.

If \( \text{info} = i \), the algorithm failed to find all the eigenvalues after \( 30n \) iterations: \( i \) off-diagonal elements have not converged to zero. On exit, \( d \) and \( e \) contain, respectively, the diagonal and off-diagonal elements of a tridiagonal matrix orthogonally similar to \( T \).

If \( \text{info} = -i \), the \( i \)-th parameter had an illegal value.

**Application Notes**

The computed eigenvalues and eigenvectors are exact for a matrix \( T+E \) such that \( \| E \|_2 = O(\varepsilon) \| T \|_2 \), where \( \varepsilon \) is the machine precision.

If \( \lambda_i \) is an exact eigenvalue, and \( \mu_i \) is the corresponding computed value, then

\[ |\mu_i - \lambda_i| \leq c(n) \| \varepsilon \|_2 \| T \|_2 \]

where \( c(n) \) is a modestly increasing function of \( n \).
If $z_i$ is the corresponding exact eigenvector, and $w_i$ is the corresponding computed vector, then the angle $\theta(z_i, w_i)$ between them is bounded as follows:

$$\theta(z_i, w_i) \leq c(n) \varepsilon^* \|T\|_2 / \min_{i \neq j} |\lambda_i - \lambda_j|.$$ 

The total number of floating-point operations depends on how rapidly the algorithm converges. Typically, it is about

- $24n^2$ if $\text{compz} = 'N'$;
- $7n^3$ (for complex flavors, $14n^3$) if $\text{compz} = 'V$ or 'I'.

?stemr

Computes selected eigenvalues and eigenvectors of a real symmetric tridiagonal matrix.

**Syntax**

```c
lapack_int LAPACKE_sstemr( int matrix_layout, char jobz, char range, lapack_int n,
                         const float* d, float* e, float vl, float vu, lapack_int il, lapack_int iu,
                         lapack_int* m, float* w, float* z, lapack_int ldz, lapack_int nzc, lapack_int* isuppz,
                         lapack_logical* tryrac);
```

```c
lapack_int LAPACKE(dstemr( int matrix_layout, char jobz, char range, lapack_int n,
                         const double* d, double* e, double vl, double vu, lapack_int il, lapack_int iu,
                         lapack_int* m, double* w, double* z, lapack_int ldz, lapack_int nzc, lapack_int* isuppz,
                         lapack_logical* tryrac);
```

```c
lapack_int LAPACKE_cstemr( int matrix_layout, char jobz, char range, lapack_int n,
                         const float* d, float* e, float vl, float vu, lapack_int il, lapack_int iu,
                         lapack_int* m, float* w, lapack_complex_float* z, lapack_int ldz, lapack_int nzc, lapack_int* isuppz,

lapack_int LAPACKE_zstemr( int matrix_layout, char jobz, char range, lapack_int n,
                         const double* d, double* e, double vl, double vu, lapack_int il, lapack_int iu,
                         lapack_int* m, double* w, lapack_complex_double* z, lapack_int ldz, lapack_int nzc, lapack_int* isuppz,
                         lapack_logical* tryrac);
```

**Include Files**

- mkl.h

**Description**

The routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix $T$. Any such unreduced matrix has a well defined set of pairwise different real eigenvalues, the corresponding real eigenvectors are pairwise orthogonal.

The spectrum may be computed either completely or partially by specifying either an interval $(vl, vu]$ or a range of indices $il:iu$ for the desired eigenvalues.

Depending on the number of desired eigenvalues, these are computed either by bisection or the $dqds$ algorithm. Numerically orthogonal eigenvectors are computed by the use of various suitable $L*D*L^T$ factorizations near clusters of close eigenvalues (referred to as RRRs, Relatively Robust Representations). An informal sketch of the algorithm follows.

For each unreduced block (submatrix) of $T$,
a. Compute $T - \sigma \cdot I = L \cdot D \cdot L^T$, so that $L$ and $D$ define all the wanted eigenvalues to high relative accuracy. This means that small relative changes in the entries of $L$ and $D$ cause only small relative changes in the eigenvalues and eigenvectors. The standard (unfactored) representation of the tridiagonal matrix $T$ does not have this property in general.

b. Compute the eigenvalues to suitable accuracy. If the eigenvectors are desired, the algorithm attains full accuracy of the computed eigenvalues only right before the corresponding vectors have to be computed, see steps c and d.

c. For each cluster of close eigenvalues, select a new shift close to the cluster, find a new factorization, and refine the shifted eigenvalues to suitable accuracy.

d. For each eigenvalue with a large enough relative separation compute the corresponding eigenvector by forming a rank revealing twisted factorization. Go back to step c for any clusters that remain.

Normal execution of ?stemr may create NaNs and infinities and may abort due to a floating point exception in environments that do not handle NaNs and infinities in the IEEE standard default manner.

For more details, see: [Dhillon04], [Dhillon04-02], [Dhillon97]

Input Parameters

matrix_layout
Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

jobz
Must be 'N' or 'V'.
If jobz = 'N', then only eigenvalues are computed.
If jobz = 'V', then eigenvalues and eigenvectors are computed.

range
Must be 'A' or 'V' or 'I'.
If range = 'A', the routine computes all eigenvalues.
If range = 'V', the routine computes all eigenvalues in the half-open interval: $[vl, vu]$.
If range = 'I', the routine computes eigenvalues with indices $il$ to $iu$.

n
The order of the matrix $T (n \geq 0)$.

d
Array, size $n$.
Contains $n$ diagonal elements of the tridiagonal matrix $T$.

e
Array, size $n$.
Contains $(n-1)$ off-diagonal elements of the tridiagonal matrix $T$ in elements 0 to $n-2$ of e. $e[n-1]$ need not be set on input, but is used internally as workspace.

vl, vu
If range = 'V', the lower and upper bounds of the interval to be searched for eigenvalues. Constraint: $vl < vu$.
If range = 'A' or 'I', vl and vu are not referenced.

il, iu
If range = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned.
Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$.
If range = 'A' or 'V', il and iu are not referenced.

ldz
The leading dimension of the output array z.
if \( \text{jobz} = 'V' \), then \( \text{idz} \geq \max(1, n) \) for column major layout and \( \text{ldz} \geq \max(1, m) \) for row major layout;

\( \text{idz} \geq 1 \) otherwise.

\( \text{nzc} \)

The number of eigenvectors to be held in the array \( z \).

- If \( \text{range} = 'A' \), then \( \text{nzc} \geq \max(1, n) \);
- If \( \text{range} = 'V' \), then \( \text{nzc} \) is greater than or equal to the number of eigenvalues in the half-open interval: \( (\text{vl}, \text{vu}] \).
- If \( \text{range} = 'I' \), then \( \text{nzc} \geq \text{iu}-\text{il}+1 \).

If \( \text{nzc} = -1 \), then a workspace query is assumed; the routine calculates the number of columns of the array \( z \) that are needed to hold the eigenvectors.

This value is returned as the first entry of the array \( z \), and no error message related to \( \text{nzc} \) is issued by the routine \( \text{xerbla} \).

\( \text{tryrac} \)

If \( \text{tryrac} \) is true, it indicates that the code should check whether the tridiagonal matrix defines its eigenvalues to high relative accuracy. If so, the code uses relative-accuracy preserving algorithms that might be (a bit) slower depending on the matrix. If the matrix does not define its eigenvalues to high relative accuracy, the code can use possibly faster algorithms.

If \( \text{tryrac} \) is not true, the code is not required to guarantee relatively accurate eigenvalues and can use the fastest possible techniques.

**Output Parameters**

\( d \)

On exit, the array \( d \) is overwritten.

\( e \)

On exit, the array \( e \) is overwritten.

\( m \)

The total number of eigenvalues found, \( 0 \leq m \leq n \).

- If \( \text{range} = 'A' \), then \( m=n \), and if \( \text{range} = 'I' \), then \( m=\text{iu}-\text{il}+1 \).

\( w \)

Array, size \( n \).

The first \( m \) elements contain the selected eigenvalues in ascending order.

\( z \)

Array \( z \) (size \( \max(1, \text{ldz} \times m) \) for column major layout and \( \max(1, \text{ldz} \times n) \) for row major layout).

- If \( \text{jobz} = 'V' \), and \( \text{info} = 0 \), then the first \( m \) columns of \( z \) contain the orthonormal eigenvectors of the matrix \( T \) corresponding to the selected eigenvalues, with the \( i \)-th column of \( z \) holding the eigenvector associated with \( w(i) \).
- If \( \text{jobz} = 'N' \), then \( z \) is not referenced.

Note: the exact value of \( m \) is not known in advance and can be computed with a workspace query by setting \( \text{nzc} = -1 \), see description of the parameter \( \text{nzc} \).

\( \text{isuppz} \)

Array, size \( 2 \times \max(1, m) \).
The support of the eigenvectors in \( z \), that is the indices indicating the nonzero elements in \( z \). The \( i \)-th computed eigenvector is nonzero only in elements \( \text{isuppz}[2*i - 2] \) through \( \text{isuppz}[2*i - 1] \). This is relevant in the case when the matrix is split. \( \text{isuppz} \) is only accessed when \( \text{jobz} = 'V' \) and \( n > 0 \).

\[ \text{tryrac} \]

On exit, \( \text{tryrac} \) is set to true. \( \text{tryrac} \) is set to false if the matrix does not define its eigenvalues to high relative accuracy.

**Return Values**

This function returns a value \( \text{info} \).

- If \( \text{info} = 0 \), the execution is successful.
- If \( \text{info} = -i \), the \( i \)-th parameter had an illegal value.
- If \( \text{info} > 0 \), an internal error occurred.

**?stedc**

*Computes all eigenvalues and eigenvectors of a symmetric tridiagonal matrix using the divide and conquer method.*

**Syntax**

\[
\begin{align*}
\text{lapack_int} & \text{ LAPACKE_sstedc( int matrix_layout, char compz, lapack_int n, float* d, float* e, float* z, lapack_int ldz );} \\
\text{lapack_int} & \text{ LAPACKE_dstedc( int matrix_layout, char compz, lapack_int n, double* d, double* e, double* z, lapack_int ldz );} \\
\text{lapack_int} & \text{ LAPACKE_cstedc( int matrix_layout, char compz, lapack_int n, float* d, float* e, lapack_complex_float* z, lapack_int ldz );} \\
\text{lapack_int} & \text{ LAPACKE_zstedc( int matrix_layout, char compz, lapack_int n, double* d, double* e, lapack_complex_double* z, lapack_int ldz );}
\end{align*}
\]

**Include Files**

- mkl.h

**Description**

The routine computes all the eigenvalues and (optionally) all the eigenvectors of a symmetric tridiagonal matrix using the divide and conquer method. The eigenvectors of a full or band real symmetric or complex Hermitian matrix can also be found if \text{sytrd/hetrd} or \text{sptrd/hptrd} or \text{sbtrd/hbtrd} has been used to reduce this matrix to tridiagonal form.

**Input Parameters**

- \( \text{matrix_layout} \) specifies whether matrix storage layout is row major (\text{LAPACK_ROW_MAJOR}) or column major (\text{LAPACK_COL_MAJOR}).
- \( \text{compz} \) must be \( 'N' \) or \( 'I' \) or \( 'V' \).
  - If \( \text{compz} = 'N' \), the routine computes eigenvalues only.
  - If \( \text{compz} = 'I' \), the routine computes the eigenvalues and eigenvectors of the tridiagonal matrix.
If \( \text{compz} = 'V' \), the routine computes the eigenvalues and eigenvectors of the original symmetric/Hermitian matrix. On entry, the array \( z \) must contain the orthogonal/unitary matrix used to reduce the original matrix to tridiagonal form.

\( n \)

The order of the symmetric tridiagonal matrix (\( n \geq 0 \)).

\( d, e \)

Arrays:

\( d \) contains the diagonal elements of the tridiagonal matrix.

The dimension of \( d \) must be at least \( \max(1, n) \).

\( e \) contains the subdiagonal elements of the tridiagonal matrix.

The dimension of \( e \) must be at least \( \max(1, n-1) \).

\( z \)

Array \( z \) is of size \( \max(1, ldz*n) \).

If \( \text{compz} = 'V' \), then, on entry, \( z \) must contain the orthogonal/unitary matrix used to reduce the original matrix to tridiagonal form.

\( ldz \)

The leading dimension of \( z \). Constraints:

\( ldz \geq 1 \) if \( \text{compz} = 'N' \);

\( ldz \geq \max(1, n) \) if \( \text{compz} = 'V' \) or \( 'I' \).

**Output Parameters**

\( d \)

The \( n \) eigenvalues in ascending order, unless \( \text{info} \neq 0 \).

See also \( \text{info} \).

\( e \)

On exit, the array is overwritten; see \( \text{info} \).

\( z \)

If \( \text{info} = 0 \), then if \( \text{compz} = 'V' \), \( z \) contains the orthonormal eigenvectors of the original symmetric/Hermitian matrix, and if \( \text{compz} = 'I' \), \( z \) contains the orthonormal eigenvectors of the symmetric tridiagonal matrix. If \( \text{compz} = 'N' \), \( z \) is not referenced.

**Return Values**

This function returns a value \( \text{info} \).

If \( \text{info} = 0 \), the execution is successful.

If \( \text{info} = -i \), the \( i \)-th parameter had an illegal value.

If \( \text{info} = i \), the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns \( ij/(n+1) \) through \( \text{mod}(i, n+1) \).

**stegr**

Computes selected eigenvalues and eigenvectors of a real symmetric tridiagonal matrix.

**Syntax**

```c
lapack_int LAPACKE_sstegr( int matrix_layout, char jobz, char range, lapack_int n, float* d, float* e, float vl, float vu, lapack_int il, lapack_int iu, float abstol, lapack_int* m, float* w, float* z, lapack_int ldz, lapack_int* isuppz );
```
lapack_int LAPACKE_dstegr( int matrix_layout, char jobz, char range, lapack_int n,
   double* d, double* e, double vl, double vu, lapack_int il, lapack_int iu, double abstol,
   lapack_int* m, double* w, double* z, lapack_int ldz, lapack_int* isuppz );

lapack_int LAPACKE_cstegr( int matrix_layout, char jobz, char range, lapack_int n,
   float* d, float* e, float vl, float vu, lapack_int il, lapack_int iu, float abstol,
   lapack_int* m, float* w, lapack_complex_float* z, lapack_int ldz, lapack_int* isuppz );

lapack_int LAPACKE_zstegr( int matrix_layout, char jobz, char range, lapack_int n,
   double* d, double* e, double vl, double vu, lapack_int il, lapack_int iu, double abstol,
   lapack_int* m, double* w, lapack_complex_double* z, lapack_int ldz, lapack_int* isuppz );

Include Files
• mkl.h

Description
The routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal
matrix $T$.
The spectrum may be computed either completely or partially by specifying either an interval $(vl, vu]$ or a
range of indices $il:iu$ for the desired eigenvalues.

stegr is a compatibility wrapper around the improved stemr routine. See its description for further details.
Note that the abstol parameter no longer provides any benefit and hence is no longer used.

Input Parameters

matrix_layout
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

jobz
  Must be 'N' or 'V'.
  If jobz = 'N', then only eigenvalues are computed.
  If jobz = 'V', then eigenvalues and eigenvectors are computed.

range
  Must be 'A' or 'V' or 'I'.
  If range = 'A', the routine computes all eigenvalues.
  If range = 'V', the routine computes eigenvalues $w[i]$ in the half-open interval:
  $vl < w[i] \leq vu$.
  If range = 'I', the routine computes eigenvalues with indices $il$ to $iu$.

n
  The order of the matrix $T$ ($n \geq 0$).

d, e
  Arrays:
  $d$ contains the diagonal elements of $T$.
  The dimension of $d$ must be at least max(1, $n$).
  $e$ contains the subdiagonal elements of $T$ in elements 1 to $n-1$; $e(n)$ need not be set on input, but it is used as a workspace.
  The dimension of $e$ must be at least max(1, $n$).
If range = 'V', the lower and upper bounds of the interval to be searched for eigenvalues.
Constraint: vl < vu.
If range = 'A' or 'I', vl and vu are not referenced.

If range = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned.
Constraint: 1 ≤ il ≤ iu ≤ n, if n > 0.
If range = 'A' or 'V', il and iu are not referenced.

Unused. Was the absolute error tolerance for the eigenvalues/eigenvectors in previous versions.

The leading dimension of the output array z. Constraints:
ldz ≥ 1 if jobz = 'N';
ldz ≥ max(1, n) if jobz = 'V'.

On exit, d and e are overwritten.
The total number of eigenvalues found,
0 ≤ m ≤ n.
If range = 'A', m = n, and if range = 'I', m = iu-il+1.

Array, size at least max(1, n).
The selected eigenvalues in ascending order, stored in w[0] to w[m - 1].

Array z(size max(1, ldz*m)).
If jobz = 'V', and if info = 0, the first m columns of z contain the orthonormal eigenvectors of the matrix T corresponding to the selected eigenvalues, with the i-th column of z holding the eigenvector associated with w[i - 1].
If jobz = 'N', then z is not referenced.
Note: if range = 'V', the exact value of m is not known in advance and an upper bound must be used. Using n = m is always safe.

Array, size at least (2*max(1, m)).
The support of the eigenvectors in z, that is the indices indicating the nonzero elements in z. The i-th computed eigenvector is nonzero only in elements isuppz[2*i - 2] through isuppz[2*i - 1]. This is relevant in the case when the matrix is split. isuppz is only accessed when jobz = 'V', and n > 0.

This function returns a value info.
If info=0, the execution is successful.
If $info = -i$, the $i$-th parameter had an illegal value.

If $info > 0$, an internal error occurred.

?pteqr

*Computes all eigenvalues and (optionally) all eigenvectors of a real symmetric positive-definite tridiagonal matrix.*

**Syntax**

```c
lapack_int LAPACKE_spteqr(int matrix_layout, char compz, lapack_int n, float* d, float* e, float* z, lapack_int ldz);
lapack_int LAPACKE_dpteqr(int matrix_layout, char compz, lapack_int n, double* d, double* e, double* z, lapack_int ldz);
lapack_int LAPACKE_cpteqr(int matrix_layout, char compz, lapack_int n, float* d, float* e, lapack_complex_float* z, lapack_int ldz);
lapack_int LAPACKE_zpteqr(int matrix_layout, char compz, lapack_int n, double* d, double* e, lapack_complex_double* z, lapack_int ldz);
```

**Include Files**

- mkl.h

**Description**

The routine computes all the eigenvalues and (optionally) all the eigenvectors of a real symmetric positive-definite tridiagonal matrix $T$. In other words, the routine can compute the spectral factorization: $T = Z \Lambda Z^T$.

Here $\Lambda$ is a diagonal matrix whose diagonal elements are the eigenvalues $\lambda_i$; $Z$ is an orthogonal matrix whose columns are eigenvectors. Thus,

$$Tz_i = \lambda_i z_i \text{ for } i = 1, 2, \ldots, n.$$  

(The routine normalizes the eigenvectors so that $||z_i||_2 = 1$.)

You can also use the routine for computing the eigenvalues and eigenvectors of real symmetric (or complex Hermitian) positive-definite matrices $A$ reduced to tridiagonal form $T$: $A = Q^*TQ^H$. In this case, the spectral factorization is as follows: $A = Q^*TQ^H = (QZ)^*\Lambda^* (QZ)^H$. Before calling ?pteqr, you must reduce $A$ to tridiagonal form and generate the explicit matrix $Q$ by calling the following routines:

<table>
<thead>
<tr>
<th>Storage Type</th>
<th>For Real Matrices</th>
<th>For Complex Matrices</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Full Storage</strong></td>
<td>?sytrd, ?orgtr</td>
<td>?hetrd, ?ungtr</td>
</tr>
<tr>
<td><strong>Packed Storage</strong></td>
<td>?sptrd, ?opgtr</td>
<td>?hptrd, ?upgtr</td>
</tr>
<tr>
<td><strong>Band Storage</strong></td>
<td>?sbtrd(\text{vec}=\text{'V'})</td>
<td>?hbtrd(\text{vec}=\text{'V'})</td>
</tr>
</tbody>
</table>

The routine first factorizes $T$ as $L^*D^*L^H$ where $L$ is a unit lower bidiagonal matrix, and $D$ is a diagonal matrix. Then it forms the bidiagonal matrix $B = L^1/2$ and calls ?bdsqr to compute the singular values of $B$, which are the square roots of the eigenvalues of $T$. 

827
Input Parameters

**matrix_layout**
Specifies whether matrix storage layout is row major (`LAPACK_ROW_MAJOR`) or column major (`LAPACK_COL_MAJOR`).

**compz**
Must be 'N' or 'I' or 'V'.
If `compz = 'N'`, the routine computes eigenvalues only.
If `compz = 'I'`, the routine computes the eigenvalues and eigenvectors of the tridiagonal matrix $T$.
If `compz = 'V'`, the routine computes the eigenvalues and eigenvectors of $A$ (and the array $z$ must contain the matrix $Q$ on entry).

**n**
The order of the matrix $T$ ($n \geq 0$).

**d, e**
Arrays:
$d$ contains the diagonal elements of $T$.
The size of $d$ must be at least $\max(1, n)$.
$e$ contains the off-diagonal elements of $T$.
The size of $e$ must be at least $\max(1, n-1)$.

**z**
Array, size $\max(1, ldz*\text{n})$
If `compz = 'N'` or 'I', $z$ need not be set.
If `compz = 'V'`, $z$ must contain the orthogonal matrix used in the reduction to tridiagonal form..

**ldz**
The leading dimension of $z$. Constraints:
$ldz \geq 1$ if `compz = 'N';`
$ldz \geq \max(1, n)$ if `compz = 'V'` or 'I'.

Output Parameters

**d**
The $n$ eigenvalues in descending order, unless $\text{info} > 0$.
See also $\text{info}$.

**e**
On exit, the array is overwritten.

**z**
If $\text{info} = 0$, contains an $n$-by-$n$ matrix the columns of which are orthonormal eigenvectors. (The $i$-th column corresponds to the $i$-th eigenvalue.)

Return Values

This function returns a value $\text{info}$.
If $\text{info}=0$, the execution is successful.
If $\text{info} = i$, the leading minor of order $i$ (and hence $T$ itself) is not positive-definite.
If $\text{info} = n + i$, the algorithm for computing singular values failed to converge; $i$ off-diagonal elements have not converged to zero.
If $\text{info} = -i$, the $i$-th parameter had an illegal value.
Application Notes

If \( \lambda_i \) is an exact eigenvalue, and \( \mu_i \) is the corresponding computed value, then

\[
|\mu_i - \lambda_i| \leq c(n) \varepsilon K^* \lambda_i
\]

where \( c(n) \) is a modestly increasing function of \( n \), \( \varepsilon \) is the machine precision, and

\[
K = \left( \| DTD \|_2 \right)^{1/2}
\]

If \( z_i \) is the corresponding exact eigenvector, and \( w_i \) is the corresponding computed vector, then the angle \( \theta(z_i, w_i) \) between them is bounded as follows:

\[
\theta(z_i, w_i) \leq c(n) \varepsilon K / \min_{i \neq j}(|\lambda_i - \lambda_j|/|\lambda_i + \lambda_j|). 
\]

Here \( \min_{i \neq j}(|\lambda_i - \lambda_j|/|\lambda_i + \lambda_j|) \) is the relative gap between \( \lambda_i \) and the other eigenvalues.

The total number of floating-point operations depends on how rapidly the algorithm converges.

Typically, it is about

- \( 30n^2 \) if \( \text{compz} = 'N' \);
- \( 6n^3 \) (for complex flavors, \( 12n^3 \)) if \( \text{compz} = 'V' \) or \( 'I' \).

?stebz

Computes selected eigenvalues of a real symmetric tridiagonal matrix by bisection.

Syntax

```c
lapack_int LAPACKE_sstebz (char range, char order, lapack_int n, float vl, float vu,
    lapack_int il, lapack_int iu, float abstol, const float* d, const float* e,
    lapack_int* m, lapack_int* nsplit, float* w, lapack_int* iblock, lapack_int* isplit);

lapack_int LAPACKE_dstebz (char range, char order, lapack_int n, double vl, double vu,
    lapack_int il, lapack_int iu, double abstol, const double* d, const double* e,
    lapack_int* m, lapack_int* nsplit, double* w, lapack_int* iblock, lapack_int* isplit);
```

Include Files

- mkl.h

Description

The routine computes some (or all) of the eigenvalues of a real symmetric tridiagonal matrix \( T \) by bisection. The routine searches for zero or negligible off-diagonal elements to see if \( T \) splits into block-diagonal form \( T = \text{diag}(T_1, T_2, \ldots) \). Then it performs bisection on each of the blocks \( T_i \) and returns the block index of each computed eigenvalue, so that a subsequent call to \( \text{stein} \) can also take advantage of the block structure.

Input Parameters

- **range**
  - Must be 'A' or 'V' or 'I'.
  - If \( \text{range} = 'A' \), the routine computes all eigenvalues.
  - If \( \text{range} = 'V' \), the routine computes eigenvalues \( w[i] \) in the half-open interval: \( vl < w[i] \leq vu \).
  - If \( \text{range} = 'I' \), the routine computes eigenvalues with indices \( il \) to \( iu \).

- **order**
  - Must be 'B' or 'E'.
If order = 'B', the eigenvalues are to be ordered from smallest to largest within each split-off block.

If order = 'E', the eigenvalues for the entire matrix are to be ordered from smallest to largest.

$n$

The order of the matrix $T$ ($n \geq 0$).

$vl, vu$

If range = 'V', the routine computes eigenvalues $w[i]$ in the half-open interval:

$vl < w[i]) \leq vu$.

If range = 'A' or 'I', $vl$ and $vu$ are not referenced.

$il, iu$

Constraint: $1 \leq il \leq iu \leq n$.

If range = 'I', the routine computes eigenvalues $w[i]$ such that $il \leq i \leq iu$ (assuming that the eigenvalues $w[i]$ are in ascending order).

If range = 'A' or 'V', $il$ and $iu$ are not referenced.

$abstol$

The absolute tolerance to which each eigenvalue is required. An eigenvalue (or cluster) is considered to have converged if it lies in an interval of width $abstol$.

If $abstol \leq 0.0$, then the tolerance is taken as $\text{eps} \cdot |T|$, where $\text{eps}$ is the machine precision, and $|T|$ is the 1-norm of the matrix $T$.

$d, e$

Arrays:

$d$ contains the diagonal elements of $T$.

The size of $d$ must be at least $\max(1, n)$.

$e$ contains the off-diagonal elements of $T$.

The size of $e$ must be at least $\max(1, n-1)$.

Output Parameters

$m$

The actual number of eigenvalues found.

$nsplit$

The number of diagonal blocks detected in $T$.

$w$

Array, size at least $\max(1, n)$. The computed eigenvalues, stored in $w[0]$ to $w[m - 1]$.

$iblock, isplit$

Arrays, size at least $\max(1, n)$.

A positive value $iblock[i]$ is the block number of the eigenvalue stored in $w[i]$ (see also info).

The leading $nsplit$ elements of $isplit$ contain points at which $T$ splits into blocks $T_j$ as follows: the block $T_1$ contains rows/columns 1 to $isplit[0]$; the block $T_2$ contains rows/columns $isplit[0]+1$ to $isplit[1]$, and so on.

Return Values

This function returns a value $info$.

If $info=0$, the execution is successful.
If $info = 1$, for $range = 'A'$ or 'V', the algorithm failed to compute some of the required eigenvalues to the desired accuracy; $iblock[i] < 0$ indicates that the eigenvalue stored in $w[i]$ failed to converge.

If $info = 2$, for $range = 'I'$, the algorithm failed to compute some of the required eigenvalues. Try calling the routine again with $range = 'A'$.

If $info = 3$:
- for $range = 'A'$ or 'V', same as $info = 1$;
- for $range = 'I'$, same as $info = 2$.

If $info = 4$, no eigenvalues have been computed. The floating-point arithmetic on the computer is not behaving as expected.

If $info = -i$, the $i$-th parameter had an illegal value.

Application Notes

The eigenvalues of $T$ are computed to high relative accuracy which means that if they vary widely in magnitude, then any small eigenvalues will be computed more accurately than, for example, with the standard QR method. However, the reduction to tridiagonal form (prior to calling the routine) may exclude the possibility of obtaining high relative accuracy in the small eigenvalues of the original matrix if its eigenvalues vary widely in magnitude.

?stein

Computes the eigenvectors corresponding to specified eigenvalues of a real symmetric tridiagonal matrix.

Syntax

```c
lapack_int LAPACKE_sstein( int matrix_layout, lapack_int n, const float* d, const float* e, lapack_int m, const float* w, const lapack_int* iblock, const lapack_int* isplit, float* z, lapack_int ldz, lapack_int* ifailv);
```

```c
lapack_int LAPACKE_dstein( int matrix_layout, lapack_int n, const double* d, const double* e, lapack_int m, const double* w, const lapack_int* iblock, const lapack_int* isplit, double* z, lapack_int ldz, lapack_int* ifailv);
```

```c
lapack_int LAPACKE_cstein( int matrix_layout, lapack_int n, const float* d, const float* e, lapack_int m, const float* w, const lapack_int* iblock, const lapack_int* isplit, lapack_complex_float* z, lapack_int ldz, lapack_int* ifailv);
```

```c
lapack_int LAPACKE_zstein( int matrix_layout, lapack_int n, const double* d, const double* e, lapack_int m, const double* w, const lapack_int* iblock, const lapack_int* isplit, lapack_complex_double* z, lapack_int ldz, lapack_int* ifailv);
```

Include Files

- mkl.h

Description

The routine computes the eigenvectors of a real symmetric tridiagonal matrix $T$ corresponding to specified eigenvalues, by inverse iteration. It is designed to be used in particular after the specified eigenvalues have been computed by ?stebz with $order = 'B'$, but may also be used when the eigenvalues have been computed by other routines.

If you use this routine after ?stebz, it can take advantage of the block structure by performing inverse iteration on each block $T_i$ separately, which is more efficient than using the whole matrix $T$. 
If $T$ has been formed by reduction of a full symmetric or Hermitian matrix $A$ to tridiagonal form, you can transform eigenvectors of $T$ to eigenvectors of $A$ by calling ?ormtr or ?opmtr (for real flavors) or by calling ?unmtr or ?upmtr (for complex flavors).

**Input Parameters**

- **matrix_layout**: Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- **$n$**: The order of the matrix $T$ ($n \geq 0$).
- **$m$**: The number of eigenvectors to be returned.
- **$d$, $e$, $w$**: Arrays:
  - $d$ contains the diagonal elements of $T$.
  - $e$ contains the sub-diagonal elements of $T$ stored in elements 1 to $n-1$.
  - $w$ contains the eigenvalues of $T$, stored in $w[0]$ to $w[m-1]$ (as returned by stebz). Eigenvalues of $T_1$ must be supplied first, in non-decreasing order; then those of $T_2$, again in non-decreasing order, and so on. Constraint:
    
    $\text{if } \text{iblock}[i] = \text{iblock}[i+1], w[i] \leq w[i+1]$. The size of $w$ must be at least max(1, $n$).

- **$\text{iblock}, \text{isplit}$**: Arrays, size at least max(1, $n$). The arrays $\text{iblock}$ and $\text{isplit}$, as returned by ?stebz with order = 'B'.
  - If you did not call ?stebz with order = 'B', set all elements of $\text{iblock}$ to 1, and $\text{isplit}[0]$ to $n$.

- **$ldz$**: The leading dimension of the output array $z$; $ldz \geq \text{max}(1, n)$ for column major layout and $ldz = \text{max}(1, m)$ for row major layout.

**Output Parameters**

- **$z$**: Array, size at least max(1, $ldz*m$) for column major layout and max(1, $ldz*n$) for row major layout.
  - If $info = 0$, $z$ contains an $n$-by-$n$ matrix the columns of which are orthonormal eigenvectors. (The $i$-th column corresponds to the $i$th eigenvalue.)

- **$\text{ifailv}$**: Array, size at least max(1, $m$).
  - If $info = i > 0$, the first $i$ elements of $\text{ifailv}$ contain the indices of any eigenvectors that failed to converge.

**Return Values**

This function returns a value $info$.

If $info=0$, the execution is successful.
If $info = i$, then $i$ eigenvectors (as indicated by the parameter $ifailv$) each failed to converge in 5 iterations. The current iterates are stored in the corresponding columns/rows of the array $z$.

If $info = -i$, the $i$-th parameter had an illegal value.

**Application Notes**

Each computed eigenvector $z_i$ is an exact eigenvector of a matrix $T+E_i$, where $||E_i||_2 = O(\epsilon) * ||T||_2$. However, a set of eigenvectors computed by this routine may not be orthogonal to so high a degree of accuracy as those computed by ?steqr.

**?disna**

*Computes the reciprocal condition numbers for the eigenvectors of a symmetric/Hermitian matrix or for the left or right singular vectors of a general matrix.*

**Syntax**

```c
lapack_int LAPACKE_sdisna (char job, lapack_int m, lapack_int n, const float* d, float* sep);

lapack_int LAPACKE_ddisna (char job, lapack_int m, lapack_int n, const double* d, double* sep);
```

**Include Files**

- mkl.h

**Description**

The routine computes the reciprocal condition numbers for the eigenvectors of a real symmetric or complex Hermitian matrix or for the left or right singular vectors of a general $m$-by-$n$ matrix.

The reciprocal condition number is the 'gap' between the corresponding eigenvalue or singular value and the nearest other one.

The bound on the error, measured by angle in radians, in the $i$-th computed vector is given by

$$\text{?lamch('E')} \times \frac{\text{anorm}}{\text{sep}(i)}$$

where $\text{anorm} = ||A||_2 = \max(|d(j)|)$. $\text{sep}(i)$ is not allowed to be smaller than $\text{slamch('E')} \times \text{anorm}$ in order to limit the size of the error bound.

?disna may also be used to compute error bounds for eigenvectors of the generalized symmetric definite eigenproblem.

**Input Parameters**

*job*

Must be 'E', 'L', or 'R'. Specifies for which problem the reciprocal condition numbers should be computed:

- $job = 'E'$: for the eigenvectors of a symmetric/Hermitian matrix;
- $job = 'L'$: for the left singular vectors of a general matrix;
- $job = 'R'$: for the right singular vectors of a general matrix.

*m*

The number of rows of the matrix ($m \geq 0$).

*n*

If $job = 'L'$, or 'R', the number of columns of the matrix ($n \geq 0$). Ignored if $job = 'E$.'
Array, dimension at least \( \max(1,m) \) if \( \text{job} = 'E' \), and at least \( \max(1,\min(m,n)) \) if \( \text{job} = 'L' \) or \( 'R' \).

This array must contain the eigenvalues (if \( \text{job} = 'E' \)) or singular values (if \( \text{job} = 'L' \) or \( 'R' \)) of the matrix, in either increasing or decreasing order.

If singular values, they must be non-negative.

Output Parameters

Array, dimension at least \( \max(1,m) \) if \( \text{job} = 'E' \), and at least \( \max(1,\min(m,n)) \) if \( \text{job} = 'L' \) or \( 'R' \). The reciprocal condition numbers of the vectors.

Return Values

This function returns a value \( \text{info} \).

If \( \text{info}=0 \), the execution is successful.

If \( \text{info} = -i \), the \( i \)-th parameter had an illegal value.

Generalized Symmetric-Definite Eigenvalue Problems: LAPACK Computational Routines

Generalized symmetric-definite eigenvalue problems are as follows: find the eigenvalues \( \lambda \) and the corresponding eigenvectors \( z \) that satisfy one of these equations:

\[
Az = \lambda Bz, \quad ABz = \lambda z, \quad BAZ = \lambda z,
\]

where \( A \) is an \( n \)-by-\( n \) symmetric or Hermitian matrix, and \( B \) is an \( n \)-by-\( n \) symmetric positive-definite or Hermitian positive-definite matrix.

In these problems, there exist \( n \) real eigenvectors corresponding to real eigenvalues (even for complex Hermitian matrices \( A \) and \( B \)).

Routines described in this section allow you to reduce the above generalized problems to standard symmetric eigenvalue problem \( Cy = \lambda y \), which you can solve by calling LAPACK routines described earlier in this chapter (see Symmetric Eigenvalue Problems).

Different routines allow the matrices to be stored either conventionally or in packed storage. Prior to reduction, the positive-definite matrix \( B \) must first be factorized using either \texttt{potrf} or \texttt{pptrf}.

The reduction routine for the banded matrices \( A \) and \( B \) uses a split Cholesky factorization for which a specific routine \texttt{pbstf} is provided. This refinement halves the amount of work required to form matrix \( C \).

Table "Computational Routines for Reducing Generalized Eigenproblems to Standard Problems" lists LAPACK routines that can be used to solve generalized symmetric-definite eigenvalue problems.

Reduces a real symmetric-definite generalized eigenvalue problem to the standard form.

**Syntax**

```c
lapack_int LAPACKE_ssygst (int matrix_layout, lapack_int itype, char uplo, lapack_int n, float* a, lapack_int lda, const float* b, lapack_int ldb);

lapack_int LAPACKE_dsygst (int matrix_layout, lapack_int itype, char uplo, lapack_int n, double* a, lapack_int lda, const double* b, lapack_int ldb);
```

**Include Files**

- `mkl.h`

**Description**

The routine reduces real symmetric-definite generalized eigenproblems

\[ A z = \lambda B z, \ A^T B z = \lambda z, \text{ or } B A^T z = \lambda z \]

to the standard form \( Cy = \lambda y \). Here \( A \) is a real symmetric matrix, and \( B \) is a real symmetric positive-definite matrix. Before calling this routine, call `?potrf` to compute the Cholesky factorization: \( B = U^T U \) or \( B = L L^T \).

**Input Parameters**

- `matrix_layout`
  
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- `itype`
  
  Must be 1 or 2 or 3.

  - **If itype = 1**, the generalized eigenproblem is \( A z = \lambda B z \)
    
    for `uplo = 'U'`: \( C = \text{inv}(U^T) A \text{inv}(U), z = \text{inv}(U) y \);
    
    for `uplo = 'L'`: \( C = \text{inv}(L) A \text{inv}(L^T), z = \text{inv}(L^T) y \).

  - **If itype = 2**, the generalized eigenproblem is \( A^T B z = \lambda z \)
    
    for `uplo = 'U'`: \( C = U^T A U^T, z = \text{inv}(U) y \);
    
    for `uplo = 'L'`: \( C = L^T A L, z = \text{inv}(L^T) y \).

  - **If itype = 3**, the generalized eigenproblem is \( B A^T z = \lambda z \)
    
    for `uplo = 'U'`: \( C = U^T A^T U, z = U^T y \);
    
    for `uplo = 'L'`: \( C = L^T A^T L, z = L^T y \).

- `uplo`
  
  Must be 'U' or 'L'.

  - If `uplo = 'U'`, the array \( a \) stores the upper triangle of \( A \); you must supply \( B \) in the factored form \( B = U^T U \).
  
  - If `uplo = 'L'`, the array \( a \) stores the lower triangle of \( A \); you must supply \( B \) in the factored form \( B = L^T L \).

- `n`
  
  The order of the matrices \( A \) and \( B \) (\( n \geq 0 \)).

- `a, b`
  
  Arrays:

  \( a \) (size \( \max(1, lda \times n) \)) contains the upper or lower triangle of \( A \).
$b$ (size max(1, $ldb \cdot n$)) contains the Cholesky-factored matrix $B$:

\[ B = U^T \cdot U \text{ or } B = L \cdot L^T \text{ (as returned by } \texttt{?potrf}). \]

$lda$
The leading dimension of $a$; at least max(1, \(n\)).

$ldb$
The leading dimension of $b$; at least max(1, \(n\)).

**Output Parameters**

$a$
The upper or lower triangle of $A$ is overwritten by the upper or lower triangle of $C$, as specified by the arguments $itype$ and $uplo$.

**Return Values**

This function returns a value $info$.

If $info=0$, the execution is successful.

If $info = -i$, the $i$-th parameter had an illegal value.

**Application Notes**

Forming the reduced matrix $C$ is a stable procedure. However, it involves implicit multiplication by $\text{inv}(B)$ (if $itype = 1$) or $B$ (if $itype = 2$ or 3). When the routine is used as a step in the computation of eigenvalues and eigenvectors of the original problem, there may be a significant loss of accuracy if $B$ is ill-conditioned with respect to inversion.

The approximate number of floating-point operations is $n^3$.

**?hegst**

*Reduces a complex Hermitian positive-definite generalized eigenvalue problem to the standard form.*

**Syntax**

```c
lapack_int LAPACKE_chegst (int matrix_layout, lapack_int itype, char uplo, lapack_int n, lapack_complex_float* a, lapack_int lda, const lapack_complex_float* b, lapack_int ldb);
```

```c
lapack_int LAPACKE_zhegst (int matrix_layout, lapack_int itype, char uplo, lapack_int n, lapack_complex_double* a, lapack_int lda, const lapack_complex_double* b, lapack_int ldb);
```

**Include Files**

- mkl.h

**Description**

The routine reduces a complex Hermitian positive-definite generalized eigenvalue problem to standard form.

<table>
<thead>
<tr>
<th>$itype$</th>
<th>Problem</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>$A x = \lambda B x$</td>
<td>$A$ overwritten by $\text{inv}(U^H) \cdot A \cdot \text{inv}(U)$ or $\text{inv}(L) \cdot A \cdot \text{inv}(L^H)$</td>
</tr>
<tr>
<td>2</td>
<td>$A B x = \lambda x$</td>
<td>$A$ overwritten by $U^H \cdot A \cdot U$ or $L^H \cdot A \cdot L$</td>
</tr>
<tr>

<td>$B A x = \lambda x$</td>
<td></td>
</tr>
</tbody>
</table>
Before calling this routine, you must call ?potrf to compute the Cholesky factorization: \( B = U^H U \) or \( B = L^H L \).

### Input Parameters

**itype**

Must be 1 or 2 or 3.

- If \( itype = 1 \), the generalized eigenproblem is \( Ax = \lambda Bx \)
  - for \( uplo = 'U' \): \( C = (U^H)^{-1} A U^{-1} \)
  - for \( uplo = 'L' \): \( C = L^{-1} A (L^H)^{-1} \)

- If \( itype = 2 \), the generalized eigenproblem is \( ABx = \lambda x \)
  - for \( uplo = 'U' \): \( C = U^H A U \)
  - for \( uplo = 'L' \): \( C = L H A L \)

- If \( itype = 3 \), the generalized eigenproblem is \( Bx = \lambda x \)
  - for \( uplo = 'U' \): \( C = U^H A U \)
  - for \( uplo = 'L' \): \( C = L H A L \)

**uplo**

Must be 'U' or 'L'.

- If \( uplo = 'U' \), the array \( a \) stores the upper triangle of \( A \); you must supply \( B \) in the factored form \( B = U^H U \).
- If \( uplo = 'L' \), the array \( a \) stores the lower triangle of \( A \); you must supply \( B \) in the factored form \( B = L^H L \).

**n**

The order of the matrices \( A \) and \( B \) (\( n \geq 0 \)).

**a, b**

Arrays:

- \( a \) (size \( \max(1, lda \times n) \)) contains the upper or lower triangle of \( A \).
- \( b \) (size \( \max(1, ldb \times n) \)) contains the Cholesky-factored matrix \( B \): \( B = U^H U \) or \( B = L^H L \) (as returned by \( ?potrf \)).

**lda**

The leading dimension of \( a \); at least \( \max(1, n) \).

**ldb**

The leading dimension of \( b \); at least \( \max(1, n) \).

### Output Parameters

**a**

The upper or lower triangle of \( A \) is overwritten by the upper or lower triangle of \( C \), as specified by the arguments \( itype \) and \( uplo \).

### Return Values

This function returns a value \( info \).

- If \( info = 0 \), the execution is successful.
- If \( info = -i \), the \( i \)-th parameter had an illegal value.
Application Notes

Forming the reduced matrix $C$ is a stable procedure. However, it involves implicit multiplication by $B^{-1}$ (if $itype = 1$) or $B$ (if $itype = 2$ or 3). When the routine is used as a step in the computation of eigenvalues and eigenvectors of the original problem, there may be a significant loss of accuracy if $B$ is ill-conditioned with respect to inversion.

The approximate number of floating-point operations is $n^3$.

?spgst

Reduces a real symmetric-definite generalized eigenvalue problem to the standard form using packed storage.

Syntax

```c
lapack_int LAPACKE_sspgst (int matrix_layout, lapack_int itype, char uplo, lapack_int n, float* ap, const float* bp);
```

```c
lapack_int LAPACKE_dspgst (int matrix_layout, lapack_int itype, char uplo, lapack_int n, double* ap, const double* bp);
```

Include Files

- mkl.h

Description

The routine reduces real symmetric-definite generalized eigenproblems

$$A^*x = \lambda B^*x, A^*B^*x = \lambda^*x, \text{ or } B^*A^*x = \lambda^*x$$

To the standard form $C^*y = \lambda^*y$, using packed matrix storage. Here $A$ is a real symmetric matrix, and $B$ is a real symmetric positive-definite matrix. Before calling this routine, call ?pptrf to compute the Cholesky factorization: $B = U^*U$ or $B = L^*L^T$.

Input Parameters

- `matrix_layout` Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- `itype` Must be 1 or 2 or 3.
  - If $itype = 1$, the generalized eigenproblem is $A^*z = \lambda B^*z$
    - for `uplo = 'U'`: $C = \text{inv}(U^T)A^*\text{inv}(U), z = \text{inv}(U)^*y$;
    - for `uplo = 'L'`: $C = \text{inv}(L)A^*\text{inv}(L^T), z = \text{inv}(L^T)^*y$.
  - If $itype = 2$, the generalized eigenproblem is $A^*B^*z = \lambda^*z$
    - for `uplo = 'U'`: $C = U^*A^*U^T, z = \text{inv}(U)^*y$;
    - for `uplo = 'L'`: $C = L^T*A^*L, z = \text{inv}(L^T)^*y$.
  - If $itype = 3$, the generalized eigenproblem is $B^*A^*z = \lambda^*z$
    - for `uplo = 'U'`: $C = U^*A^*U^T, z = U^T*y$;
    - for `uplo = 'L'`: $C = L^T*A^*L, z = L*y$.
- `uplo` Must be 'U' or 'L'.
If \( \text{uplo} = 'U' \), \( ap \) stores the packed upper triangle of \( A \); you must supply \( B \) in the factored form \( B = U^T \cdot U \).

If \( \text{uplo} = 'L' \), \( ap \) stores the packed lower triangle of \( A \); you must supply \( B \) in the factored form \( B = L \cdot L^T \).

\( n \)  
The order of the matrices \( A \) and \( B \) (\( n \geq 0 \)).

\( ap, bp \)  
Arrays:
- \( ap \) contains the packed upper or lower triangle of \( A \).
- The dimension of \( ap \) must be at least \( \max(1, n \cdot (n+1)/2) \).
- \( bp \) contains the packed Cholesky factor of \( B \) (as returned by \(?\text{pptrf}\) with the same \( \text{uplo} \) value).
- The dimension of \( bp \) must be at least \( \max(1, n \cdot (n+1)/2) \).

**Output Parameters**

- \( ap \)  
The upper or lower triangle of \( A \) is overwritten by the upper or lower triangle of \( C \), as specified by the arguments \( \text{itype} \) and \( \text{uplo} \).

**Return Values**

This function returns a value \( info \).

If \( info=0 \), the execution is successful.

If \( info = -i \), the \( i \)-th parameter had an illegal value.

**Application Notes**

Forming the reduced matrix \( C \) is a stable procedure. However, it involves implicit multiplication by \( \text{inv}(B) \) (if \( \text{itype} = 1 \)) or \( B \) (if \( \text{itype} = 2 \) or 3). When the routine is used as a step in the computation of eigenvalues and eigenvectors of the original problem, there may be a significant loss of accuracy if \( B \) is ill-conditioned with respect to inversion.

The approximate number of floating-point operations is \( n^3 \).

**\(?\text{hpgst}\)**  
Reduces a generalized eigenvalue problem with a Hermitian matrix to a standard eigenvalue problem using packed storage.

**Syntax**

```c
lapack_int LAPACKE_chpgst (int matrix_layout, lapack_int itype, char uplo, lapack_int n, lapack_complex_float* ap, const lapack_complex_float* bp);

lapack_int LAPACKE_zhpgst (int matrix_layout, lapack_int itype, char uplo, lapack_int n, lapack_complex_double* ap, const lapack_complex_double* bp);
```

**Include Files**

- \( \text{mkl.h} \)

**Description**

The routine reduces generalized eigenproblems with Hermitian matrices.
\[ A^*z = \lambda B^*z, \quad A^*B^*z = \lambda^*z, \quad \text{or} \quad B^*A^*z = \lambda^*z. \]

to standard eigenproblems \( C^*y = \lambda^*y \), using packed matrix storage. Here \( A \) is a complex Hermitian matrix, and \( B \) is a complex Hermitian positive-definite matrix. Before calling this routine, you must call \?pptrf to compute the Cholesky factorization: \( B = U^H*U \) or \( B = L*L^H \).

**Input Parameters**

**matrix_layout**

Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

**itype**

Must be 1 or 2 or 3.

If \( itype = 1 \), the generalized eigenproblem is \( A^*z = \lambda B^*z \)
for \( uplo = 'U' \): \( C = \text{inv}(U^H)*A*\text{inv}(U), \quad z = \text{inv}(U)^*y \);
for \( uplo = 'L' \): \( C = \text{inv}(L^H)*A*\text{inv}(L), \quad z = \text{inv}(L^H)^*y \).

If \( itype = 2 \), the generalized eigenproblem is \( A^*B^*z = \lambda^*z \)
for \( uplo = 'U' \): \( C = U*U^H*A, \quad z = \text{inv}(U)^*y \);
for \( uplo = 'L' \): \( C = L*L^H*A, \quad z = \text{inv}(L^H)^*y \).

If \( itype = 3 \), the generalized eigenproblem is \( B^*A^*z = \lambda^*z \)
for \( uplo = 'U' \): \( C = U^H*A*U, \quad z = U^H*y \);
for \( uplo = 'L' \): \( C = L*L^H*A, \quad z = L*y \).

**uplo**

Must be \( 'U' \) or \( 'L' \).

If \( uplo = 'U' \), \( ap \) stores the packed upper triangle of \( A \); you must supply \( B \) in the factored form \( B = U^H*U \).

If \( uplo = 'L' \), \( ap \) stores the packed lower triangle of \( A \); you must supply \( B \) in the factored form \( B = L*L^H \).

**n**

The order of the matrices \( A \) and \( B \) \((n \geq 0)\).

**ap, bp**

Arrays:

\( ap \) contains the packed upper or lower triangle of \( A \).

The dimension of \( a \) must be at least \( \max(1, n*(n+1)/2) \).

\( bp \) contains the packed Cholesky factor of \( B \) (as returned by \?pptrf with the same \( uplo \) value).

The dimension of \( b \) must be at least \( \max(1, n*(n+1)/2) \).

**Output Parameters**

**ap**

The upper or lower triangle of \( A \) is overwritten by the upper or lower triangle of \( C \), as specified by the arguments \( itype \) and \( uplo \).

**Return Values**

This function returns a value \( info \).

If \( info = 0 \), the execution is successful.

If \( info = -i \), the \( i \)-th parameter had an illegal value.
Application Notes

Forming the reduced matrix \( C \) is a stable procedure. However, it involves implicit multiplication by \( \text{inv}(B) \) (if \( \text{itype} = 1 \)) or \( B \) (if \( \text{itype} = 2 \) or 3). When the routine is used as a step in the computation of eigenvalues and eigenvectors of the original problem, there may be a significant loss of accuracy if \( B \) is ill-conditioned with respect to inversion.

The approximate number of floating-point operations is \( n^3 \).

?sbgst

Reduces a real symmetric-definite generalized eigenproblem for banded matrices to the standard form using the factorization performed by ?pbstf.

Syntax

```c
lapack_int LAPACKE_ssbgst (int matrix_layout, char vect, char uplo, lapack_int n,
lapack_int ka, lapack_int kb, float* ab, lapack_int ldab, const float* bb, lapack_int lddb, float* x, lapack_int ldx);
```

Include Files

- mkl.h

Description

To reduce the real symmetric-definite generalized eigenproblem \( A*z = \lambda*B*z \) to the standard form \( C*y = \lambda*y \), where \( A, B \) and \( C \) are banded, this routine must be preceded by a call to ?pbstf, which computes the split Cholesky factorization of the positive-definite matrix \( B: B = S^T*S \). The split Cholesky factorization, compared with the ordinary Cholesky factorization, allows the work to be approximately halved.

This routine overwrites \( A \) with \( C = X^T*A*X \), where \( X = \text{inv}(S)^T*Q \) and \( Q \) is an orthogonal matrix chosen (implicitly) to preserve the bandwidth of \( A \). The routine also has an option to allow the accumulation of \( X \), and then, if \( z \) is an eigenvector of \( C \), \( X^T*z \) is an eigenvector of the original system.

Input Parameters

- `matrix_layout` Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- `vect` Must be 'N' or 'V'.
  - If `vect` = 'N', then matrix \( X \) is not returned;
  - If `vect` = 'V', then matrix \( X \) is returned.
- `uplo` Must be 'U' or 'L'.
  - If `uplo` = 'U', \( ab \) stores the upper triangular part of \( A \).
  - If `uplo` = 'L', \( ab \) stores the lower triangular part of \( A \).
- `n` The order of the matrices \( A \) and \( B \) (\( n \geq 0 \)).
- `ka` The number of super- or sub-diagonals in \( A \).
\( (ka \geq 0). \)

\( kb \)

The number of super- or sub-diagonals in \( B \)
\( (ka \geq kb \geq 0). \)

\( ab, bb \)

\( ab \) (size at least \( \max(1, ldab*n) \) for column major layout and at least \( \max(1, ldab*(ka + 1)) \) for row major layout) is an array containing either upper or lower triangular part of the symmetric matrix \( A \) (as specified by \( uplo \)) in band storage format.

\( bb \) (size at least \( \max(1, ldbb*n) \) for column major layout and at least \( \max(1, ldbb*(kb + 1)) \) for row major layout) is an array containing the banded split Cholesky factor of \( B \) as specified by \( uplo \), \( n \) and \( kb \) and returned by \texttt{pbstf/pbstf}. 

\( ldab \)

The leading dimension of the array \( ab \); must be at least \( ka+1 \) for column major layout and \( \max(1, n) \) for row major layout.

\( ldbb \)

The leading dimension of the array \( bb \); must be at least \( kb+1 \) for column major layout and \( \max(1, n) \) for row major layout.

\( ldx \)

The leading dimension of the output array \( x \). Constraints: if \( vect = 'N' \), then \( ldx \geq 1; \) if \( vect = 'V', then ldx \geq \max(1, n). \)

Output Parameters

\( ab \)

On exit, this array is overwritten by the upper or lower triangle of \( C \) as specified by \( uplo \).

\( x \)

Array.

If \( vect = 'V', then x \) (size at least \( \max(1, ldx*n) \)) contains the \( n \)-by-\( n \) matrix \( X = \text{inv}(S)*Q. \)

If \( vect = 'N', then x \) is not referenced.

Return Values

This function returns a value \( info. \)

If \( info=0, the execution is successful. \)

If \( info = -i, the i-th parameter had an illegal value. \)

Application Notes

Forming the reduced matrix \( C \) involves implicit multiplication by \( \text{inv}(B) \). When the routine is used as a step in the computation of eigenvalues and eigenvectors of the original problem, there may be a significant loss of accuracy if \( B \) is ill-conditioned with respect to inversion.

If \( ka \) and \( kb \) are much less than \( n \) then the total number of floating-point operations is approximately \( 6n^2*kb, \) when \( vect = 'N'. Additional \( (3/2)n^3*(kb/ka) \) operations are required when \( vect = 'V'. \)
?hbgst
Reduces a complex Hermitian positive-definite
generalized eigenproblem for banded matrices to the
standard form using the factorization performed
by ?pbstf.

Syntax

lapack_int LAPACKE_chbgst (int matrix_layout, char vect, char uplo, lapack_int n,
lapack_int ka, lapack_int kb, lapack_complex_float* ab, lapack_int ldab, const
lapack_complex_float* bb, lapack_int ldbb, lapack_complex_float* x, lapack_int ldx);

lapack_int LAPACKE_zhbgst (int matrix_layout, char vect, char uplo, lapack_int n,
lapack_int ka, lapack_int kb, lapack_complex_double* ab, lapack_int ldab, const
lapack_complex_double* bb, lapack_int ldbb, lapack_complex_double* x, lapack_int ldx);

Include Files

• mkl.h

Description

To reduce the complex Hermitian positive-definite generalized eigenproblem \( A*z = \lambda*B*z \) to the standard
form \( C*x = \lambda*y \), where \( A, B \) and \( C \) are banded, this routine must be preceded by a call to pbstf/pbstf, which
computes the split Cholesky factorization of the positive-definite matrix \( B = S^H*S \). The split Cholesky
factorization, compared with the ordinary Cholesky factorization, allows the work to be approximately halved.

This routine overwrites \( A \) with \( C = X^H*A*X \), where \( X = \text{inv}(S)*Q \), and \( Q \) is a unitary matrix chosen
(implicitly) to preserve the bandwidth of \( A \). The routine also has an option to allow the accumulation of \( X \),
and then, if \( z \) is an eigenvector of \( C \), \( X*z \) is an eigenvector of the original system.

Input Parameters

matrix_layout          Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR)
                        or column major (LAPACK_COL_MAJOR).

vect                   Must be 'N' or 'V'.
                        If vect = 'N', then matrix \( X \) is not returned;
                        If vect = 'V', then matrix \( X \) is returned.

uplo                   Must be 'U' or 'L'.
                        If uplo = 'U', \( ab \) stores the upper triangular part of \( A \).
                        If uplo = 'L', \( ab \) stores the lower triangular part of \( A \).

n                       The order of the matrices \( A \) and \( B \) \((n \geq 0)\).

ka                      The number of super- or sub-diagonals in \( A \)
                        \((ka \geq 0)\).

kb                      The number of super- or sub-diagonals in \( B \)
                        \((ka \geq kb \geq 0)\).

ab, bb                  \( ab \)(size at least max(1, ldab*n) for column major layout and at least
                        max(1, ldab*(ka + 1)) for row major layout) is an array containing either
                        upper or lower triangular part of the Hermitian matrix \( A \) (as specified by
                        uplo) in band storage format.
bb (size at least max(1, lddb * n) for column major layout and at least \( \max(1, ldbb \cdot (kb + 1)) \) for row major layout) is an array containing the banded split Cholesky factor of \( B \) as specified by uplo, n and kb and returned by pbstf/pbstf.

\( ldab \)

The leading dimension of the array \( ab \); must be at least \( ka + 1 \) for column major layout and \( \max(1, n) \) for row major layout.

\( ldbb \)

The leading dimension of the array \( bb \); must be at least \( kb + 1 \) for column major layout and \( \max(1, n) \) for row major layout.

\( ldx \)

The leading dimension of the output array \( x \). Constraints:

- If \( vect = 'N' \), then \( ldx \geq 1 \);
- If \( vect = 'V' \), then \( ldx \geq \max(1, n) \).

**Output Parameters**

\( ab \)

On exit, this array is overwritten by the upper or lower triangle of \( C \) as specified by uplo.

\( x \)

Array.

- If \( vect = 'V' \), then \( x \) (size at least \( \max(1, ldx \cdot n) \)) contains the \( n \)-by-\( n \) matrix \( X = \text{inv}(S) \cdot Q \).
- If \( vect = 'N' \), then \( x \) is not referenced.

**Return Values**

This function returns a value \( info \).

- If \( info = 0 \), the execution is successful.
- If \( info = -i \), the \( i \)-th parameter had an illegal value.

**Application Notes**

Forming the reduced matrix \( C \) involves implicit multiplication by \( \text{inv}(B) \). When the routine is used as a step in the computation of eigenvalues and eigenvectors of the original problem, there may be a significant loss of accuracy if \( B \) is ill-conditioned with respect to inversion. The total number of floating-point operations is approximately \( 20n^2 \cdot kb \), when \( vect = 'N' \). Additional \( 5n^3 \cdot (kb/ka) \) operations are required when \( vect = 'V' \). All these estimates assume that both \( ka \) and \( kb \) are much less than \( n \).

**pbstf**

*Computes a split Cholesky factorization of a real symmetric or complex Hermitian positive-definite banded matrix used in *?sbgst/?hbgst.*

**Syntax**

```c
lapack_int LAPACKE_spbstf (int matrix_layout, char uplo, lapack_int n, lapack_int kb, float* bb, lapack_int ldbb);
lapack_int LAPACKE_dpbstf (int matrix_layout, char uplo, lapack_int n, lapack_int kb, double* bb, lapack_int ldbb);
lapack_int LAPACKE_cpbstf (int matrix_layout, char uplo, lapack_int n, lapack_int kb, lapack_complex_float* bb, lapack_int ldbb);
```
lapack_int LAPACKE_zpbstf (int matrix_layout, char uplo, lapack_int n, lapack_int kb, lapack_complex_double* bb, lapack_int ldbb);

Include Files
• mkl.h

Description
The routine computes a split Cholesky factorization of a real symmetric or complex Hermitian positive-
definite band matrix $B$. It is to be used in conjunction with sbgst/hbgst.

The factorization has the form $B = S^T S$ (or $B = S^H S$ for complex flavors), where $S$ is a band matrix of the same bandwidth as $B$ and the following structure: $S$ is upper triangular in the first $(n+kb)/2$ rows and lower triangular in the remaining rows.

Input Parameters

matrix_layout
Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

uplo
Must be ’U’ or ’L’.
If $uplo = ’U’$, $bb$ stores the upper triangular part of $B$.
If $uplo = ’L’$, $bb$ stores the lower triangular part of $B$.

n
The order of the matrix $B$ ($n \geq 0$).

kb
The number of super- or sub-diagonals in $B$ ($kb \geq 0$).

bb
$bb$ (size at least max(1, ldbb*n) for column major layout and at least max(1, ldbb*(kb + 1)) for row major layout) is an array containing either upper or lower triangular part of the matrix $B$ (as specified by $uplo$) in band storage format.

ldbb
The leading dimension of $bb$; must be at least $kb+1$ for column major and at least max(1, $n$) for row major.

Output Parameters

bb
On exit, this array is overwritten by the elements of the split Cholesky factor $S$.

Return Values
This function returns a value $info$.
If $info=0$, the execution is successful.
If $info = i$, then the factorization could not be completed, because the updated element $b_{ii}$ would be the square root of a negative number; hence the matrix $B$ is not positive-definite.
If $info = -i$, the $i$-th parameter had an illegal value.

Application Notes
The computed factor $S$ is the exact factor of a perturbed matrix $B + E$, where
\[ |E| \leq c(kb + 1)\varepsilon|S^H||S|, \quad |e_{ij}| \leq c(kb + 1)\varepsilon\sqrt{b_{ii}b_{jj}} \]

c(n) is a modest linear function of \( n \), and \( \varepsilon \) is the machine precision.

The total number of floating-point operations for real flavors is approximately \( n(kb+1)^2 \). The number of operations for complex flavors is 4 times greater. All these estimates assume that \( kb \) is much less than \( n \).

After calling this routine, you can call sbgst/hbgst to solve the generalized eigenproblem \( Ax = \lambda Bz \), where \( A \) and \( B \) are banded and \( B \) is positive-definite.

**Nonsymmetric Eigenvalue Problems: LAPACK Computational Routines**

This section describes LAPACK routines for solving nonsymmetric eigenvalue problems, computing the Schur factorization of general matrices, as well as performing a number of related computational tasks.

A nonsymmetric eigenvalue problem is as follows: given a nonsymmetric (or non-Hermitian) matrix \( A \), find the eigenvalues \( \lambda \) and the corresponding eigenvectors \( z \) that satisfy the equation

\[ Az = \lambda z \]  
(right eigenvectors \( z \))

or the equation

\[ z^H A = \lambda z^H \]  
(left eigenvectors \( z \)).

Nonsymmetric eigenvalue problems have the following properties:

- The number of eigenvectors may be less than the matrix order (but is not less than the number of distinct eigenvalues of \( A \)).
- Eigenvalues may be complex even for a real matrix \( A \).
- If a real nonsymmetric matrix has a complex eigenvalue \( a+bi \) corresponding to an eigenvector \( z \), then \( a-bi \) is also an eigenvalue. The eigenvalue \( a-bi \) corresponds to the eigenvector whose elements are complex conjugate to the elements of \( z \).

To solve a nonsymmetric eigenvalue problem with LAPACK, you usually need to reduce the matrix to the upper Hessenberg form and then solve the eigenvalue problem with the Hessenberg matrix obtained. Table "Computational Routines for Solving Nonsymmetric Eigenvalue Problems" lists LAPACK routines to reduce the matrix to the upper Hessenberg form by an orthogonal (or unitary) similarity transformation \( A = QH^H \) as well as routines to solve eigenvalue problems with Hessenberg matrices, forming the Schur factorization of such matrices and computing the corresponding condition numbers.

The decision tree in Figure "Decision Tree: Real Nonsymmetric Eigenvalue Problems" helps you choose the right routine or sequence of routines for an eigenvalue problem with a real nonsymmetric matrix. If you need to solve an eigenvalue problem with a complex non-Hermitian matrix, use the decision tree shown in Figure "Decision Tree: Complex Non-Hermitian Eigenvalue Problems".

*Reduces a general matrix to upper Hessenberg form.*

**Syntax**

```c
lapack_int LAPACKE_sgehrd (int matrix_layout, lapack_int n, lapack_int ilo, lapack_int ihi, float* a, lapack_int lda, float* tau);

lapack_int LAPACKE_dgehrd (int matrix_layout, lapack_int n, lapack_int ilo, lapack_int ihi, double* a, lapack_int lda, double* tau);

lapack_int LAPACKE_cgehrd (int matrix_layout, lapack_int n, lapack_int ilo, lapack_int ihi, lapack_complex_float* a, lapack_int lda, lapack_complex_float* tau);

lapack_int LAPACKE_zgehrd (int matrix_layout, lapack_int n, lapack_int ilo, lapack_int ihi, lapack_complex_double* a, lapack_int lda, lapack_complex_double* tau);
```
Include Files
• mkl.h

Description
The routine reduces a general matrix $A$ to upper Hessenberg form $H$ by an orthogonal or unitary similarity transformation $A = Q^*HQ$. Here $H$ has real subdiagonal elements.

The routine does not form the matrix $Q$ explicitly. Instead, $Q$ is represented as a product of elementary reflectors. Routines are provided to work with $Q$ in this representation.

Input Parameters

matrix_layout
Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

$n$
The order of the matrix $A (n \geq 0)$.

$ilo, ihi$
If $A$ is an output by ?gebal, then $ilo$ and $ihi$ must contain the values returned by that routine. Otherwise $ilo = 1$ and $ihi = n$. (If $n > 0$, then $1 \leq ilo \leq ihi \leq n$; if $n = 0$, $ilo = 1$ and $ihi = 0$.)

$a$
Arrays: $a$ (size max(1, lda*n)) contains the matrix $A$.

lda
The leading dimension of $a$; at least max(1, $n$).

Output Parameters

$a$
The elements on and above the subdiagonal contain the upper Hessenberg matrix $H$. The subdiagonal elements of $H$ are real. The elements below the subdiagonal, with the array $tau$, represent the orthogonal matrix $Q$ as a product of $n$ elementary reflectors.

$tau$
Array, size at least max (1, $n$-1).

Contains scalars that define elementary reflectors for the matrix $Q$.

Return Values
This function returns a value $info$.

If $info = 0$, the execution is successful.

If $info = -i$, the $i$-th parameter had an illegal value.

Application Notes
The computed Hessenberg matrix $H$ is exactly similar to a nearby matrix $A + E$, where $||E||_2 < c(n)\varepsilon||A||_2$, $c(n)$ is a modestly increasing function of $n$, and $\varepsilon$ is the machine precision.

The approximate number of floating-point operations for real flavors is $(2/3)*(ihi - ilo)^2(2ihi + 2ilo + 3n)$; for complex flavors it is 4 times greater.

?orghr
Generates the real orthogonal matrix $Q$ determined by ?gehrd.
Syntax

```c
lapack_int LAPACKE_sorghr (int matrix_layout, lapack_int n, lapack_int ilo, lapack_int ihi, float* a, lapack_int lda, const float* tau);

lapack_int LAPACKE_dorghr (int matrix_layout, lapack_int n, lapack_int ilo, lapack_int ihi, double* a, lapack_int lda, const double* tau);
```

Include Files

- mkl.h

Description

The routine explicitly generates the orthogonal matrix \( Q \) that has been determined by a preceding call to \( \text{sgehrd} / \text{dgehrd} \). (The routine \( \text{sgehrd} \) reduces a real general matrix \( A \) to upper Hessenberg form \( H \) by an orthogonal similarity transformation, \( A = Q^*H^*Q \), and represents the matrix \( Q \) as a product of \( ihi-ilo \) elementary reflectors. Here \( ilo \) and \( ihi \) are values determined by \( \text{sgebal} / \text{dgebal} \) when balancing the matrix; if the matrix has not been balanced, \( ilo = 1 \) and \( ihi = n \).)

The matrix \( Q \) generated by \( \text{orghr} \) has the structure:

\[
Q = \begin{bmatrix}
I & 0 & 0 \\
0 & Q_{22} & 0 \\
0 & 0 & I
\end{bmatrix}
\]

where \( Q_{22} \) occupies rows and columns \( ilo \) to \( ihi \).

Input Parameters

- \textit{matrix_layout} Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- \textit{n} The order of the matrix \( Q (n \geq 0) \).
- \textit{ilo, ihi} These must be the same parameters \( ilo \) and \( ihi \), respectively, as supplied to \( \text{sgehrd} \). (If \( n > 0 \), then \( 1 \leq ilo \leq ihi \leq n \); if \( n = 0 \), \( ilo = 1 \) and \( ihi = 0 \).)
- \textit{a, tau} Arrays: \( a \) (size max(1, \( lda \times n \))) contains details of the vectors which define the elementary reflectors, as returned by \( \text{sgehrd} \).
- \( tau \) contains further details of the elementary reflectors, as returned by \( \text{sgehrd} \).
- \textit{lda} The dimension of \( tau \) must be at least max \( (1, n-1) \).

Output Parameters

- \textit{a} Overwritten by the \( n \)-by-\( n \) orthogonal matrix \( Q \).

Return Values

This function returns a value \( info \).
If $\text{info}=0$, the execution is successful.
If $\text{info} = -i$, the $i$-th parameter had an illegal value.

Application Notes
The computed matrix $Q$ differs from the exact result by a matrix $E$ such that $||E||_2 = O(\epsilon)$, where $\epsilon$ is the machine precision.
The approximate number of floating-point operations is $(4/3)(ihi-ilo)^3$.
The complex counterpart of this routine is unghr.

**?ormhr**
*Multiplies an arbitrary real matrix C by the real orthogonal matrix Q determined by ?gehrd.*

**Syntax**
```c
lapack_int LAPACKE_sormhr (int matrix_layout, char side, char trans, lapack_int m, lapack_int n, lapack_int ilo, lapack_int ihi, const float* a, lapack_int lda, const float* tau, float* c, lapack_int ldc);
lapack_int LAPACKE_dormhr (int matrix_layout, char side, char trans, lapack_int m, lapack_int n, lapack_int ilo, lapack_int ihi, const double* a, lapack_int lda, const double* tau, double* c, lapack_int ldc);
```

**Include Files**
- mkl.h

**Description**
The routine multiplies a matrix $C$ by the orthogonal matrix $Q$ that has been determined by a preceding call to sgehrd/dgehrd. (The routine ?gehrd reduces a real general matrix $A$ to upper Hessenberg form $H$ by an orthogonal similarity transformation, $A = Q^*H*Q^T$, and represents the matrix $Q$ as a product of $ihi$-$ilo$ elementary reflectors. Here $ilo$ and $ihi$ are values determined by sgebal/dgebal when balancing the matrix; if the matrix has not been balanced, $ilo = 1$ and $ihi = n$.)

With ?ormhr, you can form one of the matrix products $Q^*C$, $Q^T*C$, $C*Q$, or $C*Q^T$, overwriting the result on $C$ (which may be any real rectangular matrix).

A common application of ?ormhr is to transform a matrix $V$ of eigenvectors of $H$ to the matrix $QV$ of eigenvectors of $A$.

**Input Parameters**
- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- **side**
  Must be 'L' or 'R'.
  If side= 'L', then the routine forms $Q^*C$ or $Q^T*C$.
  If side= 'R', then the routine forms $C*Q$ or $C*Q^T$.
- **trans**
  Must be 'N' or 'T'.
  If trans= 'N', then $Q$ is applied to $C$.
  If trans= 'T', then $Q^T$ is applied to $C$. 
The number of rows in $C$ ($m \geq 0$).

The number of columns in $C$ ($n \geq 0$).

These must be the same parameters $ilo$ and $ihi$, respectively, as supplied to `?gehrd`.

- If $m > 0$ and $side = 'L'$, then $1 \leq ilo \leq ihi \leq m$.
- If $m = 0$ and $side = 'L'$, then $ilo = 1$ and $ihi = 0$.
- If $n > 0$ and $side = 'R'$, then $1 \leq ilo \leq ihi \leq n$.
- If $n = 0$ and $side = 'R'$, then $ilo = 1$ and $ihi = 0$.

Arrays:

- $a$ (size max(1, $lda*n$) for $side='R$ and size max(1, $lda*m$) for $side='L$) contains details of the vectors which define the elementary reflectors, as returned by `?gehrd`.
- $tau$ contains further details of the elementary reflectors, as returned by `?gehrd`.

The dimension of $tau$ must be at least max (1, $m-1$) if $side = 'L'$ and at least max (1, $n-1$) if $side = 'R'$.

- $c$ (size max(1, $ldc*n$) for column major layout and max(1, $ldc*m$ for row major layout) contains the $m$ by $n$ matrix $C$.

The leading dimension of $a$; at least max(1, $m$) if $side = 'L'$ and at least max (1, $n$) if $side = 'R'$.

The leading dimension of $c$; at least max(1, $m$) for column major layout and at least max(1, $n$) for row major layout.

Output Parameters

$C$ is overwritten by product $Q^T C$, $Q^T C$, $C^T Q$, or $C^T Q^T$ as specified by $side$ and $trans$.

Return Values

This function returns a value $info$.

- If $info=0$, the execution is successful.
- If $info = -i$, the $i$-th parameter had an illegal value.

Application Notes

The computed matrix $Q$ differs from the exact result by a matrix $E$ such that $||E||_2 = O(\varepsilon)||C||_2$, where $\varepsilon$ is the machine precision.

The approximate number of floating-point operations is

- $2n(ihi-ilo)^2$ if $side = 'L'$;
- $2m(ihi-ilo)^2$ if $side = 'R'$.

The complex counterpart of this routine is `unmhr`.

```
```
?unghr
Generates the complex unitary matrix Q determined by ?gehrd.

Syntax

lapack_int LAPACKE_cunghr (int matrix_layout, lapack_int n, lapack_int ilo, lapack_int ihi, lapack_complex_float* a, lapack_int lda, const lapack_complex_float* tau);

lapack_int LAPACKE_zunghr (int matrix_layout, lapack_int n, lapack_int ilo, lapack_int ihi, lapack_complex_double* a, lapack_int lda, const lapack_complex_double* tau);

Include Files

• mkl.h

Description

The routine is intended to be used following a call to cgehrd/zgehrd, which reduces a complex matrix A to upper Hessenberg form H by a unitary similarity transformation: A = Q*H*Q^H. ?gehrd represents the matrix Q as a product of ihi-iloelementary reflectors. Here ilo and ihi are values determined by cgebal/zgebal when balancing the matrix; if the matrix has not been balanced, ilo = 1 and ihi = n.

Use the routine unghr to generate Q explicitly as a square matrix. The matrix Q has the structure:

\[
Q = \begin{bmatrix}
I & 0 & 0 \\
0 & Q_{22} & 0 \\
0 & 0 & I
\end{bmatrix}
\]

where Q_{22} occupies rows and columns ilo to ihi.

Input Parameters

matrix_layout

Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

n

The order of the matrix Q (n ≥ 0).

ilo, ihi

These must be the same parameters ilo and ihi, respectively, as supplied to ?gehrd. (If n > 0, then 1 ≤ ilo ≤ ihi ≤ n. If n = 0, then ilo = 1 and ihi = 0.)

a, tau

Arrays:

a (size max(1, lda*n)) contains details of the vectors which define the elementary reflectors, as returned by ?gehrd.

tau contains further details of the elementary reflectors, as returned by ?gehrd.

The dimension of tau must be at least max (1, n-1).

lda

The leading dimension of a; at least max(1, n).

Output Parameters

a

Overwritten by the n-by-n unitary matrix Q.
Return Values
This function returns a value \textit{info}.

If \textit{info}=0, the execution is successful.

If \textit{info} = -i, the i-th parameter had an illegal value.

Application Notes
The computed matrix \textit{Q} differs from the exact result by a matrix \textit{E} such that \|E\|_2 = O(\varepsilon), where \varepsilon is the machine precision.

The approximate number of real floating-point operations is \((16/3)(ihi-ilo)^3\).

The real counterpart of this routine is \texttt{orghr}.

\texttt{?unmhr}

\textit{Multiplies an arbitrary complex matrix }\textit{C} \textit{by the complex unitary matrix }\textit{Q} \textit{determined by } \texttt{?gehrd}.

Syntax
\begin{verbatim}
\end{verbatim}
\begin{verbatim}
lapack_int LAPACK_zunmhr (int \textit{matrix_layout}, char \textit{side}, char \textit{trans}, lapack_int \textit{m}, lapack_int \textit{n}, lapack_int \textit{ilo}, lapack_int \textit{ihi}, const lapack_complex_double* \textit{a}, lapack_int \textit{lda}, const lapack_complex_double* \textit{tau}, lapack_complex_double* \textit{c}, lapack_int \textit{ldc});
\end{verbatim}

Include Files
\begin{itemize}
  \item mkl.h
\end{itemize}

Description
The routine multiplies a matrix \textit{C} by the unitary matrix \textit{Q} that has been determined by a preceding call to \texttt{cgehrd/zgehrd}. (The routine \texttt{?gehrd} reduces a real general matrix \textit{A} to upper Hessenberg form \textit{H} by an orthogonal similarity transformation, \(A = Q^*HQ\), and represents the matrix \textit{Q} as a product of \textit{ihi-ilo} elementary reflectors. Here \textit{ilo} and \textit{ihi} are values determined by \texttt{cgebal/zgebal} when balancing the matrix; if the matrix has not been balanced, \textit{ilo} = 1 and \textit{ihi} = \textit{n}.)

With \texttt{?unmhr}, you can form one of the matrix products \(Q^*C\), \(Q^H*C\), \(C*Q\), or \(C*Q^H\), overwriting the result on \textit{C} (which may be any complex rectangular matrix). A common application of this routine is to transform a matrix \textit{V} of eigenvectors of \textit{H} to the matrix \textit{QV} of eigenvectors of \textit{A}.

Input Parameters
\begin{itemize}
  \item \textit{matrix_layout} \hspace{2cm} Specifies whether matrix storage layout is row major (\texttt{LAPACK_ROW_MAJOR}) or column major (\texttt{LAPACK_COL_MAJOR}).
  \item \textit{side} \hspace{2cm} Must be '\texttt{L}' or '\texttt{R}'.
    \hspace{1cm} If \textit{side} = '\texttt{L}', then the routine forms \(Q*C\) or \(Q^H*C\).
    \hspace{1cm} If \textit{side} = '\texttt{R}', then the routine forms \(C*Q\) or \(C*Q^H\).
  \item \textit{trans} \hspace{2cm} Must be '\texttt{N}' or '\texttt{C}'.
\end{itemize}
If \( \text{trans} = 'N' \), then \( Q \) is applied to \( C \).

If \( \text{trans} = 'T' \), then \( Q^H \) is applied to \( C \).

\( m \)

The number of rows in \( C \) (\( m \geq 0 \)).

\( n \)

The number of columns in \( C \) (\( n \geq 0 \)).

\( ilo, ihi \)

These must be the same parameters \( ilo \) and \( ihi \), respectively, as supplied to \(?\text{gehrd}\).

If \( m > 0 \) and \( \text{side} = 'L' \), then \( 1 \leq ilo \leq ihi \leq m \).

If \( m = 0 \) and \( \text{side} = 'L' \), then \( ilo = 1 \) and \( ihi = 0 \).

If \( n > 0 \) and \( \text{side} = 'L' \), then \( 1 \leq ilo \leq ihi \leq n \).

If \( n = 0 \) and \( \text{side} = 'R' \), then \( ilo =1 \) and \( ihi = 0 \).

\( a, \tau, c \)

Arrays:

\( a(\text{size max}(1,lda*n) \text{ for } \text{side} = 'R' \text{ and size max}(1,lda*m) \text{ for } \text{side} = 'L') \)

contains details of the vectors which define the elementary reflectors, as returned by \(?\text{gehrd}\).

\( \tau \) contains further details of the elementary reflectors, as returned by \(?\text{gehrd}\).

The dimension of \( \tau \) must be at least \( \text{max}(1, m-1) \)

if \( \text{side} = 'L' \) and at least \( \text{max}(1, n-1) \) if \( \text{side} = 'R' \).

\( c(\text{size max}(1, ldc*n) \text{ for column major layout and max}(1, ldc*m \text{ for row major layout}) \text{ contains the } m\text{-by-}n \text{ matrix } C. \)

\( lda \)

The leading dimension of \( a \); at least \( \text{max}(1, m) \) if \( \text{side} = 'L' \) and at least \( \text{max}(1, n) \) if \( \text{side} = 'R' \).

\( ldc \)

The leading dimension of \( c \); at least \( \text{max}(1, m) \) for column major layout and at least \( \text{max}(1, n) \) for row major layout.

**Output Parameters**

\( c \)

\( C \) is overwritten by \( Q*C \), or \( Q^H*C \), or \( C*Q^H \), or \( C*Q \) as specified by \( \text{side} \) and \( \text{trans} \).

**Return Values**

This function returns a value \( \text{info} \).

If \( \text{info}=0 \), the execution is successful.

If \( \text{info} = -i \), the \( i \)-th parameter had an illegal value.

**Application Notes**

The computed matrix \( Q \) differs from the exact result by a matrix \( E \) such that \( \|E\|_2 = O(\varepsilon) \|C\|_2 \), where \( \varepsilon \) is the machine precision.

The approximate number of floating-point operations is

\( 8n(\text{hi}-\text{ilo})^2 \) if \( \text{side} = 'L' \);

\( 8m(\text{hi}-\text{ilo})^2 \) if \( \text{side} = 'R' \).
The real counterpart of this routine is ormhr.

?gebal
Balances a general matrix to improve the accuracy of computed eigenvalues and eigenvectors.

Syntax

```c
lapack_int LAPACKE_sgebal( int matrix_layout, char job, lapack_int n, float* a, lapack_int lda, lapack_int* ilo, lapack_int* ihi, float* scale );
lapack_int LAPACKE_dgebal( int matrix_layout, char job, lapack_int n, double* a, lapack_int lda, lapack_int* ilo, lapack_int* ihi, double* scale );
lapack_int LAPACKE_cgebal( int matrix_layout, char job, lapack_int n, lapack_complex_float* a, lapack_int lda, lapack_int* ilo, lapack_int* ihi, float* scale );
lapack_int LAPACKE_zgebal( int matrix_layout, char job, lapack_int n, lapack_complex_double* a, lapack_int lda, lapack_int* ilo, lapack_int* ihi, double* scale );
```

Include Files

- mkl.h

Description

The routine balances a matrix $A$ by performing either or both of the following two similarity transformations:

(1) The routine first attempts to permute $A$ to block upper triangular form:

$$
P A P^T = A' = \begin{bmatrix}
A'_{11} & A'_{12} & A'_{13} \\
0 & A'_{22} & A'_{23} \\
0 & 0 & A'_{33}
\end{bmatrix}
$$

where $P$ is a permutation matrix, and $A'_{11}$ and $A'_{33}$ are upper triangular. The diagonal elements of $A'_{11}$ and $A'_{33}$ are eigenvalues of $A$. The rest of the eigenvalues of $A$ are the eigenvalues of the central diagonal block $A'_{22}$, in rows and columns $ilo$ to $ihi$. Subsequent operations to compute the eigenvalues of $A$ (or its Schur factorization) need only be applied to these rows and columns; this can save a significant amount of work if $ilo > 1$ and $ihi < n$.

If no suitable permutation exists (as is often the case), the routine sets $ilo = 1$ and $ihi = n$, and $A'_{22}$ is the whole of $A$.

(2) The routine applies a diagonal similarity transformation to $A'$, to make the rows and columns of $A'_{22}$ as close in norm as possible:

$$
A'' = D A' D^{-1} = \begin{bmatrix}
I & 0 & 0 \\
0 & D_{22} & 0 \\
0 & 0 & I
\end{bmatrix} \times \begin{bmatrix}
A'_{11} & A'_{12} & A'_{13} \\
0 & A'_{22} & A'_{23} \\
0 & 0 & A'_{33}
\end{bmatrix} \times \begin{bmatrix}
I & 0 & 0 \\
0 & D_{22}^{-1} & 0 \\
0 & 0 & I
\end{bmatrix}
$$

This scaling can reduce the norm of the matrix (that is, $||A''_{22}|| < ||A'_{22}||$), and hence reduce the effect of rounding errors on the accuracy of computed eigenvalues and eigenvectors.
**Input Parameters**

- **matrix_layout**
  Specifies whether matrix storage layout is row major (`LAPACK_ROW_MAJOR`) or column major (`LAPACK_COL_MAJOR`).

- **job**
  Must be 'N' or 'P' or 'S' or 'B'.
  - If `job` = 'N', then `A` is neither permuted nor scaled (but `ilo`, `ihi`, and `scale` get their values).
  - If `job` = 'P', then `A` is permuted but not scaled.
  - If `job` = 'S', then `A` is scaled but not permuted.
  - If `job` = 'B', then `A` is both scaled and permuted.

- **n**
  The order of the matrix `A` (\(n \geq 0\)).

- **a**
  Array `a` (size `max(1, lda*n)`) contains the matrix `A`.

- **lda**
  The leading dimension of `a`; at least `max(1, n)`.

**Output Parameters**

- **a**
  Overwritten by the balanced matrix (\(a\) is not referenced if `job` = 'N').

- **ilo, ihi**
  The values `ilo` and `ihi` such that on exit `a(i,j)` is zero if \(i > j\) and \(1 \leq j < ilo\) or \(ihi < j \leq n\).
  - If `job` = 'N' or 'S', then `ilo = 1` and `ihi = n`.

- **scale**
  Array, size at least `max(1, n)`.
  Contains details of the permutations and scaling factors.
  More precisely, if \(p_j\) is the index of the row and column interchanged with row and column \(j\), and \(d_j\) is the scaling factor used to balance row and column \(j\), then
  \[
  \text{scale}[j-1] = p_j \text{ for } j = 1, 2, \ldots, \text{ilo-1, ihi+1, \ldots, n}; \\
  \text{scale}[j-1] = d_j \text{ for } j = \text{ilo, ilo+1, \ldots, ihi}.
  \]
  The order in which the interchanges are made is \(n\) to \(ihi+1\), then \(1\) to \(ilo\).

**Return Values**

This function returns a value `info`.

- If `info=0`, the execution is successful.
- If `info = -i`, the \(i\)-th parameter had an illegal value.

**Application Notes**

The errors are negligible, compared with those in subsequent computations.

- If the matrix `A` is balanced by this routine, then any eigenvectors computed subsequently are eigenvectors of the matrix `A''` and hence you must call `gebak` to transform them back to eigenvectors of `A`.
- If the Schur vectors of `A` are required, do not call this routine with `job` = 'S' or 'B', because then the balancing transformation is not orthogonal (not unitary for complex flavors).
If you call this routine with \(\text{job} = 'P'\), then any Schur vectors computed subsequently are Schur vectors of the matrix \(A''\), and you need to call \texttt{gebak} (with \texttt{side} = 'R') to transform them back to Schur vectors of \(A\).

The total number of floating-point operations is proportional to \(n^2\).

\texttt{?gebak}

Transforms eigenvectors of a balanced matrix to those of the original nonsymmetric matrix.

**Syntax**

```c

lapack_int LAPACKE_sgebak( int matrix_layout, char job, char side, lapack_int n,
                        lapack_int ilo, lapack_int ihi, const float* scale, lapack_int m, float* v, lapack_int ldv );

lapack_int LAPACKE_dgebak( int matrix_layout, char job, char side, lapack_int n,
                        lapack_int ilo, lapack_int ihi, const double* scale, lapack_int m, double* v, lapack_int ldv );

lapack_int LAPACKE_cgebak( int matrix_layout, char job, char side, lapack_int n,
                        lapack_int ilo, lapack_int ihi, const float* scale, lapack_int m, lapack_complex_float* v, lapack_int ldv );

lapack_int LAPACKE_zgebak( int matrix_layout, char job, char side, lapack_int n,
                        lapack_int ilo, lapack_int ihi, const double* scale, lapack_int m, lapack_complex_double* v, lapack_int ldv );
```

**Include Files**

- \texttt{mkl.h}

**Description**

The routine is intended to be used after a matrix \(A\) has been balanced by a call to \texttt{?gebal}, and eigenvectors of the balanced matrix \(A''\) have subsequently been computed. For a description of balancing, see \texttt{gebal}. The balanced matrix \(A''\) is obtained as \(A'' = D*P*A*P^T \text{inv}(D)\), where \(P\) is a permutation matrix and \(D\) is a diagonal scaling matrix. This routine transforms the eigenvectors as follows:

if \(x\) is a right eigenvector of \(A''\), then \(P^T \text{inv}(D) * x\) is a right eigenvector of \(A\); if \(y\) is a left eigenvector of \(A''\), then \(P^*D^*y\) is a left eigenvector of \(A\).

**Input Parameters**

- **\texttt{matrix_layout}**
  Specifies whether matrix storage layout is row major (\texttt{LAPACK_ROW_MAJOR}) or column major (\texttt{LAPACK_COL_MAJOR}).

- **\texttt{job}**
  Must be 'N' or 'P' or 'S' or 'B'. The same parameter \texttt{job} as supplied to \texttt{?gebal}.

- **\texttt{side}**
  Must be 'L' or 'R'.

  If \texttt{side} = 'L', then left eigenvectors are transformed.

  If \texttt{side} = 'R', then right eigenvectors are transformed.

- **\texttt{n}**
  The number of rows of the matrix of eigenvectors (\(n \geq 0\)).

- **\texttt{ilo, ihi}**
  The values \texttt{ilo} and \texttt{ihi}, as returned by \texttt{?gebal}. (If \(n > 0\), then 1 \(\leq \text{ilo} \leq \text{ihi} \leq n\);
if \( n = 0 \), then \( ilo = 1 \) and \( ihi = 0 \).)

\textbf{scale}

Array, size at least \( \max(1, n) \).
Contains details of the permutations and/or the scaling factors used to balance the original general matrix, as returned by \texttt{?gebal}.

\textbf{m}

The number of columns of the matrix of eigenvectors \((m \geq 0)\).

\textbf{v}

Arrays:

\( v(\text{size } \max(1, ldv*n) \text{ for column major layout and } \max(1, ldv*m) \text{ for row major layout}) \) contains the matrix of left or right eigenvectors to be transformed.

\( ldv \)

The leading dimension of \( v \); at least \( \max(1, n) \) for column major layout and at least \( \max(1, m) \) for row major layout.

\textbf{Output Parameters}

\( v \)

Overwritten by the transformed eigenvectors.

\textbf{Return Values}

This function returns a value \( info \).
If \( info=0 \), the execution is successful.
If \( info = -i \), the \( i \)-th parameter had an illegal value.

\textbf{Application Notes}

The errors in this routine are negligible.
The approximate number of floating-point operations is approximately proportional to \( m*n \).

\texttt{?hseqr}

\textit{Computes all eigenvalues and (optionally) the Schur factorization of a matrix reduced to Hessenberg form.}

\textbf{Syntax}

\begin{verbatim}
lapack_int LAPACKE_shseqr( int \textit{matrix_layout}, char job, char compz, lapack_int n, 
lapack_int ilo, lapack_int ihi, float* h, lapack_int ldh, float* wr, float* wi, float* 
z, lapack_int ldz );

lapack_int LAPACKE_dhseqr( int \textit{matrix_layout}, char job, char compz, lapack_int n, 
lapack_int ilo, lapack_int ihi, double* h, lapack_int ldh, double* wr, double* wi, 
double* z, lapack_int ldz );

lapack_int LAPACKE_chseqr( int \textit{matrix_layout}, char job, char compz, lapack_int n, 
lapack_int ilo, lapack_int ihi, lapack_complex_float* h, lapack_int ldh, 
lapack_complex_float* w, lapack_complex_float* z, lapack_int ldz );

lapack_int LAPACKE_zhseqr( int \textit{matrix_layout}, char job, char compz, lapack_int n, 
lapack_int ilo, lapack_int ihi, lapack_complex_double* h, lapack_int ldh, 
lapack_complex_double* w, lapack_complex_double* z, lapack_int ldz );
\end{verbatim}

\textbf{Include Files}

\begin{itemize}
  \item mkl.h
\end{itemize}
Description

The routine computes all the eigenvalues, and optionally the Schur factorization, of an upper Hessenberg matrix \( H = Z^* T^* Z^H \), where \( T \) is an upper triangular (or, for real flavors, quasi-triangular) matrix (the Schur form of \( H \)), and \( Z \) is the unitary or orthogonal matrix whose columns are the Schur vectors \( z_i \).

You can also use this routine to compute the Schur factorization of a general matrix \( A \) which has been reduced to upper Hessenberg form \( H \):

\[
A = QH^*Q^H, \quad \text{where } Q \text{ is unitary (orthogonal for real flavors)};
\]

\[
A = (QZ)^*T^*(QZ)^H.
\]

In this case, after reducing \( A \) to Hessenberg form by \( \text{gehrd} \), call \( \text{orghr} \) to form \( Q \) explicitly and then pass \( Q \) to \( \text{?hseqr} \) with \( \text{compz} = 'V' \).

You can also call \( \text{gebal} \) to balance the original matrix before reducing it to Hessenberg form by \( \text{?hseqr} \), so that the Hessenberg matrix \( H \) will have the structure:

\[
\begin{bmatrix}
H_{11} & H_{12} & H_{13} \\
0 & H_{22} & H_{23} \\
0 & 0 & H_{33}
\end{bmatrix}
\]

where \( H_{11} \) and \( H_{33} \) are upper triangular.

If so, only the central diagonal block \( H_{22} \) (in rows and columns \( ilo \) to \( ihi \)) needs to be further reduced to Schur form (the blocks \( H_{12} \) and \( H_{23} \) are also affected). Therefore the values of \( ilo \) and \( ihi \) can be supplied to \( \text{?hseqr} \) directly. Also, after calling this routine you must call \( \text{gebak} \) to permute the Schur vectors of the balanced matrix to those of the original matrix.

If \( \text{?gebal} \) has not been called, however, then \( ilo \) must be set to 1 and \( ihi \) to \( n \). Note that if the Schur factorization of \( A \) is required, \( \text{?gebal} \) must not be called with \( \text{job} = 'S' \) or \( 'B' \), because the balancing transformation is not unitary (for real flavors, it is not orthogonal).

\( \text{?hseqr} \) uses a multishift form of the upper Hessenberg QR algorithm. The Schur vectors are normalized so that \( \|z_i\|_2 = 1 \), but are determined only to within a complex factor of absolute value 1 (for the real flavors, to within a factor ±1).

Input Parameters

- **job**
  
  Must be \( 'E' \) or \( 'S' \).

  If \( \text{job} = 'E' \), then eigenvalues only are required.

  If \( \text{job} = 'S' \), then the Schur form \( T \) is required.

- **compz**
  
  Must be \( 'N' \) or \( 'I' \) or \( 'V' \).

  If \( \text{compz} = 'N' \), then no Schur vectors are computed (and the array \( z \) is not referenced).

  If \( \text{compz} = 'I' \), then the Schur vectors of \( H \) are computed (and the array \( z \) is initialized by the routine).

  If \( \text{compz} = 'V' \), then the Schur vectors of \( A \) are computed (and the array \( z \) must contain the matrix \( Q \) on entry).

- **n**

  The order of the matrix \( H (n \geq 0) \).
If $A$ has been balanced by ?gebal, then ilo and ihi must contain the values returned by ?gebal. Otherwise, ilo must be set to 1 and ihi to $n$.

Arrays:

$h$, $z$
- $h$ (size max(1, ldh*$n$)) The $n$-by-$n$ upper Hessenberg matrix $H$.
- $z$ (size max(1, ldz*$n$))
  - If compz = 'V', then $z$ must contain the matrix $Q$ from the reduction to Hessenberg form.
  - If compz = 'I', then $z$ need not be set.
  - If compz = 'N', then $z$ is not referenced.

ldh
The leading dimension of $h$; at least max(1, $n$).

ldz
The leading dimension of $z$;
- If compz = 'N', then ldz ≥ 1.
- If compz = 'V' or 'I', then ldz ≥ max(1, $n$).

Output Parameters

$w$
Array, size at least max (1, $n$). Contains the computed eigenvalues, unless info>0. The eigenvalues are stored in the same order as on the diagonal of the Schur form $T$ (if computed).

$wr$, $wi$
Arrays, size at least max (1, $n$) each.
- Contain the real and imaginary parts, respectively, of the computed eigenvalues, unless info > 0. Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having positive imaginary part first. The eigenvalues are stored in the same order as on the diagonal of the Schur form $T$ (if computed).

$h$
- If info = 0 and job = 'S', $h$ contains the upper quasi-triangular matrix $T$ from the Schur decomposition (the Schur form).
- If info = 0 and job = 'E', the contents of $h$ are unspecified on exit. (The output value of $h$ when info > 0 is given under the description of info below.)

$z$
- If compz = 'V' and info = 0, then $z$ contains $Q*Z$.
- If compz = 'I' and info = 0, then $z$ contains the unitary or orthogonal matrix $Z$ of the Schur vectors of $H$.
- If compz = 'N', then $z$ is not referenced.

Return Values
This function returns a value info.
- If info = 0, the execution is successful.
- If info = -$i$, the $i$-th parameter had an illegal value.
- If info = $i$, ?hseqr failed to compute all of the eigenvalues. Elements 1,2, ..., ilo-1 and i+1, i+2, ..., $n$ of the eigenvalue arrays ($wr$ and $wi$ for real flavors and $w$ for complex flavors) contain the real and imaginary parts of those eigenvalues that have been successfully found.
If $info > 0$, and $job = 'E'$, then on exit, the remaining unconverged eigenvalues are the eigenvalues of the upper Hessenberg matrix rows and columns $ilo$ through $info$ of the final output value of $H$.

If $info > 0$, and $job = 'S'$, then on exit (initial value of $H\ast U = U\ast$ (final value of $H$), where $U$ is a unitary matrix. The final value of $H$ is upper Hessenberg and triangular in rows and columns $info+1$ through $ihi$.

If $info > 0$, and $compz = 'V'$, then on exit (final value of $Z$) = (initial value of $Z\ast U$, where $U$ is the unitary matrix (regardless of the value of $job$).

If $info > 0$, and $compz = 'I'$, then on exit (final value of $Z$) = $U$, where $U$ is the unitary matrix (regardless of the value of $job$).

If $info > 0$, and $compz = 'N'$, then $Z$ is not accessed.

Application Notes

The computed Schur factorization is the exact factorization of a nearby matrix $H + E$, where $\|E\|_2 < O(\varepsilon)$ $\|H\|_2/s_i$, and $\varepsilon$ is the machine precision.

If $\lambda_i$ is an exact eigenvalue, and $\mu_i$ is the corresponding computed value, then $|\lambda_i - \mu_i| \leq c(n) \ast \varepsilon \ast \|H\|_2/s_i$, where $c(n)$ is a modestly increasing function of $n$, and $s_i$ is the reciprocal condition number of $\lambda_i$. The condition numbers $s_i$ may be computed by calling trsna.

The total number of floating-point operations depends on how rapidly the algorithm converges; typical numbers are as follows.

If only eigenvalues are computed: $7n^3$ for real flavors

$25n^3$ for complex flavors.

If the Schur form is computed: $10n^3$ for real flavors

$35n^3$ for complex flavors.

If the full Schur factorization is computed: $20n^3$ for real flavors

$70n^3$ for complex flavors.

$hsein$

Computes selected eigenvectors of an upper Hessenberg matrix that correspond to specified eigenvalues.

Syntax

```c

Include Files
• mkl.h

Description
The routine computes left and/or right eigenvectors of an upper Hessenberg matrix \( H \), corresponding to
selected eigenvalues.

The right eigenvector \( x \) and the left eigenvector \( y \), corresponding to an eigenvalue \( \lambda \), are defined by:
\[ H^*x = \lambda^*x \quad \text{and} \quad y^*H = \lambda^*y \] (or \( H^*y = \lambda^*y \)). Here \( \lambda^* \) denotes the conjugate of \( \lambda \).

The eigenvectors are computed by inverse iteration. They are scaled so that, for a real eigenvector \( x \), \( \max| x_i | = 1 \), and for a complex eigenvector, \( \max(|\Re x_i| + |\Im x_i|) = 1 \).

If \( H \) has been formed by reduction of a general matrix \( A \) to upper Hessenberg form, then eigenvectors of \( H \)
may be transformed to eigenvectors of \( A \) by \text{ormhr} or \text{unmhr}.

Input Parameters

side
Must be 'R' or 'L' or 'B'.
If \( \text{side} = 'R' \), then only right eigenvectors are computed.
If \( \text{side} = 'L' \), then only left eigenvectors are computed.
If \( \text{side} = 'B' \), then all eigenvectors are computed.

eigsrc
Must be 'Q' or 'N'.
If \( \text{eigsrc} = 'Q' \), then the eigenvalues of \( H \) were found using \text{hseqr}; thus if \( H \)
has any zero sub-diagonal elements (and so is block triangular), then the
\( j \)-th eigenvalue can be assumed to be an eigenvalue of the block containing
the \( j \)-th row/column. This property allows the routine to perform inverse
iteration on just one diagonal block. If \( \text{eigsrc} = 'N' \), then no such
assumption is made and the routine performs inverse iteration using the
whole matrix.

initv
Must be 'N' or 'U'.
If \( \text{initv} = 'N' \), then no initial estimates for the selected eigenvectors are
supplied.
If \( \text{initv} = 'U' \), then initial estimates for the selected eigenvectors are
supplied in \( vl \) and/or \( vr \).

select
Array, size at least max (1, \( n \)). Specifies which eigenvectors are to be
computed.
For real flavors:
To obtain the real eigenvector corresponding to the real eigenvalue \( \text{wr}[j] \),
set \( \text{select}[j] \) to 1
To select the complex eigenvector corresponding to the complex eigenvalue \((wr[j - 1], wi[j - 1])\) with complex conjugate \((wr[j], wi[j])\), set \(select[j - 1]\) and/or \(select[j]\) to 1; the eigenvector corresponding to the first eigenvalue in the pair is computed.

For complex flavors:

To select the eigenvector corresponding to the eigenvalue \(w[j]\), set \(select[j]\) to 1.

The order of the matrix \(H (n \geq 0)\).

**Arrays:**

- \(h\) (size \(max(1, ldh*n)\)) The \(n\)-by-\(n\) upper Hessenberg matrix \(H\). If an \textit{NAN} value is detected in \(h\), the routine returns with \textit{info} = -6.
- \(vl\) (size \(max(1, ldvl*mm)\) for column major layout and \(max(1, ldvl*n)\) for row major layout)
  - If \(initv = 'V'\) and \(side = 'L'\) or 'B', then \(vl\) must contain starting vectors for inverse iteration for the left eigenvectors. Each starting vector must be stored in the same column or columns as will be used to store the corresponding eigenvector.
  - If \(initv = 'N'\), then \(vl\) need not be set.
  - The array \(vl\) is not referenced if \(side = 'R'\).
- \(vr\) (size \(max(1, ldvr*mm)\) for column major layout and \(max(1, ldvr*n)\) for row major layout)
  - If \(initv = 'V'\) and \(side = 'R'\) or 'B', then \(vr\) must contain starting vectors for inverse iteration for the right eigenvectors. Each starting vector must be stored in the same column or columns as will be used to store the corresponding eigenvector.
  - If \(initv = 'N'\), then \(vr\) need not be set.
  - The array \(vr\) is not referenced if \(side = 'L'\).

- \(ldh\)
  - The leading dimension of \(h\); at least \(max(1, n)\).

- \(w\)
  - Array, size at least \(max(1, n)\).
  - Contains the eigenvalues of the matrix \(H\).
  - If \(eigsrc = 'Q'\), the array must be exactly as returned by \textit{?hseqr}.

- \(wr, wi\)
  - Arrays, size at least \(max(1, n)\) each.
  - Contain the real and imaginary parts, respectively, of the eigenvalues of the matrix \(H\). Complex conjugate pairs of values must be stored in consecutive elements of the arrays. If \(eigsrc = 'Q'\), the arrays must be exactly as returned by \textit{?hseqr}.

- \(ldvl\)
  - The leading dimension of \(vl\).
  - If \(side = 'L'\) or 'B', \(ldvl \geq max(1, n)\) for column major layout and \(ldvl \geq max(1, mm)\) for row major layout.
  - If \(side = 'R'\), \(ldvl \geq 1\).

- \(ldvr\)
  - The leading dimension of \(vr\).
If $\text{side} = 'R' \lor 'B'$, $ldvr \geq \max(1, n)$ for column major layout and $ldvr \geq \max(1, mm)$ for row major layout.

If $\text{side} = 'L'$, $ldvr \geq 1$.

$mm$

The number of columns in $vl$ and/or $vr$.

Must be at least $m$, the actual number of columns required (see Output Parameters below).

For real flavors, $m$ is obtained by counting $1$ for each selected real eigenvector and $2$ for each selected complex eigenvector (see select).

For complex flavors, $m$ is the number of selected eigenvectors (see select).

Constraint:

$0 \leq mm \leq n$.

Output Parameters

$select$

Overwritten for real flavors only.

If a complex eigenvector was selected as specified above, then $select[j - 1]$ is set to $1$ and $select[j]$ to $0$.

$w$

The real parts of some elements of $w$ may be modified, as close eigenvalues are perturbed slightly in searching for independent eigenvectors.

$wr$

Some elements of $wr$ may be modified, as close eigenvalues are perturbed slightly in searching for independent eigenvectors.

$v1, vr$

If $\text{side} = 'L' \lor 'B'$, $vl$ contains the computed left eigenvectors (as specified by $select$).

If $\text{side} = 'R' \lor 'B'$, $vr$ contains the computed right eigenvectors (as specified by $select$).

The eigenvectors treated column-wise form a rectangular $n$-by-$mm$ matrix.

For real flavors: a real eigenvector corresponding to a real eigenvalue occupies one column of the matrix; a complex eigenvector corresponding to a complex eigenvalue occupies two columns: the first column holds the real part of the eigenvector and the second column holds the imaginary part of the eigenvector. The matrix is stored in a one-dimensional array as described by $\text{matrix_layout}$ (using either column major or row major layout).

For real flavors: the number of columns of $vl$ and/or $vr$ required to store the selected eigenvectors.

For complex flavors: the number of selected eigenvectors.

$ifaill, ifailr$

Arrays, size at least $\max(1, mm)$ each.

$ifaill[i - 1] = 0$ if the $i$th column of $vl$ converged;

$ifaill[i - 1] = j > 0$ if the eigenvector stored in the $i$-th column of $vl$ (corresponding to the $j$th eigenvalue) failed to converge.

$ifailr[i - 1] = 0$ if the $i$th column of $vr$ converged;
ifailr[i - 1] = j > 0 if the eigenvector stored in the i-th column of vr (corresponding to the jth eigenvalue) failed to converge.

For real flavors: if the ith and (i+1)th columns of vl contain a selected complex eigenvector, then ifaill[i - 1] and ifailr[i] are set to the same value. A similar rule holds for vr and ifailr.

The array ifaill is not referenced if side = 'R'. The array ifailr is not referenced if side = 'L'.

Return Values

This function returns a value info.

If info = 0, the execution is successful.

If info = -i, the i-th parameter had an illegal value.

If info > 0, then i eigenvectors (as indicated by the parameters ifaill and/or ifailr above) failed to converge. The corresponding columns of vl and/or vr contain no useful information.

Application Notes

Each computed right eigenvector xi is the exact eigenvector of a nearby matrix A + Ei, such that ||Ei|| < O(ε)||A||. Hence the residual is small:

||Ax_i - \lambda_i x_i|| = O(ε)||A||.

However, eigenvectors corresponding to close or coincident eigenvalues may not accurately span the relevant subspaces.

Similar remarks apply to computed left eigenvectors.

?trevc

Computes selected eigenvectors of an upper (quasi-) triangular matrix computed by ?hseqr.

Syntax

```c
lapack_int LAPACKE_strevc( int matrix_layout, char side, char howmny, lapack_logical* select, lapack_int n, const float* t, lapack_int ldt, float* vl, lapack_int ldvl, float* vr, lapack_int ldvr, lapack_int mm, lapack_int* m );
```

```c
lapack_int LAPACKE_dtrevc( int matrix_layout, char side, char howmny, lapack_logical* select, lapack_int n, const double* t, lapack_int ldt, double* vl, lapack_int ldvl, double* vr, lapack_int ldvr, lapack_int mm, lapack_int* m );
```

```c
lapack_int LAPACKE_ctrevc( int matrix_layout, char side, char howmny, const lapack_logical* select, lapack_int n, lapack_complex_float* t, lapack_int ldt, lapack_complex_float* vl, lapack_int ldvl, lapack_complex_float* vr, lapack_int ldvr, lapack_int mm, lapack_int* m );
```

```c
lapack_int LAPACKE_ztrevc( int matrix_layout, char side, char howmny, const lapack_logical* select, lapack_int n, lapack_complex_double* t, lapack_int ldt, lapack_complex_double* vl, lapack_int ldvl, lapack_complex_double* vr, lapack_int ldvr, lapack_int mm, lapack_int* m );
```

Include Files

- mkl.h
Description

The routine computes some or all of the right and/or left eigenvectors of an upper triangular matrix $T$ (or, for real flavors, an upper quasi-triangular matrix $T$). Matrices of this type are produced by the Schur factorization of a general matrix: $A = Q^* T Q^H$, as computed by hseqr.

The right eigenvector $x$ and the left eigenvector $y$ of $T$ corresponding to an eigenvalue $w$, are defined by:

$$T^* x = w^* x, \quad y^H T = w^* y^H,$$

where $y^H$ denotes the conjugate transpose of $y$.

The eigenvalues are not input to this routine, but are read directly from the diagonal blocks of $T$.

This routine returns the matrices $X$ and/or $Y$ of right and left eigenvectors of $T$, or the products $Q^* X$ and/or $Q^* Y$, where $Q$ is an input matrix.

If $Q$ is the orthogonal/unitary factor that reduces a matrix $A$ to Schur form $T$, then $Q^* X$ and $Q^* Y$ are the matrices of right and left eigenvectors of $A$.

Input Parameters

- **matrix_layout**: Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- **side**: Must be 'R' or 'L' or 'B'.
  - If $side = 'R'$, then only right eigenvectors are computed.
  - If $side = 'L'$, then only left eigenvectors are computed.
  - If $side = 'B'$, then all eigenvectors are computed.
- **howmny**: Must be 'A' or 'B' or 'S'.
  - If $howmny = 'A'$, then all eigenvectors (as specified by $side$) are computed.
  - If $howmny = 'B'$, then all eigenvectors (as specified by $side$) are computed and backtransformed by the matrices supplied in $vl$ and $vr$.
  - If $howmny = 'S'$, then selected eigenvectors (as specified by $side$ and $select$) are computed.
- **select**: Array, size at least max (1, $n$).
  - If $howmny = 'S'$, $select$ specifies which eigenvectors are to be computed.
  - If $howmny = 'A'$ or 'B', $select$ is not referenced.

  For real flavors:
  - If $omega[j]$ is a real eigenvalue, the corresponding real eigenvector is computed if $select[j]$ is 1.
  - If $omega[j - 1]$ and $omega[j]$ are the real and imaginary parts of a complex eigenvalue, the corresponding complex eigenvector is computed if either $select[j - 1]$ or $select[j]$ is 1, and on exit $select[j - 1]$ is set to 1 and $select[j]$ is set to 0.

  For complex flavors:
  - The eigenvector corresponding to the $j$-th eigenvalue is computed if $select[j - 1]$ is 1.
- **$n$**: The order of the matrix $T$ ($n \geq 0$).
Arrays:

t (size \(\max(1, ldt \times n)\)) contains the \(n\)-by-\(n\) matrix \(T\) in Schur canonical form. For complex flavors \texttt{ctrevc} and \texttt{ztrevc}, contains the upper triangular matrix \(T\).

\(vl\) (size \(\max(1, ldvl \times mm)\) for column major layout and \(\max(1, ldvl \times n)\) for row major layout)

If \texttt{howmny} = 'B' and \texttt{side} = 'L' or 'B', then \(vl\) must contain an \(n\)-by-\(n\) matrix \(Q\) (usually the matrix of Schur vectors returned by \texttt{?hseqr}).

If \texttt{howmny} = 'A' or 'S', then \(vl\) need not be set.

The array \(vl\) is not referenced if \texttt{side} = 'R'.

\(vr\) (size \(\max(1, ldvr \times mm)\) for column major layout and \(\max(1, ldvr \times n)\) for row major layout)

If \texttt{howmny} = 'B' and \texttt{side} = 'R' or 'B', then \(vr\) must contain an \(n\)-by-\(n\) matrix \(Q\) (usually the matrix of Schur vectors returned by \texttt{?hseqr}).

If \texttt{howmny} = 'A' or 'S', then \(vr\) need not be set.

The array \(vr\) is not referenced if \texttt{side} = 'L'.

\(ldt\)

The leading dimension of \(t\); at least \(\max(1, n)\).

\(ldvl\)

The leading dimension of \(vl\).

If \texttt{side} = 'L' or 'B', \(ldvl \geq n\).

If \texttt{side} = 'R', \(ldvl \geq 1\).

\(ldvr\)

The leading dimension of \(vr\).

If \texttt{side} = 'R' or 'B', \(ldvr \geq n\).

If \texttt{side} = 'L', \(ldvr \geq 1\).

\(mm\)

The number of columns in the arrays \(vl\) and/or \(vr\). Must be at least \(m\) (the precise number of columns required).

If \texttt{howmny} = 'A' or 'B', \(mm = n\).

If \texttt{howmny} = 'S': for real flavors, \(mm\) is obtained by counting 1 for each selected real eigenvector and 2 for each selected complex eigenvector; for complex flavors, \(mm\) is the number of selected eigenvectors (see \texttt{select}).

Constraint: \(0 \leq mm \leq n\).

Output Parameters

\(select\)

If a complex eigenvector of a real matrix was selected as specified above, then \texttt{select}[j] is set to 1 and \texttt{select}[j + 1] to 0.

\(t\)

\texttt{ctrevc/ztrevc} modify the \(t\) array, which is restored on exit.

\(vl, vr\)

If \texttt{side} = 'L' or 'B', \(vl\) contains the computed left eigenvectors (as specified by \texttt{howmny} and \texttt{select}).
If \( \text{side} = 'R' \) or \( 'B' \), \( \text{vr} \) contains the computed right eigenvectors (as specified by \( \text{howmny} \) and \( \text{select} \)).

The eigenvectors treated column-wise form a rectangular \( n \)-by-\( mm \) matrix.

For real flavors: a real eigenvector corresponding to a real eigenvalue occupies one column of the matrix; a complex eigenvector corresponding to a complex eigenvalue occupies two columns: the first column holds the real part of the eigenvector and the second column holds the imaginary part of the eigenvector. The matrix is stored in a one-dimensional array as described by \( \text{matrix_layout} \) (using either column major or row major layout).

For complex flavors: the number of selected eigenvectors. If \( \text{howmny} = 'A' \) or \( 'B' \), \( m \) is set to \( n \).

For real flavors: the number of columns of \( \text{vl} \) and/or \( \text{vr} \) actually used to store the selected eigenvectors. If \( \text{howmny} = 'A' \) or \( 'B' \), \( m \) is set to \( n \).

Return Values

This function returns a value \( \text{info} \).

If \( \text{info}=0 \), the execution is successful.

If \( \text{info} = -i \), the \( i \)-th parameter had an illegal value.

Application Notes

If \( x_i \) is an exact right eigenvector and \( y_i \) is the corresponding computed eigenvector, then the angle \( \theta(y_i, x_i) \) between them is bounded as follows: \( \theta(y_i, x_i) \leq \frac{c(n)\varepsilon||T||_2}{\text{sep}_i} \) where \( \text{sep}_i \) is the reciprocal condition number of \( x_i \). The condition number \( \text{sep}_i \) may be computed by calling \( \text{?trsna} \).

\texttt{?trevc3}

Computes selected eigenvectors of an upper (quasi-) triangular matrix computed by \texttt{?hseqr} using Level 3 BLAS

Syntax

\begin{align*}
\text{call strevc3} & \left( \text{side}, \text{howmny}, \text{select}, n, t, \text{ldt}, \text{vl}, \text{ldvl}, \text{vr}, \text{ldvr}, mm, m, \text{work}, \text{lwork}, \text{info} \right) \\
\text{call dtrevc3} & \left( \text{side}, \text{howmny}, \text{select}, n, t, \text{ldt}, \text{vl}, \text{ldvl}, \text{vr}, \text{ldvr}, mm, m, \text{work}, \text{lwork}, \text{info} \right) \\
\text{call ctrevc3} & \left( \text{side}, \text{howmny}, \text{select}, n, t, \text{ldt}, \text{vl}, \text{ldvl}, \text{vr}, \text{ldvr}, mm, m, \text{work}, \text{lwork}, \text{rwork}, \text{lrwork}, \text{info} \right) \\
\text{call ztrevc3} & \left( \text{side}, \text{howmny}, \text{select}, n, t, \text{ldt}, \text{vl}, \text{ldvl}, \text{vr}, \text{ldvr}, mm, m, \text{work}, \text{lwork}, \text{rwork}, \text{lrwork}, \text{info} \right)
\end{align*}

Include Files

- \texttt{mkl.fi}
Description

This routine computes some or all of the right and left eigenvectors of an upper triangular matrix \( T \) (or, for real flavors, an upper quasi-triangular matrix \( T \)) using Level 3 BLAS. Matrices of this type are produced by the Schur factorization of a general matrix: \( A = Q^* T Q \), as computed by hseqr.

The right eigenvector \( x \) and the left eigenvector \( y \) of \( T \) corresponding to an eigenvalue \( w \) are defined by the following:

\[
T^* x = w x, \quad y^* T = w y^*
\]

where \( y^* \) denotes the conjugate transpose of \( y \).

The eigenvalues are not passed to this routine but are read directly from the diagonal blocks of \( T \).

This routine returns one or both of the matrices \( X \) and \( Y \) of the right and left eigenvectors of \( T \), or one or both of the products \( Q^* X \) and \( Q^* Y \), where \( Q \) is an input matrix.

If \( Q \) is the orthogonal/unitary factor that reduces a matrix \( A \) to Schur form \( T \), then \( Q^* X \) and \( Q^* Y \) are the matrices of the right and left eigenvectors of \( A \).

Input Parameters

\( side \) \hspace{1cm} \text{CHARACTER*1}

Must be 'R', 'L', or 'B'.

- If \( side = 'R' \), only right eigenvectors are computed.
- If \( side = 'L' \), only left eigenvectors are computed.
- If \( side = 'B' \), all eigenvectors are computed.

\( howmny \) \hspace{1cm} \text{CHARACTER*1}

Must be 'A', 'B', or 'S'.

- If \( howmny = 'A' \), all eigenvectors (as specified by \( side \)) are computed.
- If \( howmny = 'B' \), all eigenvectors (as specified by \( side \)) are computed and back-transformed by the matrices supplied in \( vl \) and \( vr \).
- If \( howmny = 'S' \), selected eigenvectors (as specified by \( side \) and \( select \)) are computed.

\( select \) \hspace{1cm} \text{Array with a size of at least max (1, n)}

If \( howmny = 'S' \), \( select \) specifies which eigenvectors are to be computed. If \( howmny = 'A' \) or \( howmny = 'B' \), \( select \) is not referenced.

For real flavors:

- If \( \omega(j) \) is a real eigenvalue and \( select(j) \) is .TRUE., the corresponding real eigenvector is computed.
- If \( \omega(j) \) and \( \omega(j + 1) \) are the real and imaginary parts of a complex eigenvalue and either \( select(j) \) or \( select(j + 1) \) is .TRUE., the corresponding complex eigenvector is computed, and on exit \( select(j) \) is set to .TRUE. and \( select(j + 1) \) is set to .FALSE..

For complex flavors:
• If `select(j)` is `.TRUE.`, the eigenvector corresponding to the \( j \)th eigenvalue is computed.

\[ n \]

INTEGER

The order of the matrix \( T \) \((n \geq 0)\).

\[ t, vl, vr, work \]

• REAL for `strevc3`
• DOUBLE PRECISION for `dtrevc3`
• COMPLEX for `ctrevc3`
• DOUBLE COMPLEX for `ztrevc3`

Arrays:

• \( t(ldt,* \)\) contains the \( n \)-by-\( n \) matrix \( T \) in Schur canonical form. For complex flavors `ctrevc3` and `ztrevc3`, the array contains the upper triangular matrix \( T \).

The second dimension of \( t \) must be at least \( \max(1, n) \).

• \( vl(ldvl,*) \)

If `howmny` = 'B' and `side` = 'L' or 'B', then \( vl \) must contain an \( n \)-by-\( n \) matrix \( Q \) (usually the matrix of Schur vectors returned by `?hseqr`).

If `howmny` = 'A' or 'S', \( vl \) need not be set.

The second dimension of \( vl \) must be at least \( \max(1, mm) \) if `side` = 'L' or 'B', and at least 1 if `side` = 'R'.

The array \( vl \) is not referenced if `side` = 'R'.

• \( vr(ldvr,*) \)

If `howmny` = 'B' and `side` = 'R' or 'B', \( vr \) must contain an \( n \)-by-\( n \) matrix \( Q \) (usually the matrix of Schur vectors returned by `?hseqr`).

If `howmny` = 'A' or 'S', \( vr \) need not be set.

The second dimension of \( vr \) must be at least \( \max(1, mm) \) if `side` = 'R' or 'B', and at least 1 if `side` = 'L'.

The array \( vr \) is not referenced if `side` = 'L'.

• \( work(*) \) is a workspace array, and its dimension is \( \max(1, lwork) \).

\[ lwork \]

INTEGER

The size of the work array. Must be at least \( \max(1, 3*n) \) for real flavors, and at least \( \max(1, 2*n) \) for complex flavors.

If `lwork` = -1, a workspace query is assumed; the routine calculates only the optimal size of the work array and returns this value as the first entry of the work array, and no error message related to `lwork` is issued by `xerbla`. For details, see "Application Notes" below.

\[ ldt \]

INTEGER

The leading dimension of \( t \). It is at least \( \max(1, n) \).

\[ ldvl \]

INTEGER
The leading dimension of vl.

- If side = 'L' or 'B', ldvl≥n.
- If side = 'R', ldvl≥ 1.

ldvr

INTEGER

The leading dimension of vr.

- If side = 'R' or 'B', ldvr≥n.
- If side = 'L', ldvr≥ 1.

mm

INTEGER

The number of columns in one or both of the arrays vl and vr. Must be at least m (the precise number of columns required).

- If howmny = 'A' or 'B', mm = n.
- If howmny = 'S': for real flavors, mm is obtained by counting 1 for each selected real eigenvector and 2 for each selected complex eigenvector; for complex flavors, mm is the number of selected eigenvectors (see select).

Constraint: 0 ≤ mm ≤ n.

rwork

- REAL for ctrrvec3
- DOUBLE PRECISION for zttrvec3

The workspace array is used in complex flavors only. Its dimension is max (1, lrwork).

lrwork

INTEGER

The size of the rwork array. It must be at least max(1, n).

If lrwork = -1, a workspace query is assumed; the routine calculates only the optimal size of the work array and returns this value as the first entry of the rwork array, and no error message related to lrwork is issued by xerbla. For details, see "Application Notes" below.

Output Parameters

select

If a complex eigenvector of a real matrix was selected as specified above, then select(j) is set to .TRUE. and select(j + 1) is set to .FALSE..

t

COMPLEX for ctrrvec3
DOUBLE COMPLEX for zttrvec3

trrvec3 or zttrvec3 modifies the t(ldt,*) array, which is restored on exit.

vl, vr

If side = 'L' or 'B', vl contains the computed left eigenvectors (as specified by howmny and select).

If side = 'R' or 'B', vr contains the computed right eigenvectors (as specified by howmny and select).
Treated column-wise, the eigenvectors form a rectangular $n$-by-$m$ matrix.

**For real flavors** A real eigenvector corresponding to a real eigenvalue occupies one column of the matrix; a complex eigenvector corresponding to a complex eigenvalue occupies two columns. The first column holds the real part of the eigenvector, and the second column holds the imaginary part of the eigenvector. The matrix is stored in a one-dimensional array as described by matrix_layout (using either column major or row major layout).

$m$

**For complex flavors** The number of selected eigenvectors. If howmny = 'A' or 'B', $m$ is set to $n$.

**For real flavors** The number of columns of one or both of $vl$ and $vr$ actually used to store the selected eigenvectors. If howmny = 'A' or 'B', $m$ is set to $n$.

work(1)

On exit, if info = 0, work(1) returns the required optimal size of lwork.

rwork(1)

On exit, if info = 0, then rwork(1) returns the required optimal size of lrwork.

info

INTEGER

If info = 0, the execution is successful.
If info = -i, the $i$th parameter contained an illegal value.

**Application Notes**

If $xi$ is an exact right eigenvector and $yi$ is the corresponding computed eigenvector, the angle $\theta(yi, xi)$ between them is bounded as follows:

$$\theta(yi, xi) \leq \frac{(c(n)\varepsilon||T||_2)/sepi}{sepi}$$

where $sepi$ is the reciprocal condition number of $xi$. You can compute the condition number $sepi$ by calling ?trsna.

Include Files

- mkl.h

Description

The routine estimates condition numbers for specified eigenvalues and/or right eigenvectors of an upper triangular matrix $T$ (or, for real flavors, upper quasi-triangular matrix $T$ in canonical Schur form). These are the same as the condition numbers of the eigenvalues and right eigenvectors of an original matrix $A = Z T Z^H$ (with unitary or, for real flavors, orthogonal $Z$), from which $T$ may have been derived.

The routine computes the reciprocal of the condition number of an eigenvalue $\lambda_i$ as $s_i = \frac{|v^T u|}{\|u\| \|E\| \|v\| \|E\|}$ for real flavors and $s_i = \frac{|v^H u|}{\|u\| \|E\| \|v\| \|E\|}$ for complex flavors,

where:

- $u$ and $v$ are the right and left eigenvectors of $T$, respectively, corresponding to $\lambda_i$.
- $v^T$/$v^H$ denote transpose/conjugate transpose of $v$, respectively.

This reciprocal condition number always lies between zero (ill-conditioned) and one (well-conditioned).

An approximate error estimate for a computed eigenvalue $\lambda_i$ is then given by $\varepsilon \|T\| / s_i$, where $\varepsilon$ is the machine precision.

To estimate the reciprocal of the condition number of the right eigenvector corresponding to $\lambda_i$, the routine first calls `trexc` to reorder the diagonal elements of matrix $T$ so that $\lambda_i$ is in the leading position:

$$
T = Q \begin{bmatrix} \lambda_i & C^H \\ 0 & T_{22} \end{bmatrix} Q^H
$$

The reciprocal condition number of the eigenvector is then estimated as $sep_i$, the smallest singular value of the matrix $T_{22} - \lambda_i^* I$.

An approximate error estimate for a computed right eigenvector $u$ corresponding to $\lambda_i$ is then given by $\varepsilon \|T\| / sep_i$. 

Input Parameters

`matrix_layout` Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

`job` Must be 'E' or 'V' or 'B'.

If `job` = 'E', then condition numbers for eigenvalues only are computed.

If `job` = 'V', then condition numbers for eigenvectors only are computed.

If `job` = 'B', then condition numbers for both eigenvalues and eigenvectors are computed.

`howmny` Must be 'A' or 'S'.

If `howmny` = 'A', then the condition numbers for all eigenpairs are computed.

If `howmny` = 'S', then condition numbers for selected eigenpairs (as specified by `select`) are computed.

`select` Array, size at least max (1, n) if `howmny` = 'S' and at least 1 otherwise.

Specifies the eigenpairs for which condition numbers are to be computed if `howmny` = 'S'.

For real flavors:
To select condition numbers for the eigenpair corresponding to the real eigenvalue \( \lambda_j \), `select[j]` must be set 1;

to select condition numbers for the eigenpair corresponding to a complex conjugate pair of eigenvalues \( \lambda_j \) and \( \lambda_{j+1} \), `select[j - 1]` and/or `select[j]` must be set 1.

For complex flavors
To select condition numbers for the eigenpair corresponding to the eigenvalue \( \lambda_j \), `select[j]` must be set 1; `select` is not referenced if `howmny` = 'A'.

`n` The order of the matrix \( T \) (\( n \geq 0 \)).

`t, vl, vr` Arrays:

\( t \) (size max(1, \( ldt \times n \))) contains the \( n \)-by-\( n \) matrix \( T \).

\( vl \) (size max(1, \( ldvl \times mm \)) for column major layout and max(1, \( ldvl \times n \)) for row major layout)

If `job` = 'E' or 'B', then \( vl \) must contain the left eigenvectors of \( T \) (or of any matrix \( Q^* T Q \) with \( Q \) unitary or orthogonal) corresponding to the eigenpairs specified by `howmny` and `select`. The eigenvectors must be stored in consecutive columns of \( vl \), as returned by `trevc` or `hsein`.

The array \( vl \) is not referenced if `job` = 'V'.

\( vr \) (size max(1, \( ldvr \times mm \)) for column major layout and max(1, \( ldvr \times n \)) for row major layout)
If \( \text{job} = 'E' \) or 'B', then \( \mathbf{v} \) must contain the right eigenvectors of \( T \) (or of any matrix \( Q^{\dagger}TQ^{\dagger} \) with \( Q \) unitary or orthogonal) corresponding to the eigenpairs specified by \( \text{howmny} \) and \( \text{select} \). The eigenvectors must be stored in consecutive columns of \( \mathbf{v} \), as returned by \text{trevc} or \text{hsein}.

The array \( \mathbf{v} \) is not referenced if \( \text{job} = 'V' \).

\( \text{ldt} \)

The leading dimension of \( t \); at least \( \max(1, n) \).

\( \text{ldvl} \)

The leading dimension of \( \mathbf{v} \).

If \( \text{job} = 'E' \) or 'B', \( \text{ldvl} \geq \max(1, n) \) for column major layout and \( \text{ldvl} \geq \max(1, mm) \) for row major layout.

If \( \text{job} = 'V' \), \( \text{ldvl} \geq 1 \).

\( \text{ldvr} \)

The leading dimension of \( \mathbf{v} \).

If \( \text{job} = 'E' \) or 'B', \( \text{ldvr} \geq \max(1, n) \) for column major layout and \( \text{ldvr} \geq \max(1, mm) \) for row major layout.

If \( \text{job} = 'R' \), \( \text{ldvr} \geq 1 \).

\( mm \)

The number of elements in the arrays \( \mathbf{s} \) and \( \mathbf{sep} \), and the number of columns in \( \mathbf{v} \) and \( \mathbf{v} \) (if used). Must be at least \( m \) (the precise number required).

If \( \text{howmny} = 'A' \), \( mm = n \);

if \( \text{howmny} = 'S' \), for real flavors \( mm \) is obtained by counting 1 for each selected real eigenvalue and 2 for each selected complex conjugate pair of eigenvalues.

for complex flavors \( mm \) is the number of selected eigenpairs (see \( \text{select} \)).

Constraint:

\( 0 \leq mm \leq n \).

Output Parameters

\( s \)

Array, size at least \( \max(1, mm) \) if \( \text{job} = 'E' \) or 'B' and at least 1 if \( \text{job} = 'V' \).

Contains the reciprocal condition numbers of the selected eigenvalues if \( \text{job} = 'E' \) or 'B', stored in consecutive elements of the array. Thus \( s[j - 1] \), \( \mathbf{sep}[j - 1] \) and the \( j \)-th columns of \( \mathbf{v} \) and \( \mathbf{v} \) all correspond to the same eigenpair (but not in general the \( j \)-th eigenpair unless all eigenpairs have been selected).

For real flavors: for a complex conjugate pair of eigenvalues, two consecutive elements of \( s \) are set to the same value. The array \( s \) is not referenced if \( \text{job} = 'V' \).

\( \text{sep} \)

Array, size at least \( \max(1, mm) \) if \( \text{job} = 'V' \) or 'B' and at least 1 if \( \text{job} = 'E' \). Contains the estimated reciprocal condition numbers of the selected right eigenvectors if \( \text{job} = 'V' \) or 'B', stored in consecutive elements of the array.
For real flavors: for a complex eigenvector, two consecutive elements of sep are set to the same value; if the eigenvalues cannot be reordered to compute sep[j - 1], then sep[j - 1] is set to zero; this can only occur when the true value would be very small anyway. The array sep is not referenced if job = 'E'.

For complex flavors: the number of selected eigenpairs.
If howmny = 'A', m is set to n.

For real flavors: the number of elements of s and/or sep actually used to store the estimated condition numbers.
If howmny = 'A', m is set to n.

Return Values
This function returns a value info.
If info=0, the execution is successful.
If info = -i, the i-th parameter had an illegal value.

Application Notes
The computed values sep_i may overestimate the true value, but seldom by a factor of more than 3.

?trexc
Reorders the Schur factorization of a general matrix.

Syntax
lapack_int LAPACKE_strexc( int matrix_layout, char compq, lapack_int n, float* t, lapack_int ldt, float* q, lapack_int ldq, lapack_int* ifst, lapack_int* ilst );
lapack_int LAPACKE_dtrexc( int matrix_layout, char compq, lapack_int n, double* t, lapack_int ldt, double* q, lapack_int ldq, lapack_int* ifst, lapack_int* ilst );
lapack_int LAPACKE_ctrexc( int matrix_layout, char compq, lapack_int n, lapack_complex_float* t, lapack_int ldt, lapack_complex_float* q, lapack_int ldq, lapack_int ifst, lapack_int ilst );
lapack_int LAPACKE_ztrexc( int matrix_layout, char compq, lapack_int n, lapack_complex_double* t, lapack_int ldt, lapack_complex_double* q, lapack_int ldq, lapack_int ifst, lapack_int ilst );

Include Files
• mkl.h

Description
The routine reorders the Schur factorization of a general matrix A = Q*T*Q^H, so that the diagonal element or block of T with row index ifst is moved to row ilst.
The reordered Schur form S is computed by an unitary (or, for real flavors, orthogonal) similarity transformation: S = Z^H*T*Z. Optionally the updated matrix P of Schur vectors is computed as P = Q*Z, giving A = P*S*P^H.
**Input Parameters**

- **matrix_layout**
  Specifies whether matrix storage layout is row major (`LAPACK_ROW_MAJOR`) or column major (`LAPACK_COL_MAJOR`).

- **compq**
  Must be 'V' or 'N'.
  - If `compq` = 'V', then the Schur vectors (Q) are updated.
  - If `compq` = 'N', then no Schur vectors are updated.

- **n**
  The order of the matrix T (n ≥ 0).

- **t, q**
  Arrays:
  - `t` (size max(1, ldt*n)) contains the n-by-n matrix T.
  - `q` (size max(1, ldq*n))
    - If `compq` = 'V', then `q` must contain Q (Schur vectors).
    - If `compq` = 'N', then `q` is not referenced.

- **ldt**
  The leading dimension of `t`; at least max(1, n).

- **ldq**
  The leading dimension of `q`;
  - If `compq` = 'N', then ldq ≥ 1.
  - If `compq` = 'V', then ldq ≥ max(1, n).

- **ifst, ilst**
  1 ≤ ifst ≤ n; 1 ≤ ilst ≤ n.
  Must specify the reordering of the diagonal elements (or blocks, which is possible for real flavors) of the matrix T. The element (or block) with row index `ifst` is moved to row `ilst` by a sequence of exchanges between adjacent elements (or blocks).

**Output Parameters**

- **t**
  Overwritten by the updated matrix S.

- **q**
  If `compq` = 'V', `q` contains the updated matrix of Schur vectors.

- **ifst, ilst**
  Overwritten for real flavors only.
  - If `ifst` pointed to the second row of a 2 by 2 block on entry, it is changed to point to the first row; `ilst` always points to the first row of the block in its final position (which may differ from its input value by ±1).

**Return Values**

This function returns a value `info`.

- If `info`=0, the execution is successful.
- If `info` = -i, the i-th parameter had an illegal value.

**Application Notes**

The computed matrix S is exactly similar to a matrix $T+E$, where $||E||_2 = O(\varepsilon) * ||T||_2$, and $\varepsilon$ is the machine precision.
Note that if a 2 by 2 diagonal block is involved in the re-ordering, its off-diagonal elements are in general changed; the diagonal elements and the eigenvalues of the block are unchanged unless the block is sufficiently ill-conditioned, in which case they may be noticeably altered. It is possible for a 2 by 2 block to break into two 1 by 1 blocks, that is, for a pair of complex eigenvalues to become purely real.

The approximate number of floating-point operations is

for real flavors:

\[ 6n(\text{ifst-ilst}) \text{ if compq} = 'N'; \]
\[ 12n(\text{ifst-ilst}) \text{ if compq} = 'V'; \]

for complex flavors:

\[ 20n(\text{ifst-ilst}) \text{ if compq} = 'N'; \]
\[ 40n(\text{ifst-ilst}) \text{ if compq} = 'V'. \]

trsen
Reorders the Schur factorization of a matrix and (optionally) computes the reciprocal condition numbers for the selected cluster of eigenvalues and respective invariant subspace.

Syntax

```
lapack_int LAPACKE_strsen( int matrix_layout, char job, char compq, const lapack_logical* select, lapack_int n, float* t, lapack_int ldt, float* q, lapack_int ldq, float* wr, float* wi, lapack_int* m, float* s, float* sep );
lapack_int LAPACKE_dtrsen( int matrix_layout, char job, char compq, const lapack_logical* select, lapack_int n, double* t, lapack_int ldt, double* q, lapack_int ldq, double* wr, double* wi, lapack_int* m, double* s, double* sep );
lapack_int LAPACKE_ctrsen( int matrix_layout, char job, char compq, const lapack_logical* select, lapack_int n, lapack_complex_float* t, lapack_int ldt, lapack_complex_float* q, lapack_int ldq, lapack_complex_float* w, lapack_int* m, float* s, float* sep );
lapack_int LAPACKE_ztrsen( int matrix_layout, char job, char compq, const lapack_logical* select, lapack_int n, lapack_complex_double* t, lapack_int ldt, lapack_complex_double* q, lapack_int ldq, lapack_complex_double* w, lapack_int* m, double* s, double* sep );
```

Include Files

- mkl.h

Description

The routine reorders the Schur factorization of a general matrix \( A = Q^*T^*Q^T \) (for real flavors) or \( A = Q^*T^*Q^H \) (for complex flavors) so that a selected cluster of eigenvalues appears in the leading diagonal elements (or, for real flavors, diagonal blocks) of the Schur form. The reordered Schur form \( R \) is computed by a unitary (orthogonal) similarity transformation: \( R = Z^*T^*Z \). Optionally the updated matrix \( P \) of Schur vectors is computed as \( P = Q^*Z \), giving \( A = P^*R^*P^T \).

Let

\[
R = \begin{bmatrix}
T_{11} & T_{12} \\
0 & T_{13}
\end{bmatrix}
\]
where the selected eigenvalues are precisely the eigenvalues of the leading \( m \)-by-\( m \) submatrix \( T_{11} \). Let \( P \) be correspondingly partitioned as \((Q_1Q_2)\) where \( Q_1 \) consists of the first \( m \) columns of \( Q \). Then \( A^*Q_1 = Q_1^*T_{11} \), and so the \( m \) columns of \( Q_1 \) form an orthonormal basis for the invariant subspace corresponding to the selected cluster of eigenvalues.

Optionally the routine also computes estimates of the reciprocal condition numbers of the average of the cluster of eigenvalues and of the invariant subspace.

**Input Parameters**

- **matrix_layout**: Specifies whether matrix storage layout is row major (`LAPACK_ROW_MAJOR`) or column major (`LAPACK_COL_MAJOR`).

- **job**: Must be 'N' or 'E' or 'V' or 'B'.
  - If `job` = 'N', then no condition numbers are required.
  - If `job` = 'E', then only the condition number for the cluster of eigenvalues is computed.
  - If `job` = 'V', then only the condition number for the invariant subspace is computed.
  - If `job` = 'B', then condition numbers for both the cluster and the invariant subspace are computed.

- **compq**: Must be 'V' or 'N'.
  - If `compq` = 'V', then \( Q \) of the Schur vectors is updated.
  - If `compq` = 'N', then no Schur vectors are updated.

- **select**: Array, size at least max (1, \( n \)).
  - Specifies the eigenvalues in the selected cluster. To select an eigenvalue \( \lambda_j \), `select[j]` must be 1.
  - *For real flavors*: to select a complex conjugate pair of eigenvalues \( \lambda_j \) and \( \lambda_j + 1 \) (corresponding 2 by 2 diagonal block), `select[j - 1]` and/or `select[j]` must be 1; the complex conjugate \( \lambda_j \) and \( \lambda_j + 1 \) must be either both included in the cluster or both excluded.

- **n**: The order of the matrix \( T \) (\( n \geq 0 \)).

- **t, q**: Arrays:
  - \( t \) (size max(1, \( ldt*n \))) The upper quasi-triangular \( n \)-by-\( n \) matrix \( T \), in Schur canonical form.
  - \( q \) (size max(1, \( ldq*n \)))
    - If `compq` = 'V', then \( q \) must contain the matrix \( Q \) of Schur vectors.
    - If `compq` = 'N', then \( q \) is not referenced.

- **ldt**: The leading dimension of \( t \); at least max(1, \( n \)).

- **ldq**: The leading dimension of \( q \);
  - If `compq` = 'N', then \( ldq \geq 1 \).
  - If `compq` = 'V', then \( ldq \geq \max(1, \ n) \).
Output Parameters

Overwritten by the reordered matrix $R$ in Schur canonical form with the selected eigenvalues in the leading diagonal blocks.

$q$

If $compq = 'V'$, $q$ contains the updated matrix of Schur vectors; the first $m$ columns of the $Q$ form an orthogonal basis for the specified invariant subspace.

$w$

Array, size at least $\max(1, n)$. The recorded eigenvalues of $R$. The eigenvalues are stored in the same order as on the diagonal of $R$.

$wr, wi$

Arrays, size at least $\max(1, n)$. Contain the real and imaginary parts, respectively, of the reordered eigenvalues of $R$. The eigenvalues are stored in the same order as on the diagonal of $R$. Note that if a complex eigenvalue is sufficiently ill-conditioned, then its value may differ significantly from its value before reordering.

$m$

For complex flavors: the dimension of the specified invariant subspaces, which is the same as the number of selected eigenvalues (see select).

For real flavors: the dimension of the specified invariant subspace. The value of $m$ is obtained by counting 1 for each selected real eigenvalue and 2 for each selected complex conjugate pair of eigenvalues (see select).

Constraint: $0 \leq m \leq n$.

$s$

If $job = 'E$ or 'B', $s$ is a lower bound on the reciprocal condition number of the average of the selected cluster of eigenvalues.

If $m = 0$ or $n$, then $s = 1$.

For real flavors: if $info = 1$, then $s$ is set to zero.

$s$ is not referenced if $job = 'N$ or 'V'.

$sep$

If $job = 'V$ or 'B', $sep$ is the estimated reciprocal condition number of the specified invariant subspace.

If $m = 0$ or $n$, then $sep = |T|.$

For real flavors: if $info = 1$, then $sep$ is set to zero.

$sep$ is not referenced if $job = 'N$ or 'E'.

Return Values

This function returns a value $info$.

If $info=0$, the execution is successful.

If $info = -i$, the $i$-th parameter had an illegal value.

If $info = 1$, the reordering of $T$ failed because some eigenvalues are too close to separate (the problem is very ill-conditioned); $T$ may have been partially reordered, and $wr$ and $wi$ contain the eigenvalues in the same order as in $T$; $s$ and $sep$ (if requested) are set to zero.

Application Notes

The computed matrix $R$ is exactly similar to a matrix $T+E$, where $||E||_2 = O(\varepsilon) * ||T||_2$, and $\varepsilon$ is the machine precision. The computed $s$ cannot underestimate the true reciprocal condition number by more than a factor of $(\min(m, n-m))^{1/2}$; $sep$ may differ from the true value by $(m^*n-m^2)^{1/2}$. The angle between the
computed invariant subspace and the true subspace is $O(\epsilon) \|A\|_2/\text{sep}$. Note that if a 2-by-2 diagonal block is involved in the re-ordering, its off-diagonal elements are in general changed; the diagonal elements and the eigenvalues of the block are unchanged unless the block is sufficiently ill-conditioned, in which case they may be noticeably altered. It is possible for a 2-by-2 block to break into two 1-by-1 blocks, that is, for a pair of complex eigenvalues to become purely real.

?trsyl
Solves Sylvester equation for real quasi-triangular or complex triangular matrices.

**Syntax**

```c
lapack_int LAPACKE_strsyl( int matrix_layout, char trana, char tranb, lapack_int isgn, lapack_int m, lapack_int n, const float* a, lapack_int lda, const float* b, lapack_int ldb, float* c, lapack_int ldc, float* scale );

lapack_int LAPACKE_dtrsyl( int matrix_layout, char trana, char tranb, lapack_int isgn, lapack_int m, lapack_int n, const double* a, lapack_int lda, const double* b, lapack_int ldb, double* c, lapack_int ldc, double* scale );

lapack_int LAPACKE_ctrsyl( int matrix_layout, char trana, char tranb, lapack_int isgn, lapack_int m, lapack_int n, const lapack_complex_float* a, lapack_int lda, const lapack_complex_float* b, lapack_int ldb, lapack_complex_float* c, lapack_int ldc, float* scale );

lapack_int LAPACKE_ztrsyl( int matrix_layout, char trana, char tranb, lapack_int isgn, lapack_int m, lapack_int n, const lapack_complex_double* a, lapack_int lda, const lapack_complex_double* b, lapack_intldb, lapack_complex_double* c, lapack_int ldc, double* scale );
```

**Include Files**

- mkl.h

**Description**

The routine solves the Sylvester matrix equation $\text{op}(A)X\pm X\text{op}(B) = \alpha C$, where $\text{op}(A) = A$ or $A^\text{T}$, and the matrices $A$ and $B$ are upper triangular (or, for real flavors, upper quasi-triangular in canonical Schur form); $\alpha \leq 1$ is a scale factor determined by the routine to avoid overflow in $X$; $A$ is $m$-by-$m$, $B$ is $n$-by-$n$, and $C$ and $X$ are both $m$-by-$n$. The matrix $X$ is obtained by a straightforward process of back substitution.

The equation has a unique solution if and only if $a_i \pm b_i \neq 0$, where $\{a_i\}$ and $\{b_i\}$ are the eigenvalues of $A$ and $B$, respectively, and the sign (+ or -) is the same as that used in the equation to be solved.

**Input Parameters**

- **matrix_layout**
  Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

- **trana**
  Must be 'N' or 'T' or 'C'.
  If trana = 'N', then $\text{op}(A) = A$.
  If trana = 'T', then $\text{op}(A) = A^\text{T}$ (real flavors only).
  If trana = 'C' then $\text{op}(A) = A^H$.

- **tranb**
  Must be 'N' or 'T' or 'C'.
  If tranb = 'N', then $\text{op}(B) = B$. 
If \( tranb = 'T' \), then \( \text{op}(B) = B^T \) (real flavors only).
If \( tranb = 'C' \), then \( \text{op}(B) = B^H \).

**isgn**
Indicates the form of the Sylvester equation.
If \( isgn = +1 \), \( \text{op}(A)*X + X*\text{op}(B) = \alpha * C \).
